

*IBM MobileFirst Platform Foundation
V7.1.0*

IBM

Note

Before you use this information and the product it supports, read the information in "Notices" on page A-1.

IBM MobileFirst Platform Foundation V7.1.0

This edition applies to version V7.1.0 of IBM MobileFirst Platform Foundation and to all subsequent releases and modifications until otherwise indicated in new editions.

This edition was updated last on 24 May 2017.

This PDF document is made available for convenience and on an "as is" basis only. The master and controlling document can be found in Knowledge Center at http://ibm.biz/knowctr#SSHS8R_7.1.0/wl_welcome.html. This PDF document may contain uncontrollable formatting errors or differences from the master version in Knowledge Center.

IBM MobileFirst Platform Foundation

V7.1.0 documentation 1-1

Product overview 2-1

Introduction to mobile application development	2-1
Product main capabilities	2-4
Product components	2-7
Product editions	2-14
System requirements.	2-15
Licensing in MobileFirst Server	2-16
Matrix of features and platforms.	2-17
Accessibility	2-17
Accessibility of web app consoles	2-18
Accessibility of the MobileFirst Platform Command Line Interface	2-18
Accessibility of MobileFirst Studio	2-18
Accessibility of IBM MobileFirst Platform Foundation installation and configuration	2-23

Release notes 3-1

What's new in V7.1.0	3-1
Portability between IBM Bluemix and on-premises IBM MobileFirst Platform Foundation	3-1
Enhanced enterprise resilience	3-2
Improved development experience	3-3
Enhanced experience for developing hybrid apps	3-3
Streamlined experience for developing native apps	3-3
Additional services and other development enhancements	3-4
Improved data reach with Cloudant and JSONStore	3-6
Hardened security features	3-7
Easier deployment and management of IBM MobileFirst Platform Foundation and your apps	3-7
Improved MobileFirst API	3-10
What's new in V7.1.0 interim fixes	3-12
Token licensing (APAR PI48649)	3-12
iOS 9 support	3-13
Android 6.0 Marshmallow support	3-15
Apache Cordova	3-16
New features in the MobileFirst Analytics Console	3-16
IBM MobileFirst Platform Foundation on IBM Containers	3-17
JSONStore framework for MobileFirst iOS applications (APAR PI50359)	3-18
CloudantToolkit and IMFData frameworks are deprecated	3-18
Accessibility enhancements	3-18
Enhanced instructions for upgrading MobileFirst Server to V7.1.0	3-19
LDAP login module changes	3-19

IBM WebSphere DataPower integration enhancements	3-19
IBM Trusteer integration enhancements (APAR PI67861)	3-19
IBM MobileFirst Platform Foundation on IBM Containers	3-20
Deprecated and removed features	3-20
Deprecated features and API elements	3-20
Removed features.	3-22
Known issues	3-23
Known limitations	3-23

Troubleshooting 4-1

Tutorials, samples, and additional resources 5-1

Installing and configuring 6-1

Installation overview	6-1
Installing MobileFirst Studio	6-2
Running additional tasks for Rational Team Concert V4.0	6-3
Starting MobileFirst Studio	6-4
Installing mobile-specific tools	6-4
Installing tools for Adobe AIR	6-4
Installing tools for iOS	6-4
Installing tools for Android	6-5
Installing tools for BlackBerry	6-5
Installing tools for Windows Phone Silverlight 8	6-6
Installing tools for Windows 8	6-6
Changing the port number of the internal application server	6-6
Uninstalling MobileFirst Studio	6-7
Installing MobileFirst Studio offline workaround	6-8
Installing CLI	6-8
Installing in silent mode	6-9
Installing CLI for Windows 8.1	6-10
Installing CLI by using Console	6-11
Uninstalling command-line tools for developers	6-12
Installing and configuring IBM MobileFirst Platform Test Workbench	6-12
Troubleshooting IBM MobileFirst Platform Test Workbench	6-13
Installing MobileFirst Server	6-14
Planning the installation of MobileFirst Server	6-14
Installation prerequisites	6-15
File system prerequisites	6-16
Introduction to the MobileFirst Server components.	6-17
Planning deployment of administration components and runtimes	6-19
Stand-alone server topology	6-19
Server farm topology	6-22

WebSphere Application Server Network Deployment topologies	6-26	Configuring Apache Tomcat	6-65
Using a reverse proxy with server farm and WebSphere Application Server Network Deployment topologies.	6-29	Configuring WebSphere Application Server and WebSphere Application Server Network Deployment	6-68
Planning the creation of the databases	6-30	Installing MobileFirst Server administration with the Server Configuration Tool	6-70
Restricting database user permissions for IBM MobileFirst Platform Server runtime operations	6-31	Using Ant tasks to install MobileFirst Server administration	6-73
Using complex Oracle connection descriptors	6-32	Creating and configuring the database for MobileFirst Server administration with Ant tasks	6-73
Configuring DB2 HADR seamless failover for MobileFirst Server and Application Center data sources	6-33	Deploying the MobileFirst Operations Console and Administration Services with Ant tasks.	6-75
Planning for the use of token licensing	6-34	Manually installing MobileFirst Server administration	6-76
Tutorial for a basic installation of MobileFirst Server	6-35	Configuring the DB2 database manually for the IBM MobileFirst Platform Server administration	6-76
Installing WebSphere Application Server Liberty Core	6-36	Configuring the Apache Derby database manually for the IBM MobileFirst Platform Server administration	6-80
Creating a server for Liberty	6-37	Configuring the MySQL database manually for the IBM MobileFirst Platform Server administration	6-84
Installing the database management system	6-37	Configuring the Oracle database manually for the IBM MobileFirst Platform Server administration	6-87
Installing MobileFirst Server	6-38	Configuring the Cloudant database manually for MobileFirst Server administration	6-91
Exploring Application Center.	6-39	Deploying the Administration Services and MobileFirst Operations Console and configuring the application server manually	6-92
Installing the MobileFirst Server administration components: Administration Services and MobileFirst Operations Console	6-40	Defining the endpoint of the MobileFirst Administration services	6-102
Creating a simple MobileFirst project.	6-41	Configuring the endpoint (WebSphere Application Server full profile)	6-104
Deploying a MobileFirst runtime environment with the Server Configuration Tool	6-42	Configuring the endpoint (Liberty profile)	6-104
Restarting the Liberty server and opening the MobileFirst Operations Console.	6-42	Configuring the endpoint (Apache Tomcat).	6-105
Running IBM Installation Manager	6-43	Configuring user authentication for MobileFirst Server administration	6-106
Single-user versus multi-user installations	6-44	Configuring WebSphere Application Server full profile for MobileFirst Server administration	6-108
Installing a new version of MobileFirst Server	6-45	Configuring WebSphere Application Server Liberty profile for MobileFirst Server administration	6-109
Upgrading MobileFirst Server from a previous release	6-45	Configuring Apache Tomcat for MobileFirst Server administration	6-110
Command-line installation with XML response files (silent installation).	6-45	Declaring the Cloudant SSL configuration for the MobileFirst Server administration	6-111
Working with sample response files for IBM Installation Manager	6-46	List of JNDI properties for MobileFirst Server administration	6-111
Working with a response file recorded on a different machine	6-48	Verifying the installation of MobileFirst Server administration	6-125
Command-line (silent installation) parameters	6-49	Installing the MobileFirst runtime environment	6-125
Distribution structure of MobileFirst Server	6-53		
Installing the MobileFirst Server administration	6-58		
Optional creation of the administration database.	6-58		
Creating the DB2 database for MobileFirst Server administration	6-59		
Creating the MySQL database for MobileFirst Server administration	6-60		
Creating the Oracle database for MobileFirst Server administration	6-61		
Creating the Cloudant database for MobileFirst Server administration	6-62		
Configuration of the application server	6-63		
Configuring WebSphere Application Server Liberty profile	6-64		

Installing and configuring for token licensing	6-126	Configuring SSL between MobileFirst adapters and back-end servers by using self-signed certificates	6-192
Installation overview for token licensing	6-126	Configuring SSL by using untrusted certificates	6-193
Connecting MobileFirst Server installed on Apache Tomcat to the Rational License Key Server	6-127	Specifying a trusted SSL certificate.	6-199
Installing Rational Common Licensing libraries	6-127	Installing the root CA on iOS	6-200
Installing on Apache Tomcat server farm	6-128	Installing the root CA on Android	6-203
Connecting MobileFirst Server installed on WebSphere Application Server Liberty profile to the Rational License Key Server	6-129	Installing the root CA on Windows Phone	6-204
Installing Rational Common Licensing libraries	6-129	Installing the root CA on Windows 8	6-208
Installing on Liberty profile server farm	6-130	Updating your keystore and Liberty profile configuration to use a certificate chain	6-212
Connecting MobileFirst Server installed on WebSphere Application Server to the Rational License Key Server	6-130	Handling MySQL stale connections	6-213
Installing Rational Common Licensing library on a stand-alone server	6-131	Handling DB2 and Oracle stale connections	6-214
Installing Rational Common Licensing library on WebSphere Application Server Network Deployment	6-133	Managing the DB2 transaction log size	6-215
Limitations of supported platforms for token licensing	6-133	Installing the IBM MobileFirst Platform Operational Analytics	6-216
Troubleshooting token licensing problems	6-134	Installing MobileFirst Operational Analytics with Ant tasks	6-216
Installing a server farm	6-138	Installing IBM MobileFirst Platform Operational Analytics manually	6-218
Planning the configuration of a server farm	6-138	Installing IBM MobileFirst Platform Operational Analytics for WebSphere Application Server Liberty	6-218
Configuring a server farm	6-139	Installing IBM MobileFirst Platform Operational Analytics for WebSphere Application Server	6-219
Verifying a farm configuration	6-144	Installing IBM MobileFirst Platform Operational Analytics for Apache Tomcat	6-223
Lifecycle of a server farm node	6-145	Configuring the MobileFirst Server for the IBM MobileFirst Platform Operational Analytics	6-224
Configuring MobileFirst Server	6-147	Installing the MobileFirst Data Proxy	6-225
Backup and recovery	6-147	Planning the installation of MobileFirst Data Proxy	6-225
Disaster recovery: active-active topology.	6-147	Installation overview of the MobileFirst Data Proxy	6-225
Optimization and tuning of MobileFirst Server	6-150	Installation prerequisites for the MobileFirst Data Proxy	6-225
Optimization of MobileFirst Server project databases	6-153	File System prerequisites for MobileFirst Data Proxy	6-226
Testing MobileFirst Server performance	6-156	Installing and configuring the MobileFirst Data Proxy	6-226
Security configuration	6-162	Installing the MobileFirst Data Proxy with Ant tasks	6-226
Securing the MobileFirst Server administration	6-162	Manually installing the MobileFirst Data Proxy	6-227
Database and certificate security passwords	6-166	Configuring WebSphere Application Server Liberty profile for MobileFirst Data Proxy manually	6-227
Apache Tomcat security options	6-166	Configuring WebSphere Application Server full profile and WebSphere Application Server Network Deployment for MobileFirst Data Proxy manually	6-229
Running MobileFirst Server in WebSphere Application Server with Java 2 security enabled.	6-166	Configuring the application server to access the Cloudant database through HTTPS	6-234
Transmitting MobileFirst data on the BlackBerry Enterprise Server MDS channel	6-167	Configuring the connection between the MobileFirst Data Proxy and the Analytics server	6-235
Integration with IBM WebSphere DataPower as a security gateway and reverse proxy.	6-168	Installing and configuring the Application Center	6-235
Integrating with DataPower as a security gateway and reverse proxy	6-169		
DataPower configuration rules	6-175		
Integrating with DataPower as a reverse proxy using LTPA and form-based authentication	6-181		
Configuring MobileFirst Server to enable TLS V1.2	6-190		
Apache Tomcat	6-191		
WebSphere Application Server Liberty profile	6-191		
WebSphere Application Server full profile	6-191		

Installing Application Center with IBM Installation Manager	6-235	Configuring Liberty profile for Oracle manually for Application Center	6-256
Optional creation of databases	6-236	Configuring WebSphere Application Server for Oracle manually for Application Center	6-257
Creating the DB2 database for Application Center	6-236	Configuring Apache Tomcat for Oracle manually for Application Center	6-258
Creating the MySQL database for Application Center	6-237	Deploying the Application Center WAR files and configuring the application server manually	6-259
Creating the Oracle database for Application Center	6-237	Configuring the Liberty profile for Application Center manually	6-259
Installing Application Center in WebSphere Application Server Network Deployment	6-239	Configuring WebSphere Application Server for Application Center manually	6-261
Completing the installation	6-240	Configuring Apache Tomcat for Application Center manually	6-264
Default logins and passwords created by IBM Installation Manager for the Application Center	6-240	Deploying the Application Center EAR file and configuring the application server manually	6-265
Installing the Application Center with Ant tasks.	6-241	Configuring the Liberty profile for Application Center manually	6-266
Creating and configuring the database for Application Center with Ant tasks.	6-241	Configuring WebSphere Application Server for Application Center manually	6-267
Deploying the Application Center console and services with Ant tasks	6-242	Configuring Application Center after installation	6-269
Manually installing Application Center	6-243	Configuring user authentication for Application Center	6-270
Configuring the DB2 database manually for IBM MobileFirst Platform Application Center	6-244	Configuring the Java EE security roles on WebSphere Application Server full profile	6-271
Setting up your DB2 database manually for Application Center.	6-244	Configuring the Java EE security roles on WebSphere Application Server Liberty profile	6-272
Configuring Liberty profile for DB2 manually for Application Center	6-244	Configuring the Java EE security roles on Apache Tomcat	6-274
Configuring WebSphere Application Server for DB2 manually for Application Center	6-245	Managing users with LDAP	6-274
Configuring Apache Tomcat for DB2 manually for Application Center	6-247	LDAP with WebSphere Application Server V7	6-274
Configuring the Apache Derby database manually for Application Center	6-248	LDAP with WebSphere Application Server V8.x	6-280
Setting up your Apache Derby database manually for Application Center	6-248	LDAP with Liberty profile	6-285
Configuring Liberty profile for Derby manually for Application Center	6-248	LDAP with Apache Tomcat	6-289
Configuring WebSphere Application Server for Derby manually for Application Center	6-249	Configuring properties of DB2 JDBC driver in WebSphere Application Server	6-294
Configuring Apache Tomcat for Derby manually for Application Center	6-251	Managing the DB2 transaction log size	6-295
Configuring the MySQL database manually for Application Center.	6-251	Defining the endpoint of the application resources	6-296
Setting up your MySQL database manually for Application Center	6-251	Configuring the endpoint of application resources (full profile)	6-297
Configuring Liberty profile for MySQL manually for Application Center	6-252	Configuring the endpoint of the application resources (Liberty profile).	6-299
Configuring WebSphere Application Server for MySQL manually for Application Center	6-253	Configuring the endpoint of the application resources (Apache Tomcat)	6-300
Configuring Apache Tomcat for MySQL manually for Application Center	6-254	Configuring Secure Sockets Layer (SSL)	6-301
Configuring the Oracle database manually for IBM MobileFirst Platform Application Center	6-255	Configuring SSL for WebSphere Application Server full profile	6-302
Setting up your Oracle database manually for Application Center	6-255	Configuring SSL for Liberty profile	6-303
		Configuring SSL for Apache Tomcat	6-304
		Managing and installing self-signed CA certificates in an Application Center test environment	6-304

Troubleshooting SSL	6-306
List of JNDI properties for the Application Center	6-307
Configuring WebSphere Application Server to support applications in public app stores	6-313
Configuring WebSphere Application Server to support applications in Google play	6-313
Configuring WebSphere Application Server to support applications in Apple iTunes	6-314
Configuring Liberty profile when IBM JDK is used	6-314
Predefining MobileFirst Server configuration for several deployment environments	6-315
Creating the property file.	6-316
Using a property file in the file system	6-316
Setting the file pointer property (WebSphere Application Server full profile).	6-318
Using property files injected into a web archive file	6-319
Using a shared library of JNDI properties	6-323
Adding the shared library (WebSphere Application Server full profile)	6-326
Typical topologies of a MobileFirst instance in an extranet infrastructure	6-327
Setting up IBM MobileFirst Platform Foundation in WebSphere Application Server cluster environment	6-328
Setting up HTTP Server in a WebSphere Application Server Liberty profile farm	6-339
Troubleshooting IBM HTTP Server startup	6-346
Integrating IBM WebSphere DataPower with a cluster of instances of MobileFirst Server	6-347
Sample dynamic routing stylesheet	6-359
Endpoints of the MobileFirst Server production server	6-360
HTTP Interface of the production server.	6-364
Troubleshooting MobileFirst Server	6-368
Troubleshooting to find the cause of installation failure	6-368
Troubleshooting failure to create the DB2 database	6-369
Troubleshooting a MobileFirst Server upgrade with Derby as the database	6-369
WebSphere Application Server Liberty profile: troubleshooting Administration Services.	6-369
Versions of Administration Services and runtimes	6-370
Troubleshooting the JMX configuration	6-370
Troubleshooting communication between the runtime and the Administration Services	6-371
Troubleshooting server farm topology	6-373
WebSphere Application Server full profile: troubleshooting Administration Services in a stand-alone topology	6-373
Versions of Administration Services and runtimes	6-373
Troubleshooting the JMX configuration	6-374

Troubleshooting communication between the runtime and the Administration Services	6-374
Troubleshooting server farm topology	6-376
WebSphere Application Server Network Deployment: troubleshooting Administration Services	6-376
Versions of Administration Services and runtimes	6-376
Troubleshooting the JMX configuration	6-376
Troubleshooting communication between the runtime and the Administration Services	6-377
Apache Tomcat: troubleshooting Administration Services	6-379
Versions of Administration Services and runtimes	6-379
Troubleshooting the JMX configuration	6-380
Troubleshooting communication between the runtime and the Administration Services	6-381
Troubleshooting server farm topology	6-382
Troubleshooting server farm configuration issues	6-382
Troubleshooting failure to authenticate to Application Center and applications that use the basic registry element.	6-383

Upgrading to IBM MobileFirst Platform Foundation V7.1.0	7-1
Version compatibility	7-1
Separation of lifecycle between MobileFirst Server and MobileFirst Studio	7-4
Upgrading to MobileFirst Studio V7.1.0.	7-5
Upgrading MobileFirst Studio in the Consumer or Enterprise Editions to MobileFirst Studio V7.1.0	7-5
Upgrading MobileFirst Studio in the Developer Edition to MobileFirst Studio V7.1.0	7-6
Migrating projects to IBM MobileFirst Platform Foundation V7.1.0	7-7
Upgrading existing native iOS applications	7-10
Upgrading existing native iOS applications to IBM MobileFirst Platform Foundation version V7.1.0 manually	7-11
Upgrading existing native iOS applications to IBM MobileFirst Platform Foundation V7.1.0 with CocoaPods	7-13
Migrating projects to MobileFirst Studio V7.1.0	7-15
Impact of migrating to a new version of MobileFirst Studio for applications already in production	7-17
Upgrading projects to work in session-independent mode.	7-19
Migrating IBM SmartCloud Analytics Embedded to IBM MobileFirst Platform Operational Analytics	7-20
Migration to the V7.1.0 Analytics Console	7-21
Upgrading to MobileFirst Server V7.1.0 in a production environment	7-22
Overview of the upgrade to MobileFirst Server V7.1.0 process	7-23

Preparation for upgrades to MobileFirst Server	7-25	Manually installing the MobileFirst Server administration during the upgrade	7-71
Gathering information for MobileFirst Server V7.1.0 upgrades	7-25	Manually upgrading the MobileFirst Server V7.1.0 databases	7-71
Planning installation of the MobileFirst Administration Services and MobileFirst Operations Console	7-27	Manually upgrading the application server	7-79
Identify the MobileFirst WAR file and prepare the Ant deployment script	7-30	Verifying and updating the HTTP redirections for MobileFirst Server V7.1.0	7-79
Review and note the application server configuration for MobileFirst Server and Application Center	7-33	Updating DB2 schema names in the case of a manual installation	7-80
Verify environments of deployed apps	7-35	Upgrading with the Server Configuration Tool	7-81
In-place upgrade or rolling upgrade to MobileFirst Server V7.1.0	7-37	Rolling upgrade procedure to apply a fix pack to IBM MobileFirst Platform Foundation V7.1.0 in stateful mode	7-83
Packaging change of WebSphere Application Server Liberty profile in IBM Worklight V6.x	7-38	Planning the rolling upgrade procedure	7-84
Become familiar with IBM Installation Manager before you start	7-39	Overview of the rolling upgrade procedure	7-85
Starting the MobileFirst Server V7.1.0 upgrade process	7-42	Performing a rolling upgrade to install a fix pack	7-85
Verify the ownership of your MobileFirst Server files	7-42	Stopping management operations	7-86
Back up your application server	7-43	Installing the IBM MobileFirst Platform Foundation fix pack in a new cluster	7-86
Shutting down the application server	7-45	Completing the configuration of the new installation of IBM MobileFirst Platform Foundation	7-88
Stop all instances of the Application Center applications	7-46	Verifying the new installation of IBM MobileFirst Platform Foundation	7-89
Back up the Application Center database	7-47	Switching progressively the HTTP traffic to the new cluster, with session affinity	7-89
Running IBM Installation Manager and completing the Application Center upgrade	7-48	Performing a rollback procedure	7-92
Upgrading from MobileFirst Server V6.3.0, or later	7-49	Uninstalling IBM MobileFirst Platform Foundation from the old cluster	7-92
Upgrading from Worklight Server V6.0.0, V6.1.0, or V6.2.0	7-50	Upgrading, or applying a fix pack to the MobileFirst Data Proxy	7-92
Upgrading from Worklight Server V5.0.6.x	7-51	Applying a fix pack to IBM MobileFirst Platform Operational Analytics	7-94
Upgrading from Worklight Server V5.0.6.x (changing the Liberty server)	7-53	Applying a fix pack to Application Center installed with Ant tasks	7-95
Restore the Application Center configurations and restart the application server	7-54		
Upgrading the MobileFirst runtime environment for MobileFirst Server V7.1.0 manually, or with Ant tasks	7-55	Developing MobileFirst applications	8-1
Stop all MobileFirst Server instances	7-55	MobileFirst projects, environments, and skins	8-2
Shutting down the application server to be upgraded	7-57	MobileFirst Studio overview	8-3
Installation or upgrade of MobileFirst Server Administration Services	7-58	Creating MobileFirst projects with MobileFirst Studio	8-6
Back up the runtime database	7-59	Creating an application in a MobileFirst project with MobileFirst Studio	8-8
Upgrade the runtime database	7-61	Creating the client side of a MobileFirst application with MobileFirst Studio	8-9
Upgrade the MobileFirst Server runtime environment	7-63	Features of MobileFirst Studio	8-11
Upgrading server farms for MobileFirst Server V7.1.0	7-65	Building and deploying in MobileFirst Studio	8-15
Restore the MobileFirst Server configuration	7-67	The Run on MobileFirst Development Server command	8-17
Restart the application server	7-68	The Build All Environments command	8-18
Updating deployment scripts	7-69	The Preview command	8-19
Additional MobileFirst Server V7.1.0 upgrade information	7-70	The Build Settings and Deploy Target command	8-19
Recovering from an unsuccessful upgrade to MobileFirst Server V7.1.0	7-70	Additional Run As menu options	8-22
		Working with multiple MobileFirst Server instances in MobileFirst Studio	8-23
		MobileFirst Filtered Export	8-31
		MobileFirst CLI overview	8-31
		CLI commands usage	8-32
		Getting started with CLI	8-33

Creating an app back-end runtime	8-33	Development guidelines for desktop and web environments	8-141
Optimizing applications with CLI	8-34	Specifying the application taskbar for Adobe AIR applications	8-141
Creating a build-settings entry by using CLI	8-34	Configuring the authentication for web widgets.	8-141
Updating a build-settings entry by using CLI	8-35	Writing login form files for web widgets	8-142
Deleting a build-settings entry by using CLI	8-35	Setting the size of the login screen for web widgets	8-142
Troubleshooting a Request Timeout error	8-35	Signing Adobe AIR applications	8-142
Developing cross-platform apps	8-36	Signing Windows 8 Universal apps	8-143
Cordova apps versus MobileFirst hybrid apps	8-36	Embedding widgets in predefined web pages	8-143
Developing hybrid and web apps	8-39	Developing globalized hybrid applications	8-144
Anatomy of a MobileFirst project	8-40	Globalization in JavaScript frameworks	8-144
Anatomy of a MobileFirst application	8-41	Globalization mechanisms in IBM MobileFirst Platform Foundation	8-155
The application folder	8-41	Globalization of web services	8-164
Application resources	8-43	Globalization of push notifications.	8-165
The application descriptor	8-50	Enforce language preference for MobileFirst messages	8-168
Login form and authenticator.	8-58	Developing Cordova apps	8-169
Setting up a new MobileFirst environment for your application	8-58	Anatomy of a MobileFirst Cordova project	8-169
Developing hybrid applications	8-60	The Cordova application descriptor	8-170
Developing hybrid applications for iOS	8-61	Cordova app resources	8-174
Developing hybrid applications for Android	8-66	Creating a Cordova project with the CLI	8-176
Developing hybrid applications for BlackBerry	8-76	Managing platforms	8-177
Developing hybrid applications for Windows Phone Silverlight 8	8-79	Managing Cordova plug-ins.	8-178
Developing hybrid applications for Windows 8 Universal	8-80	Enabling a Cordova app to support Android SDK version 23 permissions.	8-178
Managing the splash screen	8-81	Connecting to MobileFirst Server	8-179
Sending actions and data objects between JavaScript code and native code	8-86	Converting existing MobileFirst hybrid app into a Cordova app.	8-179
Guidelines for testing hybrid MobileFirst applications.	8-89	Converting a MobileFirst Cordova project to an Android Studio-based project	8-181
Developing user interface of hybrid applications.	8-90	Developing native applications	8-182
JavaScript API for UI controls.	8-90	Integrating IBM MobileFirst Platform Foundation APIs into native applications	8-184
Using JavaScript toolkits	8-92	Developing native applications for iOS	8-185
Application skins	8-115	Application descriptor of native API applications for iOS	8-185
Settings page to change the server URL	8-117	Client property file for iOS	8-188
Rich Page Editor.	8-117	Methods of setting up your environment	8-190
Web and native code in iPhone, iPad, and Android	8-136	Copying SDK and configuration files from the project	8-190
Switching between native and web views	8-136	Adding the IBM MobileFirst Platform Foundation iOS SDK to a new application with CocoaPods	8-192
Receiving data from the web view in an Objective-C page	8-137	Configuring a Swift application.	8-194
Returning control to the web view from an Objective-C page	8-137	Using Logger in Swift Projects	8-194
Animating the transition from an Objective-C page to a web view	8-138	Enforcing TLS-secure connections in iOS apps.	8-198
Animating the transition from a web view to an Objective-C page.	8-138	Disabling bitcode in Xcode builds	8-199
Receiving data from the web view in a Java page	8-138	Developing native applications for Android	8-200
Returning control to the web view from a Java page	8-139	Application Descriptor of Native API application for Android	8-200
Animating the transitions from and to a Java page	8-140	Client property file for Android	8-203
Guidelines for using native code in hybrid MobileFirst projects	8-140	Methods of setting up your environment	8-204
		Copying SDK and configuration files from the MobileFirst project	8-204

Adding the IBM MobileFirst Platform Foundation SDK to a new or existing application with Android Studio	8-206	Developing JavaScript adapters.	8-263
Extracting a public signing key from native apps.	8-208	Creating a JavaScript MobileFirst adapter.	8-263
Developing native applications for Java Platform, Micro Edition	8-211	Setting up connectivity to back-end configuration.	8-275
Application descriptor of native API applications for Java Platform, Micro Edition (Java ME)	8-211	Developing JavaScript adapter code	8-305
Client property file for Java Platform, Micro Edition (Java ME)	8-213	USSD Support	8-316
Copying files of Native API applications for Java Platform, Micro Edition (Java ME) .	8-214	Invoking a back-end service for USSD	8-318
Developing native C# applications for Windows Phone Silverlight 8	8-214	Deploying adapters.	8-321
Application descriptor of native C# API application for Windows Phone Silverlight 8	8-214	Testing adapters.	8-322
Client property file for Windows Phone Silverlight 8	8-217	Session-independent mode	8-324
Copying files of Native API applications for Windows Phone Silverlight 8	8-218	Attribute store over IBM WebSphere eXtreme Scale.	8-327
Developing native C# applications for Windows 8 Universal and Windows Phone 8 Universal	8-219	eXtreme Scale Grid Definition	8-328
Application Descriptor of native C# API application for Windows 8 Universal and Windows Phone 8 Universal.	8-219	IBM MobileFirst Platform Server configuration.	8-329
Client property file for Windows 8 Universal and Windows Phone 8 Universal. .	8-222	Persisting the eXtreme Scale cache to the IBM MobileFirst Platform Server relational database	8-330
Copying files of native API applications for Windows 8 Universal and Windows Phone 8 Universal	8-222	Persisting the eXtreme Scale cache to Cloudant	8-332
Adding MobileFirst web capabilities to an existing native app	8-224	Client access to adapters	8-334
Token licensing: setting the license app type	8-229	Accessing adapters from the /adapters endpoint	8-334
Artifacts produced during development cycle	8-230	Accessing adapters from the /apps/services/api/query endpoint	8-336
Developing the server side of a MobileFirst application	8-231	Accessing adapters from the /invoke endpoint	8-336
Overview of MobileFirst adapters	8-231	Integrating with source control systems	8-337
MobileFirst Java adapters.	8-233	The MobileFirst Development Server and the MobileFirst Operations Console	8-339
Structure of Java adapters	8-234	Connecting to MobileFirst Server	8-341
Developing Java adapters.	8-235	Removing a project from MobileFirst Operations Console.	8-342
Creating a Java adapter using MobileFirst Studio	8-235	The jvm.options file	8-342
Creating a Java adapter using MobileFirst CLI commands	8-236	Mobile Browser Simulator	8-343
Developing Java adapter code	8-236	Testing mobile applications with the Mobile Browser Simulator	8-345
MobileFirst JavaScript adapters.	8-245	Switching devices	8-346
Structure of the adapter XML file	8-247	Adding devices	8-346
Cast Iron adapter connectionPolicy element.	8-250	Calibrating the Mobile Browser Simulator	8-347
HTTP adapter connectionPolicy element.	8-252	Enabling user agent switching	8-347
JMS adapter connectionPolicy element	8-255	Previewing your MobileFirst applications	8-348
SAP Gateway adapter connectionPolicy element.	8-257	Previewing web resource changes on an emulator or mobile device	8-355
SAP JCo adapter connectionPolicy element.	8-260	Testing hybrid location service applications	8-356
SQL adapter connectionPolicy element	8-261	Mobile Browser Simulator geolocation widget	8-356
		Mobile Browser Simulator network widget	8-358
		Developing accessible applications.	8-359
		Optimizing MobileFirst applications	8-360
		Including and excluding application features	8-361
		Application cache management in Desktop Browser and Mobile Web apps	8-364
		Managing the application Cache Manifest in MobileFirst Studio	8-365
		MobileFirst application build settings.	8-369
		Minification of JS and CSS files.	8-371
		Concatenation of JS and CSS files	8-373
		Optimizing MobileFirst applications for use over slow networks.	8-376

Configuring and customizing direct update.	8-378	SQLCipher on Windows Phone	
Direct updates of app versions to mobile devices	8-379	Silverlight 8 and Windows 8 Universal	8-454
Direct updates of app versions to desktop apps.	8-382	Setting up Touch ID support for JSONStore.	8-455
Direct Update as a security realm	8-382	JSONStore multiple user support	8-456
Enabling Direct Update Authenticity checks	8-385	JSONStore performance	8-456
Serving direct update requests from a CDN	8-387	JSONStore concurrency	8-458
Customizing the direct update interface and process	8-390	Work with external data	8-459
Updating mobile apps with IBM MobileFirst Platform Foundation and the Application Center	8-395	JSONStore wizard (JavaScript only)	8-465
Accelerating application development by reusing resources	8-397	JSONStore analytics	8-466
Configuring application component and template preferences	8-397	JSONStore security utilities	8-467
Application components	8-398	JSONStore security utilities overview	8-467
Creating application components from MobileFirst projects.	8-398	JSONStore security utilities setup	8-468
Viewing the contents of an application component	8-399	JSONStore security utilities examples.	8-468
Adding hooks to an application component	8-401	JSONStore security utilities iOS examples	8-468
CordovaPlugin element	8-402	JSONStore security utilities Android examples	8-469
Activities element	8-403	JSONStore security utilities JavaScript examples	8-470
UserPermissions element	8-405	Storing mobile data in Cloudant	8-471

Protecting resources on WebSphere Application Server or WebSphere Application Server Liberty	8-537	Implementing server-side components for custom device provisioning	8-610
Protecting resources with the token validation endpoint	8-543	Implementing client-side components for custom device provisioning	8-612
The test token endpoint	8-546	Configuring login modules	8-617
Exposing mobile services to non-mobile (confidential) clients	8-547	Non-validating login module	8-619
Custom requests to resources using Objective-C	8-549	Single identity login module	8-619
Custom requests to resources using Java	8-550	Header login module	8-620
Custom requests to resources using JavaScript	8-551	WASLTPAModule login module	8-620
Custom requests to resources using C#	8-552	LDAP login module	8-621
HTTP-based custom authentication	8-553	Configuring authenticators and realms	8-626
Challenge handling in a gateway topology	8-558	Implementing basic authenticators	8-626
Classic security model	8-559	Implementing form-based authenticators	8-629
MobileFirst application authenticity overview	8-564	Implementing Java-based custom authenticators	8-632
Security tests	8-569	Header authenticator	8-637
Security configurations of protected resources	8-571	Persistent cookie authenticator	8-637
Authentication realms	8-573	Implementing adapter-based authenticators	8-638
User certificate authentication realm	8-573	LTPA authenticator	8-644
Anti-cross site request forgery (anti-XSRF) realm	8-574	Device single sign-on (SSO)	8-645
Certificate pinning	8-574	Configuring device single sign-on	8-646
User certificate authentication	8-577	Device single sign-on with the IBM Security Access Manager Web reverse proxy	8-650
User certificate authentication overview	8-577	Configuring device single sign-on with a reverse proxy	8-650
Protecting resources with user certificate authentication	8-579	Configuring MobileFirst web application authorization	8-652
User certificate authentication on the server	8-580	Location services	8-652
SSL configuration	8-580	Platform support for location services	8-654
PKI bridge configuration	8-581	Location services permissions	8-654
Embedded PKI bridge	8-581		
External/adaptor-based PKI bridge	8-583		
Custom PKI bridge	8-587		

Location services permissions in Android	8-654
Location services permissions in iOS	8-656
Location services permissions in Windows Phone Silverlight 8	8-656
Triggers	8-657
Setting an acquisition policy	8-658
Working with geofences and triggers	8-660
Differentiating between indoor areas	8-663
Securing server resources based on location	8-668
Tracking the current location of devices	8-670
Keeping the application running in the background	8-672
Client-side log capture	8-673
Configuring the MobileFirst Logger	8-677
Set log level after IBM MobileFirst Platform Foundation starts	8-677
Select log levels	8-677
Log different data types	8-678
Filter log levels	8-678
Log package whitelist and blacklist	8-679
Create log for package	8-679
Stringify	8-680
Callback	8-680
Log message tags	8-681
Method chaining	8-681
Pretty-print JSON objects	8-682
Print stack traces	8-682
Logger Android check and override	8-682
Environment-specific settings	8-683
JavaScript module example	8-684
Server preparation for uploaded log data	8-686
Client-side log capture configuration from MobileFirst Operations Console	8-688

Migrating applications created on IBM Bluemix to IBM MobileFirst Platform

Foundation	9-1
Migration scenario	9-1
Adapting the server-side code	9-3
Migrating a Bluemix app that uses HTTP-based custom authentication to on-premises MobileFirst Server	9-3
Migrating a Bluemix app that uses an OAuth TAI filter to on-premises MobileFirst Server	9-5
Migrating a Bluemix app that uses a Node.js filter to on-premises MobileFirst Server	9-9
Adapting the iOS client application	9-11
Installing required components	9-12
Configuring the Xcode project	9-13
Modifying the application code	9-13
Additional migration steps for Cloudant data	9-15

Testing with IBM MobileFirst Platform

Foundation	10-1
Getting started	10-6
Creating a Test Workbench project	10-6
Managing mobile applications for testing	10-7
Creating mobile tests	10-7
Editing mobile tests	10-8
Running mobile tests	10-9

Evaluating results	10-9
Using MobileFirst Studio and Application Center	10-9
Initiating mobile testing from Android, iPad, and iPhone environments in MobileFirst Studio	10-9
Using the Application Center and the MobileFirst Test Workbench to share applications	10-11
Publishing test-ready iOS applications to the Application Center	10-12

Administering adapters and apps in MobileFirst Operations Console	12-88	Security configuration for IBM MobileFirst Platform Foundation on IBM Containers.	12-140
Deploying apps	12-88	Configuring App Transport Security (ATS)	12-144
Deleting apps.	12-89	LDAP configuration for containers	12-145
Exporting adapter configuration files	12-89	Removing a container from Bluemix	12-148
Deploying adapters.	12-89	Removing the database service configuration app from Bluemix	12-149
Modifying adapters.	12-90	Log and trace collection	12-149
Deleting adapters	12-90	Accessing log files.	12-150
MobileFirst security overview	12-90	Logging overrides.	12-152
MobileFirst security configuration	12-92	Troubleshooting tips	12-152
MobileFirst Security and LTPA	12-94	Application not configured correctly	12-152
Configuring the MobileFirst LTPA realm	12-95	Docker-related error while running	script
Supported configurations for LTPA	12-96	script	12-152
LTPA topologies and use cases	12-100	Bluemix registry error	12-153
Configuring the MobileFirst Server for Trusteer	12-100	Unable to create the runtime .xml file	12-153
Accessing Trusteer risk assessment	12-104	Taking a long time to push image	12-153
Advanced security features.	12-105	Binding is incomplete error.	12-154
Obfuscating Android code with ProGuard	12-106	Script fails and returns message about tokens.	12-154
Example	12-106	No runtimes listed in console	12-154
Creating an obfuscated APK file from MobileFirst Studio.	12-107	prepareserver.sh script fails.	12-155
Creating an obfuscated APK file from a command line	12-108	Applying IBM MobileFirst Platform Foundation interim fixes in an IBM Containers environment.	12-155
Restoring an obfuscated stack trace	12-109	Resolving problems	12-156
Code size reduction from obfuscation	12-110	Deploying MobileFirst Server on IBM PureApplication System	12-156
High availability	12-110	Installing IBM MobileFirst Platform Foundation System Patterns	12-159
Clustering	12-110	Token licensing requirements for IBM MobileFirst Platform Foundation System Patterns	12-160
Configuring the load balancer	12-111	Deploying MobileFirst Server on a single-node WebSphere Application Server Liberty profile server.	12-160
Adding a node to the cluster	12-111	Deploying MobileFirst Server on a multiple-node WebSphere Application Server Liberty profile server.	12-166
Firewalls	12-111	Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server	12-171
Disaster Recovery Site	12-112	Deploying MobileFirst Server on a multiple-node WebSphere Application Server full profile server	12-177
Updating MobileFirst apps in production	12-113	Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers	12-183
Deploying to the cloud in an IBM Container	12-115	MobileFirst runtime synchronization limitation with WebSphere Application Server Network Deployment	12-189
IBM MobileFirst Platform Foundation on IBM Containers	12-115	Restarting the IBM MobileFirst Platform runtime from the WebSphere Application Server administrative console	12-190
Package structure and contents	12-117	Configuring MobileFirst administration security with an external LDAP repository	12-192
Setting up MobileFirst Platform Foundation on IBM Containers	12-118	Deploying and configuring MobileFirst Operational Analytics	12-196
MobileFirst Server containers	12-118		
Configuring a database instance on IBM Cloudant	12-119		
Customizing MobileFirst Server containers	12-120		
Building and running the MobileFirst Server container	12-122		
Adding, updating, and removing projects	12-126		
Configuring session-independent mode	12-126		
Script overview and usage	12-127		
Using the MobileFirst Data Proxy	12-132		
MobileFirst Operational Analytics containers	12-134		
Customizing MobileFirst Operational Analytics containers	12-134		
Building and running the MobileFirst Operational Analytics container	12-135		
Script overview and usage	12-136		
Securing containers	12-140		

Deploying several MobileFirst runtimes in a pattern in MobileFirst Server	12-203
Deploying MobileFirst Server without the Reports database	12-208
Deployment of the Application Center to the cloud	12-209
Deploying the Application Center on IBM PureApplication System	12-210
Predefined templates for MobileFirst Platform Patterns	12-212
Script packages for MobileFirst Server	12-223
Upgrading IBM MobileFirst Platform Application Pattern	12-238

Administering MobileFirst applications. 13-1

Administering MobileFirst applications with MobileFirst Operations Console	13-2
Locking an application	13-3
Remotely disabling application connectivity	13-3
Displaying a notification message on application startup	13-5
Defining administrator messages from MobileFirst Operations Console in multiple languages	13-5
Application status and token licensing.	13-8
Error log of operations on runtime environments	13-9
Audit log of administration operations	13-10
Administering MobileFirst applications through Ant	13-12
Calling the wladm Ant task	13-13
Commands for adapters	13-16
Commands for apps	13-19
Commands for beacons	13-24
Commands for devices	13-31
Commands for troubleshooting.	13-33
A complex example of a wladm Ant task	13-36
Administering MobileFirst applications through the command line	13-37
Calling the wladm program	13-38
Commands for adapters	13-43
Commands for apps	13-45
Commands for beacons	13-51
Commands for devices	13-58
Commands for troubleshooting.	13-60
Administering push notifications with the MobileFirst Operations Console	13-64
Application Center	13-65
Concept of Application Center	13-65
Specific platform requirements	13-66
General architecture	13-68
Preliminary information	13-70
Preparations for using the mobile client	13-71
Importing and building the project (Android, iOS, Windows Phone)	13-73
Customizing features (for experts):	
Android, iOS, Windows Phone	13-74
Microsoft Windows 8: Building the project	13-76
Importing and building the project (BlackBerry)	13-77

Customizing features (for experts):	
BlackBerry.	13-78
Deploying the mobile client in Application Center	13-79
Push notifications of application updates	13-80
Configuring push notifications for application updates.	13-81
Configuring the Application Center server for connection to Google Cloud Messaging .	13-82
Configuring the Application Center server for connection to Apple Push Notification Services	13-83
Building a version of the mobile client that does not depend on the GCM API.	13-85
The Application Center console.	13-86
Starting the Application Center console	13-86
Troubleshooting a corrupt login page (Apache Tomcat)	13-87
Troubleshooting a corrupted login page in Safari browsers	13-88
Application Management.	13-88
Adding a mobile application	13-89
Adding an application from a public app store.	13-91
Application properties.	13-94

IBM MobileFirst Platform Foundation V7.1.0 documentation

Welcome to the IBM MobileFirst™ Platform Foundation V7.1.0 documentation, where you can find information about how to install, maintain, and use the IBM MobileFirst Platform Foundation.

Getting started

“Product overview” on page 2-1

IBM MobileFirst Platform Foundation is an integrated platform that helps you extend your business to mobile devices.

“Notices” on page A-1

“Release notes” on page 3-1

You can identify the latest information about this product release and all its fix packs.

“Tutorials, samples, and additional resources” on page 5-1

Tutorials and samples help you get started with and learn about IBM MobileFirst Platform Foundation. Use them to evaluate what the product can do for you.

“Installation overview” on page 6-1

IBM MobileFirst Platform Foundation provides the following installable components: MobileFirst Studio, MobileFirst Server, and IBM MobileFirst Platform Test Workbench. This section gives an overview of the installation process.

“Configuring MobileFirst Server” on page 6-147

Consider your backup and recovery policy, optimize your MobileFirst Server configuration, and apply access restrictions and security options.

“System requirements” on page 2-15

System requirements for IBM MobileFirst Platform Foundation include operating systems, Eclipse versions, SDKs, and other software.

Common tasks

“Developing MobileFirst applications” on page 8-1

You use either MobileFirst Platform Command Line Interface or MobileFirst Studio, and the MobileFirst client- and server-side APIs to develop cross-platform mobile applications, desktop applications, or web applications.

“Testing with IBM MobileFirst Platform Foundation” on page 10-1

The mobile testing features of IBM MobileFirst Platform Test Workbench automate the creation, execution, and analysis of functional tests for MobileFirst native, hybrid, and web applications on Android and iOS devices. A superset of these features is available in Rational® Test Workbench Mobile Test Edition. Testing BlackBerry applications is not currently supported.

“Deploying MobileFirst projects” on page 12-1

After you have created projects and apps with MobileFirst Studio, you must deploy them to the production environment.

“Administering MobileFirst applications” on page 13-1

Run and maintain MobileFirst applications in production.

“Application Center” on page 13-65

Learn about the Application Center: what it is for, the different components and features, and how to use the console and the client.

Troubleshooting and support

“Troubleshooting” on page 4-1

You can find advice on how to troubleshoot problems, and more information about known limitations and technotes (Troubleshooting).

“Known issues” on page 3-23

You can identify the latest known issues and their resolutions, for this product release and all its fix packs, by browsing this dynamic list of documents.

“Accessibility” on page 2-17

Accessibility features enable people with disabilities, such as restricted mobility and limited vision, to work successfully with IBM MobileFirst Platform Foundation.

Mobile Application Developer skills

Product overview

IBM MobileFirst Platform Foundation is an integrated platform that helps you extend your business to mobile devices.

IBM MobileFirst Platform Foundation includes a comprehensive development environment, mobile-optimized runtime middleware, a private enterprise application store, and an integrated management and analytics console, all supported by various security mechanisms.

With IBM MobileFirst Platform Foundation, your organization can efficiently develop, connect, run, and manage rich mobile applications (apps) that can access the full capabilities of your target mobile devices. IBM MobileFirst Platform Foundation can help reduce time-to-market, cost, and complexity of development, and enables an optimized customer and employee user experience across multiple environments.

As part of this comprehensive mobile solution, IBM MobileFirst Platform Foundation can be integrated with application lifecycle, security, management, and analytics capabilities to help you address the unique mobile needs of your business.

Introduction to mobile application development

With IBM MobileFirst Platform Foundation, you can develop mobile applications by using any of four different approaches: web development, hybrid development, hybrid mixed development, and native development.

IBM MobileFirst Platform Foundation provides capabilities to help you respond to the fast-paced development of mobile devices. This flexible structure gives you more options when you implement your mobile communication channel, or release a new version of your application, be it a hybrid or native application. You can evaluate the best approach for each situation, according to skills, time, and functionality, without being limited by a specific approach to mobile application development.

With IBM MobileFirst Platform Foundation, you can develop mobile applications by using a spectrum of supported approaches. See Figure 2-1 on page 2-2.

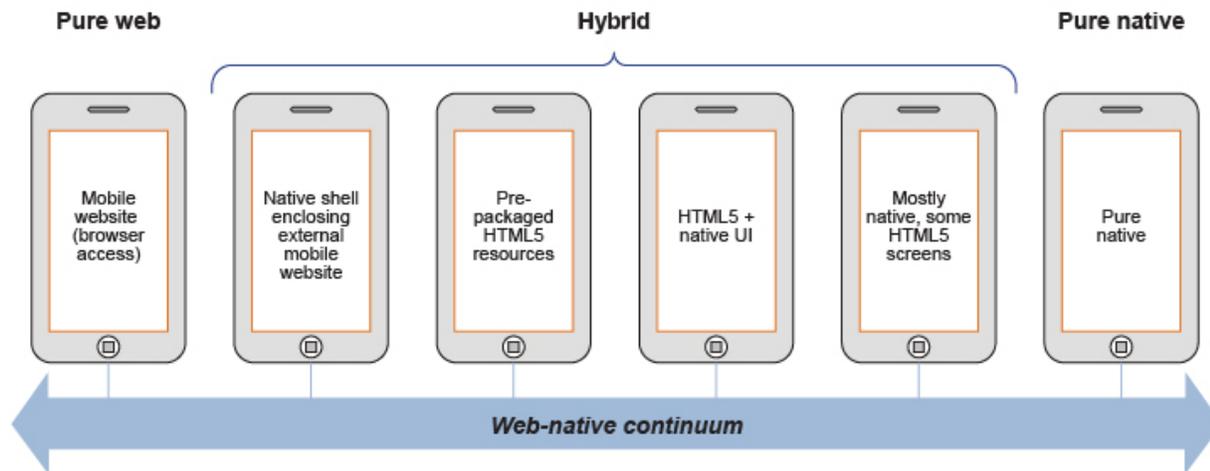

Figure 2-1. Spectrum of mobile app development approaches

Desktop and mobile website development

With the website development approach, users start their preferred browser and navigate to the enterprise website. The application runs inside the browser of the mobile device, and uses standard technologies such as HTML5, CSS3, and JavaScript to create the website. Your application is platform independent, so you do not need to develop a new application to support a new mobile platform. Modifications to your application might be required to support a different browser engine. On the downside, however, mobile web applications cannot access device functions such as contact list because they rely only on the browser and the associated web standards. In addition, if the website, and especially the enterprise back-end systems are not optimized for mobile interactions, user experience is less than pleasing. Mobile web applications are not distributed through an application store. They are accessed through a link on a website, or a bookmark in the mobile browser of the user.

Hybrid development

With the hybrid development approach, you can create applications that use parts of both the native and web development approaches with standards such as HTML5, JavaScript and CSS. Your hybrid application runs inside a native container and uses the browser engine to display the application interface. The interface is often based on HTML and JavaScript and can also incorporate native elements. The native container allows your application to access device capabilities that are not accessible to web applications, such as the accelerometer, camera, and local storage on a smartphone. These capabilities can be leveraged from JavaScript using Apache Cordova. The application is built using the mobile OS native IDE, such as Xcode. Similar to pure-native applications, hybrid applications are distributed through the application store of the platform.

As shown in the diagram, there are several possible approaches to hybrid development:

Native shell application enclosing an external mobile website

Using this approach is similar to mobile website development, however your mobile website is displayed inside of a native shell that is provided by IBM MobileFirst Platform Foundation instead of the device browser. By

using this approach, your mobile website is able to access device native functionality through APIs exposed by the native container. There are several drawbacks with this approach: drawing the app code and user interface remotely from a website might significantly downgrade user experience; when your only in-browser caching options are manual or through the HTML5 manifest, offline functioning is not optimized.

Pre-packaged HTML5 resources

This is the most common approach when developing hybrid mobile applications. With this approach, you can create applications that use a container to access device capabilities, but also use other native, platform-specific components such as libraries, or specific user-interface elements, to enhance the mobile application. Unlike the previous approach, the web resources are not loaded from an external website but are packaged within the application itself. In addition to leveraging the native functionality that is provided by a native container, the application can achieve better performance and responsiveness since all the resources required for application functionality are packaged within the app itself and do not need to be loaded over a network. By using this approach, your application acquires the ability to work and store data in offline mode. To achieve the best user experience, it is important to optimize for various form factors by using techniques such as responsive web design.

Mixing web and native in code and UI (HTML5 + native UI/mostly native with some HTML5 screens)

Here, you mix web and native elements in one of two approaches: either you have a hybrid app to which you add native user interface components and gestures or you have a mostly native app and add HTML5 screens. By developing in this style, you are able, for example, to start your application with a native screen and move to a web screen at a later stage, or even mix native and web components on the same screen. There are several benefits:

- You fully leverage all platform functions such as accessing the camera or contact list from both native and JavaScript code.
- You achieve enhanced performance and user experience where you need it, by using native capabilities.
- You reuse code and web development skills by using HTML5/JavaScript/CSS where you can.

Pure native development

With the pure native development approach, you can create applications that are written for a specific platform and run on that platform only. Your applications achieve great performance and can fully leverage all platform functions such as accessing the camera or contact list, enabling gestures, or interacting with other applications on the device. To support platforms such as Android, iOS, Java™ ME, and Windows Phone, you must develop separate applications with different programming languages, such as Objective-C for iOS, or Java for Android, or C# for Windows Phone Silverlight 8. Unlike desktop and mobile web applications, native and hybrid applications are distributed through an application store.

Aspects of each development approach

Each of these development approaches has advantages and disadvantages. You must select the appropriate development approach according to the specific requirements for an individual mobile solution. This choice depends heavily on the specifics of your mobile application and its functional requirements. Mapping your

requirements to select an appropriate development approach is the first step in a mobile development project. Table 2-1 outlines the major aspects of the four development approaches, and can help you decide which development approach is appropriate for your specific mobile application.

Table 2-1. Comparison of mobile development approaches. In this table, you can find the different aspects of mobiles developments and the level of difficulty or possibilities that web development, hybrid development, hybrid mixed development, and native development, can bring for each aspect.

Aspect	Mobile website development	Native shell, external mobile website	Pre-packaged HTML5 resources	Mixing web and native in code and UI	Pure native development
Easy to learn	Easiest	Easiest	Medium	Harder	Hardest
Application performance	Slowest	Moderate	Good	Fastest	Fastest
Device knowledge required	None	Some	Some	Some	A lot
Development lifecycle (build/test/deploy)	Shortest	Shortest	Medium	Medium	Longest
Application portability to other platforms	Highest	High	High	Medium	None
Support for native device functionality	Some	Most	Most	All	All
Distribution with built-in mechanisms	No	No	Yes	Yes	Yes
Ability to write extensions to device capabilities	No	No	Yes	Yes	Yes

Product main capabilities

With IBM MobileFirst Platform Foundation, you can use capabilities such as development, testing, back-end connections, push notifications, offline mode, update, security, analytics, monitoring, and application publishing.

Development

IBM MobileFirst Platform Foundation provides a framework that enables the development, optimization, integration, and management of secure mobile applications (apps). IBM MobileFirst Platform Foundation does not introduce a proprietary programming language or model that users must learn.

You can develop apps by using HTML5, CSS3, and JavaScript. You can optionally write native code (Java or Objective-C). IBM MobileFirst Platform Foundation

provides an SDK that includes libraries that you can access from native code.

Testing

IBM MobileFirst Platform Foundation includes IBM MobileFirst Platform Test Workbench for testing mobile applications. With the mobile testing capabilities of MobileFirst Test Workbench, you can automate the creation, execution, and analysis of functional tests for IBM MobileFirst Platform Foundation native and hybrid applications on Android and iOS devices.

Back-end connections

Some mobile applications run strictly offline with no connection to a back-end system, but most mobile applications connect to existing enterprise services to provide the critical user-related functions. For example, customers can use a mobile application to shop anywhere, at any time, independent of the operating hours of the store. Their orders must still be processed by using the existing e-commerce platform of the store. To integrate a mobile application with enterprise services, you must use middleware such as a mobile gateway. IBM MobileFirst Platform Foundation can act as this middleware solution and make communication with back-end services easier.

Push notifications

With push notifications, enterprise applications can send information to mobile devices, even when the application is not being used. IBM MobileFirst Platform Foundation includes a unified notification framework which provides a consistent mechanism for such push notifications. With this unified notification framework, you can send push notifications without having to know the details of each targeted device or platform because each mobile platform has a different mechanism for push notification.

Offline mode

In terms of connectivity, mobile applications can operate offline, online, or in a mixed mode. IBM MobileFirst Platform Foundation uses a client/server architecture that can detect whether a device has network connectivity, and the quality of the connection. Acting as a client, mobile applications periodically attempt to connect to the server and to assess the strength of the connection. An offline-enabled mobile application can be used when a mobile device lacks connectivity but some functions can be limited. When you create an offline-enabled mobile application, it is useful to store information about the mobile device that can help preserve its functionality in offline mode. This information typically comes from a back-end system, and you must consider data synchronization with the back end as part of the application architecture. IBM MobileFirst Platform Foundation includes a feature that is called JSONStore for data exchange and storage. With this feature, you can create, read, update, and delete data records from a data source. Each operation is queued when operating offline. When a connection is available, the operation is transferred to the server and each operation is then performed against the source data.

Update

IBM MobileFirst Platform Foundation simplifies version management and mobile application compatibility. Whenever a user starts a mobile application, the application communicates with a server. By using this server, IBM MobileFirst

Platform Foundation can determine whether a more recent version of the application is available, and if so, give information to the user about it, or push an application update to the device. The server can also force an upgrade to the latest version of an application to prevent continued use of an outdated version.

Security

Protecting confidential and private information is critical for all applications within an enterprise, including mobile applications. Mobile security applies at various levels, such as mobile application, mobile application services, or back-end service. You must ensure customer privacy and protect confidential data from being accessed by unauthorized users. Dealing with privately owned mobile devices means giving up control on certain lower levels of security, such as the mobile operating system.

IBM MobileFirst Platform Foundation provides secure, end-to-end communication by positioning a server that oversees the flow of data between the mobile application and your back-end systems. With IBM MobileFirst Platform Foundation, you can define custom security handlers for any access to this flow of data. Because any access to data of a mobile application has to go through this server instance, you can define different security handlers for mobile applications, web applications, and back-end access. With this kind of granular security, you can define separate levels of authentication for different functions of your mobile application. You can also prevent mobile applications from accessing sensitive information.

Analytics

The operational analytics feature enables searching across apps, services, devices, and other sources to collect data about usage, or to detect problems.

In addition to reports that summarize app activity, IBM MobileFirst Platform Foundation includes a scalable operational analytics platform accessible in the MobileFirst Operations Console. The analytics feature enables enterprises to search across logs and events that are collected from devices, apps, and servers for patterns, problems, and platform usage statistics. You can enable analytics, reports, or both, depending on your needs.

Monitoring

IBM MobileFirst Platform Foundation includes a range of operational analytics and reporting mechanisms for collecting, viewing, and analyzing data from your IBM MobileFirst Platform Foundation applications and servers, and for monitoring server health.

Application publishing

IBM MobileFirst Platform Foundation Application Center is an enterprise application store. With the Application Center, you can install, configure, and administer a repository of mobile applications for use by individuals and groups across your enterprise. You can control who in your organization can access the Application Center and upload applications to the Application Center repository, and who can download and install these applications onto a mobile device. You can also use the Application Center to collect feedback from users and access information about devices on which applications are installed.

The concept of the Application Center is similar to the concept of the Apple public App Store or the Google Play store, except that it targets the development process.

The Application Center provides a repository for storing the mobile application files and a web-based console for managing that repository. The Application Center also provides a mobile client application to allow users to browse the catalog of applications that are stored by the Application Center, install applications, leave feedback for the development team, and expose production applications to IBM® Endpoint Manager. Access to download and install applications from the Application Center is controlled by using access control lists (ACLs).

Product components

IBM MobileFirst Platform Foundation consists of the following components: MobileFirst Platform Command Line Interface, MobileFirst Studio, MobileFirst Server, client-side runtime components, MobileFirst Operations Console, Application Center, IBM MobileFirst Platform Cloudant® Data Layer Local Edition, IBM MobileFirst Platform Foundation System Patterns, and IBM Connect.

Component overview

The following figure shows the components of IBM MobileFirst Platform Foundation:

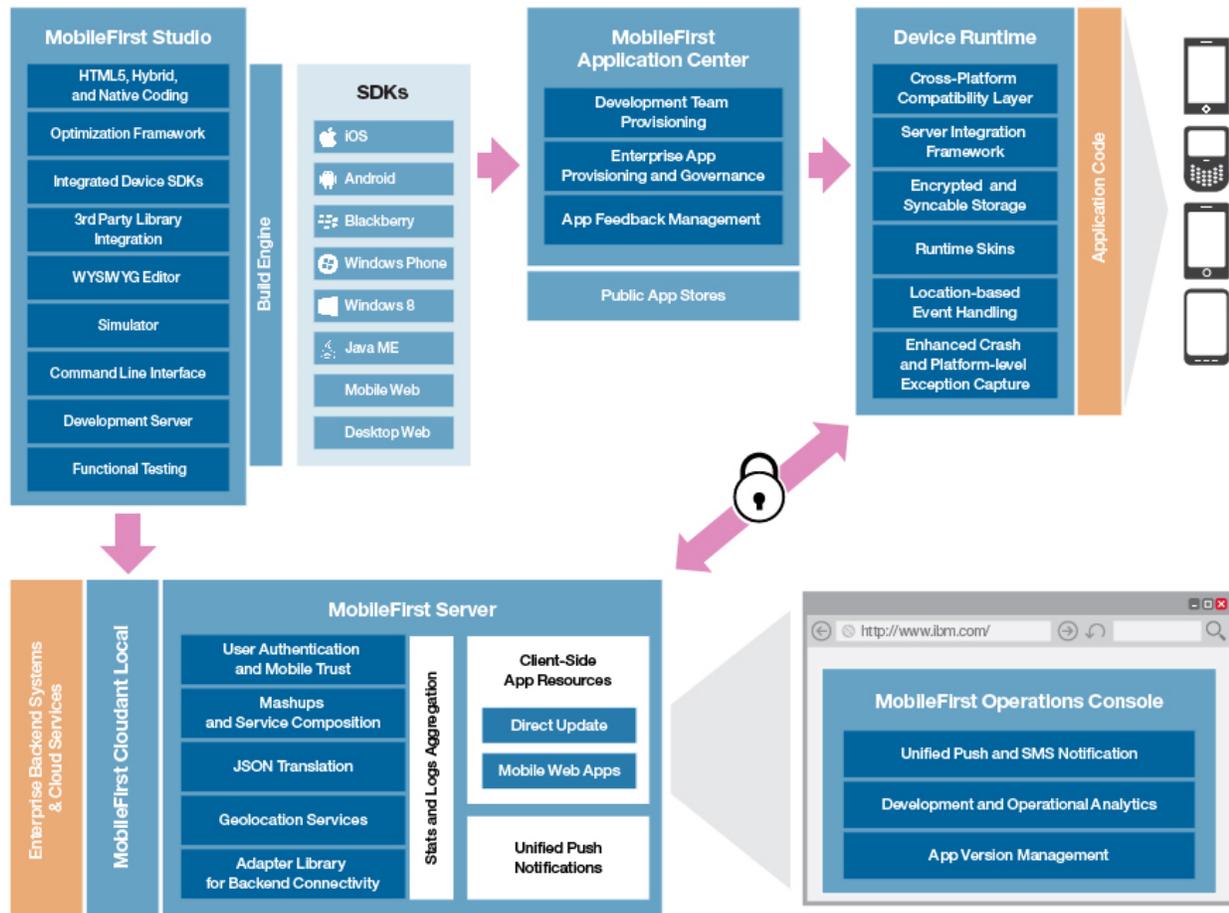

Figure 2-2. IBM MobileFirst Platform Foundation architecture

MobileFirst Studio

In a mobile development platform, cross-platform portability of the application code is critical for mobile device application development. Various methods exist to achieve this portability. With IBM MobileFirst Platform Foundation, you can develop multiplatform applications by using MobileFirst Studio, which is an integrated development environment for mobile applications.

You can use MobileFirst Studio for the following tasks:

- Develop rich HTML5, hybrid and native applications for all supported modern devices by using native code, a bidirectional WYSIWYG editor, and standard web technologies and tools.
- Maximize code sharing by defining custom behavior and styling guidelines that match the target environment.
- Access device APIs by using native code or standard web languages over a uniform Apache Cordova bridge.

Important: Because Apache Cordova is preinstalled with IBM MobileFirst Platform Foundation, do not download your own Apache Cordova version.

- Use both native and standard web languages within the same application to achieve development efficiency and provide a rich user experience.

- Use third-party tools, libraries, and frameworks such as JQuery Mobile, Sencha Touch, and Dojo Mobile.
- Implement runtime skins to build apps that automatically adjust to environment guidelines such as form factor, screen density, HTML support, and UI input method.

MobileFirst Test Workbench

MobileFirst Test Workbench provides you with a subset of Rational Test Workbench Mobile Test Edition features to help you automate the creation, execution, and analysis of functional tests for MobileFirst native, hybrid, and web applications on Android and iOS devices. MobileFirst Test Workbench is an add-on component for MobileFirst Studio that you install separately.

MobileFirst Server

The MobileFirst Server is a runtime container for the mobile applications that you develop by using MobileFirst tooling. It is not an application server in the Java Platform, Enterprise Edition (Java EE) sense. It acts as a container for IBM MobileFirst Platform Foundation application packages, and is in fact a collection of web applications. Optionally, those web applications are packaged as EAR (enterprise archive) files, which run on top of traditional application servers.

MobileFirst Server integrates into your enterprise environment and uses existing resources and infrastructure. This integration is based on adapters that are server-side software components responsible for channeling back-end enterprise systems and cloud-based services to the user device. You can use adapters to retrieve and update data from information sources, and to allow users to perform transactions and start other services and applications.

You can use MobileFirst Server for the following tasks:

- Empower hundreds of thousands of users with transactional capabilities and enable their direct access to back-end systems and cloud-based services.
- Configure, test, and deploy descriptive XML files to connect to various back-end systems by using standard MobileFirst tools.
- Directly update deployed hybrid and web applications, without going through the different app stores (subject to the terms of service of the vendor).
- Automatically convert hierarchical data to JSON format for optimal delivery and consumption.
- Enhance user interaction with a uniform push notification architecture.
- Define complex mashups of multiple data sources to reduce overall traffic.
- Integrate with the existing security and authentication mechanisms of your organization.

MobileFirst Server environments can also be built as Docker images that you can deploy and run on the cloud using IBM Containers for Bluemix®.

IBM MobileFirst Platform Cloudant Data Layer Local Edition

MobileFirst Platform Local is an advanced NoSQL database, which can handle a wide variety of data types, such as JSON, full-text, and geospatial data.

As a JSON document store, MobileFirst Platform Local is ideal for managing multi-structured or unstructured data. With advanced indexing, you can enrich applications with location-based, geospatial services, full-text search, and real-time analytics.

MobileFirst Cloudant extensions include an SDK and proxy.

The SDK extends the Cloudant APIs with support for native language objects for iOS and Android developers, offline access, and online remote access. For more information, see “Storing mobile data in Cloudant” on page 8-471.

Authentication with OAuth is available through integration with the MobileFirst Data Proxy. For more information, see “Installing the MobileFirst Data Proxy” on page 6-225.

Client-side runtime components

IBM MobileFirst Platform Foundation provides client-side runtime code that embeds server functionality within the target environment of deployed apps. These runtime client APIs are libraries that are integrated into the locally stored app code. They complement MobileFirst Server by defining a predefined interface for apps to access native device functions. Among these APIs, IBM MobileFirst Platform Foundation uses the Apache Cordova development framework. This framework delivers a uniform bridge between standard web technologies (HTML5, CSS3, JavaScript) and the native functions that different mobile platforms provide.

The client-side runtime components provide the following functions:

- Mobile data integration: connectivity and authentication APIs
- Security features: on-device encryption, offline authentication, and remote disablement of the ability to connect to MobileFirst Server
- Cross-platform support: runtime skins, UI abstractions, and HTML5 toolkits compatibility
- Mobile client functionality: hybrid app framework, access to device APIs and push notification registration
- Resource serving: direct update of app web resources and HTML5 caching

The version of Apache Cordova that is included in V7.1.0 consists of the following components.

Note: Apache Cordova-related tools are applicable only to MobileFirst Platform Command Line Interface (CLI), not to MobileFirst Studio.

Platforms

- cordova-android: 3.6.4
- cordova-blackberry10: 3.6.3
- cordova-ios: 3.7.0
- cordova-windows: 3.7.1
- cordova-wp8: 3.7.0

Plug-ins

- org.apache.cordova.battery-status: 0.2.12
- org.apache.cordova.camera: 0.3.4
- org.apache.cordova.console: 0.2.12

- org.apache.cordova.contacts: 0.2.15

- ios-deploy: 1.5.0

MobileFirst Operations Console

The MobileFirst Operations Console is used for the control and management of the mobile applications.

You can use the MobileFirst Operations Console for the following tasks:

- Monitor all deployed applications, adapters, and push notification rules from a centralized, web-based console.
- Assign device-specific identifiers (IDs) to ensure secure application provisioning.
- Remotely disable the ability to connect to MobileFirst Server by using preconfigured rules of app version and device type.
- Customize messages that are sent to users on application launch.
- Collect user statistics from all running applications.
- Generate built-in, preconfigured reports about user adoption and usage (number and frequency of users that are engaging with the server through the applications).
- Configure data collection rules for application-specific events.
- Export raw reporting data to be analyzed by the business intelligence systems of your organization.

IBM MobileFirst Platform Operational Analytics

IBM MobileFirst Platform Foundation includes a scalable operational analytics feature that is accessible from the MobileFirst Operations Console. The analytics feature enables enterprises to search across logs and events that are collected from devices, apps, and servers for patterns, problems, and platform usage statistics.

The data for operational analytics includes the following sources:

- Crash events of an application on iOS and Android devices (crash events for native code and JavaScript errors).
- Interactions of any application-to-server activity (anything that is supported by the MobileFirst client/server protocol, including push notification).
- Server-side logs that are captured in traditional MobileFirst log files.

MobileFirst Server and MobileFirst Operational Analytics environments can also be built as Docker images that you can deploy and run on the cloud using IBM Containers for Bluemix.

Application Center

With the Application Center, you can share mobile applications that are under development within your organization in a single repository of mobile applications. Development team members can use the Application Center to share applications with members of the team. This process facilitates collaboration between all the people who are involved in the development of an application.

Your company can typically use the Application Center as follows:

1. The development team creates a version of an application.
2. The development team uploads the application to the Application Center, enters its description, and asks the extended team to review and test it.
3. When the new version of the application is available, a tester runs the Application Center installer application, which is the mobile client. Then, the tester locates this new version of the application, installs it on their mobile device, and tests it.
4. After the tests, the tester rates the application and submits feedback, which is visible to the developer from the Application Center console.

The Application Center is aimed for private use within a company, and you can target some mobile applications to specific groups of users. You can use the Application Center as an enterprise application store.

With the Application Center, you can manage native or hybrid applications that are installed on mobile devices. The Application Center supports applications that are built for the Google Android platform, the Apple iOS platform, the Windows Phone 8 platform, and the BlackBerry OS 6 and 7 platform. Application Center does not target mobile web applications.

Note: Windows Phone 7, Windows RT, and BlackBerry OS 10 are not supported by the current version of the Application Center.

IBM MobileFirst Platform Foundation System Patterns

With the MobileFirst Platform Patterns, you can deploy MobileFirst Server on IBM PureApplication® System or IBM PureApplication Service on SoftLayer®. With these patterns, administrators and corporations can respond quickly to changes in the business environment by taking advantage of on-premises Cloud technologies. This approach simplifies the deployment process, and improves the operational efficiency to cope with increased mobile demand. The demand accelerates iteration of solutions that exceed traditional demand cycles. Using MobileFirst Platform Patterns also gives access to best practices and built-in expertise, such as built-in scaling policies.

PureApplication System

IBM PureApplication System is an integrated, highly scalable system that is based on IBM X-Architecture, providing an application-centric computing model in a cloud environment.

An application-centric system is an efficient way to manage complex applications and the tasks and processes that are invoked by the application. The entire system implements a diverse virtual computing environment, in which different resource configurations are automatically tailored to different application workloads. The application management capabilities of the IBM PureApplication System platform make deployment of middleware and other application components quick, easy, and repeatable.

IBM PureApplication System provides virtualized workloads and a scalable infrastructure that is delivered in one integrated system.

Virtual System Patterns

Virtual system patterns are a logical representation of a recurring topology for a set of deployment requirements.

Virtual system patterns enable efficient and repeatable deployments of systems that include one or more virtual machine instances, and the applications that run on them. You can completely automate the deployment and eliminate multiple time-consuming manual tasks. Such a deployment eliminates problems that are introduced by error-prone, manual configuration processes, especially in complex production topologies such as server farms, and accelerates solution deployment.

MobileFirst Platform Command Line Interface

To help you get a better tools experience, IBM MobileFirst Platform Foundation provides a command-line interface (CLI) tool to easily create and manage apps. By working with the CLI, you can use your preferred text editors or alternative IDEs to create mobile applications.

The commands support tasks such as creating, adding, and configuring with the API library, adding the client-side properties file, and building and deploying the application. From the command line, you can create and deploy adapters, and test them locally. You can administer your project from CLI or REST services, or the MobileFirst Operations Console, where you can control the local server and observe the logs.

IBM API Connect

IBM API Connect is a management solution that addresses all aspects of the application programming interface (API) lifecycle for both on-premises and cloud environments. It offers capabilities to create, run, manage, secure, and monetize APIs and microservices.

With IBM MobileFirst Platform Foundation V7.1.0 and IBM API Connect V5.0.0, you can complement your mobile strategy with multi-channel API creation and management:

- Create and run APIs for multi-channel systems of engagements, including mobile.
- Add lifecycle management and a layer of governance to your multi-channel APIs.

- Enforce API and mobile security together at the edge of the network with IBM WebSphere® DataPower® Gateways.
- Extend business analytics from points of interaction and mobile server down to the data layer with IBM API Analytics.
- Add developer self-service API onboarding and discovery by using IBM API Connect Developer Portal.

For more information, see the IBM API Connect V5.0.0 product documentation.

Product editions

IBM MobileFirst Platform Foundation is available in several editions: IBM MobileFirst Platform Foundation Developer Edition, IBM MobileFirst Platform Foundation, IBM MobileFirst Platform Foundation System Pattern, IBM MobileFirst Platform Foundation Consumer, and IBM MobileFirst Platform Foundation Enterprise.

IBM MobileFirst Platform Foundation Developer Edition

IBM MobileFirst Platform Foundation Developer Edition is a free, non-warranted collection of self-contained development tools for IBM MobileFirst Platform Foundation. It must not be used in production. It is available from the IBM MobileFirst Platform Developer Center website. IBM MobileFirst Platform Foundation Developer Edition contains the following components:

- IBM MobileFirst Platform Studio, which is available as an Eclipse plug-in.
- IBM MobileFirst Platform Test Workbench, which is available as an Eclipse plug-in. After you install MobileFirst Studio, you can then optionally install the test workbench in Eclipse.
- IBM MobileFirst Platform Command Line Interface, which is available as an installable download. You can install and use MobileFirst Platform Command Line Interface as an alternative to the integrated development environment MobileFirst Studio.

IBM MobileFirst Platform Foundation

IBM MobileFirst Platform Foundation is supported through an IBM International License Agreement and is available from IBM Passport Advantage®. IBM MobileFirst Platform Foundation contains the following components:

- An IBM-supported version of the IBM MobileFirst Platform Foundation Developer Edition.
- A separate IBM MobileFirst Platform Server component, which is available as an IBM Installation Manager package

IBM MobileFirst Platform Foundation System Pattern

IBM MobileFirst Platform Foundation System Pattern is supported through an IBM International License Agreement and is available from IBM Passport Advantage. IBM MobileFirst Platform Foundation System Pattern contains the following components:

- An IBM-supported version of the IBM MobileFirst Platform Foundation Developer Edition
- A separate IBM MobileFirst Platform Foundation System Patterns component, which is available as an installable download

IBM MobileFirst Platform Foundation Consumer and IBM MobileFirst Platform Foundation Enterprise

IBM MobileFirst Platform Foundation Consumer and IBM MobileFirst Platform Foundation Enterprise are supported through an IBM International License Agreement and are available from IBM Passport Advantage. These two editions differ in licensing model only. IBM MobileFirst Platform Foundation Consumer is licensed by 10,000 addressable devices, and must not be used for employees. IBM MobileFirst Platform Foundation Enterprise is licensed by 200 addressable devices and can be used for any type of user. IBM MobileFirst Platform Foundation Consumer and IBM MobileFirst Platform Foundation Enterprise contain the following components:

- An IBM-supported version of the IBM MobileFirst Platform Foundation Developer Edition
- A separate IBM MobileFirst Platform Server component, which is available as an IBM Installation Manager package

Choosing the appropriate edition

- Choose IBM MobileFirst Platform Foundation Developer Edition if you want to start developing and learning about IBM MobileFirst Platform Foundation. MobileFirst Studio and IBM MobileFirst Platform Command Line Interface both include an embedded MobileFirst Development Server. This edition is useful to quickly develop and test applications.
- Choose IBM MobileFirst Platform Foundation if you plan to develop and deploy production applications. Licenses are sold per application. This edition provides full production support. Customers can obtain support through the IBM Support home for IBM MobileFirst Platform Foundation.
- Choose IBM MobileFirst Platform Foundation Consumer or IBM MobileFirst Platform Foundation Enterprise to develop and deploy production applications by using an alternative licensing model based on addressable devices. This model allows clients to invest less in up-front licenses and to pay as they grow.
- Choose IBM MobileFirst Platform Foundation System Pattern if you plan to develop, test, and deploy mobile applications to IBM PureSystems®.

Note: Additionally, users of any edition can get help on the Stack Overflow community, where support is provided on a best-effort basis.

System requirements

System requirements for IBM MobileFirst Platform Foundation include operating systems, Eclipse versions, SDKs, and other software.

IBM MobileFirst Platform Foundation has a number of system requirements that must be met for you to install and configure the product successfully. The system requirements include the following items:

- Operating systems that support IBM MobileFirst Platform Foundation, including mobile device operating systems
- Required hardware configuration
- Editions of Eclipse that support MobileFirst Studio, which is an Eclipse-based IDE
- Supported software development kits (SDKs)
- Application servers, database management systems, and other software that are required or supported by IBM MobileFirst Platform Foundation

System requirements by type (high-level)

The requirements in the following links are organized by high-level categories:

- Operating systems
- Software
- Hardware

System requirements by platform (detail)

The requirements in the following links are organized by installation target platform:

- AIX®
- Linux
- Mac OS
- Mobile OS
- Solaris
- Windows

System requirements by component (detail)

The requirements in the following links are organized by product component:

- IBM MobileFirst Platform Application Center
- IBM MobileFirst Platform Cloudant Data Layer Local Edition
- IBM MobileFirst Platform for IBM Containers
- IBM MobileFirst Platform Foundation System Patterns
- IBM MobileFirst Platform Operational Analytics
- IBM MobileFirst Platform Server
- IBM MobileFirst Platform Command Line Interface
- IBM MobileFirst Platform Studio
- IBM MobileFirst Platform Test Workbench
- IBM MobileFirst Platform Device Runtime

Licensing in MobileFirst Server

The IBM MobileFirst Platform Server supports two different licensing methods based on what you have purchased.

If you have purchased *Perpetual licenses*, you can consume what you have purchased and verify your usage and compliance through the **License tracking page** in the MobileFirst Operations Console and through “License Tracking report” on page 14-135. If you have purchased *Token licenses*, configure your MobileFirst Server to communicate with a remote token license server.

Token Licensing

In a token environment, every product consumes a predefined token value per license, compared to a traditional floating environment where a predefined quantity per license is consumed. The license key has a pool of tokens from which the license server calculates the tokens that are checked in and checked out. Tokens are either consumed or released when a product checks in or checks out licenses from the license server.

Your licensing contract defines whether you might be able to use token licensing, the number of tokens available, and features that are validated by tokens. See “Token license validation” on page 14-139.

If you have purchased token-based licenses, install a version of the MobileFirst Server that supports token licenses and configure your application server so that your server can communicate with the remote token server. See “Installing and configuring for token licensing” on page 6-126.

With token licensing, you can specify the license app type in the application descriptor of each one of your apps before deploying them. The license app type can be either APPLICATION or ADDITIONAL_BRAND_DEPLOYMENT. For testing, you can set the value of the license app type to NON_PRODUCTION. For more information, see “Token licensing: setting the license app type” on page 8-229.

The Rational License Key Server Administration and Reporting tool that is released with Rational License Key Server 8.1.4.9 can administer and generate reports for the license consumed by IBM MobileFirst Platform Foundation. You can identify the relevant parts of the report by the following display names: **Mobile First Platform Foundation Application** or **Mobile First Platform Additional Brand Deployment**. These names refer to the license app type for which the tokens are consumed. For more information, see Rational License Key Server Administration and Reporting Tool overview and Rational License Key Server Fix Pack 9 (8.1.4.9).

For information on planning to use token licensing with MobileFirst Server, see “Planning for the use of token licensing” on page 6-34.

To obtain the license keys for IBM MobileFirst Platform Foundation, you need to access IBM Rational License Key Center. For more information about generating and managing your license keys, see IBM Support - Licensing.

Matrix of features and platforms

IBM MobileFirst Platform Foundation provides many features and supports many platforms.

The Mobile OS feature mapping for IBM MobileFirst Platform Foundation technote on the IBM Support Portal lists the features that are available on each of the platforms that IBM MobileFirst Platform Foundation supports.

Consider compatibility with earlier releases before you decide what version of each product component to install. For more information, see “Version compatibility” on page 7-1.

Accessibility

Accessibility features enable people with disabilities, such as restricted mobility and limited vision, to work successfully with IBM MobileFirst Platform Foundation.

This product supports the following accessibility features:

Magnification

You can use the settings of display systems to magnify development interfaces and supporting documentation.

Screen reading

You can use a screen reader with a digital speech synthesizer, such as IBM Easy Web Browsing, to hear what is displayed on your screen. Consult the documentation with your assistive technology for details on using it with this product and its documentation.

Technical documentation

IBM knowledge center is a browser-based environment that you can access by using a web browser. The HTML files that are supported by browsers are validated for accessibility. The equivalent PDF file for the same content is provided for convenience only and is not fully accessible.

Accessibility of web app consoles

To navigate web application consoles, use the accessibility features of your browser.

You can navigate through the different MobileFirst environments and their documentation by using keyboard shortcuts. Eclipse provides accessibility features for its development environments. Internet browsers also provide accessibility features for web applications, such as the IBM MobileFirst Platform Operations Console, the IBM MobileFirst Platform Application Center console, and the IBM MobileFirst Platform Application Center mobile client.

If you are using the latest interim fix of IBM MobileFirst Platform Foundation, the IBM MobileFirst Platform Operational Analytics Console also provides accessibility features.

Accessibility of the MobileFirst Platform Command Line Interface

For accessibility, you can turn off the multicolor display of output that is provided by the MobileFirst Platform Command Line Interface.

By default, status messages that are displayed by the MobileFirst Platform Command Line Interface use various colors to indicate success, errors, and warnings. You can use the `--no-color` option on any MobileFirst Platform Command Line Interface command to suppress the use of these colors for that command. When `--no-color` is specified, output is displayed in the text display colors that are set for your operating system console.

Accessibility of MobileFirst Studio

The MobileFirst Studio graphical user interface provides its own accessibility features in addition to the accessibility features of the Eclipse environment.

Help menu

Because MobileFirst Studio is based on the Eclipse development environment, you benefit from Eclipse accessibility features.

- Select **Help** > **Key Assist** or press Ctrl-Shift-L to access the alphabetical list of keyboard shortcuts.
- Select **Help** > **Help Contents** to open the Eclipse SDK help system.

- Select **Concepts > Accessibility features in Eclipse** to learn about the major Eclipse accessibility features and access links to more topics about Eclipse accessibility.
- Select **Tasks > Accessing help** to learn how to change the font and color settings of the help browser.
- Select **Reference > Preferences > Accessibility** to learn what preferences you can change in text editors.

MobileFirst Studio

The following tables list MobileFirst Studio keyboard shortcuts. Some commands and their keyboard shortcuts are available only in some contexts.

Table 2-2. Keyboard shortcuts for the Help menu

Action	Command name in the Help menu	Key combination
Access the alphabetical list of keyboard shortcuts.	Key Assist	Ctrl-Shift-L

The keyboard shortcuts for the **File** menu are the standard Eclipse shortcuts.

Table 2-3. Keyboard shortcuts for the File menu

Action	Command name in the File menu	Key combination
Opens the New submenu	New	Alt-Shift-N
Close a file	Close	Ctrl-W
Close all open files	Close All	Ctrl-Shift-W
Save a file	Save	Ctrl-S
Save all open files	Save All	Ctrl-Shift-S
Rename a file	Rename	F2
Refresh the file contents	Refresh	F5
Print the contents of the active tab	Print	Ctrl-P
Open the Properties window of the active tab	Properties	Alt-Enter

The keyboard shortcuts for the **Edit** menu are the standard Eclipse shortcuts, except the last one, **Content Assist**, which is a MobileFirst command. The keyboard shortcuts for the MobileFirst specific **Expand selection to** submenu are documented in Table Table 2-5 on page 2-20.

Table 2-4. Keyboard shortcuts for the Edit menu

Action	Command name in the Edit menu	Key combination
Deletes the latest action	Undo	Ctrl-Z
Restores the action that has just been undone	Redo	Ctrl-Y
Removes the selection and places it in the Clipboard	Cut	Ctrl-X

Table 2-4. Keyboard shortcuts for the **Edit** menu (continued)

Action	Command name in the Edit menu	Key combination
Places a copy of the selection into the Clipboard	Copy	Ctrl-C
Copies the content of the Clipboard at the selected place	Paste	Ctrl-V
Deletes the selection	Delete	Delete key
Selects the entire contents of the active editor.	Select All	Ctrl-A
Opens the dialog box to find a string and, optionally, replace it with a different one.	Find/Replace	Ctrl-F
Display proposals for Dojo attributes	Content Assist	Ctrl-Space

Table 2-5. Keyboard shortcuts for **Edit > Expand selection to**

Action	Command name in the submenu	Key combination
Select also the enclosing element	Enclosing element	Alt-Shift-Up
Select also the next element	Next element	Alt-Shift-Right
Select also the previous element	Previous element	Alt-Shift-Left
Restore the last selection	Restore last selection	Alt-Shift-Down

The **Source** menu is a MobileFirst menu. It is not available if you select a project in the Studio Project Explorer. It becomes available when the editor is active.

Table 2-6. Keyboard shortcuts for the **Source** menu

Action	Command name in the Source menu	Key combination
Comment out a code line or, conversely, make a comment as a code line	Toggle comment	Ctrl-Shift-C
Add empty comment delimiters, for you to complete	Add block comment	Ctrl-Shift-/ (forward slash)
Remove comment delimiters (the comment itself is not removed).	Remove block comment	Ctrl-Shift-\ (backslash)
Format the layout of all the code lines in the editor	Format	Ctrl-Shift-F
Format the layout of the selected code lines	Format Active Elements	Ctrl-I

Table 2-6. Keyboard shortcuts for the **Source** menu (continued)

Action	Command name in the Source menu	Key combination
Find all occurrences of a selected Java element in its file and display the results in the Search tab	Occurrences in file	Alt-Shift-A

Table 2-7. Keyboard shortcuts for the **Navigate** menu

Action	Command name in the Navigate menu	Key combination
Display in the Properties tab	Show In > Properties	Alt-Shift-W
Navigate to the next item in a list or table in the active view	Next	Ctrl+. (period)
Navigate to the previous item in a list or table in the active view	Previous	Ctrl+, (comma)
Jump to the last edit position.	Last Edit Location	Ctrl-Q
Navigate to the previous resource that was viewed in an editor. Analogous to the Back button on a web browser.	Back	Alt+left arrow
Navigate to the next resource that was viewed in an editor. Analogous to the Forward button on a web browser	Forward	Alt+right arrow

Table 2-8. Keyboard shortcuts for the **Search** menu

Action	Command name in the Search menu	Key combination
Open the Search dialog box	Search	Ctrl-H
Search for the selected text within the scope of the workspace	Text > Workspace	Ctrl-Alt-G

Table 2-9. Keyboard shortcut for the **Project** menu

Action	Command name in the Project menu	Key combination
Build incrementally all projects in the workbench	Build All	Ctrl-B

When the editor is active, the **Page** menu provides keyboard shortcuts.

Table 2-10. Keyboard shortcuts for the **Page** menu

Action	Command name in the Page menu	Key combination
Bring the Design tab to the front	Design	Ctrl-Shift-G
Bring the Source tab to the front	Source	Ctrl-Shift-S
Bring the Split tab to the front, which displays both the Design and Source frames	Split	Ctrl-Shift-B
Highlight the Design toolbar buttons	Design Mode	F6
	Portrait	Ctrl-Shift-O
	Landscape	Ctrl-Shift-L
The Split tab shows the frames above each other.	Horizontal Split	Ctrl-Shift-H
The Split tab shows the frames next to each other.	Vertical Split	Ctrl-Shift-V
Refresh the page content	Refresh Page	F5
	Internet Explorer	Ctrl-Shift-2

Table 2-11. Keyboard shortcuts for the **Window > Show View** submenu

Action	Command name in the Window > Show View submenu	Key combination
Open the Show View dialog box where you select other views to display as a tab.	Other	Alt-Shift-Q, Q

Table 2-12. Keyboard shortcuts for the **Window > Navigation** submenu

Effect	Command name in the Window > Show View submenu	Key combination
Display the System menu	Show System Menu	Alt+ - (minus sign)
Displays the drop-down menu that is available in the toolbar of the active view.	Show View Menu	Ctrl-F10
Display an editor where you can type what you want to display	Quick Access	Ctrl-3
Make the editor occupy the entire workbench space and hide all the rest	Maximize Active View or Editor	Ctrl-M
Activate the editor when it is hidden	Activate Editor	F12
Display the next available editor	Next Editor	Ctrl-6
Display the previous active editor	Previous Editor	Ctrl-Shift-6

Table 2-12. Keyboard shortcuts for the Window > Navigation submenu (continued)

Effect	Command name in the Window > Show View submenu	Key combination
Open the Switch Editor window to active a different editor	Switch to Editor	Ctrl-Shift-E
Displays the Views panel for you to choose a different view	Next View	Ctrl-7
Displays the Views panel for you to choose a different view	Previous View	Ctrl-Shift-7
Displays the Perspectives panel for you to choose a different perspective	Next Perspective	Ctrl-8
Displays the Perspectives panel for you to choose a different perspective	Previous Perspective	Ctrl-Shift-8

Accessibility of IBM MobileFirst Platform Foundation installation and configuration

The installation and configuration of IBM MobileFirst Platform Foundation can be carried out by using command-line and Ant tasks.

There are two ways to install and configure IBM MobileFirst Platform Foundation: by graphical user interface (GUI), or by command-line.

Although the graphical user interface (IBM Installation Manager in wizard mode or Server Configuration Tool) does not provide information about user interface objects, equivalent function is available with the command-line interface. All the functions in the GUI are supported through the command-line, and some particular installation and configuration features are only available with the command-line.

The following topics provide you with the information on how the installation and configuration can be done without GUI:

- “Working with sample response files for IBM Installation Manager” on page 6-46
This method enables silent installation and configuration of MobileFirst Server and Application Center. You have the possibility to not install Application Center by using the response file named `install-no-appcenter.xml`. You can then use Ant task to install it at a later stage. See “Installing the Application Center with Ant tasks” on page 6-241. In this case, the installation and the upgrading of Application Center can be done independently.
- “Using Ant tasks to install MobileFirst Server administration” on page 6-73
- “Using Ant tasks to deploy the project WAR file” on page 12-15
- “Installing the Application Center with Ant tasks” on page 6-241
- “Installing MobileFirst Operational Analytics with Ant tasks” on page 6-216

Note: MobileFirst Operational Analytics can be installed only by Ant tasks, there is no GUI equivalent.

Release notes

You can identify the latest information about this product release and all its fix packs.

What's new in V7.1.0

Discover the new features and changes in IBM MobileFirst Platform Foundation V7.1.0 compared to the previous version of this product.

Portability between IBM Bluemix and on-premises IBM MobileFirst Platform Foundation

New features help you to move your app between the cloud and your on-premises platforms. This portability gives you the flexibility to develop and test your app in one environment, and deploy your app to production in another.

IBM MobileFirst Platform Foundation on IBM Containers

You can run MobileFirst applications in the cloud using IBM Containers on Bluemix.

The evaluation of MobileFirst Platform Foundation on IBM Containers (available from IBM developerWorks[®]) is for MobileFirst users who want to work with apps and images locally and deploy images to the IBM Containers service on Bluemix. Using this evaluation offering, you can quickly deploy and run mobile apps without the need for IT involvement but some set up and configuration is required. To use the evaluation, see Run Foundation on Bluemix tutorial.

Note: For production-level use, see “IBM MobileFirst Platform Foundation on IBM Containers” on page 3-17 in the list of V7.1.0 interim fixes.

Migrate IBM Bluemix apps to IBM MobileFirst Platform Foundation

You can now migrate apps that are developed on IBM MobileFirst Platform for iOS on IBM Bluemix to IBM MobileFirst Platform Foundation in a few steps. A new API translates the IBM MobileFirst Platform for iOS on Bluemix API to the IBM MobileFirst Platform Foundation iOS API. For more information, see Migrating iOS apps from Bluemix. For more information about the API, see “Objective-C client-side API for migrated Bluemix iOS apps” on page 11-6.

REST API compatibility for server-side code

Back-end server applications deployed outside of MobileFirst Server can now interact directly with some Push service functions through new REST APIs. The new Push REST API for the MobileFirst runtime makes it more convenient for server applications to integrate with the Push capabilities of IBM MobileFirst Platform Foundation because you no longer need to develop server-side adapter code to expose those functions.

Enhanced enterprise resilience

Added capabilities let you better handle dynamic workloads and deal with disaster recovery.

Running application in session-independent mode

Session-independent mode was introduced as the *default* mode for MobileFirst Server, starting with V7.1.0.

The session-independent mode decouples the link between authentication context and HTTP sessions by using an attribute store module for caching the authentication context. In this mode, work between the client and MobileFirst Server is session-independent, allowing IT to auto-scale the network as needed and use a load-balancer without requiring sticky HTTP sessions.

For more information, see “Session-independent mode” on page 8-324.

Important: By default, new projects that are created in V7.1.0 are *session independent*. Old projects, even after upgrade, remain session-dependent. For more information about upgrading older apps to work in session-independent mode in V7.1.0, see Upgrading projects to work in session-independent mode.

Disaster recovery: active-active topology

If your system is operating in session-independent mode, you can provide high availability and disaster recovery to your distributed network. The topology involves several instances of IBM MobileFirst Platform Server that are deployed in two or more active data centers, in combinations with IBM Cloudant and IBM WebSphere eXtreme scale. Optionally, this configuration might use a load-balancer to determine which site handles the client requests.

For more information, see “Disaster recovery: active-active topology” on page 6-147.

Using Cloudant as a supporting database for MobileFirst Server and MobileFirst Server administration

When you install IBM MobileFirst Platform Foundation, you are now able to use Cloudant as your database management system for MobileFirst Server and MobileFirst Server administration. You can now benefit from a NoSQL local or Cloud-based Cloudant database for your MobileFirst runtime and administration.

To use a Cloudant database, you must have an account at cloudant.com that uses the Cloudant database in the Cloud, or you must install IBM MobileFirst Platform Cloudant Data Layer Local Edition, as described in the Cloudant Data Layer Local Edition user documentation.

For more information about how to use Cloudant as your database, see:

- “Planning the creation of the databases” on page 6-30
- “Creating the Cloudant database for MobileFirst Server administration” on page 6-62
- “Creating the Cloudant database” on page 12-9

Improved development experience

New APIs, frameworks, capabilities, and tools make developing apps with IBM MobileFirst Platform Foundation simpler and help make developers more productive.

Enhanced experience for developing hybrid apps

If you develop hybrid apps, you can now leverage support for standard-based frameworks with large, open ecosystems, as well as exploiting capabilities provided by IBM MobileFirst Platform Foundation

Simplified cross-platform development with Cordova development model and tooling

IBM MobileFirst Platform Foundation 7.1.0 features a new development model based on Apache Cordova. You can now add third-party or custom plugins to your app, and use the standard, familiar Cordova development model for your IBM MobileFirst Platform Foundation app. New Cordova-specific commands are available from the IBM MobileFirst Platform Command Line Interface. For more information, see “Developing Cordova apps” on page 8-169.

Use mfp push to accelerate development

With V7.1, the IBM MobileFirst Platform Command Line Interface (CLI) provides a new command, **mfp push**, that enables you to register, build and deploy your app all with a single command. With **push**, you can deploy to remote as well as local instances of the MobileFirst Server. You can now proceed through the entire MobileFirst development process by using only the CLI and your preferred source code editor or IDE. For more information, see “**push**” on page 16-19.

Enhanced mfp config simplifies app configuration

The V7.1 IBM MobileFirst Platform Command Line Interface (CLI) also provides an enhanced **mfp config** command. With these enhancements, you can configure MobileFirst features without requiring manual editing of the application descriptor file. For more information, see “**config**” on page 16-7.

iOS libraries now packaged as frameworks

Starting with IBM MobileFirst Platform Foundation 7.1.0, the iOS Client SDK static libraries are packaged as iOS frameworks.

When you import an existing hybrid application that was developed in a previous IBM MobileFirst Platform Foundation version into version 7.1.0, the import process replaces the existing static library with the iOS framework and updates the Xcode project configuration and the SDK public header imports to correspond to the framework configuration.

Streamlined experience for developing native apps

As a native app developer, you can take advantage of streamlined methods to get the IBM MobileFirst Platform Foundation SDK, as well a simplified workflow in your native app development environment.

Use mfp push to accelerate development

With V7.1, the IBM MobileFirst Platform Command Line Interface (CLI) provides a new command, **mfp push**, that enables you to register, build and deploy your app

all with a single command. With **push**, you can deploy to remote as well as local instances of the MobileFirst Server. You can now proceed through the entire MobileFirst development process by using only the CLI and your preferred source code editor or IDE. For more information, see “**push**” on page 16-19.

Enhanced mfp config simplifies app configuration

The V7.1 IBM MobileFirst Platform Command Line Interface (CLI) also provides an enhanced **mfp config** command. With these enhancements, you can configure MobileFirst features without requiring manual editing of the application descriptor file. For more information, see “**config**” on page 16-7.

Use CocoaPods to get the IBM MobileFirst Platform Foundation iOS SDK

You can now use CocoaPods to get the IBM MobileFirst Platform Foundation iOS SDK. For more information, see “Adding the IBM MobileFirst Platform Foundation iOS SDK to a new application with CocoaPods” on page 8-192.

Use Gradle to get the IBM MobileFirst Platform Foundation Android SDK

You can now use Gradle to get the IBM MobileFirst Platform Foundation Android SDK. For more information, see “Adding the IBM MobileFirst Platform Foundation SDK to a new or existing application with Android Studio” on page 8-206.

iOS libraries now packaged as frameworks

Starting with IBM MobileFirst Platform Foundation 7.1.0, the iOS Client SDK static libraries are packaged as iOS frameworks.

To develop native iOS apps that were originally developed in IBM MobileFirst Platform Foundation, version 7.0.0 or earlier in IBM MobileFirst Platform Foundation, version 7.1.0, you must modify your code. For more information, see “Upgrading existing native iOS applications to IBM MobileFirst Platform Foundation version V7.1.0 manually” on page 7-11.

Additional services and other development enhancements

Various new features and services provide additional functions and capabilities for you to build, test, deploy, and monitor enterprise-grade apps.

New support for Windows Universal applications

When you create a hybrid app, you can create a Windows 8 Universal environment that supports both desktops (and tablets) and mobile phones. Two individual elements are added to the associated application descriptor file: one for desktops and tablets, the other for phones. Two associated .wlappp files are produced at build time: one for desktops and tablets, the other for phones.

When you create native API applications, you can create either a Windows 8 Universal or Windows Phone 8 Universal environment that supports desktops (and tablets) or phones.

For more information, see “Developing hybrid applications for Windows 8 Universal” on page 8-80 and “Developing native C# applications for Windows 8 Universal and Windows Phone 8 Universal” on page 8-219.

Performance improvements for Windows 8 Universal native and hybrid applications

Starting with V7.1.0, the ability to compress data from backend through MobileFirst adapters is provided to Windows 8 Universal native and hybrid applications.

For more information, see the following topics:

- `invokeProcedure` method of `WL.Client` class for hybrid app development
- `WLProcedureInvocationData` class for native app development

Standard-based authentication (OAuth) with Windows 8 Universal native applications

The authentication mechanism based on standard OAuth 2.0 specification is now extended to Windows 8 Universal apps.

For more information, see the following topics:

- “OAuth-based security model” on page 8-527
- `WLAuthorizationManager` class in “C# client-side API for Windows 8 Universal and Windows Phone 8 Universal apps” on page 11-7
- “Custom requests to resources using C#” on page 8-552

Device authentication support for Windows 8 Universal hybrid libraries

The device authentication support is also extended to Windows 8 Universal hybrid libraries starting with V7.1.

For more information, see “Mobile device authentication” on page 8-599.

Basic and extended app authenticity support for Windows 8 Universal and Windows Phone 8 Universal environments

Starting with V7.1, the basic and extended application authenticity features for Android, iOS, and Windows Phone Silverlight 8 environments are extended to Windows 8 Universal and Windows Phone 8 Universal environments.

For more information, see:

- “MobileFirst application authenticity overview” on page 8-564
- “Configuring extended app authenticity checking” on page 12-56
- “Developing native C# applications for Windows 8 Universal and Windows Phone 8 Universal” on page 8-219
- “The authentication configuration file” on page 8-603

Easy access to adapter resource with native Windows 8 Universal and Windows Phone 8 Universal

New API is introduced in V7.1 to allow native Windows 8 Universal or native Windows Phone 8 Universal client to access the adapter resource.

For more information, see:

- “Accessing adapters from the /adapters endpoint” on page 8-334
- `WLResourceRequest` class and its methods

Web resources checksum support for Windows 8 Universal hybrid applications

Starting with V7.1, the integrity of web resources can be verified each time the application runs on mobile device for Windows 8 Universal hybrid app.

For more information, see the `<testWebResourcesChecksum>` under `<security>` element that is documented in “The application descriptor” on page 8-50.

Windows Phone 8 and Windows 8 naming

From IBM MobileFirst Platform Foundation V7.1.0 onwards, Windows Phone 8 is referred to as Windows Phone Silverlight 8 and Windows 8 is referred to as Windows 8 Universal. However, in some product components, the old names are kept. When you create a Windows 8 Universal app in MobileFirst Studio, the folder that is named as `windows8` is created. The same when you create a Windows Phone Silverlight 8 app in MobileFirst Studio. The folder that is named as `windowsphone8` is created. In these cases, treat `windows8` as Windows 8 Universal and `windowsphone8` as Windows Phone Silverlight 8.

Discovery of OData and Azure services

Starting with V7.1, the discovery of both basic OData services and Microsoft Azure OData services are supported. You can use adapters to access these back-end services. For more information, see “Microsoft Azure OData adapters” on page 8-292 and “OData adapters” on page 8-292.

Liberty Server upgrade

Starting with V7.1, WebSphere Application Server Liberty Core that is embedded with MobileFirst Studio and the MobileFirst Platform Command Line Interface has been upgraded from V8.5.5.4 to V8.5.5.5.

Improved data reach with Cloudant and JSONStore

Leverage Cloudant and JSONStore to keep mobile app responsive when they are off the network, while taking advantage of on-device encryption to keep data secure.

Encrypt device data with Cloudant

You can encrypt data on Android or iOS devices with the SQLCipher open source extension to the SQLite library. This library provides transparent 256-bit Advanced Encryption Standard (AES) encryption of database files. To use SQLCipher commercially, you must obtain the necessary license.

Cloudant does not support Federal Information Processing Standard (FIPS) 140-2 compliance at this time.

For more information, see “Encrypting data on the device” on page 8-475.

64-bit support for JSONStore on iOS

JSONStore is supported on 64-bit architecture on iOS. For more information, see “JSONStore” on page 8-416.

Hardened security features

New IBM MobileFirst Platform Foundation security features strengthen the security of your app and its communication with back-end systems.

Certificate pinning

Version 7.1 supports the use of certificate pinning, which can help to reduce man-in-the-middle attacks on communications that are secured with the SSL/TLS protocol. With certificate pinning, your mobile client accepts only a specific digital certificate, instead of any certificate that corresponds to a trusted CA root certificate. For more information, see “Certificate pinning” on page 8-574.

64-bit support for FIPS 140-2 on iOS

Starting with Version 7.1, FIPS 140-2 is supported on 64-bit architecture on iOS. For more information, see “FIPS 140-2 support” on page 13-165.

Secure access of corporate back ends to protected resources

Starting with Version 7.1, organizations can let a confidential (non-mobile) client connect to mobile services in a secure way.

The confidential client flow is based on the client credentials flow, as defined in the OAuth specification. The client authenticates with the authorization server using a certificate. The authentication server validates the certificate, and if it is valid, issues an access token to the client. The certificate has to be signed by a trusted signer certificate that is configured at the authorization server.

For more information, see “Exposing mobile services to non-mobile (confidential) clients” on page 8-547.

Easier deployment and management of IBM MobileFirst Platform Foundation and your apps

Various new tools and other improvements make it easier for you to deploy and manager IBM MobileFirst Platform Foundation and your apps.

Improvements to the MobileFirst Analytics Console

In V7.1.0, the user interface of the MobileFirst Analytics Console was improved to provide an enhanced user experience for viewing your analytics data. For more information, see “Navigating the Analytics Console” on page 14-21.

The improved MobileFirst Analytics Console also requires migration of your analytics data. For more information, see “Migration to the V7.1.0 Analytics Console” on page 7-21.

Improvements to the MobileFirst Operations Console

Changes to the interface controls and the behavior of MobileFirst Operations Console are intended to provide an enhanced user experience for deploying and managing your applications. See for example:

- “Deploying applications and adapters to MobileFirst Server” on page 12-87
- “Deleting apps” on page 12-89

- “Defining administrator messages from MobileFirst Operations Console in multiple languages” on page 13-5

Easier upgrade process with the Server Configuration Tool

You can now use the Server Configuration Tool to upgrade a configuration of MobileFirst Server that was previously deployed with the Server Configuration Tool, from IBM Worklight® Foundation V6.2.0, or later.

For more information, see “Upgrading with the Server Configuration Tool” on page 7-81.

Asymmetric deployment in a WebSphere Application Server Network Deployment cell

You can deploy MobileFirst administration components and runtimes asymmetrically in different clusters of a WebSphere Application Server Network Deployment cell. Therefore, the administration components are deployed in a different Java Virtual Machine (JVM) from the runtimes.

For more information, see “WebSphere Application Server Network Deployment topologies” on page 6-26.

Asymmetric deployment of MobileFirst administration components and runtimes is only supported with WebSphere Application Server Network Deployment.

Deploy MobileFirst Server to WebSphere Application Server Network Deployment on IBM PureApplication System

IBM MobileFirst Platform Foundation System Patterns now include a new pattern that supports deployment to clusters of WebSphere Application Server Network Deployment servers. The MobileFirst Platform (WAS ND) template enables you to build your pattern in a simple way.

For more information about deploying a pattern based on this new template, see “Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers” on page 12-183.

Deploy multiple MobileFirst Server runtimes on IBM PureApplication System

You can now deploy and configure the MobileFirst Server to install multiple runtimes on all the supported IBM MobileFirst Platform Foundation System Patterns topologies. For more information, see “Deploying several MobileFirst runtimes in a pattern in MobileFirst Server” on page 12-203.

New documentation for deploying Application Center to the cloud

New documentation topics explain how to deploy Application Center to the cloud on the supported version of IBM PureApplication System. For details, see the following topics:

- “Deployment of the Application Center to the cloud” on page 12-209
- “Deploying the Application Center on IBM PureApplication System” on page 12-210

Removal of the reports database from the installation process

The reports database is a deprecated feature, and is no longer part of the installation of the product by default. You should use IBM MobileFirst Platform Operational Analytics instead.

However, if you still need it, you can perform extra steps to install, configure, and upgrade the reports database. For more information, see “Manually creating and configuring the reports database” on page 14-122, and “Upgrading the reports database” on page 14-126.

Installation of IBM MobileFirst Platform Operational Analytics with Ant tasks

You can now use Ant tasks to install MobileFirst Operational Analytics and deploy it to your application server. For more information, see the following topics:

- “Installing MobileFirst Operational Analytics with Ant tasks” on page 6-216
- “Ant tasks for installation of MobileFirst Operational Analytics” on page 16-65
- “Sample configuration files for MobileFirst Operational Analytics” on page 16-82

If you installed MobileFirst Operational Analytics with Ant tasks, you can also use Ant tasks to upgrade this component to a fix pack, or interim fix. For more information, see “Applying a fix pack to IBM MobileFirst Platform Operational Analytics” on page 7-94.

Support of the Addressable Device metric

In IBM MobileFirst Platform Foundation V7.1.0, from the MobileFirst Operations Console, you can see the number of addressable devices in the current calendar month for applications that you can define for IBM MobileFirst Platform Foundation Consumer, or for IBM MobileFirst Platform Foundation Enterprise. The License Tracking report tracks devices that run native or hybrid applications on iOS, Android, or Windows.

For more information, see “License tracking” on page 14-133.

For more information about how to set the target category for your application, see the topics about application descriptor for hybrid applications, for Android, for iOS, for Windows 8, and for Windows Phone 8.

Multicultural support in MobileFirst Operations Console

Multicultural support has been added to MobileFirst Operations Console to make it easier to deploy and manage applications in languages other than English. MobileFirst Operations Console is translated into the following languages: Brazilian Portuguese, French, German, Italian, Japanese, Korean, Russian, Simplified Chinese, Spanish, and Traditional Chinese. Dates and numbers are now formatted according to the appropriate cultural environment.

Installation of the Application Center with Ant tasks

In V7.1.0, you can use Ant tasks to install and upgrade Application Center.

For more information, see:

- “Installing the Application Center with Ant tasks” on page 6-241

- “Ant tasks for installation of Application Center” on page 16-56
- “Applying a fix pack to Application Center installed with Ant tasks” on page 7-95

Improved MobileFirst API

New features improve and extend the APIs that you can use to develop mobile applications.

New client-side API for migrated Bluemix iOS apps

The Objective-C client-side API for migrated apps from IBM Bluemix provides a compatibility layer that translates the code that is in your original Bluemix app to code that is recognized by IBM MobileFirst Platform Foundation. For more information, see “Objective-C client-side API for migrated Bluemix iOS apps” on page 11-6.

Updated JavaScript client-side API

IBM MobileFirst Platform Foundation V7.1.0 includes updates in its JavaScript client-side API to develop hybrid apps, as follows:

Updated classes:

WL.Client

- The logout function has been enhanced.
The logout mechanism in this version has changed. In addition to calling the logout in the server, the logout function deletes the access token and ID token from the client device. The next time the OAuth flow starts, the client is required to again log in to the realm from which it was logged out.
- The `pinTrustedCertificatePublicKey` method has been added to support certificate pinning.
- The `invokeProcedure` method now extends the response compression support for Windows 8 Universal.

For more information, see WL.Client class

Updated JavaScript server-side API

IBM MobileFirst Platform Foundation V7.1.0 includes updates in its JavaScript server-side API that you can use to extend the MobileFirst Server, as follows:

New API:

`getClientId()`

With this new API, you can return the String value of the ClientID associated with this client.

For more information, see the WL.Server class.

For more information, see “JavaScript server-side API” on page 11-8.

Updated Objective-C client-side API for iOS

IBM MobileFirst Platform Foundation V7.1.0 includes updates in its Objective-C client-side API to develop native apps on iOS, as follows:

Updated API classes:

WLClient

- The following functions have been enhanced:
 - `logout:withDelegate:options`
 - `logout:withDelegate`

The logout mechanism in this version has changed. In addition to calling the logout in the server, both logout functions delete the access token and ID token from the client device. The next time the OAuth flow starts, the client is required to again log in to the realm from which it was logged out.

- The `pinTrustedCertificatePublicKeyFromFile` method has been added to support certificate pinning.

For more information, see `WLClient` class

Updated Java client-side API for Android

IBM MobileFirst Platform Foundation V7.1.0 includes updates in its Java client-side API to develop native apps on Android, as follows:

Updated API classes:

WLClient

- The logout function has been enhanced.

The logout mechanism in this version has changed. In addition to calling the logout URL on the server, the logout function deletes the access token and ID token from the client device. The next time the OAuth flow starts, the client is required to again log in to the realm from which it was logged out.

- The `pinTrustedCertificatePublicKey` method has been added to support certificate pinning.

For more information, see `WLClient` class

Updated Java server-side API

IBM MobileFirst Platform Foundation V7.1.0 includes updates in its Java server-side API that you can use to extend the MobileFirst Server, as follows:

New API:

`getClientId()`

With this new API, you can return a unique identifier associated with this client.

For more information, see the `OAuthSecurityContext` interface.

For more information, see “Java server-side API” on page 11-8.

Updated C# client-side API for Windows 8 Universal and Windows Phone 8 Universal

IBM MobileFirst Platform Foundation V7.1.0 includes updates in its C# client-side API for Windows 8 Universal and Windows Phone 8 Universal.

New API classes:

WLAuthorizationManager

The WLAuthorizationManager class manages the entire OAuth flow, from client registration to token generation.

WLResourceRequest

The WLResourceRequest class encapsulates a resource request and provides several send methods with different inputs for the body of a request. This class allows REST adapter support in native Windows 8 Universal and Windows Phone 8 universal environment.

Updated API classes:

WLProcedureInvocationData

An optional parameter is added to this class to allow the compression of data from backend through MobileFirst adapters.

For more information about these classes and their methods, see “C# client-side API for Windows 8 Universal and Windows Phone 8 Universal apps” on page 11-7.

What's new in V7.1.0 interim fixes

Interim fixes provide patches and updates to correct problems and keep IBM MobileFirst Platform Foundation current for new releases of mobile operating systems.

Interim fixes are cumulative. When you download the latest V7.1.0 interim fix, you get all of the fixes from earlier interim fixes.

Download and install the latest interim fix to obtain all of the fixes that are described in the following sections. If you install earlier fixes, you might not get all of the fixes described here.

Where an APAR number is listed, you can confirm that an interim fix has that feature by searching the interim fix README file for that APAR number.

Token licensing (APAR PI48649)

Token licensing was introduced with interim fix 7.1.0.0-MFPPF-IF201509132345 and is also included when you download IBM MobileFirst Platform Foundation V7.1.0 from Passport Advantage after 15 September 2015.

Token licensing overview

Interim fixes 7.1.0.0-MFPPF-IF201509132345 and later provide IBM MobileFirst Platform Foundation with an alternative licensing method that is based on tokens.

In a token environment, every product consumes a predefined token value per license. Licensing is handled by a license server that has a pool of tokens from which the license server calculates the tokens that are checked in and checked out. Tokens are either consumed or released when a product checks in or checks out licenses from the license server (Rational License Key Server).

Your product contract defines whether you must use token licensing or not. The contract defines the number of tokens available and the features that are validated by tokens. If you purchased token licenses, you must install a version of

MobileFirst Server that supports token licensing and also configure your application server so that it communicates with the remote license server.

For each application, you must specify the license app type in the application descriptor before deployment. The license app type can be NON_PRODUCTION, APPLICATION, or ADDITIONAL_BRAND_DEPLOYMENT.

For more information, see the following topics:

- “Licensing in MobileFirst Server” on page 2-16
- “Installing and configuring for token licensing” on page 6-126
- “Token licensing: setting the license app type” on page 8-229

Important:

- You cannot activate token licensing in IBM MobileFirst Platform Foundation V7.1.0 and any interim fixes that are delivered before 14 September 2015. If the graphic mode installation does not display the **Token Licensing** panel, or if the silent installation with `imc1` does not confirm that token licensing is activated, then token licensing is not activated. The installation is then not compliant with token licensing. You must download IBM MobileFirst Platform Foundation V7.1.0 from Passport Advantage after 15 September 2015, or download and apply interim fix 7.1.0.0-MFPF-IF201509132345 or later.
- Rational License Key Server 8.1.4.8 or later must be installed and configured. For more information, see Rational License Key Server Portal.
- Make sure that the license keys for IBM MobileFirst Platform Foundation are generated. For more information about generating and managing your license keys with IBM Rational License Key Center, see IBM Support - Licensing.

Token licensing in MobileFirst Platform Patterns (APAR PI49322)

Token licensing support for MobileFirst Platform Patterns on IBM PureApplication System does not use the shared service for IBM Rational License Key Server. Token licensing for the patterns depends on a Rational License Key Server external to your PureApplication System.

The **MobileFirst Platform (WAS ND)** pattern template does not support token licensing. If you want to use this pattern, you must use perpetual licensing.

All other patterns support token licensing.

iOS 9 support

If you use Xcode 7 to compile your apps, or if you use extended authenticity protection for your apps, install the latest interim fix and review the following sections to ensure that your apps continue to work on iOS 9.

If you build your apps with Xcode 6.4 and do not use extended authenticity protection, you can rebuild your apps with iOS 9 support without installing the latest IBM MobileFirst Platform Foundation interim fix.

Extended authenticity checking for apps that undergo app thinning

App thinning was introduced by Apple in iOS 9 for apps that are compiled with Xcode 7. App thinning reduces the size of files that are downloaded from the App

Store. The feature might affect the extended authenticity features of IBM MobileFirst Platform Foundation apps because the binary file in the App Store might differ from the one that is downloaded to the client device.

After you apply latest interim fix, the app thinning feature is available for any app that uses iOS 9 and later and Xcode 7 and later and that was created by using IBM MobileFirst Platform Foundation V7.0.0 and later.

For more information, see “Enabling extended authenticity checking for apps that undergo app thinning” on page 12-57.

Disabling bitcode-enabled Xcode builds

Starting with Xcode 7, bitcode is a default, but optional option for iOS apps. The bitcode option is not currently supported in IBM MobileFirst Platform Foundation. To use the MobileFirst SDK in any project that uses Xcode 7, you must disable bitcode.

Applications that are based on Apple watchOS 2 require the bitcode to be enabled and are currently not supported in IBM MobileFirst Platform Foundation.

For more information, see “Disabling bitcode in Xcode builds” on page 8-199.

Support for dynamic .tbd libraries in Xcode 7

Xcode 7 replaces dynamic .dylib libraries with more lightweight .tbd files. Up to now, IBM MobileFirst Platform Foundation projects link with .dylib libraries such as: libcplusplus.dylib, libstdc++.dylib, and libz.dylib. These libraries must be replaced with the corresponding .tbd libraries.

For guidelines, see the following topics:

- “Upgrading existing native iOS applications to IBM MobileFirst Platform Foundation version V7.1.0 manually” on page 7-11
- “Copying SDK and configuration files from the project” on page 8-190
- Modifying code in Bluemix apps

Enforcing TLS-secure connections in iOS apps

Apple's App Transport Security (ATS) is a new feature of iOS 9 that enforces best practices for connections between the app and the server. By default, this feature enforces some connection requirements that improve security. These include client-side HTTPS requests and server-side certificates and connection ciphers that conform to Transport Layer Security (TLS) version 1.2 using forward secrecy.

For **development purposes**, you can override the default behavior by specifying an exception in the Info.plist file in your app. However, in a full **production environment**, all iOS apps must enforce TLS-secure connections for them to work properly.

By applying the latest interim fix, the apps that you develop in IBM MobileFirst Platform Foundation V6.0.0 and later automatically turn off transport security to allow all non-secure connections to the MobileFirst Development Server.

For more information, see “Enforcing TLS-secure connections in iOS apps” on page 8-198.

Android 6.0 Marshmallow support

Android 6.0 Marshmallow introduces a number of changes that might require you to install the latest IBM MobileFirst Platform Foundation interim fix for your app to work on Android 6.0.

Review the following sections to learn about changes in Android that might affect your apps and determine whether you need to install the latest interim fix for your app to support Android 6.0 Marshmallow.

Allowing runtime access to location services in Android 6.0 Marshmallow

In Android 6.0 Marshmallow and later, geo acquisition (location) permissions also require runtime permissions.

According to the new model, in addition to defining permissions at installation, users must allow or deny access to different features at runtime. Before an app accesses location services, it must check whether permission has already been granted and, if needed, request permission. Developers are responsible to perform the check before the app accesses any of the following methods in the `WLDevice` interface:

- `startAcquisition`
- `acquireGeoPosition`
- `stopAcquisition`

For more information, see [Allowing runtime access to location services starting from Android 6.0 Marshmallow](#).

Preventing Android 6.0 Marshmallow automatic backup of MobileFirst data

By default, app data on devices that are running under Android 6.0 Marshmallow is automatically backed up to Google Drive.

The MobileFirst SDK holds app web resources, logs, and some other artifacts that are stored on the device. The volume of this data is potentially large and even if deleted can be easily recovered. Thus, there is no need for it to be backed up.

By applying latest interim fix, you can prevent most of the MobileFirst SDK internal data from being backed up to Google Drive.

Note: After you apply the interim fix, some artifacts, for example residual logs might still be backed up to Google Drive.

Continued support of Apache HTTP client

Android 6.0 Marshmallow removes support for Apache HTTP client. However, by applying the latest interim fix, you can continue to use the MobileFirst APIs that expose `org.apache.http.*` classes.

The SDK stubs are available in IBM MobileFirst Platform Foundation V7.0 and later.

Apache Cordova

The requirements of Apache Cordova might be updated as new versions of the platform SDKs are released.

Added support for Android SDK version 23 permissions (APAR PI61332)

Applications can target Android SDK version 23 and request permissions at run time. The following core Cordova plug-ins that are provided with the IBM MobileFirst Platform Foundation version 7.1 were updated to support the new permission handling:

- Camera
- Contacts
- File
- Media
- Media-capture

Third-party Cordova plug-ins that request permissions must be updated to use the new permission model. In addition to updating the third-party Cordova plug-ins, you must add the `PermissionHelper.java` file to your project that uses the new permission handling.

For the file update levels, see “Product components” on page 2-7. For the procedure that is required to update your plug-ins, see “Enabling a Cordova app to support Android SDK version 23 permissions” on page 8-178.

Extra steps are required when you prepare a IBM MobileFirst Platform Foundation Cordova app with the camera plug-in for the Android platform (APAR PI73910)

Starting with Android N, a file URI can be accessed only by the same app. This access restriction causes a `FileUriExposedException` when you use the Cordova camera plug-in on the Android platform. The camera app of the device passes the URI of a photo to the camera plug-in, but the plug-in cannot access the photo. Cordova provides a solution for this restriction that requires extra setup steps so the camera plug-in can access the URI of the photo.

If you require the Cordova camera plug-in for your Android platform app, you must complete the steps in “Preparing a project that uses the Cordova camera plug-in with the Android platform” on page 8-73.

New features in the MobileFirst Analytics Console

If you are using the latest interim fix of IBM MobileFirst Platform Foundation, you can use the new features in the MobileFirst Analytics Console.

Alert definitions with thresholds (APAR PI50260)

You can set thresholds in alert definitions in the MobileFirst Analytics Console to better monitor your activities.

For more information, see “Alerts” on page 14-27.

Exporting and importing custom chart definitions (APAR PI50263)

You can export and import your custom chart definitions programmatically or in the MobileFirst Analytics Console.

For more information, see “Exporting and importing custom chart definitions” on page 14-71.

Application crash analytics (APAR PI53648)

You can quickly see information about your application crashes in the Dashboard page of the MobileFirst Analytics Console. Two new charts are available: **Crash Overview** and **Crashes**.

For more information, see “Application crash monitoring” on page 14-40.

To better administer your apps, you can view app crash analytics. In the Dashboard page of the MobileFirst Analytics Console, a **Crash Summary** tab is available.

For more information, see “Application crash troubleshooting” on page 14-41.

You can create an alert definition to receive an alert when the number of app crashes or the crash rate for your applications exceeds your defined threshold.

For more information, see “Creating an alert definition for application crashes” on page 14-36.

IBM MobileFirst Platform Foundation on IBM Containers

In addition to the evaluation version of IBM MobileFirst Platform Foundation on IBM Containers released for V7.1 (available from IBM developerWorks), IBM MobileFirst Platform Foundation on IBM Containers is now available for production use with the interim fix update available on the IBM Passport Advantage site.

The interim fix for APAR PI55391 on Fix Central, applied to IBM MobileFirst Platform Foundation on IBM Containers V7.1 (available from IBM Passport Advantage site) supports IBM MobileFirst Platform Foundation to be deployed on container groups.

For details on applying the interim fix refer to Applying IBM MobileFirst Platform Foundation interim fixes in an IBM Containers environment.

Note: The updated *Prerequisites* section in IBM MobileFirst Platform Foundation on IBM Containers is applicable for IBM MobileFirst Platform Foundation on IBM Containers with the interim fix for APAR PI55391.

Learn more about “Deploying to the cloud in an IBM Container” on page 12-115.

JSONStore framework for MobileFirst iOS applications (APAR PI50359)

After you install the latest interim fix of IBM MobileFirst Platform Foundation, JSONStore becomes an optional feature for native MobileFirst iOS applications. To upgrade your hybrid iOS applications from a previous version, you must complete some additional steps.

JSONStore framework for native MobileFirst iOS applications

To use JSONStore in a native MobileFirst iOS application, you must import the `<IBMMobileFirstPlatformFoundationJSONStore/IBMMobileFirstPlatformFoundationJSONStore.h>` umbrella header file. You can obtain the JSONStore feature in two ways:

- You can import the JSONStore framework from the `worklight api` folder. For more information, see “Copying SDK and configuration files from the project” on page 8-190.
- You can use CocoaPods. For more information, see “Enabling JSONStore” on page 8-421.

For more information about creating native MobileFirst iOS applications, see “Developing native applications for iOS” on page 8-185.

CloudantToolkit and IMFData frameworks are deprecated

Use the CDTDatstore SDK as a replacement for CloudantToolkit and IMFData frameworks.

Use the Cloudant Sync Android SDK as a replacement for CloudantToolkit and IMFData frameworks. With Cloudant Sync, you can persist data locally and replicate with a remote data store.

If you want to access remote stores directly, use REST calls in your application and refer to the Cloudant API Reference.

For more information about how to use Cloudant Sync in your mobile apps, see “Storing mobile data in Cloudant” on page 8-471.

Accessibility enhancements

Accessibility improvements were made to the IBM MobileFirst Platform Command Line Interface and to the technical documentation.

IBM MobileFirst Platform Command Line Interface

To improve accessibility, a `--no-color` option that suppresses the use of varying text colors was added to the IBM MobileFirst Platform Command Line Interface. For more information, see “CLI commands usage” on page 8-32.

To install and configure the product without graphical user interface, see “Accessibility of IBM MobileFirst Platform Foundation installation and configuration” on page 2-23. For more information about the accessibility features, see “Accessibility” on page 2-17.

Technical documentation

The IBM MobileFirst Platform Foundation documentation is accessible when you are using screen reading software. The IBM Knowledge Center documentation is hosted in the IBM Knowledge Center - Hosted Edition service. To request the current accessibility status for the IBM Knowledge Center - Hosted Edition service, see IBM Product Accessibility information and select the entry for IBM Knowledge Center - Hosted Edition.

Enhanced instructions for upgrading MobileFirst Server to V7.1.0

A series of steps-by-steps topics is introduced to guide you through the entire upgrading process of your MobileFirst Server in production. Each topic provides you a complete procedure to upgrade from a specific version to V7.1.0:

- Applying a fix pack for MobileFirst Server V7.1.0
- Upgrading MobileFirst Server from V7.0.0 to V7.1.0
- Upgrading MobileFirst Server from V6.3.0 to V7.1.0
- Upgrading MobileFirst Server from V6.2.0 to V7.1.0
- Upgrading MobileFirst Server from V6.1.0 to V7.1.0
- Upgrading MobileFirst Server from V6.0.0 to V7.1.0
- Upgrading MobileFirst Server from V5.0.6 to V7.1.0

For more information, see “Upgrading to MobileFirst Server V7.1.0 in a production environment” on page 7-22.

LDAP login module changes

The LDAPLoginModule class was modified to add a `searchUniqueUser validationType` configuration-parameter value, and the following related configuration parameters were added: `ldapSearchUserName`, `ldapSearchPassword`, `ldapUseAttributeToExtract`, and `ldapAttributeToExtract`. For more information, see `searchUniqueUser`.

IBM WebSphere DataPower integration enhancements

The support for integrating with IBM WebSphere DataPower as a reverse proxy and security gateway was improved. A preconfigured DataPower pattern, related MobileFirst samples, and detailed documentation for integrating with DataPower by using LTPA and DataPower HTML forms-based authentication are provided. For more information, see “Integrating with DataPower as a reverse proxy using LTPA and form-based authentication” on page 6-181.

IBM Trusteer integration enhancements (APAR PI67861)

It is now possible to disable the automatic initialization of IBM Trusteer Mobile SDK instances that are integrated with MobileFirst projects. When the automatic initialization is disabled, you can initialize the Trusteer Mobile SDK manually by using either the Trusteer Mobile SDK or the MobileFirst client-side API. For more information, see “Integrating IBM Trusteer for iOS” on page 15-11 and “Integrating IBM Trusteer for Android” on page 15-12.

IBM MobileFirst Platform Foundation on IBM Containers

IBM MobileFirst Platform Foundation on IBM Containers now supports enterprise dashDB database on IBM Bluemix.

Important: Enterprise Transactional Plans that support OLTP workloads are the only supported dashDB plans.

Note: See prerequisites for deploying IBM MobileFirst Platform Foundation on IBM Containers.

Learn more about Deploying to the cloud in an IBM Container.

Deprecated and removed features

If you are migrating from an earlier release of the product, be aware of the various features that have been deprecated or removed in this and earlier releases.

Deprecated features

Definition: Pertaining to an entity, such as a programming element or feature, that is supported but no longer recommended and that might become obsolete.

For a list of deprecated features, see “Deprecated features and API elements”

Removed features

Definition: Pertaining to a feature that is no longer included in a product.

For a list of removed features, see “Removed features” on page 3-22

Deprecated features and API elements

The following features and API elements are deprecated from this and earlier releases of this product.

Features deprecated in V7.1.0

Table 3-1. Features deprecated in V7.1.0.

Category	Deprecation	Recommended Action
iOS 6	The iOS 6 environment is deprecated.	
IBM MobileFirst Mobile Patterns	IBM MobileFirst Mobile Patterns are deprecated in MobileFirst Studio.	
mfp bd	This CLI command is deprecated.	Use mfp push instead.
mfp build	This CLI command is deprecated.	Use mfp push instead.
mfp create-server	This CLI command is deprecated.	Use mfp server create instead.
mfp deploy	This CLI command is deprecated.	Use mfp push instead.

Features deprecated in V7.0.0

Table 3-2. Features deprecated in V7.0.0.

Category	Deprecation	Recommended Action
BlackBerry 6 and BlackBerry 7 environments	BlackBerry 6 and BlackBerry 7 environments are deprecated.	
Analytics Reports database	The Reports database, often referenced as WLREPORT in the documentation, is deprecated in IBM MobileFirst Platform Foundation V7.0.0.	Use IBM MobileFirst Platform Operational Analytics instead. Note that setting up the Reports database is optional in this release and earlier releases. Also note that the use of the Reports database is redundant with MobileFirst Operational Analytics in this release and recent earlier releases.
Analytics BIRT predefined reports	The predefined BIRT reports are deprecated.	Use IBM MobileFirst Platform Operational Analytics console and custom chart support instead.
The JAR files and JavaScript libraries that enable SSO between IBM MobileFirst Platform Foundation and other external services	The external-server-libraries directory and its contents are deprecated. The following API URLs are also deprecated: <application root context>/oauth/*	Use the MobileFirst OAuth-based security model instead. For more information about this model, see “OAuth-based security model” on page 8-527.

API elements deprecated in V7.0.0

Table 3-3. API elements deprecated in V7.0.0.

Category	Deprecation	Recommended Action
Objective-C: WLClient	[WLClient lastAccessToken]	Use [WLAAuthorizationManager cachedAuthorizationHeader] instead.
	[WLClient lastAccessTokenForScope]	Use [WLAAuthorizationManager cachedAuthorizationHeader] instead.
	[WLClient obtainAccessTokenForScope]	Use [WLAAuthorizationManager obtainAuthorizationHeaderForScope] instead.
Objective-C: WLResponse	[WLResponse getResponse]son]	Use the response]son property instead.

Table 3-3. API elements deprecated in V7.0.0 (continued).

Category	Deprecation	Recommended Action
Java	WLClient.obtainAccessToken (String scope, WLResponseListener responseListener)	Use the WLAAuthorizationManager class instead.
	WLClient.getLastAccessToken	Use the WLAAuthorizationManager class instead.
	WLClient.obtainAccessToken (String scope, WLResponseListener responseListener, WLRequestOptions requestOptions)	Use the WLAAuthorizationManager class instead.
	WLClient.getRequiredAccessTokenScope (int status, String header)	Use the WLAAuthorizationManager class instead.
	WLClient.logActivity	Use the Logger class instead.
JavaScript	WLClient.obtainAccessToken	Use the WLAAuthorizationManager class instead.
	WLClient.getRequiredAccessTokenScope	Use the WLAAuthorizationManager class instead.
	WLClient.getLastAccessToken	Use the WLAAuthorizationManager class instead.
	WLClient.logActivity	Use the WLogger class instead.

Features deprecated in V6.3.0

Table 3-4. Features deprecated in V6.3.0.

Category	Deprecation	Recommended action
Sencha Touch tools	Sencha Touch tools are deprecated in MobileFirst Studio. Specific Sencha Touch tools might be removed from MobileFirst Studio in a future release. Note: Sencha Touch is still supported by the product.	You can continue to use Sencha Touch by copying the relevant files into your MobileFirst application to a directory of your choosing. Then, add the necessary reference tags into the main index.html file.

Removed features

The following features are removed from this and earlier releases of this product.

Features removed in V7.1.0

Table 3-5. Features removed in V7.1.0

Feature
The IBM MobileFirst Starter on Bluemix (ibm-mobilefirst-starter) which provides a fully functional instance of IBM MobileFirst Platform Foundation, is now removed from V7.1.0.

Features removed in V7.0.0

Table 3-6. Features removed in V7.0.0.

Feature
The JAR files and JavaScript libraries that enable SSO between IBM MobileFirst Platform Foundation and other external services are removed. Use the MobileFirst OAuth-based security model instead.
For more information about the OAuth-based security model, see “OAuth-based security model” on page 8-527.
The “shake to refresh” feature is removed in IBM MobileFirst Platform Foundation V7.0.0.

Features removed in V6.3.0

Table 3-7. Features removed in V6.3.0.

Feature
The IBM Worklight Application Framework (beta) set of tools is removed in IBM MobileFirst Platform Foundation V6.3.0.

Known issues

You can identify the latest known issues and their resolutions, for this product release and all its fix packs, by browsing this dynamic list of documents.

Click the following link to receive a dynamically generated list of documents for this specific release and all its fix packs, including known issues and their resolutions, and relevant downloads: <http://www.ibm.com/support/search.wss?tc=SSVNUQ&tc=SSHT2F&atrn=SWVersion&atrv=7.1>

The following websites provide helpful community resources:

- Developer Center for IBM MobileFirst Platform (Help page), where you can post questions to Stack Overflow website, and get answers, by using the following tags:
 - mobilefirst
 - worklight for past releases
- dW Answers website, where you can post questions and get answers, by using the following tags:
 - mobilefirst
 - worklight for past releases

Known limitations

General limitations apply to IBM MobileFirst Platform Foundation as detailed here. Limitations that apply to specific features are explained in the topics that describe these features.

In this documentation, you can find the description of IBM MobileFirst Platform Foundation known limitations in different locations:

- When the known limitation applies to a specific feature, you can find its description in the topic that explains this specific feature. You can then immediately identify how it affects the feature.

- When the known limitation is general, that is, applies to different and possibly not directly related topics, you can find its description here.

Note: For more information about product known limitations or issues, see “Known issues” on page 3-23.

Globalization

If you are developing globalized apps, notice the following restrictions:

- Part of the product IBM MobileFirst Platform Foundation V7.1.0, including its documentation, is translated in the following languages: Simplified Chinese, Traditional Chinese, French, German, Italian, Japanese, Korean, Portuguese (Brazil), Russian, and Spanish. Mainly user-facing text is translated.
- The applications that are generated by IBM MobileFirst Platform Foundation are not fully bidirectional enabled. Mirroring of the graphic user interface (GUI) elements and the control of the text direction are not provided by default. However, there is no hard dependency from the generated applications on this limitation. It is possible for the developers to achieve full bidi compliance by manual adjustments in the generated code.
- Although translation into Hebrew is provided for IBM MobileFirst Platform Foundation core functionality, some GUI elements are not mirrored.
- Names of projects, apps, adapters, Dojo custom builds and Dojo library projects must be composed only of the following characters:
 - Uppercase and lowercase letters (A-Z and a-z)
 - Digits (0-9)
 - Underscore (_)

Some examples of the problems that you might encounter if the names of your Dojo library projects are NL strings are the incorrect display of the UI pattern preview, the failure of the generation of the Dojo custom build, and the failure to display the NL string in the Dojo custom build console.

- There is no support for Unicode characters outside the Basic Multilingual Plane.

IBM MobileFirst Platform Application Center mobile client

The Application Center mobile client follows the cultural conventions of the running device, such as the date formatting. It does not always follow the stricter International Components for Unicode (ICU) rules.

The Application Center mobile client for BlackBerry has the following known limitations:

- It supports only a limited set of languages. In particular, it does not fully support right-to-left languages, such as Arabic and Hebrew.
- It does not support Unicode characters outside the Basic Multilingual Plane.
- It supports Unicode characters inside the Basic Multilingual Plane but how these characters are displayed depends on the fonts that are available on the device

IBM MobileFirst Platform Operational Analytics

The IBM MobileFirst Platform Operational Analytics has the following limitations:

- In Analytics Console, the format for numbers does not follow the International Components for Unicode (ICU) rules.
- In Analytics Console, the numbers do not use the user's preferred number script.

- In Analytics Console, the format for dates, times, and numbers are displayed according to the language setting of the operating system rather than the locale of Microsoft Internet Explorer.
- When you create a custom filter for a custom chart, the numerical data must be in base 10, Western, or European numerals, such as 0, 1, 2, 3, 4, 5, 6, 7, 8, 9.
- When you create a custom filter for a custom chart, the query of a custom filter does not use Unicode Normalization Forms C (NFC) for comparison. The query does not consider language sensitivity such as normal matching, accent-insensitive, case-insensitive, and 1-to-2 mapping for search function to run correctly in different languages. The message property uses NFC and considers language sensitivity though.
- If you are using the latest interim fix of IBM MobileFirst Platform Foundation, the numerical data must be in base 10, Western, or European numerals, such as 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, when you create an alert in the Alert Management page of the Analytics Console.
- The Analytics page of the MobileFirst Operations Console supports the following browsers:
 - Microsoft Internet Explorer version 10 or later
 - Mozilla Firefox ESR or later
 - Apple Safari on iOS version 7.0 or later
 - Google Chrome latest version

IBM MobileFirst Platform Operations Console

The MobileFirst Operations Console has the following limitations:

- Provides only partial support for bidirectional languages.
- The text direction cannot be changed when notification messages are sent to an Android device :
 - if the first letters typed are in a right-to-left language, such as Arabic and Hebrew, the whole text direction is automatically right-to-left.
 - if the first letters typed are in a left-to-right language, the whole text direction is automatically left-to-right.
- Some error messages of the MobileFirst Operations Console are not translated because they are generated at the server side.

IBM MobileFirst Platform Studio

The MobileFirst Studio has the following limitations:

- Provides only partial support for bidirectional languages.
- The dates and numbers might not be formatted according to the locale.

Server Configuration Tool

The Server Configuration Tool has the following restrictions:

- The descriptive name of a server configuration can contain only characters that are in the system character set. On Windows, it is the ANSI character set.
- Passwords that contain single quotation mark or double quotation mark characters might not work correctly.
- The console of the Server Configuration Tool has the same globalization limitation as the Windows console to display strings that are out of the default code page.

You might also experience restrictions or anomalies in various aspects of globalization because of limitations in other products, such as browsers, database management systems, or software development kits in use. For example:

- You must define the user name and password of the Application Center with ASCII characters only. This limitation exists because IBM WebSphere Application Server (full or Liberty profiles) does not support non-ASCII passwords and user names. See Characters that are valid for user IDs and passwords.
- On Windows:
 - To see any localized messages in the log file that the test server that is embedded in MobileFirst Studio creates, you must open this log file with the UTF8 encoding.
 - In the test server console in Eclipse, the localized messages are not properly displayed.

These limitations exist because of the following causes:

- The test server is installed on IBM WebSphere Application Server Liberty profile, which creates log file with the ANSI encoding except for its localized messages for which it uses the UTF8 encoding.
- The test server console in Eclipse displays the content by using the ANSI encoding, not the UTF8 encoding.
- In Java 7.0 Service Refresh 4-FP2 and previous versions, you cannot paste Unicode characters that are not part of the Basic Multilingual Plane into the input field. To avoid this issue, create the path folder manually and choose that folder during the installation.
- Custom title and button names for the alert, confirm, and prompt methods must be kept short to avoid truncation at the edge of the screen.
- The applications that are developed with MobileFirst Application Framework running in Portuguese (Portugal) will see runtime messages in Portuguese (Brazil).
- JSONStore does not handle normalization. The Find functions for the JSONStore API do not take account of language sensitivity such as accent insensitive, case insensitive, and 1 to 2 mapping.
- The sorted results of JSONStore Find API are not language-specific and not compliant with Common Locale Data Repository (CLDR) rules.

Adapters

Third-party adapter dependencies

MobileFirst Server comes packaged with the following third-party dependencies. Ensure that you do not package different versions of those dependencies in your project.

- commons-cli:commons-cli:jar:1.2
- commons-fileupload:commons-fileupload:jar:1.3.1
- com.fasterxml.jackson.core:jackson-databind:jar:2.2.2
- com.fasterxml.jackson.core:jackson-annotations:jar:2.2.2
- com.fasterxml.jackson.core:jackson-core:jar:2.2.2
- com.fasterxml.jackson.jaxrs:jackson-jaxrs-json-provider:jar:2.2.2
- com.fasterxml.jackson.jaxrs:jackson-jaxrs-base:jar:2.2.2
- com.fasterxml.jackson.module:jackson-module-jaxb-annotations:jar:2.2.2
- commons-logging:commons-logging:jar:1.1.3

isSuccessful is a reserved JSON object key

isSuccessful is a reserved key name in the JSON object that is used by the MobileFirst server-client protocol. You cannot use isSuccessful as a key name in the JSON object that is returned in any of your adapter procedures.

Add button in Mobile Navigation view does not work

The **Add** button in the Mobile Navigation view does not work on files that are created with the jQuery Mobile HTML template. This template is part of the **New Web Page** wizard that you use to create a new web page for your app.

The work-around for this limitation is to force set WLJQ. Add the following line to the head element of the web page if you are using the embedded Safari browser. Safari is the default embedded browser option on Mac.

```
<script>window.$ = window.jQuery = WLJQ;</script>
```

This change is not required if you are using the Firefox or Internet Explorer browsers on Windows.

Application authenticity

Extended application authenticity for iOS

Extended application-authenticity validation is not supported for iOS apps that are installed from the Apple app store. You can still use basic application-authenticity validation for such apps. For more information, see *Note About Application Authenticity Failures in Applications Downloaded from the Apple App Store*. For information about the different types of MobileFirst application-authenticity validations, see “MobileFirst application authenticity overview” on page 8-564.

Application Center mobile client: refresh issues on Android 4.0.x

Android 4.0.x WebView component is known to have several refresh issues. Updating devices to Android 4.1.x should provide a better user experience.

If you build the Application Center client from sources, disabling the hardware acceleration at the application level in the Android manifest should improve the situation for Android 4.0.x. In that case, the application must be built with Android SDK 11 or later.

Application Center and Microsoft Windows Phone 8.1

Application Center supports the distribution of applications as Windows Phone application package (.xap) files for Microsoft Windows Phone 8.0 and Microsoft Windows Phone 8.1. With Microsoft Windows Phone 8.1, Microsoft introduced a new universal format as app package (.appx) files for Windows Phone. Currently, Application Center does not support the distribution of app package (.appx) files for Microsoft Windows Phone 8.1, but is limited to Windows Phone application package (.xap) files only.

Application Center supports the distribution of app package (.appx) files for Microsoft Windows Store (Desktop applications) only.

Application servers restrictions for MobileFirst Data Proxy

You cannot install MobileFirst Data Proxy on the following application servers:

- Apache Tomcat
- Versions of WebSphere Application Server Liberty profile earlier than V8.5.5.0.

Analytics page of the MobileFirst Operations Console

Response times in the Analytics page of the MobileFirst Operations Console depend on several factors, such as hardware (RAM, CPUs), quantity of accumulated analytics data, and IBM MobileFirst Platform Operational Analytics clustering. Consider testing your load before you integrate IBM MobileFirst Platform Operational Analytics into production.

Deploying MobileFirst Server on IBM PureApplication System

For a list of limitations that apply when deploying MobileFirst Server on IBM PureApplication System, see "Limitations" on page 12-158.

Deployment of an app from MobileFirst Studio to Tomcat

If you use Tomcat as an external server in Eclipse (for example to test and debug the applications directly in MobileFirst Studio), the following restrictions apply:

- The context path that you set to your project is ignored. When you deploy your app from MobileFirst Studio to Tomcat, the default context path, which is the project name, is used instead of the context path. The URL of the MobileFirst Operations Console for your app similarly uses the project name.
- When you deploy your app from MobileFirst Studio to Tomcat, the deployed WAR file is not visible in the **Server** view of Eclipse (in MobileFirst Studio), even if the application is correctly deployed.

To avoid these issues, keep the default value of the context path of your project, which is the project name.

Error when importing a MobileFirst Studio-compressed project on Mac OS X

When you try to import a compressed project into your workspace, the import process might stop due to a file permissions issue.

You see a FWLPL0019E error in the MobileFirst Studio console and logs. For example: FWLPL0019E: Migrating the <projectName> project from version <x> to version <y> has failed because Cannot read file <z> after that the project will stay in closed state in the user's workspace.

The compressed (.zip) file does not always preserve UNIX file permissions correctly. Thus, complete the following steps to edit the imported compressed file.

1. Expand the compressed file to a directory and change all of the file permissions to allow read access.
2. Compress the file again.
3. Reimport the file by using MobileFirst Studio.

You can change the file permissions in either the Finder or on the command line if you run **chmod 755** on all of the files.

Error when pushing an application or an adapter to a MobileFirst Server

When you push an application or an adapter to a MobileFirst Server, a message reports the following error: **Runtime '<YourRuntime>' is not available on this server.**

All applications and adapters are pushed to a MobileFirst Server runtime. The runtime is defined by your MobileFirst project that contains the applications and adapters. Before you push these applications and adapters to the MobileFirst Server, the associated runtime must also be deployed to the MobileFirst Server, and the server must be running. The error that you encountered indicates that the CLI can not locate the associated runtime on the target MobileFirst Server.

The CLI can not detect a given runtime on a MobileFirst Server for one or more of the following reasons:

- The MobileFirst Server is not running.
- There is no network connectivity between the system running the CLI and the MobileFirst Server.
- You have not deployed the runtime to the MobileFirst Server.

Actions:

1. Confirm that the MobileFirst Server is running.
 - Local MobileFirst Server:
 - a. Run **mfp status**. For more information, see “**status**” on page 16-24.
 - b. If the MobileFirst Server is not running:
 - 1) Change directories into the top level directory of the associated project. Run **cd <your mfp back-end project>**.
 - 2) Run **mfp start**.

- 3) Run **mfp status** to ensure that the MobileFirst Server started.
- Remote MobileFirst Server:
 - a. Run the **mfp server info** command and identify the target remote server. Note the corresponding URL and Name values.
 - b. Ping the host specified in the target server's URL. Do not include the port or protocol. For example: `ping remotehost.com`. If the host is unreachable or the pings timeout, contact the server administrator to have the server started and verify that there are no network connectivity issues.
 - c. Assuming the server is running, run the **mfp server info <server>** command, where `<server>` is the Name value from the previous **mfp server info** command.
 - d. If the MobileFirst Server information is displayed, the MobileFirst Server is running. Otherwise contact your server administrator to start the MobileFirst Server. For more information, see “**server info**” on page 16-23.
2. Determine the required runtime name.
 - The runtime name is the value of the `<name>` argument given at the time of creation via the **mfp create <name>** command. This is also the default top level project directory name of your project.
 3. If you know that the MobileFirst Server is running, confirm that the required runtime is installed and running on that MobileFirst Server. For both a local and remote server:
 - a. Run the **mfp server info** command and identify the target remote server Name value. The local MobileFirst Server name is typically `local`.
 - b. Run the **mfp server info <server>** command, where `<server>` is the Name value from the previous step.
 - c. Look at the command output and find the runtimes listed under the Runtime section.
 - d. If the runtime name from Step 2 is not included, proceed to step 4.
 4. Build, install and start a runtime on the MobileFirst Server.
 - Local MobileFirst Server:
 - a. Change directories into the associated project's root directory. Run **cd <your mfp back-end project>**.
 - b. Confirm that the local MobileFirst Server is started by running the **mfp status** command. If the server is not running, run **mfp start**.
 - c. Run **mfp push local**. This builds the runtime WAR file, and automatically installs it on the local MobileFirst Server. For more information, see “**push**” on page 16-19.
 - d. Refer to step 3 to ensure that the runtime is correctly installed and running on the local MobileFirst Server.
 - e. If the runtime is not present, run **mfp restart** to restart the local MobileFirst Server. For more information, see “**restart**” on page 16-21.
 - Remote MobileFirst Server:
 - a. Change directories into the associated project's root directory. Run **cd <your mfp back-end project>**.
 - b. Run the **mfp push --nosend** command to build the runtime WAR file, but not install it. The WAR file can only be deployed on a local server. For more information, see “**push**” on page 16-19.
 - c. Complete the instructions here: “Deploying MobileFirst projects” on page 12-1.

- d. Refer to step 3 to ensure that the runtime is correctly installed and running on the target remote MobileFirst Server.

FileNotFoundExceptions when file paths include spaces

The MobileFirst Development Server (an instance of the WebSphere Application Server Liberty profile server) cannot handle an Eclipse workspace path with white space. As a result, a simple app cannot be deployed or previewed. In MobileFirst Operations Console, an error message is displayed:

Server error. Contact the server administrator.

In the log file, the following error messages are logged:

```
[12/11/14 10:27:57:376 IST] 0000002f m.ibm.ws.container.service.app.deploy.ManifestClassPathUtils W
[12/11/14 10:27:57:376 IST] 0000002f m.ibm.ws.container.service.app.deploy.ManifestClassPathUtils W
[12/11/14 10:27:57:376 IST] 0000002f m.ibm.ws.container.service.app.deploy.ManifestClassPathUtils W
[12/11/14 10:27:57:377 IST] 0000002f m.ibm.ws.container.service.app.deploy.ManifestClassPathUtils W

```

This is a known limitation of WebSphere Application Server Liberty profile 8.5.5.3. The error can happen on production MobileFirst Server if it is based on WebSphere Application Server Liberty profile 8.5.5.3. For more information, see PI26149: FILENOTFOUNDEXCEPTIONS WHEN FILE PATHS INCLUDE SPACES.

Do not use an Eclipse workspace path or a file path with white space.

FIPS 140-2 feature limitations

The following known limitations apply when you use the FIPS 140-2 feature in IBM MobileFirst Platform Foundation:

- This FIPS 140-2 validated mode applies only to the protection (encryption) of local data that is stored by the JSONStore feature and protection of HTTPS communications between the MobileFirst client and the MobileFirst Server.
 - For HTTPS communications, only the communications between the MobileFirst client and the MobileFirst Server use the FIPS 140-2 libraries on the client. Direct connections to other servers or services do not use the FIPS 140-2 libraries.
- This feature is only supported on the iOS and Android platforms.
 - On Android, this feature is only supported on devices or simulators that use the **x86** or **armv7** architectures. It is not supported on Android using **armv5** or **armv6** architectures. The reason is because the OpenSSL library used did not obtain FIPS 140-2 validation for **armv5** or **armv6** on Android. FIPS 140-2 is not supported on 64-bit architecture even though the MobileFirst library does support 64-bit architecture. FIPS 140-2 can be run on 64-bit devices if there are only 32-bit native NDK libraries in the project.
 - On iOS, it is supported on **i386**, **armv7**, and **armv7s** architectures.
- This feature works with hybrid applications only (not native).
- The use of the user enrollment feature on the client is not supported by the FIPS 140-2 feature.
- The Application Center client does not support the FIPS 140-2 feature.

For more information about this feature, see “FIPS 140-2 support” on page 13-165.

IBM MobileFirst Platform for iOS compatibility framework limitations

The compatibility framework has the following limitations:

- `IMFClient:unregisterAuthenticationDelegateForRealm` has no effect as `WLClient` does not support unregistering challenge handlers. The work-around is to create an empty challenge handler that does nothing and register it for the same realm name.
- `IMFResourceRequest:setHTTPMethod` has no effect as the HTTP method is immutable in `WLResourceRequest` class.
- In `[IMFClient initializeWithBackendRoute:backendGUID]`, the **backendGUID** parameter is ignored.

IBM MobileFirst Platform Foundation components cannot contain multiple environments

During the creation of a MobileFirst component, you include Android as well as iPhone or iOS environments. The addition of the same component fails because it contains multiple environments.

Separate MobileFirst component needs to be created for each environment, such as Android, iOS or iPhone.

Installation of a fix pack or interim fix to the Application Center or the MobileFirst Server

When you apply a fix pack or an interim fix to Application Center or MobileFirst Server, manual operations are required, and you might have to shut down your applications for some time. For more information, see “Upgrading to IBM MobileFirst Platform Foundation V7.1.0” on page 7-1 or “Upgrading to MobileFirst Server V7.1.0 in a production environment” on page 7-22.

Installation on a cluster of IBM WebSphere Application Servers Liberty profile that you administer with a collective controller

The following limitations apply if you install MobileFirst Server on a cluster of IBM WebSphere Application Servers, Liberty profile, that you administer with a collective controller:

- The Application Center installation with the MobileFirst Server installer does not use the collective controller. You must install MobileFirst Server on each server separately.
- The MobileFirst Operations Console installation with the `<configureApplicationServer>` Ant task does not use the collective controller. You must run the `<configureApplicationServer>` Ant task for each server separately.

JSONStore resources for iPhone and iPad

When you develop apps for iPhone and iPad, the JSONStore resources are always packaged in the application, regardless of whether you enabled JSONStore or not in the application descriptor. The application size is not reduced even if JSONStore is not enabled.

JSONStore supported architectures

For Android, JSONStore supports the following architectures: ARM, ARM v7, and x86 32-bit. Other architectures are not currently supported. Trying to use other architectures will lead to exceptions and potential application crashes.

JSONStore is not supported for native Windows Universal.

Liberty server limitations

If you use the Liberty studio server on a 32-bit JDK 7, Eclipse might not start, and you might receive the following error: Error occurred during initialization of VM. Could not reserve enough space for object heap. Error: Could not create the Java Virtual Machine. Error: A fatal exception has occurred. Program will exit.

To fix this issue, use the 64-bit JDK with the 64-bit Eclipse and 64-bit Windows. If you use the 32-bit JDK on a 64-bit machine, you might configure JVM preferences to *mx512m* and *-Xms216m*.

Limited device count by application when the runtime database is Cloudant

The license tracking report can show the device count for 200 deployed applications only. Even in cases where more applications are deployed, the device count of these additional deployed applications cannot be displayed.

LTPA token limitations

An SESN0008E exception occurs when an LTPA token expires before the user session expires.

An LTPA token is associated with the current user session. If the session expires before an LTPA token expires, a new session is created automatically. However, when an LTPA token expires before a user session expires, the following exception occurs:

```
com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException: SESN0008E: A user authenticat
```

To resolve this limitation, you must force the user session to expire when the LTPA token expires.

- On WebSphere Application Server Liberty, set the `httpSession` attribute `invalidateOnUnauthorizedSessionRequestException` to `true` in the `server.xml` file.
- On WebSphere Application Server, add the session management custom property `InvalidateOnUnauthorizedSessionRequestException` with the value `true` to fix the issue.

Note: On certain versions of WebSphere Application Server or WebSphere Application Server Liberty, the exception is still logged, but the session is correctly invalidated. For more information, see APAR PM85141.

Minification of resources limitations

If you write your JavaScript code in a way that is not recommended, but allowed, and use the Google Closure Compiler, you might encounter problems. For more

information about this limitation, see Google Closure Compiler forum.

OAuth API support

The `WLAuthorizationManager` and `WLResourceRequest` classes exist in JavaScript for developing hybrid apps, in Java for developing native apps on Android environment, and in Objective-C for developing native apps on iOS environment. However, they are not available in the C# API for developing native apps on Windows Phone Silverlight 8 and Windows 8 Universal environments.

Obfuscation of Windows Phone Silverlight 8 environment does not render the HTML page

If you add a Windows Phone Silverlight 8 environment to an app, and build and deploy that app with the optimization level set to **simple**, the HTML page is not displayed. The HTML page is not rendered on both devices and emulator.

To render the HTML page, use the following settings in your `build-settings.xml` file.

```
<windowsPhone8>
  <minification level="simple" excludes="cordova.js">
    <concatenation includes="*">
  </windowsPhone8>
```

For more information about the `build-settings.xml` file, see “MobileFirst application build settings” on page 8-369.

Physical iOS device required for testing extended app authenticity

The testing of the extended app authenticity feature requires a physical iOS device, because an IPA cannot be installed on an iOS simulator.

Rich Page Editor

The Rich Page Editor fails to show your page when the code that initializes it attempts to communicate with MobileFirst Server.

The Rich Page Editor simulates the mobile device environment without any connection to a real server. If the code that initializes your page tries to communicate with MobileFirst Server, a failure occurs. Because of this failure, the page content remains hidden, and you cannot use the Design pane of the Rich Page Editor.

As an example, a failure occurs if your page calls an adapter procedure in the `wlCommonInit()` function or the `wlEnvInit()` function.

In general, however, the initialization code is not strictly necessary to get a reasonable visual rendering of your page. To avoid this limitation, temporarily remove the `"display: none"` style from the body element in your page. Your page then renders even if the initialization functions do not execute completely.

Note:

- The standard Eclipse editor does not handle UTF-8 with the BOM (byte order mark) properly, therefore the Rich Page Editor does not support UTF-8 with byte order mark.

- The Rich Page Editor supports jQuery mobile 1.4.2. It does not support jQuery mobile 1.4.1.

Session-independent mode limitations

Session-independent mode became available starting from V7.1.0.

- Clients that were created using a version of IBM MobileFirst Platform Foundation earlier than V7.1.0 do not work with a MobileFirst Server that is operating in the new session-independent mode.
- Session-independent mode is not supported in configurations of IBM MobileFirst Platform Foundation that include any of the following components or environments:
 - Blackberry
 - Windows Phone Silverlight 8 (native)
 - Adobe AIR
 - Desktop browser
 - Mobile web apps
 - JavaME native
 - Geolocation
 - USSD

For more information, see “Session-independent mode” on page 8-324.

Support for Android Emulator 2.3.x

IBM MobileFirst Platform Foundation does not support Android Emulator 2.3.x because of known issues, as detailed in the Android list of issues at <https://code.google.com/p/android/issues/list> (search for issue 12987).

Support of Oracle 12c by MobileFirst Server

The installation tools of the MobileFirst Server (Installation Manager, Server Configuration Tool, and Ant tasks) support installation with Oracle 12c as a database.

The users and tables can be created by the installation tools but the database, or databases, must exist before you run the installation tools.

User Certificate Authentication feature limitations

The following known limitations apply when you use the User Certificate Authentication feature in IBM MobileFirst Platform Foundation:

- This feature is available only on the hybrid iOS and Android environments for this current release.
- This feature is not supported by the FIPS 140-2 feature.
- This feature is supported on WebSphere Application Server and WebSphere Application Server Liberty profile.
- This feature does not support an environment where the MobileFirst Server is protected by container security that requires a CLIENT-CERT authentication method. Instead, the server must be configured to accept the client certificate optionally, and not require one.

- Self-signed certificates are not supported by the User Certificate Authentication feature.
- This feature cannot be used when you use the IBM HTTP Server between the client device and the MobileFirst Server. The IBM HTTP Server is unable to provide user identity to the MobileFirst Server after authenticating with the client certificate.

Windows Phone 8 and Windows 8 naming

From IBM MobileFirst Platform Foundation V7.1.0 onwards, Windows Phone 8 is referred to as Windows Phone Silverlight 8 and Windows 8 is referred to as Windows 8 Universal. However, in some product components, the old names are kept. When you create a Windows 8 Universal app in MobileFirst Studio, the folder named as `windows8` is created. The same when you create a Windows Phone Silverlight 8 app in MobileFirst Studio. The folder name named as `windowsphone8` is created. In these cases, treat `windows8` as Window 8 Universal and `windowsphone8` as Windows Phone Silverlight 8.

Troubleshooting

You can find advice on how to troubleshoot problems, and more information about known limitations and technotes (Troubleshooting).

The following links point to troubleshooting topics in other parts of this user documentation. To navigate from there back to this topic, click **Back** in your Web browser.

For more information about known limitations or issues in the product, and removed or deprecated features, see “Release notes” on page 3-1.

Important: If you have to contact IBM Support for help, see the information in Collect troubleshooting data. This document details how to gather the necessary information about your environment so that IBM Support can help diagnose and resolve your problem.

Tutorials, samples, and additional resources

Tutorials and samples help you get started with and learn about IBM MobileFirst Platform Foundation. Use them to evaluate what the product can do for you.

Tutorials and associated samples

For you to learn the most important features of IBM MobileFirst Platform Foundation, tutorials are available on the Getting Started page of the Developer Center for IBM MobileFirst Platform Foundation.

Tutorials are organized in categories.

Each tutorial is composed of web pages to learn the steps and one or two companion samples to practice and reuse. The samples are provided as compressed files and contain pieces of code or script files that support the step-by-step instructions. When a tutorial includes some exercises, a companion sample provides the solutions to these exercises.

The same page provides links for you to download compressed files that contain the materials for the tutorials and samples.

Sample applications

Demonstrations are available from the Starter application samples page of the Developer Center for a collection of features.

Additional documentation

The Additional documentation page of the Developer Center provides more useful links, including a guide to scalability and hardware sizing.

Terms and conditions

Before you use the IBM MobileFirst Platform Foundation Getting Started modules, exercises, and code samples that are available from Getting Started pages, you must agree on the terms and conditions that are set forth here:

This information contains sample code provided in source code form. You may copy, modify, and distribute these sample programs in any form without payment to IBM for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample code is written. Notwithstanding anything to the contrary, IBM PROVIDES THE SAMPLE SOURCE CODE ON AN "AS IS" BASIS AND IBM DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, ANY IMPLIED WARRANTIES OR CONDITIONS OF MERCHANTABILITY, SATISFACTORY QUALITY, FITNESS FOR A PARTICULAR PURPOSE, TITLE, AND ANY WARRANTY OR CONDITION OF NON-INFRINGEMENT. IBM SHALL NOT BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY OR ECONOMIC CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR OPERATION OF THE SAMPLE SOURCE CODE. IBM SHALL NOT BE LIABLE FOR LOSS OF, OR DAMAGE TO, DATA, OR FOR LOST PROFITS, BUSINESS REVENUE,

GOODWILL, OR ANTICIPATED SAVINGS. IBM HAS NO OBLIGATION TO PROVIDE MAINTENANCE, SUPPORT, UPDATES, ENHANCEMENTS OR MODIFICATIONS TO THE SAMPLE SOURCE CODE.

The resources might include applicable third-party licenses. Review the third-party licenses before you use any of the resources. You can find the third-party licenses that apply to each sample in the `notices.txt` file that is included with each sample.

Installing and configuring

This topic is intended for developers and administrators who want to install and configure IBM MobileFirst Platform Foundation.

This topic describes the tasks required to install and configure the different components of IBM MobileFirst Platform Foundation. It also contains information about installing and configuring database and application server software that you need to support the runtime database.

For more information about how to size your system, see the Scalability and Hardware Sizing document and the hardware calculator spreadsheet at the Developer Center website for IBM MobileFirst Platform Foundation.

Consider compatibility with earlier releases before you decide what version of each product component to install. For more information, see “Version compatibility” on page 7-1.

Installation overview

IBM MobileFirst Platform Foundation provides the following installable components: MobileFirst Studio, MobileFirst Server, and IBM MobileFirst Platform Test Workbench. This section gives an overview of the installation process.

Installing MobileFirst Studio on Eclipse with a P2 update site

You install MobileFirst Studio into an existing installation of Eclipse by using its P2 install and update features. For actual instructions, see “Installing MobileFirst Studio” on page 6-2.

After the MobileFirst Studio installation, you must also install extra software development kits (SDKs) and Eclipse plug-ins for each mobile environment that you are developing for (for example, the Android Development Toolkit).

Installing MobileFirst Platform Command Line Interface (CLI)

You install the CLI by downloading the CLI .zip file and decompressing it on your computer. Then, you must run the installer in the correct platform.

Installing MobileFirst Test Workbench on Eclipse with a P2 update site

You must install IBM MobileFirst Platform Test Workbench into an existing, properly configured installation of MobileFirst Studio by using the Eclipse P2 install and update feature. For actual instructions, see “Installing and configuring IBM MobileFirst Platform Test Workbench” on page 6-12.

Installing MobileFirst Server with IBM Installation Manager

To ensure the correct installation of MobileFirst Server, see “Installation prerequisites” on page 6-15.

You must install IBM Installation Manager 1.6.3 or later separately before installing IBM MobileFirst Platform Foundation. For more information, see “Running IBM Installation Manager” on page 6-43.

Note: IBM Installation Manager is sometimes referred to as *IBM Rational Enterprise Deployment* on the eXtreme Leverage, Passport Advantage sites, and on the distribution disks. The file names for the images take the form IBM Rational Enterprise Deployment <version number><hardware platform> <language>; for example, IBM Rational Enterprise Deployment V1.6.3.1Windows Multilingual.

You then use IBM Installation Manager to install MobileFirst server-side components on your application server, and to create databases on your database management system. Some application server and database configuration is required. For actual instructions, see “Installing MobileFirst Server” on page 6-14.

Upgrading from earlier versions

The preceding sections provide an overview of IBM MobileFirst Platform Foundation “first time” installations. For information about upgrading existing installations of MobileFirst Studio and MobileFirst Server to a later version, see “Upgrading to IBM MobileFirst Platform Foundation V7.1.0” on page 7-1.

Consider compatibility with earlier releases before you decide what version of each product component to install. For more information about compatibility between releases, see “Version compatibility” on page 7-1.

Installing MobileFirst Studio

You install MobileFirst Studio from your existing Eclipse IDE workbench.

Before you begin

- Ensure that your computer meets the system requirements for the software that you install, as detailed in “System requirements” on page 2-15. In particular, note the required versions of Eclipse (errors might occur if you use other versions or editions).
- If you anticipate using IBM Dojo Toolkit V1.10.1 that is available as part of MobileFirst Studio, ensure that Eclipse V4.4.1 or higher is installed.
- For Android development, ensure that Android SDK and Oracle JDK are installed.
- Ensure that an Internet connection is available in case dependencies that are required by the installation are not already included in the Eclipse IDE.

About this task

MobileFirst Studio is installed with a P2 Eclipse update.

To install MobileFirst Studio as part of IBM MobileFirst Platform Foundation Developer Edition, go to the IBM MobileFirst Platform Foundation development website at <https://developer.ibm.com/mobilefirstplatform/>.

To install MobileFirst Studio as part of an IBM-supported edition of IBM MobileFirst Platform Foundation, complete the following procedure.

Procedure

1. Start your Eclipse IDE workbench. Verify that your version of Eclipse is one of the versions that is listed in “System requirements” on page 2-15.
2. Click **Help > Install new software**.
3. Beside the **Work with** field, click **Add**.
4. In the Add Repository window, click **Archive**.
5. Browse to the location of the P2 update .zip file on the DVD, or to the location of the archive file on your machine, and click **Open**.
6. Click **OK** to close the Add Repository window.
7. On the Available Software page, select **IBM MobileFirst Platform Studio Development Tools**, and then click **Next**. If you want to see the components to be installed, expand **IBM MobileFirst Platform Studio Development Tools**, and select the components that you want:
 - Always select **IBM MobileFirst Platform Studio**.
 - Select **IBM Dojo Mobile Tools** if you anticipate using that JavaScript library.
 - Select **IBM jQuery Mobile Tools** if you anticipate using that JavaScript library.
8. On the Install Details page, review the features of MobileFirst Studio to be installed, and then click **Next**.
9. On the Review Licenses page, review the license text. If you agree to the terms, select **I accept the terms of the license agreement** and then click **Finish**. The installation process starts.
10. Follow the prompts (during which you might be asked to restart Eclipse) to complete the installation.

What to do next

Before you run MobileFirst Studio, determine whether you must run extra post-installation tasks.

You can now optionally install IBM MobileFirst Platform Test Workbench, . For more information about IBM MobileFirst Platform Test Workbench, see “Installing and configuring IBM MobileFirst Platform Test Workbench” on page 6-12.

Running additional tasks for Rational Team Concert V4.0

Before you run MobileFirst Studio, you might need to clean the Eclipse environment.

About this task

If your Eclipse workbench is installed with IBM Rational Team Concert™ V4.0 Eclipse client, the MobileFirst Studio plug-ins might not be properly activated when you open an existing workbench. For example, the wizard **New > MobileFirst Project** might not be available. To work around this problem, follow these instructions.

Note: You need to perform these steps only the first time that you start the product.

Procedure

1. Stop the workbench.
2. Locate the `eclipse.ini` file in `eclipse_installation_directory\eclipse\`.
3. Make a copy of the `eclipse.ini` file, or back it up.
4. Open the `eclipse.ini` file in a text editor.
5. Append the following text after the existing lines, on a new line: `-clean`
6. Save and close the file.
7. Start the product and select a workspace. You should be able to successfully open the workspace.
8. Remove the `-clean` line from the `eclipse.ini` file and save the file.

Starting MobileFirst Studio

Start MobileFirst Studio by running the Eclipse executable file.

Procedure

- On Linux systems, run the `eclipse` file.
- On Windows systems, run the `eclipse.exe` file.

Installing mobile-specific tools

When you develop mobile applications, you must install and use specialized tools, such as SDKs. These tools depend on the operating system that you develop the applications for, such as iOS or Android.

Installing tools for Adobe AIR

To build and sign applications for Adobe AIR, you must install the Adobe AIR SDK.

Procedure

1. Download the Adobe AIR SDK from the Adobe website at <http://www.adobe.com/>.
2. Unpack the archive into a folder of your choice.
3. Set an environment variable (either locally or on the central build server) named `AIR_HOME`, pointing to the place where you opened the SDK. The MobileFirst Builder uses this environment variable to run the build and sign tool when building AIR applications.

Installing tools for iOS

To build and sign applications for iOS, you must install the latest Xcode IDE, including the iOS simulator, on a Mac computer.

Procedure

1. Register as an Apple developer on the Apple Registration Center website at <https://developer.apple.com/programs/register/>.
2. Download Xcode from the Mac App Store at <http://www.apple.com/osx/apps/app-store.html>.
3. Install Xcode on your Mac.

For more information about the iOS development environment, see the Setting up the iOS development environment tutorial on the Getting Started page of the Developer Center.

Installing tools for Android

To build and sign applications for Android, you must install the Android SDK and the Android Development Tools (ADT) plug-in for Eclipse. Alternatively, you can install Android Studio.

Procedure

- Using the Android SDK and the Android Development Tools plug-in for Eclipse:
 1. Install the Android SDK, available from the Android website at <http://developer.android.com/sdk/>.
 2. Install the Android Development Tools plug-in for Eclipse, available at <https://dl-ssl.google.com/android/eclipse/>.
 3. Add SDK Platform and Virtual Devices to the SDK.
For more information about the Android development environment, see the Setting up your development environments tutorial category on the Getting Started page of the Developer Center.

- Using Android Studio:
 1. Install Android Studio, available from the Android website at <http://developer.android.com/sdk/installing/studio.html>.
 2. Update the MobileFirst Studio preferences with the location of Android Studio. From MobileFirst Studio, click **Window > Preferences > MobileFirst** (or **Eclipse > Preferences > MobileFirst** on Mac OS), and specify the directory where your Android Studio is installed.
 3. Right-click your Android applications, and click **Run As > Android Studio project** to start Android Studio.

Installing tools for BlackBerry

To build and sign applications for BlackBerry OS 6, 7, or 10, you must install the WebWorks tools.

Procedure

1. Download Ripple emulator from the BlackBerry website at <https://developer.blackberry.com/html5/download/> and install it.
2. Download WebWorks SDK from the same site, at <https://developer.blackberry.com/html5/download/>, and install it in the folder of your choice.
3. (Only for BlackBerry 10) Set the **WEBWORKS_HOME** environment variable, either locally or on the central build server, to the SDK root folder. The MobileFirst Builder uses this environment variable when it builds BlackBerry 10 applications. On each build, the environment variable value is transferred to `native\project.properties`.

You must set the **WEBWORKS_HOME** variable before you start MobileFirst Studio. This variable is important for the normal operation of the client. If you use Ant scripts to build and deploy the application to the device, and the **WEBWORKS_HOME** value is incorrectly set, your file structure might become corrupted, and produce a new directory with the incorrect **WEBWORKS_HOME** value.

Note: BlackBerry OS 10 is not supported by the current version of the Application Center.

4. Download and install a simulator.

For more information about the BlackBerry development environment, see the Setting up your development environments tutorial category on the Getting Started page of the Developer Center.

Installing tools for Windows Phone Silverlight 8

To build and sign applications for Windows Phone Silverlight 8, you must install Microsoft Visual Studio Express 2012 for Windows Phone.

Procedure

Download Microsoft Visual Studio Express 2012 from the Windows website at <http://www.microsoft.com/visualstudio/eng/products/visual-studio-express-for-windows-phone> and install it.

For more information about the Windows Phone Silverlight 8 development environment, see the Setting up your development environments tutorial category on the Getting Started page of the Developer Center.

Installing tools for Windows 8

Windows Store apps run only on Windows 8. Therefore, to develop Windows Store apps, you need Windows 8 and some developer tools.

Procedure

1. After you install Windows 8, go to the Windows website at <http://msdn.microsoft.com/en-us/windows/apps/br229516.aspx>.
2. Select the option to download the Windows SDK.
3. Download Microsoft Visual Studio Express 2013 from the Visual Studio website at <http://www.visualstudio.com/> and install it. Microsoft Visual Studio Express 2013 for Windows 8 includes the Windows 8 SDK. It also gives you tools to code, debug, package, and deploy a Windows Store app.
4. Start Visual Studio Express 2013. You are prompted to obtain a developer license. You need a developer license to install, develop, test, and evaluate Windows Store apps. For more information about obtaining a developer license, see the Windows site at <http://msdn.microsoft.com/en-us/library/windows/apps/br211384.aspx>.

Changing the port number of the internal application server

If the default port number is already in use, edit the `eclipse.ini` file to change to a different port.

About this task

When you start Eclipse with MobileFirst Studio, an embedded application server is started automatically to host a MobileFirst Server instance for your adapters and apps. This internal server uses port 10080 by default.

If port 10080 is occupied by another application that is running on your development computer, you can configure the MobileFirst Studio internal server to use a different port.

Procedure

1. Open the Servers view in Eclipse.
2. Expand the **MobileFirst Development Server** list.
3. Double-click **Server Configuration [server.xml] worklight**.

4. In the Server Configuration window, click **HTTP endpoint**.
5. Change the **Port** value to any port number of your choice.

Uninstalling MobileFirst Studio

You uninstall MobileFirst Studio from your existing Eclipse IDE workbench.

About this task

Follow this procedure to uninstall MobileFirst Studio and the optional IBM mobile libraries, if those libraries were also installed on your computer along with MobileFirst Studio.

Procedure

1. In Eclipse, go to **Help > About Eclipse SDK > Installation Details**.

Figure 6-1. About Eclipse SDK

2. In **Eclipse SDK Installation Details**, select **IBM MobileFirst Platform Studio**, and **IBM Dojo Mobile Tools** and **IBM jQuery Mobile Tools** if those components are also listed in the list of **Installed Software**.

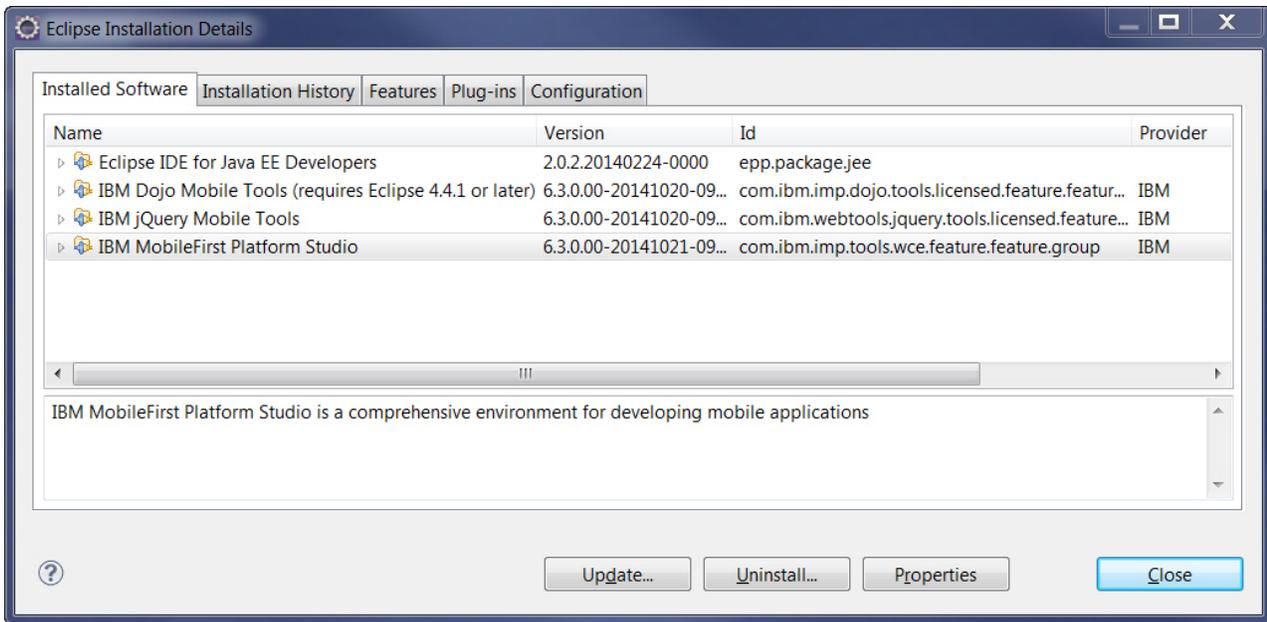

Figure 6-2. List of installed software in Eclipse SDK Installation Details

3. Click **Uninstall**.
4. In the **Uninstall** wizard, review the components to uninstall, and click **Finish**.
5. Wait until the uninstallation process finishes, and click **Yes** when you are prompted to restart Eclipse to complete the uninstallation.

Installing MobileFirst Studio offline workaround

There is no offline installation option for MobileFirst Studio. Instead, use this work-around for each user-supported platform.

Procedure

1. Install the latest supported version of Eclipse.
2. Install MobileFirst Studio from the Eclipse Marketplace.
3. Add your plug-ins.
4. Close Eclipse.
5. Create an archive of the Eclipse installation directory. For example, a .zip file, or a .tar file.
6. Extract the archive into each target workstation.

Installing CLI

Follow these instructions to install IBM MobileFirst Platform Command Line Interface (CLI).

Before you begin

You must have the Java Developer Kit (JDK) installed on your machine to use the CLI. Additionally, certain operating systems require certain software as a prerequisite. To generate a compatibility report, see Software Product Compatibility Reports.

You must have the `JAVA_HOME` environment variable set to your JDK directory. For example:

- Windows: `C:\Program Files\Java\jdk1.7.0_60`
- Mac OSX: `/Library/Java/JavaVirtualMachines/jdk1.7.0_67.jdk/Contents/Home`

Procedure

Go to the IBM Developer Center - Install the Command Line Interface and complete the necessary steps to download the **CLI package**.

Note: If you are installing in silent mode, installing for Windows 8.1, or performing a console installation, complete only steps 1-3 in the IBM Developer Center - Install the Command Line Interface.

Installing in silent mode

You can complete an unattended installation if you create a response file, then run the silent installation command.

Before you begin

To complete an unattended installation, you must download the CLI package. For instructions about how to download the CLI package, see “Installing CLI” on page 6-8.

Note: Mac does not support silent installation.

Procedure

Create a response file and proceed with the silent installation:

1. Create an empty `installer.properties` file in the same directory as the installer.
2. Copy the contents of the following response file.

```
# Indicate whether the license agreement has been accepted
#-----
LICENSE_ACCEPTED=FALSE

# Choose Install Folder
# Uncomment one of the properties below, and (optionally) change the value
# if you prefer to install to a non-default location.
#-----
# Linux default
#USER_INSTALL_DIR=/opt/ibm/Worklight-CLI

# Windows default
#USER_INSTALL_DIR=C:\\Program Files\\IBM\\Worklight-CLI

#-----
```

3. Paste the contents into your `installer.properties` response file.
4. Read the license terms and change the `LICENSE_ACCEPTED` value to `TRUE` to accept the license terms. To read the license terms, run the installer in non-silent mode, then cancel the installation after you read the license.
5. Remove the leading `#` from one of the `USER_INSTALL_DIR` properties.
6. Change the value to the location where you want to install.
7. Install the **CLI** with the silent installation by running one of the following command lines.

- Windows: `install_windows.exe -i silent`
- Linux: `./install_linux.bin -i silent`

To use a response file with a different name or location, use the `-f` command-line option. For example: `install_windows.exe -i silent -f path/to/installer.properties`.

Installing CLI for Windows 8.1

If you are using Windows 8.1, you need to ensure that the installer is run in **compatibility mode**.

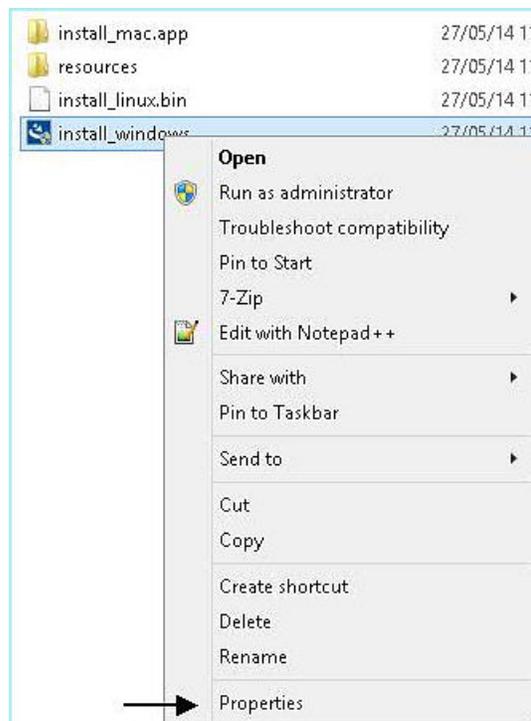

Before you begin

You must download the MobileFirst Platform Command Line Interface (CLI) package. For instructions about how to download and extract the CLI package, see [IBM Developer Center - Install the Command Line Interface](#) and complete steps 1 - 3.

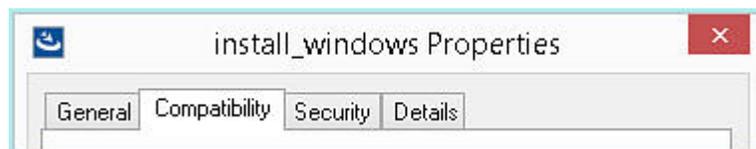

Procedure

Follow these steps to run the installer in compatibility mode.

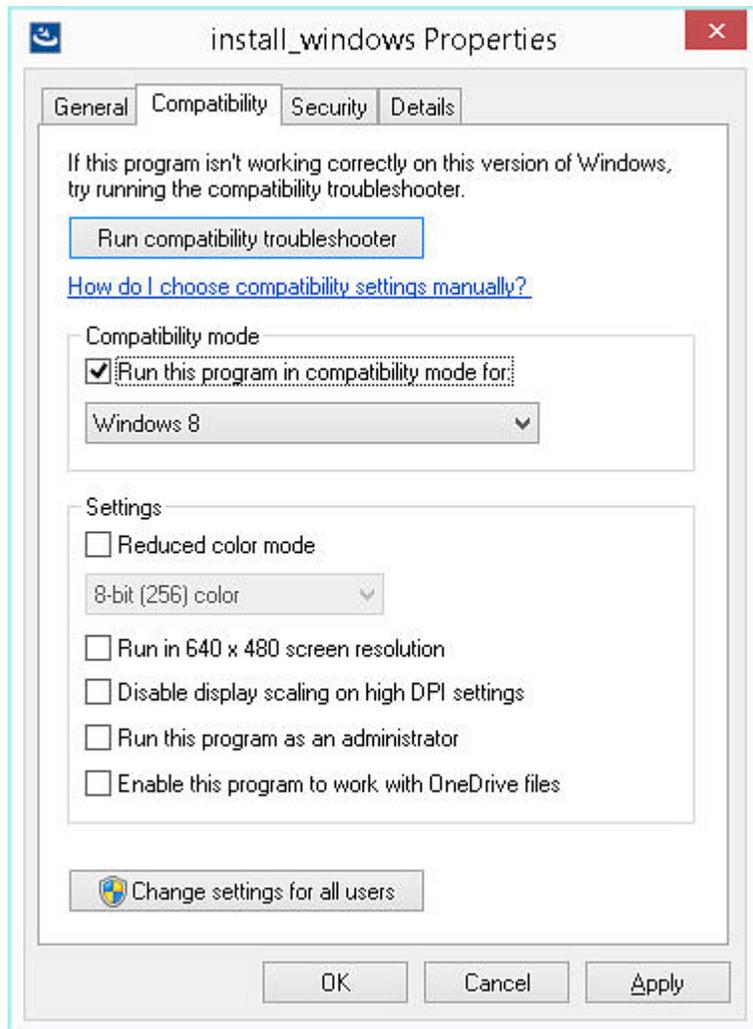

1. Right-click `install_windows.exe` and click **Properties**:

2. You can see the **Properties** window, click the **Compatibility** tab.

3. Check the option **Run this program in compatibility mode for**:

4. Click **Apply** and then **OK**.
5. Then, double-click `install_windows.exe`.
6. The installer opens and works as expected.

Installing CLI by using Console

Console installation is an alternative installation method that provides a text-only interaction that is easily read by screen readers such as JAWS. You can also use a console installation for Linux environments that accepts connections only through Secure Shell (SSH) and Telnet.

Before you begin

You must download the MobileFirst Platform Command Line Interface (CLI) package. For instructions about how to download and extract the CLI package, see IBM Developer Center - Install the Command Line Interface and complete steps 1 - 3.

Note: Mac does not support console installation.

Procedure

1. Open your command-line terminal and change the directory to the folder where your extracted `mobilefirst_cli_installer_7.0.0.zip` file is located.
2. Select the installer that is appropriate to your platform and run the installer by using the next command line:
 - Windows: `install_windows.exe -i console`
 - Linux: `/install_linux.bin -i console`
3. A new command-line terminal window appears which guides you through the installation of IBM MobileFirst Platform Command Line Interface. Follow the instructions to complete your installation.
4. On completion of your installation, log out and then log back in. This action ensures that the `mobilefirst` and `mfp` commands are on your system path.

Uninstalling command-line tools for developers

Follow these instructions to uninstall the IBM MobileFirst Platform Command Line Interface.

Before you begin

Open your command-line terminal to the path where you installed the IBM MobileFirst Platform Command Line Interface, and change the directory to the Uninstaller folder.

Procedure

1. **GUI Uninstallation:** Select and run the `uninstall`. A GUI appears which guides you through the uninstallation of the IBM MobileFirst Platform Command Line Interface. Follow the instructions to complete your uninstallation.

Note: Mac OS X users can only uninstall the product with the GUI.

2. **Console Uninstallation:** Run the `uninstall` by using the appropriate command line:

- Windows: `Uninstall.exe -i console`
- Linux: `./Uninstall -i console`

A new command-line terminal window appears which guides you through the uninstallation of the IBM MobileFirst Platform Command Line Interface. Follow the instructions to complete your uninstallation.

3. **Silent Uninstallation:** Run the `uninstall` by using the appropriate command line:
 - Windows: `Uninstall.exe -i silent`
 - Linux: `./Uninstall -i silent`

Installing and configuring IBM MobileFirst Platform Test Workbench

You must install IBM MobileFirst Platform Test Workbench into an Eclipse IDE where Worklight Studio V6.0.0 or later is already installed.

Before you begin

- Your computer must meet the system requirements for the software that you install. For more information, see “System requirements” on page 2-15.
- Worklight Studio V6.0.0 or later must be already installed on your computer.

- Ensure that an Internet connection is available in case dependencies that are required by the installation are not already included in the Eclipse IDE.

About this task

- To install IBM MobileFirst Platform Test Workbench on top of MobileFirst Studio as part of IBM MobileFirst Platform Foundation Developer Edition, go to the IBM MobileFirst Platform Foundation development website at <https://developer.ibm.com/mobilefirstplatform/>.
- To install IBM MobileFirst Platform Test Workbench on top of MobileFirst Studio as part of an IBM-supported edition of IBM MobileFirst Platform Foundation, complete the following procedure.

Procedure

1. Start your Eclipse IDE workbench.
2. Click **Help > Install new software**.
3. Beside the **Work with** field, click **Add**.
4. In the Add Repository window, click **Archive**.
5. Browse to the location of the P2 update .zip file on the DVD, or of the archive file on your machine, and click **Open**.
6. Click **OK** to exit the Add Repository window.
7. Select the features of IBM MobileFirst Platform Test Workbench that you want to install, and then click **Next**.
8. On the Install Details page, review the features that you install, and then click **Next**.
9. On the Review Licenses page, review the license text. If you agree to the terms, click **I accept the terms of the license agreement** and then click **Finish**. The installation process starts.
10. Follow the prompts to complete the installation.

What to do next

When IBM MobileFirst Platform Test Workbench is installed, you can install the mobile test client for Android and the mobile test client for the iOS Simulator. For more information about the mobile test client installation, see *Installing the mobile test client*.

You can then configure the mobile test client. For details, see *Configuring the mobile test client*.

To understand the various available features, see “Testing with IBM MobileFirst Platform Foundation” on page 10-1.

Make sure you add a JDK to your path in Eclipse. For more information, see “Troubleshooting IBM MobileFirst Platform Test Workbench.”

Troubleshooting IBM MobileFirst Platform Test Workbench

If you do not set Eclipse to use a JDK installed on your system, you cannot test Android applications with IBM MobileFirst Platform Test Workbench. The testing process fails and you get error messages.

About this task

To test Android applications with IBM MobileFirst Platform Test Workbench, you must add the path to the JDK in Eclipse.

Procedure

1. In Eclipse, go to **Window > Preferences > Java > Installed JREs**.
2. Select **JDK** to set the JDK as the default JRE.

Installing MobileFirst Server

IBM installations are based on an IBM product called IBM Installation Manager. Install IBM Installation Manager 1.6.3.1 or later separately before you install IBM MobileFirst Platform Foundation.

Important: Ensure that you use IBM Installation Manager 1.6.3.1 or later. This version contains an important fix for an issue identified in IBM Installation Manager 1.6.3. See <http://www.ibm.com/support/docview.wss?uid=swg24035049>.

The MobileFirst Server installer copies onto your computer all the tools and libraries that are required for deploying a MobileFirst project or the IBM MobileFirst Platform Application Center in production, and IBM SmartCloud[®] Analytics Embedded.

MobileFirst Server can also automatically deploy the Application Center at installation time. In this case, a database management system and an application server are required as prerequisites and must be installed before you start the MobileFirst Server installer.

The installer can also help with upgrading an existing installation of MobileFirst Server to the current version. See “Upgrading to IBM MobileFirst Platform Foundation V7.1.0” on page 7-1.

Before you install, take the time to consider the server topology in which you will deploy the administration components and the runtimes. The supported topologies are introduced in “Planning deployment of administration components and runtimes” on page 6-19.

The following topics describe the installation of MobileFirst Server, installation prerequisites, and the procedures for a manual installation and configuration of Application Center. After MobileFirst Server is installed, a MobileFirst project must be deployed to an application server. This deployment installs a IBM MobileFirst Platform Operations Console that can be used to upload applications and adapters. The instructions in “Tutorial for a basic installation of MobileFirst Server” on page 6-35 are based on a simple installation scenario. For a complete description of the process of deploying a MobileFirst project, see “Deploying MobileFirst projects” on page 12-1.

Planning the installation of MobileFirst Server

You must plan your installation and choose one installation scenario. You must also plan the creation of your databases and the topology of the application server.

To install the MobileFirst Server, you can choose one of the following scenarios:

- With the Server Configuration Tool.

The Server Configuration Tool is a graphical tool and is available for Windows, Linux on x86, and Mac OS. With this tool, you get easily started, but expect some limitations when you maintain an application in production, in particular for some upgrade scenarios. This tool can export Ant files.

Restriction:

- The Server Configuration Tool does not support server farms. Therefore, you cannot use it to define, install, upgrade, or uninstall server farms. For server farms, use the provided Ant script or follow manual steps in your application server. For more information, see “Installing a server farm” on page 6-138.
- The Server Configuration Tool for Mac OS is available for development and test purposes only.
- Ant tasks: Ant command-line files automate the process of creating or upgrading a database, either automatically or as a complement of a database preparation by a database administrator. The Ant tasks also automate the process of installing or upgrading the Administration Services and the MobileFirst Operations Console in an application server. Ant tasks provide a high level of control for individual operations on the database or on the application server.
- Manual installation.

Installation prerequisites

For smooth installation of MobileFirst Server, ensure that you fulfill all required environment setup and software prerequisites before you attempt installation.

You can find a complete list of supported hardware together with prerequisite software in “System requirements” on page 2-15.

Important: If a version of MobileFirst Server is already installed, review “Upgrading to IBM MobileFirst Platform Foundation V7.1.0” on page 7-1 before you install MobileFirst Server and deploy a MobileFirst project on the same application server or databases. Failure to do so can result in an incomplete installation and a non-functional MobileFirst Server.

Download the IBM MobileFirst Platform Foundation package from IBM Passport Advantage.

Ensure that you have the latest fix packs for the IBM MobileFirst Platform Foundation product. If you are connected to the Internet during the installation, IBM Installation Manager can download the latest fix packs for you.

The package contains an Install Wizard that guides you through the MobileFirst Server installation.

MobileFirst Server requires an application server and relies on a database management system.

You can use any of the following application servers:

- WebSphere Application Server Liberty Core
- WebSphere Application Server
- Apache Tomcat

You can use any of the following database management systems:

- IBM DB2®
- MySQL

- Oracle
- Apache Derby in embedded mode. Included in the installation image.
- IBM Cloudant

Verify that the application server you selected provides support for your database.

Note: Apache Derby is supplied for evaluation and testing purposes only and is not supported for production-grade MobileFirst Server.

The MobileFirst installer can install the IBM MobileFirst Platform Application Center and deploy it to your application server. In this case, the application server and the database management system (if different from Apache Derby) must be installed before you start the MobileFirst Server installer. If you do not need the Application Center or decide to install it manually, you do not need to install the application server and database management system before you start the MobileFirst Server installer. However, you need them before you deploy IBM MobileFirst Platform Foundation projects.

The IBM MobileFirst Platform Foundation packages include the following installers:

- IBM DB2 Workgroup Server Edition
- IBM DB2 Enterprise Server Edition (on Linux for System z[®] only)
- IBM WebSphere Application Server Liberty Core
- IBM MobileFirst Platform Cloudant Data Layer Local Edition (on Linux)

File system prerequisites

To install IBM MobileFirst Platform Foundation to an application server, the MobileFirst installation tools must be run by a user that has specific file system privileges.

The installation tools include:

- IBM Installation Manager
- The Server Configuration Tool
- The Ant tasks to deploy the MobileFirst Server

For WebSphere Application Server Liberty profile, you must have the right to perform the following actions:

- Read the files in the Liberty installation directory.
- Create files in the configuration directory of the Liberty server, which is typically `usr/servers/<servername>`, to create backup copies and modify `server.xml` and `jvm.options`.
- Create files and directories in the Liberty shared resource directory, which is typically `usr/shared`.
- Create files in the Liberty server apps directory, which is typically `usr/servers/<servername>/apps`.

For WebSphere Application Server full profile and WebSphere Application Server Network Deployment, you must have the right to perform the following actions:

- Read the files in the WebSphere Application Server installation directory.
- Read the configuration file of the selected WebSphere Application Server full profile or of the Deployment Manager profile.
- Run the **wsadmin** command.

- Create files in the profiles configuration directory. The installation tools put resources such as shared libraries or JDBC drivers in that directory.

For Apache Tomcat, you must have the right to perform the following actions:

- Read the configuration directory.
- Create backup files and modify files in the configuration directory, such as `server.xml`, and `tomcat-users.xml`.
- Create backup files and modify files in the `bin` directory, such as `setenv.bat`.
- Create files in the `lib` directory.
- Create files in the `webapps` directory.

For all these application servers, the user who runs the application server must be able to read the files that were created by the user who ran the MobileFirst installation tools.

Introduction to the MobileFirst Server components

The MobileFirst Server is composed of one or more runtime environments, an administration console and administration services, an enterprise application store, and an operational analytics feature.

MobileFirst Server components run as web applications on an application server. To set up MobileFirst Server, you must first choose which of the following supported application servers you want to use:

- WebSphere Application Server
- WebSphere Application Server Liberty
- Apache Tomcat

For implementations that require several servers, you might want to set up one of the following topologies:

- A server cluster that is defined by using the WebSphere Application Server Network Deployment solution. (Use the hardware-sizing tool on developerWorks to decide on the number of servers and the size of the database.)
- A farm of individual application servers. Specific installation steps must be taken. See “Installing a server farm” on page 6-138.

The following sections describe each of the following MobileFirst Server components:

- “MobileFirst runtime environments.”
- “IBM MobileFirst Platform Operations Console and Administration Services” on page 6-18
- “IBM MobileFirst Platform Application Center” on page 6-18
- “Operational Analytics” on page 6-19

MobileFirst runtime environments

The MobileFirst runtime environment is a mobile-optimized server-side component that runs the server side of your mobile applications (back-end integration, version management, security, unified push notification).

Each runtime environment is packaged as a web application (WAR file), which is created by using MobileFirst Studio. Each runtime environment can host one or more MobileFirst applications.

Each runtime environment requires a database to host information such as the list of devices that connect to it. Different runtime environments (different project WAR files) cannot share database tables. If you have multiple runtime environments, the tables must be in different schemas or different databases, depending on your database management system. Similar runtime environments (project WAR files) that run in the same cluster of farm must use the same database unless you implement a disaster recovery topology with replication and conflict management as described in Active/Active topology for the MobileFirst Platform Foundation Server.

IBM MobileFirst Platform Operations Console and Administration Services

The MobileFirst Administration component consists of two applications that are used for the administration of the runtime environments:

- The MobileFirst Operations Console application.
- The MobileFirst Administration Services application.

The MobileFirst Operations Console is the web-based interface that an IT administrator uses to run administration tasks on the mobile application such as application deployment, management, version enforcement, and management of push notifications.

The MobileFirst Operations Console is supported by the MobileFirst Administration Services application. This application acts as host for all the REST services and administration tasks. Both the MobileFirst Operations Console and the Administration Services can be secured through standard Java Platform, Enterprise Edition security. Several administration user roles are available to cover different administration scenarios.

One MobileFirst Operations Console can be used for the administration of several runtime environments. The administration tasks are run through standard JMX (Java Management Extension) calls.

Note: Since V6.2.0, the MobileFirst runtime environment registers an MBean called `com.worklight.core.jmx.ProjectManagementMXBean` and exposes the JMX API with this MBean. This MBean is exposed with all other MBeans that are registered in the application server. It is used by the runtime environment for such things as the management of deployed applications and adapters, devices, and push services. This MBean is intended to be used only by the MobileFirst Administration Services, so methods in this MBean are private and are not meant to be accessed directly.

A database is required for the MobileFirst Operations Console and Administration Services.

IBM MobileFirst Platform Application Center

The Application Center is a private application store that developers can use to get feedback about their mobile applications from testers and stakeholders. The Application Center is used to distribute private or public applications to employees and partners. The Application Center is an optional component that can be installed separately from the other MobileFirst Server components.

The Application Center consists of two web applications:

- The Application Center console application that provides the user interface.

- The Application Center services application that provides the REST services.

A database is required for the Application Center. For more information, see “Application Center” on page 13-65.

Operational Analytics

MobileFirst Operational Analytics

The operational analytics feature enables searching across apps, services, devices, and other sources to collect data about usage or to detect problems.

The feature is packaged as a web application. To enable the collection of analytics information, you must configure the runtime environment with the URL of the analytics platform. For more information, see “Operational analytics” on page 14-9.

Planning deployment of administration components and runtimes

Plan the deployment of MobileFirst administration components and runtimes depending on the server topology that you use.

See “Introduction to the MobileFirst Server components” on page 6-17 for an introduction to the administration components and runtimes.

You can use the following topologies of application servers:

- Stand-alone server: WebSphere Application Server Liberty profile, Apache Tomcat, or WebSphere Application Server full profile
- Server farm: WebSphere Application Server Liberty profile, Apache Tomcat, or WebSphere Application Server full profile
- WebSphere Application Server Network Deployment cell

Depending on the application server topology that you use, you can deploy either symmetrically or asymmetrically. In symmetrical deployment, you must install runtimes and administration components on the same application server. In asymmetric deployment, you can install the runtimes on different application servers from the administration components.

Modes of deployment

Two modes are available to deploy the MobileFirst administration components and the runtimes in the application server infrastructure.

- Symmetric deployment: the MobileFirst administration components (MobileFirst Operations Console and administration service applications) are deployed in the same Java Virtual Machine (JVM) as the runtimes.
- Asymmetric deployment: The administration components are deployed in a different JVM from the runtimes.

Asymmetric deployment is only supported for WebSphere Application Server Network Deployment cell topology.

Stand-alone server topology:

You can configure a stand-alone topology for WebSphere Application Server full profile, WebSphere Application Server Liberty profile, and Apache Tomcat.

In this topology, all the administration components and the runtimes are deployed in a single Java Virtual Machine (JVM).

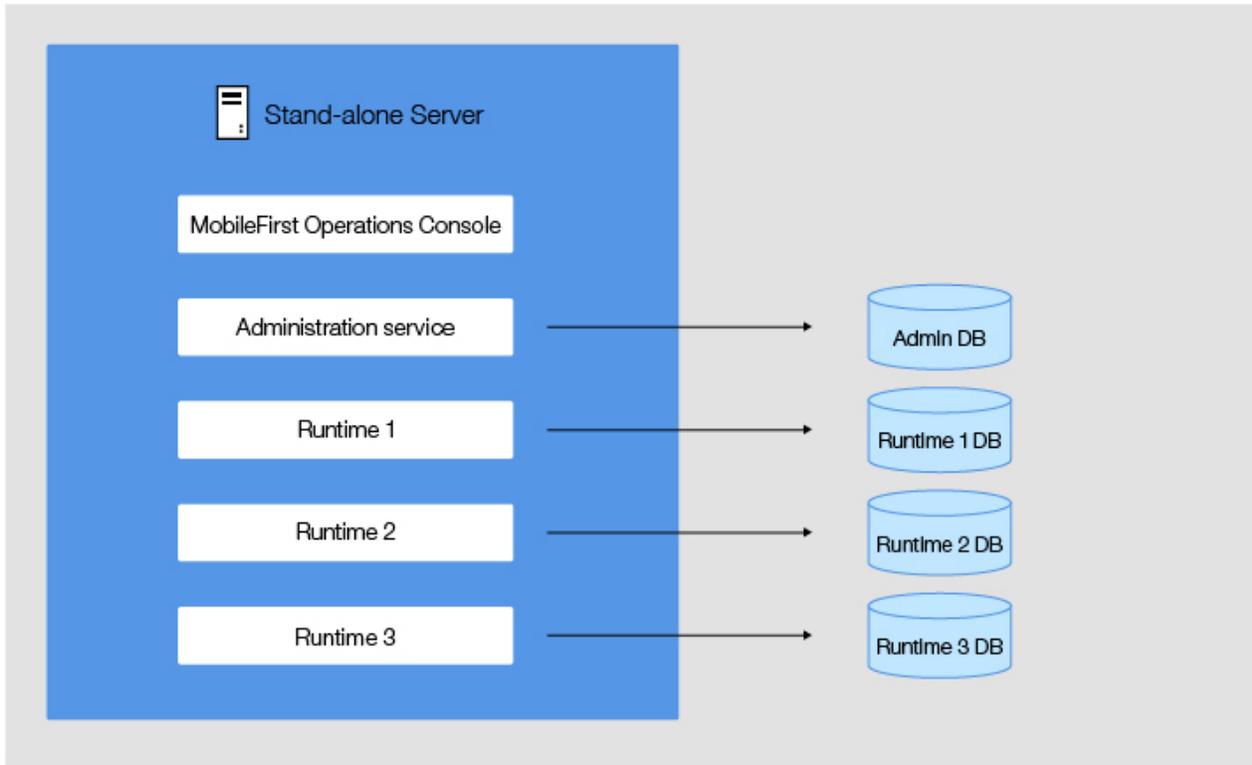

Figure 6-3. Topology of a stand-alone server

With one JVM, only symmetric deployment is possible with the following characteristics:

- One or several administration components can be deployed. Each MobileFirst Operations Console communicates with one administration service.
- One or several runtimes can be deployed.
- One MobileFirst Operations Console can manage several runtimes.
- One runtime is managed by only one MobileFirst Operations Console.
- Each administration service uses its own administration database schema.
- Each runtime uses its own runtime database schema.

Configuration of JNDI properties

Some JNDI properties are required to enable Java Management Extensions (JMX) communication between the administration service and the runtime, and to define the administration service that manages a runtime. For details about these properties, see “List of JNDI properties for MobileFirst Server administration” on page 6-111 and “JNDI environment entries for MobileFirst projects in production” on page 12-68.

Stand-alone WebSphere Application Server Liberty profile server

The following global JNDI properties are required for the administration services and for the runtimes.

Table 6-1. Global JNDI properties for administration services and runtimes in WebSphere Application Server Liberty stand-alone topology

JNDI properties	Values
ibm.worklight.topology.platform	"Liberty"
ibm.worklight.topology.clustermode	"Standalone"
ibm.worklight.admin.jmx.host	Hostname of the WebSphere Application Server Liberty profile server
ibm.worklight.admin.jmx.port	Port of the REST connector that is the port of the httpsPort attribute declared in the <httpEndpoint> element of the server.xml file of WebSphere Application Server Liberty profile server. This property has no default value.
ibm.worklight.admin.jmx.user	The user name of the WebSphere Application Server Liberty administrator, which must be identical to the name defined in the <administrator-role> element of the server.xml file of the WebSphere Application Server Liberty profile server.
ibm.worklight.admin.jmx.pwd	Password of the WebSphere Application Server Liberty administrator user.

Several administration components can be deployed to enable the same JVM to run on separate administration components that manage different runtimes.

When you deploy several administration components, you must specify:

- On each administration service, a unique value for the local **ibm.worklight.admin.environmentid** JNDI property.
- On each runtime, the same value for the local **ibm.worklight.admin.environmentid** JNDI property as the value defined for the administration service that manages the runtime.

Stand-alone Apache Tomcat server

The following local JNDI properties are required for the administration services and for the runtimes.

Table 6-2. Local JNDI properties for administration services and runtimes in Apache Tomcat stand-alone topology

JNDI properties	Values
ibm.worklight.topology.platform	"Tomcat"
ibm.worklight.topology.clustermode	"Standalone"

JVM properties are also required to define Java Management Extensions (JMX) Remote Method Invocation (RMI). For more information, see "Configuring Apache Tomcat" on page 6-65.

If the Apache Tomcat server is running behind a firewall, the **ibm.worklight.admin.rmi.registryPort** and **ibm.worklight.admin.rmi.serverPort** JNDI properties are required for the administration service. See "Configuring Apache Tomcat" on page 6-65.

Several administration components can be deployed to enable the same JVM to run on separate administration components that manage different runtimes.

When you deploy several administration components, you must specify:

- On each administration service, a unique value for the local **ibm.worklight.admin.environmentid** JNDI property.
- On each runtime, the same value for the local **ibm.worklight.admin.environmentid** JNDI property as the value defined for the administration service that manages the runtime.

Stand-alone WebSphere Application Server

The following local JNDI properties are required for the administration services and for the runtimes.

Table 6-3. Local JNDI properties for administration services and runtimes in WebSphere Application Server stand-alone topology

JNDI properties	Values
ibm.worklight.topology.platform	"WAS"
ibm.worklight.topology.clustermode	"Standalone"
ibm.worklight.admin.jmx.connector	The JMX connector type; the value can be "SOAP" or "RMI".

Several administration components can be deployed to enable the same JVM to run on separate administration components that manage different runtimes.

When you deploy several administration components, you must specify:

- On each administration service, a unique value for the local **ibm.worklight.admin.environmentid** JNDI property.
- On each runtime, the same value for the local **ibm.worklight.admin.environmentid** JNDI property as the value defined for the administration service that manages the runtime.

Server farm topology:

You can configure a farm of WebSphere Application Server full profile, WebSphere Application Server Liberty profile, or Apache Tomcat application servers.

A farm is a set of individual servers where the same components are deployed and where the same administration database and runtime database are shared between the servers. The farm topology enables the load of MobileFirst applications to be distributed across several servers. Each server in the farm must be a Java Virtual Machine (JVM) of the same type of application server; that is, a homogeneous server farm.

In this topology, all the administration components and the runtimes are deployed on every server in the farm.

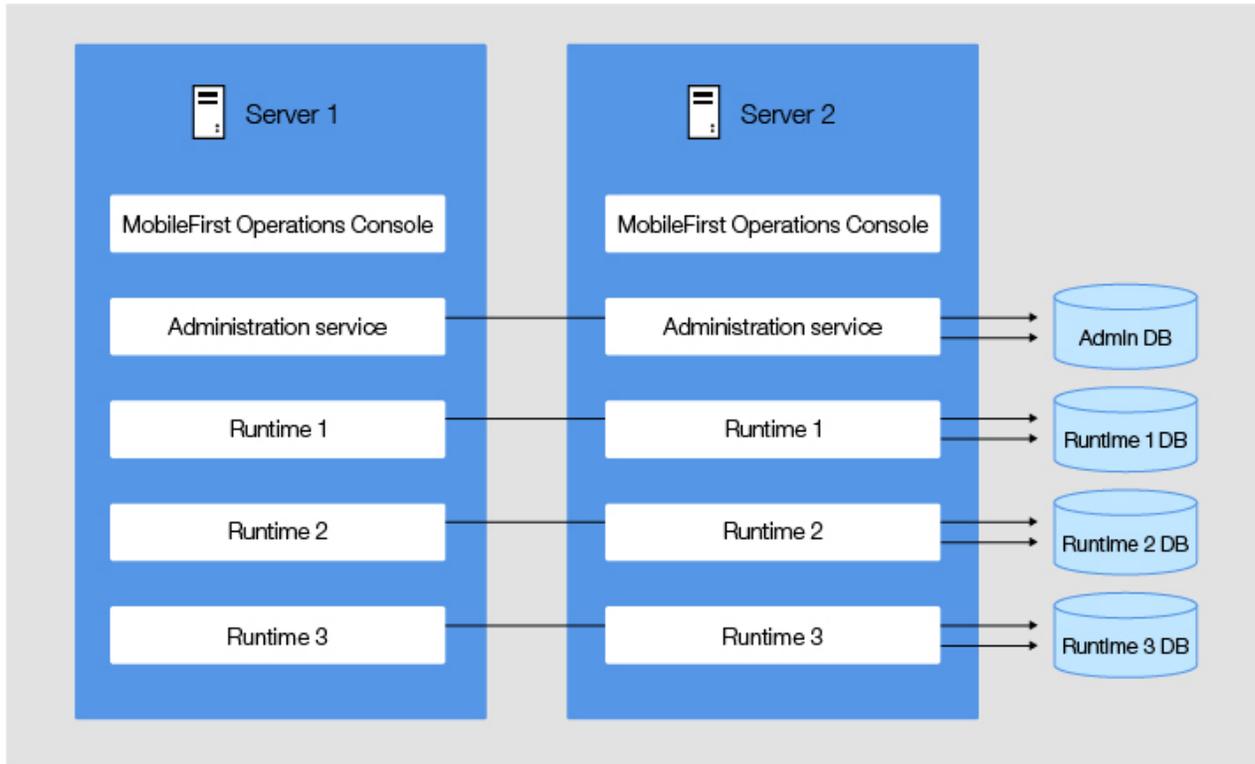

Figure 6-4. Topology of a server farm

This topology supports only symmetric deployment. The runtimes and the administration components must be deployed on every server in the farm. The deployment of this topology has the following characteristics:

- One or several administration components can be deployed. Each instance of MobileFirst Operations Console communicates with one administration service.
- The administration components must be deployed on all servers in the farm.
- One or several runtimes can be deployed.
- The runtimes must be deployed on all servers in the farm.
- One MobileFirst Operations Console can manage several runtimes.
- One runtime is managed by only one MobileFirst Operations Console.
- Each administration service uses its own administration database schema. All deployed instances of the same administration service share the same administration database schema.
- Each runtime uses its own runtime database schema. All deployed instances of the same runtime share the same runtime database schema.

Configuration of JNDI properties

Some JNDI properties are required to enable JMX communication between the administration service and the runtime of the same server, and to define the administration service that manages a runtime. For convenience, the tables in this section list these properties. For instructions about how to install a server farm, see “Installing a server farm” on page 6-138. For details about the JNDI properties, see “List of JNDI properties for MobileFirst Server administration” on page 6-111 and “JNDI environment entries for MobileFirst projects in production” on page 12-68.

WebSphere Application Server Liberty profile server farm

The following global JNDI properties are required in each server of the farm for the administration services and for the runtimes.

Table 6-4. Global JNDI properties for administration services and runtimes in server farm topology of WebSphere Application Server Liberty profile

JNDI properties	Values
ibm.worklight.topology.platform	"Liberty"
ibm.worklight.topology.clustermode	"Farm"
ibm.worklight.admin.jmx.host	Hostname of the WebSphere Application Server Liberty profile server
ibm.worklight.admin.jmx.port	Port of the REST connector that must be identical to the value of the httpsPort attribute declared in the <httpEndpoint> element of the server.xml file of the WebSphere Application Server Liberty profile server. <pre><httpEndpoint id="defaultHttpEndpoint" httpPort="9080" httpsPort="9443" host="*" /></pre>
ibm.worklight.admin.jmx.user	The user name of the WebSphere Application Server Liberty administrator that is defined in the <administrator-role> element of the server.xml file of the WebSphere Application Server Liberty profile server. <pre><administrator-role> <user>WorklightRESTUser</user> </administrator-role></pre>
ibm.worklight.admin.jmx.pwd	Password of the WebSphere Application Server Liberty administrator user.

The **ibm.worklight.admin.serverid** JNDI property is required for the administration service to manage the server farm configuration. Its value is the server identifier, which must be different for each server in the farm.

Several administration components can be deployed to enable the same JVM to run on separate administration components that manage different runtimes.

When you deploy several administration components, you must specify:

- On each administration service, a unique value for the local **ibm.worklight.admin.environmentid** JNDI property.
- On each runtime, the same value for the local **ibm.worklight.admin.environmentid** JNDI property as the value defined for the administration service that manages the runtime.

Apache Tomcat server farm

The following global JNDI properties are required in each server of the farm for the administration services and for the runtimes.

Table 6-5. Global JNDI properties for administration services and runtimes in server farm topology of Apache Tomcat

JNDI properties	Values
ibm.worklight.topology.platform	"Tomcat"
ibm.worklight.topology.clustermode	"Farm"

JVM properties are also required to define Java Management Extensions (JMX) Remote Method Invocation (RMI). For more information, see “Configuring Apache Tomcat” on page 6-65.

The **ibm.worklight.admin.serverid** JNDI property is required for the administration service to manage the server farm configuration. Its value is the server identifier, which must be different for each server in the farm.

Several administration components can be deployed to enable the same JVM to run on separate administration components that manage different runtimes.

When you deploy several administration components, you must specify:

- On each administration service, a unique value for the local **ibm.worklight.admin.environmentid** JNDI property.
- On each runtime, the same value for the local **ibm.worklight.admin.environmentid** JNDI property as the value defined for the administration service that manages the runtime.

WebSphere Application Server full profile server farm

The following global JNDI properties are required on each server in the farm for the administration services and for the runtimes.

Table 6-6. Global JNDI properties for administration services and runtimes in server farm topology of WebSphere Application Server full profile

JNDI properties	Values
ibm.worklight.topology.platform	“WAS”
ibm.worklight.topology.clustermode	“Farm”
ibm.worklight.admin.jmx.connector	“SOAP”

The following JNDI properties are required for the administration service to manage the server farm configuration.

JNDI properties	Values
ibm.worklight.admin.jmx.user	The user name of WebSphere Application Server. This user must be defined in the WebSphere Application Server user registry.
ibm.worklight.admin.jmx.pwd	The password of the WebSphere Application Server user.
ibm.worklight.admin.serverid	The server identifier, which must be different for each server in the farm and identical to the value of this property used for this server in the server farm configuration file.

Several administration components can be deployed to enable the same JVM to run on separate administration components that manage different runtimes.

When you deploy several administration components, you must specify the following values:

- On each administration service, a unique value for the local **ibm.worklight.admin.environmentid** JNDI property.

- On each runtime, the same value for the local `ibm.worklight.admin.environmentid` JNDI property as the value defined for the administration service that manages the runtime.

WebSphere Application Server Network Deployment topologies:

The administration components and the runtimes are deployed in servers or clusters of the WebSphere Application Server Network Deployment cell.

Examples of these topologies support either asymmetric or symmetric deployment, or both. You can, for example, deploy the administration components in one cluster and the runtimes managed by these components in another cluster.

Symmetric deployment in the same server or cluster

Figure 6-5 shows symmetric deployment where the runtimes and the administration components are deployed in the same server or cluster.

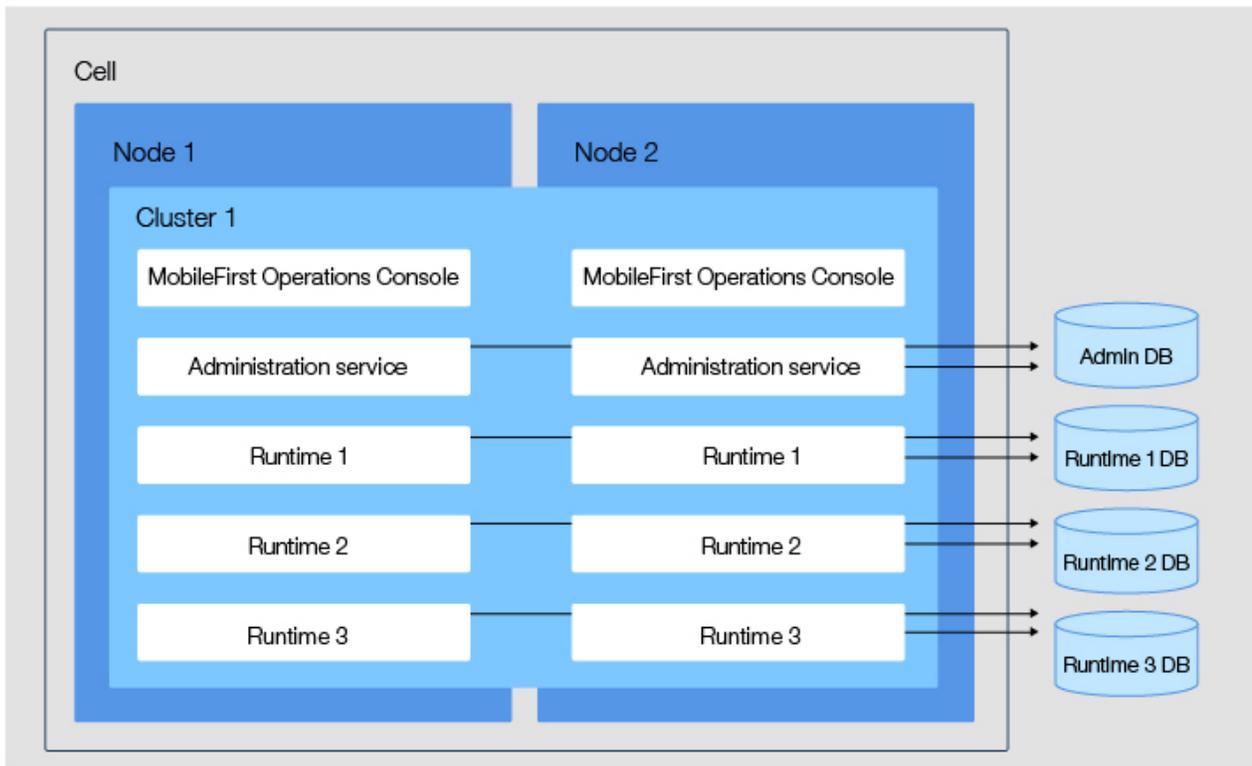

Figure 6-5. Symmetric deployment, same server or cluster

The deployment of this topology has the following characteristics:

- One or several administration components can be deployed in one or several servers or clusters of the cell. Each instance of MobileFirst Operations Console communicates with one administration service.
- One or several runtimes can be deployed in the same server or cluster as the administration components that manage them.
- One runtime is managed by only one MobileFirst Operations Console.
- Each administration service uses its own administration database schema.
- Each runtime uses its own runtime database schema.

Asymmetric deployment with runtimes and administration services in different server or cluster

Figure 6-6 shows a topology where the runtimes are deployed in a different server or cluster from the administration services.

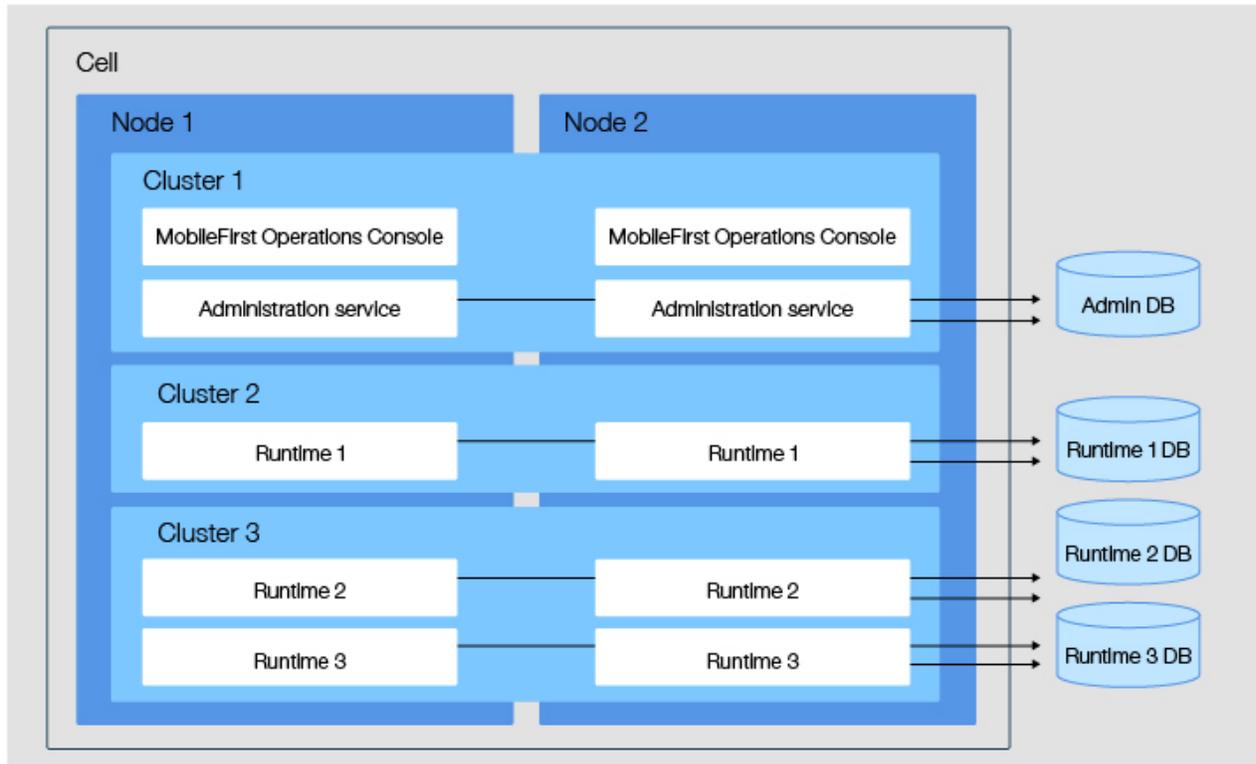

Figure 6-6. Asymmetric deployment, different server or cluster

The deployment of this topology has the following characteristics:

- One or several administration components can be deployed in one or several servers or clusters of the cell. Each instance of MobileFirst Operations Console communicates with one administration service.
- One or several runtimes can be deployed in other servers or clusters of the cell.
- One MobileFirst Operations Console manages several runtimes deployed in the other servers or clusters of the cell.
- One runtime is managed by only one MobileFirst Operations Console.
- Each administration service uses its own administration database schema.
- Each runtime uses its own runtime database schema.

This topology is advantageous, because it enables the runtimes to be isolated from the administration components and from other runtimes. It can be used to provide performance isolation, to isolate critical applications, and to enforce Service Level Agreement (SLA).

Symmetric and asymmetric deployment

Figure 6-7 on page 6-28 shows an example of symmetric deployment in Cluster1 and of asymmetric deployment in Cluster2, where Runtime2 and Runtime3 are deployed in a different cluster from the administration components. MobileFirst

Operations Console manages the runtimes deployed in Cluster1 and Cluster2.

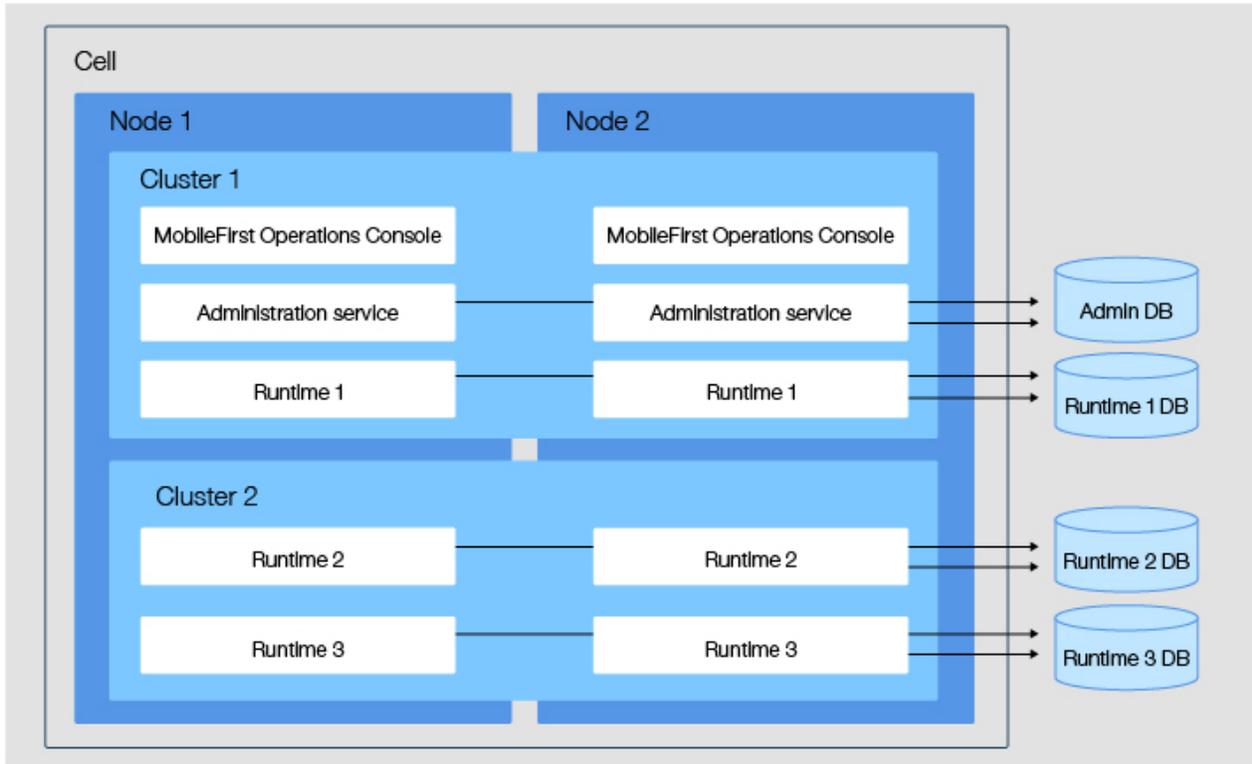

Figure 6-7. Symmetric and asymmetric deployment in different clusters of a cell

The deployment of this topology has the following characteristics:

- One or several administration components can be deployed in one or several servers or clusters of the cell. Each instance of MobileFirst Operations Console communicates with one administration service.
- One or several runtimes can be deployed in one or several servers or clusters of the cell.
- One MobileFirst Operations Console can manage several runtimes deployed in the same or other servers or clusters of the cell.
- One runtime is managed by only one MobileFirst Operations Console.
- Each administration service uses its own administration database schema.
- Each runtime uses its own runtime database schema.

Configuration of JNDI properties

Some JNDI properties are required to enable JMX communication between the administration service and the runtime, and to define the administration service that manages a runtime. For details about these properties, see “List of JNDI properties for MobileFirst Server administration” on page 6-111 and “JNDI environment entries for MobileFirst projects in production” on page 12-68.

The following local JNDI properties are required for the administration services and for the runtimes:

Table 6-7. Local JNDI properties for administration services and runtimes in WebSphere Application Server Network Deployment topologies.

JNDI properties	Values
ibm.worklight.topology.platform	WAS
ibm.worklight.topology.clustermode	Cluster
ibm.worklight.admin.jmx.connector	The JMX connector type to connect with the Deployment Manager. The value can be SOAP or RMI. SOAP is the default and preferred value. Use RMI if the SOAP port is disabled.
ibm.worklight.admin.jmx.dmgr.host	The host name of the Deployment Manager.
ibm.worklight.admin.jmx.dmgr.port	The RMI or the SOAP port used by the Deployment Manager, depending on the value of ibm.worklight.admin.jmx.connector .

Several administration components can be deployed to enable you to run the same server or cluster with separate administration components managing each of the different runtimes. When several administration components are deployed, you must specify:

- On each administration service, a unique value for the local **ibm.worklight.admin.environmentid** JNDI property.
- On each runtime, the same value for the local **ibm.worklight.admin.environmentid** as the value defined for the administration service that manages that runtime.

If the virtual host that is mapped to an administration services application is not the default host, you must set the following properties on the administration services application:

- **ibm.worklight.admin.jmx.user**: the user name of the WebSphere Application Server administrator
- **ibm.worklight.admin.jmx.pwd**: the password of the WebSphere Application Server administrator

Using a reverse proxy with server farm and WebSphere Application Server Network Deployment topologies:

You can use a reverse proxy with distributed topologies. If your topology uses a reverse proxy, configure the required JNDI properties for the administration service.

See the Glossary for the definition of a reverse proxy.

You can use a reverse proxy, such as IBM HTTP Server, to front server farm or WebSphere Application Server Network Deployment topologies. In this case, you must configure the administration components appropriately.

You can call the reverse proxy from:

- The browser when you access MobileFirst Operations Console.
- The runtime when it calls the administration service.
- The MobileFirst Operations Console component when it calls the Administration services.

If the reverse proxy is in a DMZ (a firewall configuration for securing local area networks) and a firewall is used between the DMZ and the internal network, this firewall must authorize all incoming requests from the application servers.

When a reverse proxy is used in front of the application server infrastructure, the following JNDI properties must be defined for the administration service.

Table 6-8. JNDI properties for reverse proxy.

JNDI properties	Values
<code>ibm.worklight.admin.proxy.protocol</code>	The protocol used to communicate with the reverse proxy, which can be HTTP or HTTPS.
<code>ibm.worklight.admin.proxy.host</code>	The host name of the reverse proxy.
<code>ibm.worklight.admin.proxy.port</code>	The port number of the reverse proxy.

The `ibm.worklight.admin.endpoint` property that references the URL of the reverse proxy is also required for MobileFirst Operations Console. See “Defining the endpoint of the MobileFirst Administration services” on page 6-102.

For detailed instructions to configure an IBM HTTP Server or a Data Store, see “Typical topologies of a MobileFirst instance in an extranet infrastructure” on page 6-327.

Related information

- “Integration and authentication with a reverse proxy” on page 15-3

Planning the creation of the databases

You must plan the creation of the databases that are needed for the Administration Services, the MobileFirst runtime environments, and the Application Center Services, if you choose to install Application Center.

The installation of the MobileFirst Server requires the following databases:

- For the Administration Services, an administration database.
- For each MobileFirst runtime environment, a runtime database.

Note: By default, the relational databases have the following names and kind attributes, as defined in table 1 of “Ant `configuredatabase` task reference” on page 16-25:

- The default name of the administration database is `WLADMIN`, and its kind is `WorklightAdmin`.
- The default name of the runtime database is `WRKLGHT`, and its kind is `Worklight`.

By default, the Cloudant databases have the following names, and kind attributes:

- The default name of the administration database is `mfp_admin_db`, and its kind is `WorklightAdmin`.
- The default name of the runtime database is in the form `prefix_contextroot_runtime_db`, where `prefix` is an optional prefix, and `contextroot` is the context root of your MobileFirst runtime, without the leading slash, and the database kind is `Worklight`.

Optionally, the Application Center can be installed. The Application Center also requires a database. Its database kind is **ApplicationCenter**, as defined in Table 16-1 on page 16-26 of the page “Ant **configuredatabase** task reference” on page 16-25.

An installation of MobileFirst Server includes at least one MobileFirst runtime environment, which is the web application that is in contact with the mobile devices, but might contain more than one MobileFirst runtime environment.

The relational databases can be instantiated automatically by the Server Configuration Tool or by the Ant tasks. In these two installation scenarios, it is also possible that a database administrator creates the relational database beforehand. For more information about the creation of these databases, see “Optional creation of the administration database” on page 6-58. For more information about the MobileFirst runtime environments, see “Optional creation of databases” on page 12-6.

For DB2, the administration, and the runtime databases can be in the same database, but they must be in different schemas.

For Oracle, these databases must be created for a different user.

For each relational database, it is possible to restrict the privileges of the database user that uses the data source at run time.

Restricting database user permissions for IBM MobileFirst Platform Server runtime operations:

When the databases are operational, you can decide to create a database user with restricted privileges. You use this database user to perform database underlying operations from the MobileFirst administration and runtime components. The user credentials appear in the application server configuration.

MobileFirst Server data is stored in the databases that are described in “Introduction to the MobileFirst Server components” on page 6-17. The database administrator might require you to provide specific permissions that you need when you access those databases at run time. The connection to the MobileFirst Server databases at run time, which is established in the data source credentials, and any subsequent requests to the databases, are handled through a single database user or one distinct user per database. Using different users that can access only one kind of database, and especially to separate the databases of the MobileFirst runtime environment from the database of the MobileFirst administration component, improves security. These database users have no relation to the standard MobileFirst Server groups. The following table shows the minimal permissions that the database administrator must define on the MobileFirst Server databases for these users:

Table 6-9. Minimal permissions defined by the database administrator.

Database permission	Use MobileFirst Server Operation
ALTER TABLE	Not required
CREATE INDEX	Not required
CREATE ROLE	Not required
CREATE SEQUENCE	Not required
CREATE TABLE	Not required

Table 6-9. Minimal permissions defined by the database administrator (continued).

Database permission	Use MobileFirst Server Operation
CREATE VIEW	Not required
DROP INDEX	Not required
DROP SEQUENCE	Not required
DROP TABLE	Not required
DROP VIEW	Not required
SELECT TABLE	Required
INSERT TABLE	Required
UPDATE TABLE	Required
DELETE TABLE	Required
SELECT SEQUENCE	Required

These minimal permissions also apply to the database user of the (optional) Application Center database.

Using complex Oracle connection descriptors:

For some topologies of the Oracle DBMS, for example Oracle Real Application Clusters (RAC), you might have to use complex Oracle Net connection descriptors. In that case, review the following steps.

Procedure

1. You must create the databases manually for the Application Center, the MobileFirst Server administration, and the MobileFirst project WAR file. This step is mandatory and cannot be performed with the Ant tasks or Server Configuration Tool. See the following links for instructions on how to create these databases.
 - For installing the Application Center, see “Creating the Oracle database for Application Center” on page 6-237.
 - For installing the MobileFirst Server administration, see “Creating the Oracle database for MobileFirst Server administration” on page 6-61.
 - For deploying the MobileFirst project WAR file, see “Creating the Oracle database” on page 12-8.
2. In IBM Installation Manager, or in the Server Configuration Tool, you must use a generic Oracle JDBC URL instead of the host name and port.

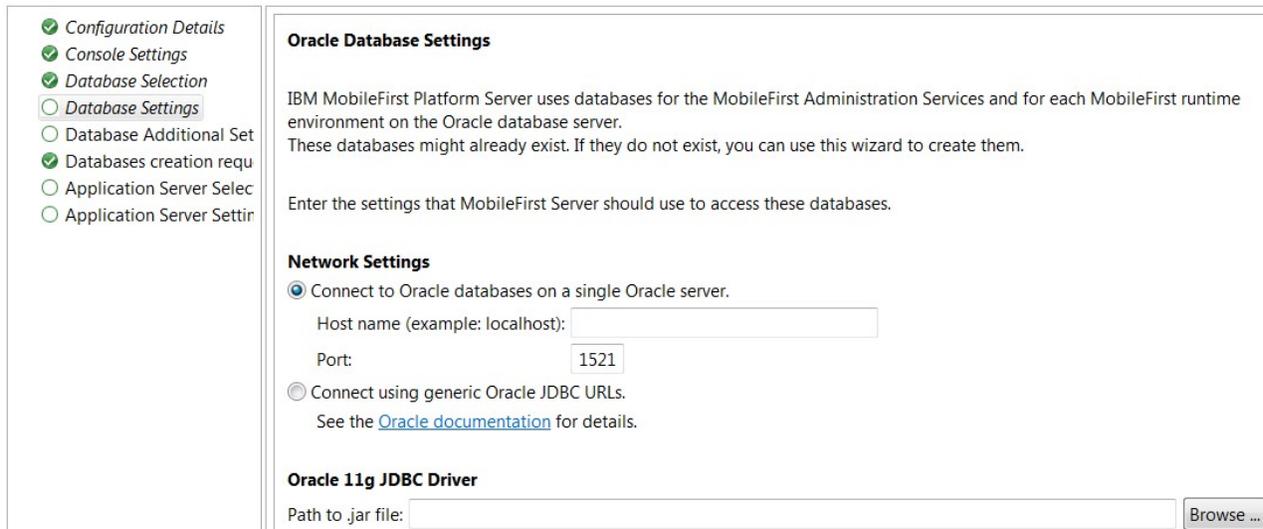

Figure 6-8. Oracle Database Settings window

- For Ant tasks, you must use the alternative attributes for the `<oracle>` element. For more information, see “Ant **configuredatabase** task reference” on page 16-25, table 19.

Note: The example files in “Sample configuration files” on page 16-77 do not use the alternative attributes for the `<oracle>` element. If you use an example file, you must modify the `<oracle>` elements in the file so that they use the alternative attributes.

- The URL must be a URL for the Oracle thin driver. It must not include the user name and password, for example: `jdbc:oracle:thin:@(DESCRIPTION= [Oracle Net connection descriptor])`.

Configuring DB2 HADR seamless failover for MobileFirst Server and Application Center data sources:

You must enable the seamless failover feature with WebSphere Application Server Liberty profile and WebSphere Application Server. With this feature, you can manage an exception when a database fails over and gets rerouted by the DB2 JDBC driver.

Note: DB2 HADR failover is not supported for Apache Tomcat.

By default with DB2 HADR, when the DB2 JDBC driver performs a client reroute after detecting that a database failed over during the first attempt to reuse an existing connection, the driver triggers `com.ibm.db2.jcc.am.ClientRerouteException`, with `ERRORCODE=-4498` and `SQLSTATE=08506`. WebSphere Application Server maps this exception to `com.ibm.websphere.ce.cm.StaleConnectionException` before it is received by the application.

In this case, the application would have to catch the exception and execute again the transaction. The MobileFirst and Application Center runtime environments do not manage the exception but rely on a feature that is called seamless failover. To enable this feature, you must set the **enableSeamlessFailover** JDBC property to "1".

WebSphere Application Server Liberty profile configuration

You must edit the `server.xml` file, and add the **enableSeamlessFailover** property to the `properties.db2.jcc` element of the MobileFirst and Application Center data sources. For example:

```
<dataSource jndiName="jdbc/WorklightAdminDS" transactional="false">
  <jdbcDriver libraryRef="DB2Lib"/>
  <properties.db2.jcc databaseName="WLADMIN" currentSchema="WLADMSC"
    serverName="db2server" portNumber="50000"
    enableSeamlessFailover= "1"
    user="worklight" password="worklight"/>
</dataSource>
```

WebSphere Application Server configuration

From the WebSphere Application Server administrative console for each MobileFirst and Application Center data source:

1. Go to **Resources > JDBC > Data sources > DataSource name**.
2. Select **New** and add the following custom property, or update the values if the properties already exist:
enableSeamlessFailover : 1
3. Click **Apply**.
4. Save your configuration.

For more information about how to configure a connection to an HADR-enabled DB2 database, see [Setting up a connection to an HADR-enabled DB2 database](#).

Planning for the use of token licensing

If the token licensing is purchased for MobileFirst Server, you have extra steps to consider in the installation planning.

Technical restrictions

Here are the technical restrictions for the use of token licensing:

Supported Platforms:

The list of platforms that support token licensing is listed at “Limitations of supported platforms for token licensing” on page 6-133. The MobileFirst Server running on a platform that is not listed might not be possible to install and configure for token licensing. The native libraries for the Rational Common Licensing client might not be available for the platform or not supported.

Supported Topologies:

From the list of topologies that are listed at “Planning deployment of administration components and runtimes” on page 6-19, the non-symmetric deployments are not supported. The number of tokens that are used by a MobileFirst cluster might be incorrect. In particular, the asymmetric deployment with runtimes and administration services in different server or cluster is not supported on WebSphere Application Server Network Deployment.

Network requirement

MobileFirst Server must be able to communicate with the Rational License Key Server.

This communication requires the access to the following two ports of the license server:

- License manager daemon (**lmgrd**) port - the default port number is 27000.
- Vendor daemon (**ibmrat1**) port

To configure the ports so that they use static values, see *How to serve a license key to client machines through a firewall*.

Installation Process

You need to activate token licensing when you run the IBM Installation Manager at installation time. For more information about the instructions for enabling token licensing, see *“Installation overview for token licensing”* on page 6-126.

After MobileFirst Server is installed, you must manually configure the server for token licensing. For more information, see *“Installing and configuring for token licensing”* on page 6-126.

The MobileFirst Server is not functional before you complete this manual configuration. In *“Installing and configuring for token licensing”* on page 6-126, the Rational Common Licensing client library is to be installed in your application server, and you define the location of the Rational License Key Server.

Operations

The tokens are checked out per application. The tokens are checked out when an application is uploaded, a runtime server starts, or a token is refreshed after its expiration date. At server starts, if IBM MobileFirst Platform Foundation fails to obtain the tokens it needs, the server will not be functional. If IBM MobileFirst Platform Foundation fails to renew its expired tokens during operations, the applications are deactivated. The mobile app users can no longer access the applications.

If you need to test a non-production application on a production server with token licensing enabled, you can declare the application as non-production. For more information about declaring the application type, see `<licenseAppType>` element in *The application descriptor* and also *“Token licensing: setting the license app type”* on page 8-229.

For more information about the retrieval of tokens during operations, see *“Token license validation”* on page 14-139.

Development

When you develop your application, you must declare the type of application and the license entitlement it matches (such as `NON_PRODUCTION`, `APPLICATION`, or `ADDITIONAL_BRAND_DEPLOYMENT`). For more information, see `<licenseAppType>` element in *The application descriptor* and also *“Token licensing: setting the license app type”* on page 8-229.

Tutorial for a basic installation of MobileFirst Server

Learn about the MobileFirst Server installation process by walking through a simple configuration, which creates a functional MobileFirst Server for demonstration purposes or tests.

Before you begin

1. Make sure that the following tool and component are installed:
 - IBM Installation Manager. Check the required version in the Detailed System Requirements page. To learn how to install and run Installation Manager, see *“Become familiar with IBM Installation Manager before you start”* on page 7-39 and *“Running IBM Installation Manager”* on page 6-43.

- MobileFirst Studio. See “Installing MobileFirst Studio” on page 6-2.
2. Use MobileFirst Studio to create a project, which you can then run on MobileFirst Server.

About this task

This tutorial uses a simple configuration to show how to install MobileFirst Server. It is designed as an overview, to show you where to find the following tools and information:

- Tools to install a MobileFirst Server and the Application Center, and tools to deploy a MobileFirst project.
- Information about configuring MobileFirst Server and the Application Center.
- Information about manual MobileFirst Server installation.

Note: Manual installation provides greater flexibility, but can make the diagnosis of issues more complex, and make the subsequent description of your configuration to IBM Support more difficult.

This tutorial goes through the following steps:

1. “Installing WebSphere Application Server Liberty Core”
2. “Creating a server for Liberty” on page 6-37
3. “Installing the database management system” on page 6-37
4. “Installing MobileFirst Server” on page 6-38
5. “Exploring Application Center” on page 6-39
6. “Installing the MobileFirst Server administration components: Administration Services and MobileFirst Operations Console” on page 6-40
7. “Creating a simple MobileFirst project.” on page 6-41
8. “Deploying a MobileFirst runtime environment with the Server Configuration Tool” on page 6-42
9. “Restarting the Liberty server and opening the MobileFirst Operations Console” on page 6-42

Installing WebSphere Application Server Liberty Core

About this task

The installer for WebSphere Application Server Liberty Core is provided as part of the package for IBM MobileFirst Platform Foundation.

Procedure

1. Load the repository for WebSphere Application Server Liberty Core in IBM Installation Manager and install the product.

Note: IBM Installation Manager is sometimes referred to as *IBM Rational Enterprise Deployment* on the eXtreme Leverage and Passport Advantage sites, and on the distribution disks. The file names for the images take the form IBM Rational Enterprise Deployment <version number><hardware platform> <language>; for example, IBM Rational Enterprise Deployment V1.6.3.1 Windows Multilingual.

For more information about loading repositories with IBM Installation Manager, see step 1 of “Installing MobileFirst Server” on page 6-38. See also the IBM

Installation Manager user documentation at https://www.ibm.com/support/knowledgecenter/SSDV2W_1.7.0/com.ibm.cic.agent.ui.doc/helpindex_imic.html.

2. During the installation process, take note of the installation directory of Liberty. You need this information later on in the procedure.

Creating a server for Liberty

About this task

You use this server to install the Application Center and to deploy a MobileFirst project and its console.

Procedure

1. Go to the installation directory of Liberty. For example, on Windows, if the product is installed with administrator rights, it is located by default in `C:\Program Files\IBM\WebSphere\Liberty`.
2. Type the command that creates a server. In this scenario, the server name is `simpleServer`.
 - On UNIX and Linux systems:
`bin/server create simpleServer`
 - On Windows systems:
`bin\server.bat create simpleServer`

The server is created with all default settings. Default settings are sufficient for this tutorial.

For more information about configuring a Liberty server, read the `README.txt` file in the Liberty installation directory.

Installing the database management system

About this task

You install a database management system so that you can use this DBMS to install the Application Center and to deploy a MobileFirst project and its console.

Procedure

Proceed as follows, depending on your database system.

- If you use IBM DB2, the installer for IBM DB2 is provided as part of the package for IBM MobileFirst Platform Foundation.
 1. Run the installer and follow the instructions.
 2. On Windows, when you are asked whether to install the IBM Secure Shell Server for Windows, say Yes.
 3. In the following steps, you must have a Secure Shell server installed and running so that the MobileFirst tools can create the required databases.
 - On Windows, use the IBM Secure Shell Server for Windows or the Cygwin `openssh` package, as described at http://docs.oracle.com/cd/E25178_01/install.1111/e22624/preinstall_req_cygwin_ssh.htm
 - On UNIX, use the `sshd` daemon.
 4. Take note of the user name and password for the DB2 administrator role.
- If you use MySQL:
 1. Install MySQL on your computer.
 2. Take note of the user name and password for the administrator.

- By default for some installations, the administrator is root and no password is requested.
- If no password is requested for the MySQL administrator in your installation, set a password for the administrator. Follow the instructions from the MySQL documentation.
- If you use Oracle:
 1. Install the Oracle database on your computer.
 2. Install an ssh shell on your computer. On Windows, install cygwin and the openssh package.
 3. Start the ssh server. On Windows, you need administrator rights.
 4. In subsequent steps, you must have that Secure Shell server running.
- If you use Cloudant, you can install IBM MobileFirst Platform Cloudant Data Layer Local Edition, which is provided as part of the package for IBM MobileFirst Platform Foundation, or you can use an account at Cloudant.com.

Important: Application Center does not support Cloudant.

Installing MobileFirst Server Procedure

1. Add the MobileFirst Server repository in IBM Installation Manager:
 - a. Download the **Installation Manager Repository for IBM MobileFirst Platform Server** from Passport Advantage.
 - b. Extract the file on your disk.
 - c. Start IBM Installation Manager.
 - d. Select **File > Preferences**.
 - e. In the Preferences dialog, click **Add Repositories**.
 - f. Select the `disk1/diskTag.inf` file from the repository directory that you extracted.
 - g. Click **OK** and close the Preferences dialog.
2. Load the repository for MobileFirst Server in IBM Installation Manager and install the product.
 - a. In the Configuration Choice panel, select the first choice. This option installs Application Center.
 - b. In that Database Choice panel, select the name of the database management system that you installed.

Restriction: Apache Derby is not supported by the Server Configuration Tool, which is used later in this tutorial.

- c. In the following database panels of the installer:
 - If you use IBM DB2:
 - In the **Database Server Properties** panel:
 - Enter localhost as the **host name**.
 - Select the `db2jcc4.jar` JAR file in the JDBC driver directory (in `<DB2InstallDir>/Java`).
 - In the **Database Server Additional Properties** panel:
 - Select **Simple Mode**.
 - Enter a database user and password. This user must exist.
 - In the **Create Database** panel:

- Enter the name and password of a user account on the database server that has DB2 privilege SYSADM or SYSCTRL.
- The installer creates the database.
- If you use MySQL:
 - In the **Database Server Properties** panel:
 - Enter localhost as the **host name**.
 - Enter the name of the JDBC JAR file for MySQL.
 - In the **Database Server Additional Properties** panel:
 - Select **Simple Mode**.
 - Enter a database user and password. This user is already created by the installer.
 - In the **Create Database** panel:
 - Enter the name and password of a superuser account in your MySQL database server. The default superuser account is root.
 - The installer creates the database.
- If you use Oracle:
 - In the **Database Server Properties** panel:
 - Enter localhost as the **host name**.
 - Enter the name of the JDBC JAR file for Oracle.
 - In the **Database Server Additional Properties** panel:
 - Select **Simple Mode**.
 - Enter a password for the user APPCENTER. This user is created by the installer.
 - The installer creates a database if it does not exist.
 - In the **Create Database** panel:
 - For **Administrator Login Name and Passwords**, enter an administrator login name and password that can be used to run an ssh session. The default Oracle Administrator Login name is oracle.
 - If the database exists, provide the password of the SYSTEM user that is used to create the user APPCENTER. If the database does not exist, enter the passwords for the SYS and SYSTEM users that are created to manage the database.
- d. In the **Application Server Selection** panel, select **WebSphere Application Server**.
- e. In the **Application Server Configuration** panel, select the installation directory for IBM WebSphere Application Server Liberty Core that is installed in step 2.
- f. Select **simpleServer** as the server name.
- g. Install the product.

The files that are described in “Distribution structure of MobileFirst Server” on page 6-53 are installed on your computer.

Exploring Application Center

About this task

Application Center is now functional. The artifacts of the Application Center are deployed into the Liberty server, which now includes the features that Application Center requires, and a demonstration user account exists. The required database also exists.

Procedure

1. To test the Application Center, start the Liberty server.
 - On UNIX and Linux systems:
`bin/server start simpleServer`
 - On Windows systems:
`bin\server.bat start simpleServer`
2. Open the Application Center console by using the program shortcut that the installer creates: **IBM MobileFirst Platform Server > Application Center**.
Alternatively, you can enter the URL into a browser window. When a Liberty server is created with default settings, the default URL for Application Center is `http://localhost:9080/appcenterconsole/`.
3. Log in to the Application Center with the demonstration account credentials: `demo/demo` as both the user name and the password.
4. Explore further by using any of the following resources:
 - See “Configuring user authentication for Application Center” on page 6-270.
 - See “Distribution structure of MobileFirst Server” on page 6-53 for a list of MobileFirst applications that you can compile and upload to the Application Center. These applications provide access to the Application Center for mobile devices.
 - If you are considering a manual installation of Application Center, see “Manually installing Application Center” on page 6-243. In some cases, manual installations can make the diagnosis of issues more complex, and can make the description of a configuration to IBM Support more difficult.

Installing the MobileFirst Server administration components: Administration Services and MobileFirst Operations Console Procedure

1. Start the Server Configuration Tool.
 - On Linux, click the desktop menu **IBM MobileFirst Platform Server > Server Configuration Tool**.
 - On Windows, click **Start > IBM MobileFirst Platform Server > Server Configuration Tool**.
 - On Mac OS X, in the Finder, double-click the file `mf_server_install_dir/shortcuts/configuration-tool.sh`.
The `mf_server_install_dir` directory is where you installed MobileFirst Server. `mf_server` is the shortcut for MobileFirst Server.

Restriction: MobileFirst Server is not supported for production use on Mac OS X.

2. Select **Create a MobileFirst Server Configuration**.
3. Name the configuration My MobileFirst Server.
4. Do not change the default entries in the Configuration Description panel.
5. Do not change the default entries in the Console Settings panel, except to create a shortcut file.
6. To create the `mobilefirst-console.url` shortcut file, select the **Create MobileFirst Server shortcuts** checkbox in the Console Settings panel and select a destination directory.
7. In the Database Properties panel:
 - a. Select your database.

- b. Proceed as described in “Installing MobileFirst Server” on page 6-38 when you entered data to create the database for Application Center.

Note: If you selected Cloudant, you must provide credentials to access an existing valid Cloudant account.

8. In the Application Server panel:
 - a. Proceed as described in “Installing MobileFirst Server” on page 6-38 when you entered data to create the database for Application Center.
 - b. Take note of the default password and login: admin (for both).
9. In the Analytics settings panel, make sure that the check box to connect to MobileFirst Operational Analytics is not selected.
10. When all the data is entered, click **Deploy**.
 - The log of the deployment operations is displayed in the console.
 - An **Administration - Server deployment** folder appears in the tree view under **Log Files**.
 - After the database operation is completed, an admndatabases log file appears in the tree view.
 - After the deployment to the application server is complete, an admininstall log file appears in the tree view.

Creating a simple MobileFirst project.

You create a MobileFirst runtime environment.

Before you begin

Make sure that MobileFirst Studio is installed. “Installing MobileFirst Studio” on page 6-2

Procedure

1. Complete the following steps:
 - a. Start MobileFirst Studio.
 - b. Create a MobileFirst project by selecting **File > New > MobileFirst Project**.
 - c. Assign the name simpleProject, and accept the default project template **Hybrid Application**.
 - d. In the next panel, name the application simpleApp, and then click **Finish**.
2. Build the application.
 - a. In the Project Explorer view in MobileFirst Studio, open the project.
 - b. Open the **apps** folder, right-click the subfolder **simpleApp**, and then click **Run As > Run on MobileFirst Development Server**.
 - c. In the Project Explorer view, open the **bin** folder that was created by this task.
 - d. Right-click **simpleProject.war** and click **Properties**.

The properties show the path to the WAR file. This path is used in “Deploying a MobileFirst runtime environment with the Server Configuration Tool” on page 6-42. For example, if the path of the Eclipse workspace is C:\workspaces\WorklightStudioWorkspace, the path to the WAR file is C:\workspaces\WorklightStudioWorkspace\simpleProject\bin\simpleProject.war.

Deploying a MobileFirst runtime environment with the Server Configuration Tool Procedure

1. In the Server Configuration Tool, click **Add a MobileFirst runtime environment to a configuration** on the main panel or select **Runtime environments > File/Add MobileFirst runtime environment**.
Selecting **Runtime environments** makes **File/Add MobileFirst runtime environment** available for selection.
2. In the dialog box, select the **Hello MobileFirst Server** configuration that you created in “Installing the MobileFirst Server administration components: Administration Services and MobileFirst Operations Console” on page 6-40.
3. In **Enter the name of the new runtime**, enter `First Runtime`.
4. In the **MobileFirst runtime environment Configuration Description** panel, load the WAR file that you created in the previous part.
5. In the Database Properties panel, proceed as described in “Installing MobileFirst Server” on page 6-38 when you entered data to create the database for Application Center.
The database is selected because it is already defined in the configuration.
6. When all the data is entered, click **Deploy**.
 - The log of the deployment operations appears in the console.
 - The **Runtime** appears in the tree view.
 - After the database operation is completed, a databases log file appears in the tree view, under **Runtime**.
 - After the deployment to the application server is complete, an install log file appears in the tree view, under **Runtime**.

Restarting the Liberty server and opening the MobileFirst Operations Console Procedure

1. Go to the Liberty installation directory and type the following command:
 - On Linux and UNIX systems:
`bin/server stop simpleServer`
 - On Windows systems:
`bin\server.bat stop simpleServer`
2. Restart the server by running the following command:
 - On Linux and UNIX systems:
`bin/server start simpleServer`
 - On Windows systems:
`bin\server.bat start simpleServer`
3. In the shortcut directory that you specified in the **MobileFirst runtime environment Configuration Description** panel of the Server Configuration Tool, proceed as follows:
 - On Linux and UNIX systems, run the `mobilefirst-console.sh` script.
 - On Windows systems, double-click the `mobilefirst-console.url` file. On Windows 7, this shortcut can appear as `mobilefirst-console`, with a file type of Internet Shortcut.

You can see the MobileFirst Operations Console. You can log in with the default user login and password that you created in step “Installing the

MobileFirst Server administration components: Administration Services and MobileFirst Operations Console” on page 6-40 (by default admin/admin).

What to do next

For more information about the Server Configuration Tool, see “Deploying, updating, undeploying, or upgrading MobileFirst Server by using the Server Configuration Tool” on page 12-11.

If you want to use MobileFirst Operational Analytics, see “Installing the IBM MobileFirst Platform Operational Analytics” on page 6-216.

If you want to explore the MobileFirst Operations Console further, you can complete the following tasks:

- Deploy an application as described in “Deploying applications and adapters to MobileFirst Server” on page 12-87.
- Review “Administering MobileFirst applications” on page 13-1.
- Review “Deploying the project WAR file” on page 12-5.
- Review “Configuration of MobileFirst applications on the server” on page 12-50 and “Configuring a MobileFirst project in production by using JNDI environment entries” on page 12-66
- Review the options to deploy an IBM MobileFirst Platform Foundation project manually. See “Deploying a project WAR file and configuring the application server manually” on page 12-37.

Running IBM Installation Manager

IBM Installation Manager installs the IBM MobileFirst Platform Foundation files and tools on your computer.

IBM Installation Manager helps you install, update, modify, and uninstall packages on your computer. The installer for MobileFirst Server does not support rollback operations and updates from one version to another cannot be undone.

The way that you use IBM Installation Manager to upgrade from a previous release depends on your upgrade path.

You can use IBM Installation Manager to install IBM MobileFirst Platform Foundation in several different modes, including single-user and multi-user installation modes.

You can also use silent installations to deploy IBM MobileFirst Platform Foundation to multiple systems, or systems without a GUI interface.

For more information about Installation Manager, see the IBM Installation Manager user documentation.

Note: IBM Installation Manager is sometimes referred to as *IBM Rational Enterprise Deployment* on the eXtreme Leverage, Passport Advantage sites, and on the distribution disks. The file names for the images take the form *IBM Rational Enterprise Deployment <version number><hardware platform> <language>*; for example, *IBM Rational Enterprise Deployment V1.6.3.1Windows Multilingual*.

Installation of the Application Center with IBM Installation Manager

Run IBM Installation Manager. If you plan to install the Application Center with IBM Installation Manager, verify that the user who runs IBM Installation Manager has the privileges that are described in “File system prerequisites” on page 6-16, then see “Installing and configuring the Application Center” on page 6-235 and install the Application Center before you proceed to the installation of MobileFirst Operations Console. For more information, see “Installing the MobileFirst Server administration” on page 6-58.

If you plan to install the Application Center by running Ant tasks, or manually, answer **No** to the question **Install IBM Application Center**.

Single-user versus multi-user installations

You can install MobileFirst Server in two different IBM Installation Manager modes.

Administrator installation

It is an administrator installation when IBM Installation Manager is installed through the **install** command. In this case, it requires administrator privileges to run, and it produces multi-user installations of products.

When you have chosen an administrator installation of MobileFirst Server, it is advisable to run the application server from a non-administrator user account. Running it from an administrator or root user account is dangerous in terms of security risks.

Because of this, during an administrator installation of MobileFirst Server, you can choose an operating system user or an operating system user group. Each of the users in this group can:

- Run the specified application server (if WebSphere Application Server Liberty, or Apache Tomcat).
- Modify the Application Center Derby database (if Apache Derby is chosen as your database management system).

In this case, the MobileFirst Server installer sets restrictive access permissions on the Liberty or Tomcat configuration files, so as to:

1. Allow the specified users to run the application server.
2. At the same time, protect the database or user passwords that these files contain.

Nonadministrator (single-user) installation

It is a nonadministrator (single-user) installation when IBM Installation Manager is installed through the **userinst** command. In this case, only the user who installed this copy of IBM Installation Manager can use it.

The following constraints regarding user accounts on UNIX apply:

- If the application server is owned by a non-root user, you can install MobileFirst Server in either of two ways:
 - Through a nonadministrator (single-user) installation of IBM Installation Manager, as the same non-root user.
 - Through an administrator installation of IBM Installation Manager, as root, and afterward change the owner of all files and directories added or modified during the installation to that user. The result is a single-user installation.

- If the application server is owned by root, you can install MobileFirst Server only through an administrator installation of IBM Installation Manager; a single-user installation of IBM Installation Manager does not work, because it lacks the necessary privileges.

Note: MobileFirst Server does not support the group mode of IBM Installation Manager.

Installing a new version of MobileFirst Server

Create a fresh installation of IBM MobileFirst Platform Server by creating a new package group in IBM Installation Manager.

Procedure

1. Start IBM Installation Manager.
2. On the IBM Installation Manager main page, click **Install**.
3. In the panel that prompts for the package group name and the installation directory, select **Create a new package group**.
4. Complete the installation by following the instructions that are displayed.

Upgrading MobileFirst Server from a previous release

The way that you use IBM Installation Manager to upgrade to the latest version of MobileFirst Server depends on your upgrade path.

Before you begin

Before you apply these instructions, see “Upgrading to IBM MobileFirst Platform Foundation V7.1.0” on page 7-1. It describes important steps to upgrade MobileFirst applications, or to upgrade a production server in a production environment.

Procedure

1. Start the IBM Installation Manager.
2. Depending on your upgrade path, take one of the following actions:
 - To upgrade from Worklight Server to MobileFirst Server:
 - a. Click **Install**.
 - b. In the panel that prompts for the package group name and the installation directory, select **Use the existing package group**. In this situation, installation MobileFirst Server automatically removes a Worklight Server installation that was installed in the same directory.
 - To upgrade from MobileFirst Server to a more recent version, click **Update**.

Command-line installation with XML response files (silent installation)

With IBM Installation Manager, you can complete a command-line installation of MobileFirst Server with XML response files, on multiple computers, or on computers where a GUI interface is not available. In the following documentation, this installation is referred to as silent installation.

About this task

Silent installation uses predetermined answers to wizard questions, rather than presenting a GUI that asks the questions and records the answers. Silent installation is useful when:

- You want to install MobileFirst Server on a set of computers that are configured in the same way.
- You want to install MobileFirst Server on a computer where a GUI is not readily available. For example, a GUI might not be available on a production server behind a firewall that prevents the use of VNC, RDP, remote X11, and ssh -X.

Silent installations are defined by an XML file that is called a response file. This file contains the necessary data to complete installation operations silently. Silent installations are started from the command line or a batch file.

You can use IBM Installation Manager to record preferences and installation actions for your response file in user interface mode. Alternatively, you can create a response file manually by using the documented list of response file commands and preferences.

You can use one response file to install, update, or uninstall multiple products.

You can use a response file to do almost anything that is possible by using IBM Installation Manager in wizard mode. For example, with a response file you can specify the location of the repository that contains the package, the package to install, and the features to install for that package. You can also use a response file to apply updates or interim fixes or to uninstall a package.

Silent installation is described in the IBM Installation Manager user documentation, see *Working in silent mode*.

There are two ways to create a suitable response file:

- Working with sample response files provided in the MobileFirst user documentation.
- Working with a response file recorded on a different computer.

Both of these methods are documented in the following sections.

In addition, for a list of the parameters that are created in the response file by the IBM Installation Manager wizard, see “Command-line (silent installation) parameters” on page 6-49.

Working with sample response files for IBM Installation Manager:

Instructions for working with sample response files for IBM Installation Manager to facilitate creating a silent MobileFirst Server installation.

Procedure

Sample response files for IBM Installation Manager are provided in the `Silent_Install_Sample_Files.zip` compressed file. The following procedures describe how to use them.

1. Pick the appropriate sample response file from the compressed file. The `Silent_Install_Sample_Files.zip` file contains one subdirectory per release.

Important: For an installation that does not install Application Center on an application server, use the file named `install-no-appcenter.xml`. The installation of Application Center can be done later by using Ant tasks. For more information, see “Installing the Application Center with Ant tasks” on page 6-241.

For an installation that installs Application Center, pick the sample response file from the following table, depending on your application server and database.

Table 6-10. Sample installation response files in the *Silent_Install_Sample_Files.zip* file to install the Application Center

Application server where you install the Application Center	Derby	IBM DB2	MySQL	Oracle
WebSphere Application Server Liberty profile	install-liberty-derby.xml	install-liberty-db2.xml	install-liberty-mysql.xml (See Note)	install-liberty-oracle.xml
WebSphere Application Server full profile, stand-alone server	install-was-derby.xml	install-was-db2.xml	install-was-mysql.xml (See Note)	install-was-oracle.xml
WebSphere Application Server Network Deployment	n/a	install-wasnd-cluster-db2.xml install-wasnd-server-db2.xml install-wasnd-node-db2.xml install-wasnd-cell-db2.xml	install-wasnd-cluster-mysql.xml (See Note) install-wasnd-server-mysql.xml (See Note) install-wasnd-node-mysql.xml install-wasnd-cell-mysql.xml (See Note)	install-wasnd-cluster-oracle.xml install-wasnd-server-oracle.xml install-wasnd-node-oracle.xml install-wasnd-cell-oracle.xml
Apache Tomcat	install-tomcat-derby.xml	install-tomcat-db2.xml	install-tomcat-mysql.xml	install-tomcat-oracle.xml

Note: MySQL in combination with WebSphere Application Server Liberty profile or WebSphere Application Server full profile is not classified as a supported configuration. For more information, see WebSphere Application Server Support Statement. You can use IBM DB2 or another DBMS that is supported by WebSphere Application Server to benefit from a configuration that is fully supported by IBM Support.

For uninstallation, use a sample file that depends on the version of MobileFirst Server or Worklight Server that you initially installed in the particular package group:

- MobileFirst Server uses the package group **IBM MobileFirst Platform Server**.
- Worklight Server V6.x, or later, uses the package group **IBM Worklight**.
- Worklight Server V5.x uses the package group **Worklight**.

Table 6-11. Sample uninstallation response files in the *Silent_Install_Sample_Files.zip*

Initial version of MobileFirst Server	Sample file
Worklight Server V5.x	uninstall-initially-worklightv5.xml
Worklight Server V6.x	uninstall-initially-worklightv6.xml
IBM MobileFirst Platform Server V6.x or later	uninstall-initially-mfpserver.xml

- Change the file access rights of the sample file to be as restrictive as possible. Step 4 requires that you supply some passwords. If you must prevent other users on the same computer from learning these passwords, you must remove the read permissions of the file for users other than yourself. You can use a command, such as the following examples:

- On UNIX:

```
chmod 600 <target-file.xml>
```
- On Windows:

```
cacls <target-file.xml> /P Administrators:F %USERDOMAIN%\%USERNAME%:F
```

- Similarly, if the server is a WebSphere Application Server Liberty profile or Apache Tomcat server, and the server is meant to be started only from your user account, you must also remove the read permissions for users other than yourself from the following file:

- For WebSphere Application Server Liberty profile: `wlp/usr/servers/<server>/server.xml`
- For Apache Tomcat: `conf/server.xml`

- Adjust the list of repositories, in the `<server>` element. For more information about this step, see section named *Information about the repositories* in “Become familiar with IBM Installation Manager before you start” on page 7-39 and the IBM Installation Manager documentation at [Repositories](#).

In the `<profile>` element, adjust the values of each key/value pair.

In the `<offering>` element in the `<install>` element, set the version attribute to match the release you want to install, or remove the version attribute if you want to install the newest version available in the repositories.

- Type the following command:

```
<InstallationManagerPath>/eclipse/tools/imcl input <responseFile> -log /tmp/installwl.log -accept
```

Where:

- `<InstallationManagerPath>` is the installation directory of IBM Installation Manager.
- `<responseFile>` is the name of the file that is selected and updated in step 1.

For more information, see the IBM Installation Manager documentation at [Installing a package silently by using a response file](#).

Working with a response file recorded on a different machine:

Instructions for working with response files for IBM Installation Manager created on another machine to facilitate creating a silent MobileFirst Server installation.

Procedure

- Record a response file, by running IBM Installation Manager in wizard mode and with option `-record responseFile` on a machine where a GUI is available. For more details, see [Record a response file with Installation Manager](#).

2. Change the file access rights of the response file to be as restrictive as possible. Step 4 requires that you supply some passwords. If you must prevent other users on the same computer from learning these passwords, you must remove the read permissions of the file for users other than yourself. You can use a command, such as the following examples:
 - On UNIX:

```
chmod 600 response-file.xml
```
 - On Windows:

```
cacls response-file.xml /P Administrators:F %USERDOMAIN%\%USERNAME%:F
```
3. Similarly, if the server is a WebSphere Application Server Liberty or Apache Tomcat server, and the server is meant to be started only from your user account, you must also remove the read permissions for users other than yourself from the following file:
 - For WebSphere Application Server Liberty: `wlp/usr/servers/<server>/server.xml`
 - For Apache Tomcat: `conf/server.xml`
4. Modify the response file to take into account differences between the machine on which the response file was created and the target machine.
5. Install MobileFirst Server by using the response file on the target machine, as described in Install a package silently by using a response file.

Command-line (silent installation) parameters:

The response file that you create for silent installations by running the IBM Installation Manager wizard supports a number of parameters.

Table 6-12. Parameters available for silent installation.

Key	When necessary	Description	Allowed values
<code>user.licensed.by.tokens</code>	Always	<p>Activation of token licensing</p> <p>If you plan to use the product with the Rational License Key Server, you must activate token licensing. In this case, set value = "true".</p> <p>If you do not plan to use the product with Rational License Key Server, set value = "false".</p> <p>If you activate license tokens, specific configuration steps are required after you deploy the product to an application server. For more information, see "Installing and configuring for token licensing" on page 6-126.</p>	true or false

Table 6-12. Parameters available for silent installation (continued).

Key	When necessary	Description	Allowed values
<code>user.appserver.selection2</code>	Always	Type of application server. <code>was</code> means preinstalled WebSphere Application Server 7.0, 8.0, or 8.5. <code>tomcat</code> means Tomcat 7.0 or later.	<code>was</code> , <code>tomcat</code> , <code>none</code> The value <code>none</code> means that the installer will not install the Application Center. If this value is used, both <code>user.appserver.selection2</code> and <code>user.database.selection2</code> must take the value <code>none</code> .
<code>user.appserver.was.installdir</code>	<code>\${user.appserver.selection2} == was</code>	WebSphere Application Server installation directory.	An absolute directory name.
<code>user.appserver.was.profile</code>	<code>\${user.appserver.selection2} == was</code>	Profile into which to install the applications. For WebSphere Application Server Network Deployment, specify the Deployment Manager profile. Liberty means the Liberty profile (subdirectory <code>wlp</code>).	The name of one of the WebSphere Application Server profiles.
<code>user.appserver.was.cell</code>	<code>\${user.appserver.selection2} == was && \${user.appserver.was.profile} != Liberty</code>	WebSphere Application Server cell into which to install the applications.	The name of the WebSphere Application Server cell.
<code>user.appserver.was.node</code>	<code>\${user.appserver.selection2} == was && \${user.appserver.was.profile} != Liberty</code>	WebSphere Application Server node into which to install the applications. This corresponds to the current machine.	The name of the WebSphere Application Server node of the current machine.
<code>user.appserver.was.scope</code>	<code>\${user.appserver.selection2} == was && \${user.appserver.was.profile} != Liberty</code>	Type of set of servers into which to install the applications. <code>server</code> means a standalone server. <code>nd-cell</code> means a WebSphere Application Server Network Deployment cell. <code>nd-cluster</code> means a WebSphere Application Server Network Deployment cluster. <code>nd-node</code> means a WebSphere Application Server Network Deployment node (excluding clusters). <code>nd-server</code> means a managed WebSphere Application Server Network Deployment server.	<code>server</code> , <code>nd-cell</code> , <code>nd-cluster</code> , <code>nd-node</code> , <code>nd-server</code>
<code>user.appserver.was.serverInstance</code>	<code>\${user.appserver.selection2} == was && \${user.appserver.was.profile} != Liberty && \${user.appserver.was.scope} == server</code>	Name of WebSphere Application Server server into which to install the applications.	The name of a WebSphere Application Server server on the current machine.
<code>user.appserver.was.nd.cluster</code>	<code>\${user.appserver.selection2} == was && \${user.appserver.was.profile} != Liberty && \${user.appserver.was.scope} == nd-cluster</code>	Name of WebSphere Application Server Network Deployment cluster into which to install the applications.	The name of a WebSphere Application Server Network Deployment cluster in the WebSphere Application Server cell.

Table 6-12. Parameters available for silent installation (continued).

Key	When necessary	Description	Allowed values
<code>user.appserver.was.nd.node</code>	<code>\${user.appserver.selection2} == was && \${user.appserver.was.profile} != Liberty && (\${user.appserver.was.scope} == nd-node \${user.appserver.was.scope} == nd-server)</code>	Name of WebSphere Application Server Network Deployment node into which to install the applications.	The name of a WebSphere Application Server Network Deployment node in the WebSphere Application Server cell.
<code>user.appserver.was.nd.server</code>	<code>\${user.appserver.selection2} == was && \${user.appserver.was.profile} != Liberty && \${user.appserver.was.scope} == nd-server</code>	Name of WebSphere Application Server Network Deployment server into which to install the applications.	The name of a WebSphere Application Server Network Deployment server in the given WebSphere Application Server Network Deployment node.
<code>user.appserver.was.admin.name</code>	<code>\${user.appserver.selection2} == was && \${user.appserver.was.profile} != Liberty</code>	Name of WebSphere Application Server administrator.	
<code>user.appserver.was.admin.password2</code>	<code>\${user.appserver.selection2} == was && \${user.appserver.was.profile} != Liberty</code>	Password of WebSphere Application Server administrator, optionally encrypted in a specific way.	
<code>user.appserver.was.appcenteradmin.password</code>	<code>\${user.appserver.selection2} == was && \${user.appserver.was.profile} != Liberty</code>	Password of appcenteradmin user to add to the WebSphere Application Server users list, optionally encrypted in a specific way.	
<code>user.appserver.was.serial</code>	<code>\${user.appserver.selection2} == was && \${user.appserver.was.profile} != Liberty</code>	Suffix that distinguishes the applications to be installed from other installations of MobileFirst Server.	String of 10 decimal digits.
<code>user.appserver.was85liberty.serverInstance_</code>	<code>\${user.appserver.selection2} == was && \${user.appserver.was.profile} == Liberty</code>	Name of WebSphere Application Server Liberty server into which to install the applications.	
<code>user.appserver.tomcat.installDir</code>	<code>\${user.appserver.selection2} == tomcat</code>	Apache Tomcat installation directory. For a Tomcat installation that is split between a CATALINA_HOME directory and a CATALINA_BASE directory, here you need to specify the value of the CATALINA_BASE environment variable.	An absolute directory name.
<code>user.database.selection2</code>	Always	Type of database management system used to store the databases.	derby, db2, mysql, oracle, none The value none means that the installer will not install the Application Center. If this value is used, both <code>user.appserver.selection2</code> and <code>user.database.selection2</code> must take the value none.

Table 6-12. Parameters available for silent installation (continued).

Key	When necessary	Description	Allowed values
<code>user.database.preinstalled</code>	Always	true means a preinstalled database management system, false means Apache Derby to install.	true, false
<code>user.database.derby.datadir</code>	<code>\${user.database.selection2} == derby</code>	The directory in which to create or assume the Derby databases.	An absolute directory name.
<code>user.database.db2.host</code>	<code>\${user.database.selection2} == db2</code>	The host name or IP address of the DB2 database server.	
<code>user.database.db2.port</code>	<code>\${user.database.selection2} == db2</code>	The port where the DB2 database server listens for JDBC connections. Usually 50000.	A number between 1 and 65535.
<code>user.database.db2.driver</code>	<code>\${user.database.selection2} == db2</code>	The absolute file name of <code>db2jcc.jar</code> or <code>db2jcc4.jar</code> .	An absolute file name.
<code>user.database.db2.appcenter.username</code>	<code>\${user.database.selection2} == db2</code>	The user name used to access the DB2 database for Application Center.	Non-empty.
<code>user.database.db2.appcenter.password</code>	<code>\${user.database.selection2} == db2</code>	The password used to access the DB2 database for Application Center, optionally encrypted in a specific way.	Non-empty password.
<code>user.database.db2.appcenter.dbname</code>	<code>\${user.database.selection2} == db2</code>	The name of the DB2 database for Application Center.	Non-empty; a valid DB2 database name.
<code>user.database.oracle.appcenter.isservername.jdbc.url</code>	Optional	Indicates if <code>user.database.mysql.appcenter.dbname</code> is a Service name or a SID name. If the parameter is absent then <code>user.database.mysql.appcenter.dbname</code> is considered to be a SID name.	true (indicates a Service name) or false (indicates a SID name)
<code>user.database.db2.appcenter.schema</code>	<code>\${user.database.selection2} == db2</code>	The name of the schema for Application Center in the DB2 database.	
<code>user.database.mysql.host</code>	<code>\${user.database.selection2} == mysql</code>	The host name or IP address of the MySQL database server.	
<code>user.database.mysql.port</code>	<code>\${user.database.selection2} == mysql</code>	The port where the MySQL database server listens for JDBC connections. Usually 3306.	A number between 1 and 65535.
<code>user.database.mysql.driver</code>	<code>\${user.database.selection2} == mysql</code>	The absolute file name of <code>mysql-connector-java-5.*-bin.jar</code> .	An absolute file name.
<code>user.database.mysql.appcenter.username</code>	<code>\${user.database.selection2} == mysql</code>	The user name used to access the MySQL database for Application Center.	Non-empty.
<code>user.database.mysql.appcenter.password</code>	<code>\${user.database.selection2} == mysql</code>	The password used to access the MySQL database for Application Center, optionally encrypted in a specific way.	

Table 6-12. Parameters available for silent installation (continued).

Key	When necessary	Description	Allowed values
<code>user.database.mysql.appcenter.dbname</code>	<code>\${user.database.selection2} == mysql</code>	The name of the MySQL database for Application Center.	Non-empty, a valid MySQL database name.
<code>user.database.oracle.host</code>	<code>\${user.database.selection2} == oracle</code> , unless <code>\${user.database.oracle.appcenter.jdbc.url}</code> is specified	The host name or IP address of the Oracle database server.	
<code>user.database.oracle.port</code>	<code>\${user.database.selection2} == oracle</code> , unless <code>\${user.database.oracle.appcenter.jdbc.url}</code> is specified	The port where the Oracle database server listens for JDBC connections. Usually 1521.	A number between 1 and 65535.
<code>user.database.oracle.driver</code>	<code>\${user.database.selection2} == oracle</code>	The absolute file name of <code>ojdbc6.jar</code> .	An absolute file name.
<code>user.database.oracle.appcenter.username</code>	<code>\${user.database.selection2} == oracle</code>	The user name used to access the Oracle database for Application Center.	A string consisting of 1 to 30 characters: ASCII digits, ASCII uppercase and lowercase letters, '_', '#', '\$' are allowed.
<code>user.database.oracle.appcenter.username.jdbc</code>	<code>\${user.database.selection2} == oracle</code>	The user name used to access the Oracle database for Application Center, in a syntax suitable for JDBC.	Same as <code>\${user.database.oracle.appcenter.username}</code> if it starts with an alphabetic character and does not contain lowercase characters, otherwise it must be <code>\${user.database.oracle.appcenter.username}</code> surrounded by double quotes.
<code>user.database.oracle.appcenter.password</code>	<code>\${user.database.selection2} == oracle</code>	The password used to access the Oracle database for Application Center, optionally encrypted in a specific way.	The password must be a string consisting of 1 to 30 characters: ASCII digits, ASCII uppercase and lowercase letters, '_', '#', '\$' are allowed.
<code>user.database.oracle.appcenter.dbname</code>	<code>\${user.database.selection2} == oracle</code> , unless <code>\${user.database.oracle.appcenter.jdbc.url}</code> is specified	The name of the Oracle database for Application Center.	Non-empty, a valid Oracle database name.
<code>user.database.oracle.appcenter.is servicename.jdbc.url</code>	Optional	Indicates if <code>user.database.oracle.appcenter.dbname</code> is a Service name or a SID name. If the parameter is absent then <code>user.database.oracle.appcenter.dbname</code> is considered to be a SID name.	true (indicates a Service name) or false (indicates a SID name)
<code>user.database.oracle.appcenter.jdbc.url</code>	<code>\${user.database.selection2} == oracle</code> , unless <code>\${user.database.oracle.host}</code> , <code>\${user.database.oracle.port}</code> , <code>\${user.database.oracle.appcenter.dbname}</code> are all specified	The JDBC URL of the Oracle database for Application Center.	A valid Oracle JDBC URL. Starts with "jdbc:oracle:".
<code>user.writable.data.user</code>	Always	The operating system user that is allowed to run the installed server.	An operating system user name, or empty.
<code>user.writable.data.group2</code>	Always	The operating system users group that is allowed to run the installed server.	An operating system users group name, or empty.

Distribution structure of MobileFirst Server

The MobileFirst Server files and tools are installed in the MobileFirst Server installation directory.

Table 6-13. Files and subdirectories in the MobileFirst Server installation directory

Item	Description
shortcuts	Launcher scripts for Apache Ant, the MobileFirst Server Server Configuration Tool, and the wladm command, which are supplied with MobileFirst Server.

Table 6-14. Files and subdirectories in the WorklightServer subdirectory

Item	Description
worklight-jee-library.jar	The MobileFirst Server library for production. For instructions on deploying a MobileFirst project and this library to an Application Server, see “Deploying MobileFirst projects” on page 12-1. The deployment is typically performed by using Ant tasks, but instructions for manual deployment are also provided.
worklight-ant-deployer.jar	A set of Ant tasks that help you deploy projects, applications, and adapters to your MobileFirst Server. For documentation about the Ant tasks that are provided in this library, see “Deploying MobileFirst projects” on page 12-1.
worklight-ant-builder.jar	A set of Ant tasks that help you build projects, applications, and adapters for use in MobileFirst Server. For more information about the Ant tasks that are provided in this library, see Ant tasks for building and deploying applications and adapters.
configuration-samples	Contains the sample Ant files for configuring a database for the MobileFirst Server and deploying a MobileFirst project to an application server. For instructions on how to use these Ant projects, see “Sample configuration files” on page 16-77.
databases	SQL scripts to be used for the manual creation of tables for MobileFirst Server and the Administration Services, instead of using Ant tasks for the automatic configuration of these tables. For information about these scripts, see “Creating and configuring the databases manually” on page 12-20.
encrypt.bat and encrypt.sh	Tools to encrypt confidential properties that are used to configure a MobileFirst Server, such as a database password or a certificate. For information about this tool, see “Storing properties in encrypted format” on page 12-62.
report-templates	Report templates to configure BIRT reports for your Application Server. For information about these BIRT reports, see “Manually configuring BIRT Reports for your application server” on page 14-118.
wladm-schemas	XML schemas that describe the format of input and output of the <wladm> Ant task.
worklightadmin.war	The WAR file for the Administration Services web application.
worklightconsole.war	The WAR file for the MobileFirst Operations Console user interface web application.

Table 6-14. Files and subdirectories in the *WorklightServer* subdirectory (continued)

Item	Description
external-server-libraries	<p>JAR file and manifest file of the OAuth Trust Association Interceptor (TAI) that is used to protect application resources on WebSphere Application Server or WebSphere Application Server Liberty. For more information, see “Protecting resources on WebSphere Application Server or WebSphere Application Server Liberty” on page 8-537.</p> <p>JAR file of the eXtreme Scale plug-in that is used in attribute store over IBM WebSphere eXtreme Scale. For more information, see “Attribute store over IBM WebSphere eXtreme Scale” on page 8-327.</p>
tokensLibs	<p>This directory contains the native libraries for the Rational License Key Server client. It is installed if you activated token licensing from the installation wizard, or with the parameter user.licensed.by.tokens for silent installations. For more information about how to install these libraries in your application server, see “Installing and configuring for token licensing” on page 6-126.</p>

Table 6-15. Files and subdirectories in the *ApplicationCenter* subdirectory

Item	Description
configuration-samples	<p>Contains the sample Ant files for configuring a database for the Application Center. Also, for deploying both the Application Center console user interface and the Application Center REST services web applications to an application server.</p>
ApplicationCenter/installer	<p>IBMApplicationCenter.apk The Android version of the Application Center Mobile client.</p> <p>IBMApplicationCenterBB6.zip The BlackBerry version of the Application Center Mobile client.</p> <p>IBMApplicationCenterUnsigned.xap The Windows Phone 8 version of the Application Center Mobile client. You must sign the .xap file with your company account before you use it.</p>
ApplicationCenter/installer/IBMAppCenterBlackBerry6	<p>Contains the BlackBerry project for the mobile Client for OS V6 and V7. You must compile this project to create the BlackBerry version of the mobile client.</p>
ApplicationCenter/installer/IBMAppCenter	<p>Contains the MobileFirst project for the mobile Client. You must build this project to create the iOS version of the mobile client.</p>

Table 6-15. Files and subdirectories in the ApplicationCenter subdirectory (continued)

Item	Description
ApplicationCenter/console/	<p>appcenterconsole.war The WAR file for the Application Center console user interface web application.</p> <p>applicationcenter.war The WAR file for the Application Center REST services web application.</p> <p>applicationcenter.ear The enterprise application archive (EAR) file to be deployed under IBM PureApplication System.</p>
ApplicationCenter/databases	<p>create-appcenter-derby.sql The SQL script to re-create the application center database on derby.</p> <p>create-appcenter-db2.sql The SQL script to re-create the application center database on DB2.</p> <p>create-appcenter-mysql.sql The SQL script to re-create the application center database on mySQL.</p> <p>create-appcenter-oracle.sql The SQL script to re-create the application center database on Oracle.</p> <p>In addition, this directory contains the SQL scripts to upgrade the database from earlier versions of IBM MobileFirst Platform Foundation.</p>

Table 6-15. Files and subdirectories in the ApplicationCenter subdirectory (continued)

Item	Description
ApplicationCenter/tools	<p>android-sdk The directory that contains the part of the Android SDK required by the Application Center console.</p> <p>applicationcenterdeploytool.jar The JAR file that contains the Ant task to deploy an application to the Application Center.</p> <p>acdeploytool.bat The startup script of the deployment tool for use on Microsoft Windows systems.</p> <p>acdeploytool.sh The startup script of the deployment tool for use on UNIX systems.</p> <p>build.xml Example of an Ant script to deploy applications to the Application Center.</p> <p>dbconvertertool.sh The startup script of the database converter tool for use on UNIX systems.</p> <p>dbconvertertool.bat The startup script of the database converter tool for use on Microsoft Windows systems.</p> <p>dbconvertertool.jar The main library of the database converter tool.</p> <p>lib The directory that contains all Java Archive (JAR) files that are required by the database converter tool.</p> <p>json4j.jar The required JSON4J Java archive file.</p> <p>README.TXT Readme file that explains how to use the deployment tool.</p>

Table 6-16. Files and subdirectories in the License subdirectory

Item	Description
Text	License for IBM MobileFirst Platform Foundation

Table 6-17. Files and subdirectories in the *tools* subdirectory

Item	Description
tools/apache-ant-<version>	A binary installation of Apache Ant that can be used to run the Ant tasks. For more information, see “Deploying MobileFirst projects” on page 12-1.

Table 6-18. Files and subdirectories in the *Analytics* subdirectory

Item	Description
analytics.ear	The IBM MobileFirst Platform Operational Analytics EAR file. Contains the analytics-service.war file for deployment on WebSphere Application Server and WebSphere Application Server Liberty. For installation instructions, see “Installing the IBM MobileFirst Platform Operational Analytics” on page 6-216.
analytics-ui.war	The WAR file for the analytics console user interface web application.
analytics-service.war	The WAR file for the analytics REST services web application.
configuration-samples	Contains the sample Ant files for deploying both the analytics console user interface and the analytics REST services web applications to an application server. For more information about how to use these Ant projects, see Sample configuration files for MobileFirst Operational Analytics.

Table 6-19. Files and subdirectories in the *Datastore* subdirectory.

Item	Description
imf-data-proxy.war	The WAR file for the MobileFirst Data Proxy.
configuration-samples	Contains the sample Ant files for deploying a MobileFirst Data Proxy to an application server. For more information about how to use these Ant projects, see “Installing the MobileFirst Data Proxy with Ant tasks” on page 6-226.

Installing the MobileFirst Server administration

You must install the Administration Services, and optionally the MobileFirst Operations Console, as part of the MobileFirst Server installation.

Optional creation of the administration database

If you want to activate the option to install the administration relational database when you run the Ant tasks or the Server Configuration Tool, you must have certain database access rights that entitle you to create the databases, or the users, or both, that are required by the MobileFirst Server administration.

If you have sufficient administration credentials on the relational databases, and if you enter the administrator user name and password when prompted, or use Ant files with dba tags, the installation tools can create the databases for you.

Otherwise, you need to ask your database administrator to create the required database for you. In this case, the database must be created before you start the installation tools.

If you want to use a Cloudant database for the MobileFirst administration, ensure that you have access to a valid Cloudant account, and that a user with basic authentication credentials is defined to create the databases. Unlike relational databases, the Cloudant databases are not created during the installation process, but when the MobileFirst administration is started after it was deployed on the application server. Both the Cloudant account URL and user credentials that are mentioned above are used to create the databases.

The following topics describe the procedure for the supported database management systems.

Important: This step is optional if you install IBM MobileFirst Platform Foundation with the Server Configuration Tool or the Ant tasks because the Server Configuration Tool and the Ant tasks can create the databases automatically.

Creating the DB2 database for MobileFirst Server administration:

During the installation of IBM MobileFirst Platform Foundation, the installation tools can create the administration database for you.

Before you begin

You perform this procedure to create the databases before you run Ant tasks or the Server Configuration Tool to populate them. For a fully manual database installation, see “Configuring the DB2 database manually for the IBM MobileFirst Platform Server administration” on page 6-76 instead.

About this task

The installation tools can create the administration database for you if you enter the name and password of a user account on the database server that has the DB2 SYSADM or SYSCTRL privilege, and the account can be accessed through SSH. Otherwise, the database administrator can create the administration database for you. For more information, see the DB2 Solution user documentation.

When you create the database manually, you can replace the database name (here WLADMIN) and the password with a database name and password of your choice.

Important: You can name your database and user differently, or set a different password, but ensure that you enter the appropriate database name, user name, and password correctly across the DB2 database setup. DB2 limits:

- Database names: no more than 8 characters on all platforms
- User name and passwords: no more than 8 characters for UNIX and Linux, and no more than 30 characters for Windows

Procedure

1. Create a system user named, for example, `wluser` in a DB2 admin group such as `DB2USERS`, by using the appropriate commands for your operating system. Give it a password, for example, `wluser`.
If you want multiple MobileFirst Server instances to connect to the same database, use a different user name for each connection. Each database user has a separate default schema. For more information about database users, see the DB2 documentation and the documentation for your operating system.
2. Open a DB2 command-line processor, with a user that has `SYSADM` or `SYSCTRL` permissions.
 - On Windows systems, click **Start > IBM DB2 > Command Line Processor**.
 - On Linux or UNIX systems, navigate to `~/sqllib/bin` and enter `./db2`.
3. To create the administration database, enter database manager and SQL statements similar to the following example.

Replace the user name `wluser` with your own.

```
CREATE DATABASE WLADMIN COLLATE USING SYSTEM PAGESIZE 32768
CONNECT TO WLADMIN
GRANT CONNECT ON DATABASE TO USER wluser
DISCONNECT WLADMIN
QUIT
```

What to do next

The installation tools can create the database tables and objects for MobileFirst Server administration in a specific schema. You can then use the same database for MobileFirst Server administration and for a MobileFirst project.

- If the `IMPLICIT_SCHEMA` authority is granted to the user that you created in Step 1, no further action is required. This is the default in the database creation script of Step 2.
- If the user does not have the `IMPLICIT_SCHEMA` authority, create a `SCHEMA` for the administration database tables and objects.

Creating the MySQL database for MobileFirst Server administration:

During the MobileFirst installation, the installation tools can create the administration database for you.

Before you begin

You perform this procedure to create the databases before you run Ant tasks or the Server Configuration Tool to populate them. For a fully manual database installation, see “Configuring the MySQL database manually for the IBM MobileFirst Platform Server administration” on page 6-84 instead.

About this task

The installation tools can create the database for you if you enter the name and password of the superuser account. For more information, see *Securing the Initial MySQL Accounts on your MySQL database server*. Your database administrator can also create the databases for you. When you create the database manually, you can replace the database name (here `WLADMIN`) and password with a database name and password of your choice.

Attention: On UNIX, MySQL database names are case-sensitive.

Procedure

1. Start the MySQL command-line tool.
2. Enter the following commands:

```
CREATE DATABASE WLADMIN CHARACTER SET utf8 COLLATE utf8_general_ci;  
GRANT ALL PRIVILEGES ON WLADMIN.* TO 'worklight'@'Worklight-host' IDENTIFIED BY 'password';  
GRANT ALL PRIVILEGES ON WLADMIN.* TO 'worklight'@'localhost' IDENTIFIED BY 'password';  
FLUSH PRIVILEGES;
```

Here, you need to replace *Worklight-host* with the name of the host on which IBM MobileFirst Platform Foundation runs.

Creating the Oracle database for MobileFirst Server administration:

During the installation of IBM MobileFirst Platform Foundation, the installation tools can create the administration database, except for the Oracle 12c database type, or the user and schema inside an existing database.

Before you begin

You perform this procedure to create the databases before you run Ant tasks or the Server Configuration Tool to populate them. For a fully manual database installation, see “Configuring the Oracle database manually for the IBM MobileFirst Platform Server administration” on page 6-87 instead.

About this task

The installation tools can create the database, except for the Oracle 12c database, or the user and schema inside an existing database, if you enter the name and password of the Oracle administrator on the database server, and the account can be accessed through SSH. Otherwise, the database administrator can create the database or user and schema for you. When you manually create the database or user, you can use database names, user names, and a password of your choice.

Attention: Lowercase characters in Oracle user names can lead to unwanted results.

Procedure

1. If you do not already have a database named ORCL, use the Oracle Database Configuration Assistant (DBCA) and follow the steps in the wizard to create a new general-purpose database named ORCL:
 - a. Use global database name *ORCL_your_domain*, and system identifier (SID) ORCL.
 - b. On the **Custom Scripts** tab of the step **Database Content**, do not run the SQL scripts because you must first create a user account.
 - c. On the **Character Sets** tab of the step **Initialization Parameters**, select **Use Unicode (AL32UTF8) character set and UTF8 - Unicode 3.0 UTF-8 national character set**.
 - d. Complete the procedure, accepting the default values.
2. Create a database user by using either Oracle Database Control or the Oracle SQLPlus command-line interpreter.
 - Using Oracle Database Control.
 - a. Connect as SYSDBA.
 - b. Go to the **Users** page and click **Server**, then **Users** in the **Security** section.

- c. Create a user, for example WLADMIN. If you want multiple MobileFirst Server instances to connect to the general-purpose database that you created in Step 1, use a different user name for each connection. Each database user has a separate default schema.
- d. Assign the following attributes:
 - Profile: **DEFAULT**
 - Authentication: **password**
 - Default tablespace: **USERS**
 - Temporary tablespace: **TEMP**
 - Status: **Unlocked**
 - Add system privilege: **CREATE SESSION**
 - Add system privilege: **CREATE SEQUENCE**
 - Add system privilege: **CREATE TABLE**
 - Add quota: **Unlimited for tablespace USERS**
- Using the Oracle SQLPlus command-line interpreter.

The commands in the following example create a user named WLADMIN for the database:

```
CONNECT SYSTEM/<SYSTEM_password>@ORCL
CREATE USER WLADMIN IDENTIFIED BY WLADMIN_password DEFAULT TABLESPACE USERS QUOTA UNLIMITED ON
GRANT CREATE SESSION, CREATE SEQUENCE, CREATE TABLE TO WLADMIN;
DISCONNECT;
```

Creating the Cloudant database for MobileFirst Server administration:

Learn how to create Cloudant databases.

General information

To use a Cloudant database, you either need an account at cloudant.com that uses the Cloudant database in the Cloud, or you must install IBM MobileFirst Platform Cloudant Data Layer Local Edition on your own hardware, as described in the Cloudant Data Layer Local Edition user documentation. Whether you use cloudant.com or Cloudant Local, the Cloudant database is accessible via http or https, and you must have the URL to access it, as well as a user name and password.

Cloudant account

To create or access a Cloudant database at cloudant.com for the MobileFirst Server administration, you must already have registered a valid account for cloudant.com. The account registration provides you with the following information:

- The account name: The Cloudant account name is displayed in the URL. For example, the account *exampleaccount* corresponds to the URL <https://exampleaccount.cloudant.com>.

Important: You must always use the https protocol, and not the http protocol, when accessing <https://exampleaccount.cloudant.com>. Otherwise, your credentials are compromised.

- A user name: By default, the account name serves also as the administrator user name of the databases that are created in your account. Access is granted per database. By default, all databases that you create are only accessible to your

account. If you are using a shared database that is accessible to multiple users, you need a user name that has sufficient permissions to write and read documents of the database.

- A password to access the account at `cloudant.com`.

For more information about creating an account at `cloudant.com`, see the sign up page for IBM Cloudant.

IBM MobileFirst Platform Cloudant Data Layer Local Edition

If you use a Cloudant Local installation instead of `cloudant.com`, you must configure the following information:

- The URL to access your Cloudant Local installation.
- A user name to access your Cloudant Local installation, which has sufficient permissions to write and read documents in the database.
- A password for this user in your Cloudant Local installation.

For more information about creating and administering users for Cloudant Local, see *Configuring database-level security*.

Permissions

The default permissions for a new account at `cloudant.com`, or at Cloudant Local, are sufficient for the MobileFirst Server administration.

The database can be created through the Cloudant dashboard. The user must have at least the following roles set for your database:

- `_reader`: Gives the user permission to read documents from the database.
- `_writer`: Gives the user permission to create and modify documents in the database.
- `_admin`: Gives the user permission to install and update design documents in the database.

This permission is needed at least the first time for the application server to access the database after its creation. It is also needed the first time for the application server to access the database after a MobileFirst Server upgrade.

Unlike relational databases, there is no concept of tables in Cloudant, so there is no need to create any tables ahead of time or to set any permissions on tables.

If the database is not already created, it is automatically created when the MobileFirst Server administration is started on the application server. In this case, the user name must be set to the administrator user name of the Cloudant account, because only the administrator has permission to create new databases.

Default database name for MobileFirst Server administration

The default name of the administration database is `mfp_admin_db`. The database name can be changed through the JNDI property `mfp.db.cloudant.adminDbName`.

Configuration of the application server

IBM MobileFirst Platform Foundation has some requirements for the configuration of the application server that are detailed in the following topics.

Configuring WebSphere Application Server Liberty profile:

You must configure a secure JMX connection for WebSphere Application Server Liberty profile.

Procedure

MobileFirst Server requires the secure JMX connection to be configured.

- The Server Configuration Tool and the Ant tasks can configure a default secure JMX connection, which includes the generation of a self-signed SSL certificate with a validity period of 365 days. This configuration is not intended for production use.
- To configure the secure JMX connection for production use, follow the instructions from the page [Configuring secure JMX connection to the Liberty profile](#).
- The rest-connector is available for WebSphere Application Server, Liberty Core, and other editions of Liberty, but it is possible to package a Liberty Server with a subset of the available features. To verify that the rest-connector feature is available in your installation of Liberty, enter the following command:

```
<libertyInstallDir>/bin/productInfo featureInfo
```

Note: Verify that the output of this command contains `restConnector-1.0`.

- If you are going to use a Cloudant database for the administration or for a deployed project WAR file, configure the application server as described in [“Configuring WebSphere Application Server Liberty profile for use with Cloudant.”](#)

What to do next

For more information about the optimization of MobileFirst Server, especially the tuning of the JVM memory allocation, see [“Optimization and tuning of MobileFirst Server”](#) on page 6-150.

Configuring WebSphere Application Server Liberty profile for use with Cloudant:

You must ensure that the truststore declared for the Liberty server through JVM properties recognizes the SSL certificate from the Cloudant server. The truststore declared in `server.xml` is irrelevant here.

Procedure

1. Determine the location of the truststore that is declared for the Liberty server through JVM properties:
 - Look into the file `WLP_DIR/usr/servers/servername/jvm.options`. If this file does not exist, look into the file `WLP_DIR/etc/jvm.options`. If you find an option of the form `-Djavax.net.ssl.trustStore=...`, the value is the truststore location that you are looking for.
 - If there is no option of the previously mentioned form, or if none of the files previously mentioned exist, you can find the truststore location in `JRE_DIR/lib/security/cacerts`.
 - If you are unsure about the truststore location, you can determine it as follows:

- a. Make sure that you have a file `WLP_DIR/usr/servers/servername/jvm.options`. If this file does not exist, create it as a copy of the file `WLP_DIR/etc/jvm.options`, or create an empty file, if neither of these two files exists.
 - b. Add a line `-Djavax.net.debug=ssl` to this `jvm.options` file.
 - c. Restart the Liberty server.
 - d. In `WLP_DIR/usr/servers/servername/logs/messages.log`, look for lines that contain `0 trustStore is:`
 - e. You can then remove the option `-Djavax.net.debug=ssl` that you added.
2. If the truststore location is a `JRE_DIR/lib/security/cacerts` file:
 - If the Cloudant server is on the internet, such as `account.cloudant.com`, or if it is a Cloudant Local server with a certificate that is signed by a trusted certificate authority, you have nothing to do, because the `cacerts` file already contains the root certificates for most internet servers.
 - Otherwise, do as follows:
 - a. Create a new truststore file that contains both the contents of the `cacerts` file and the signer certificate of the Cloudant server, by using the **keytool** command that is contained in the JRE.
 - b. Make sure that you have a file `WLP_DIR/usr/servers/servername/jvm.options`. If this file does not exist, create it as a copy of the file `WLP_DIR/etc/jvm.options`, or create an empty file, if neither of these two files exists.
 - c. Augment the file `WLP_DIR/usr/servers/servername/jvm.options` with options to set the JVM properties `javax.net.ssl.trustStore`, `javax.net.ssl.trustStoreType`, and `javax.net.ssl.trustStorePassword`, as documented in the JSSE Reference Guide, one per line.
 3. If the truststore location is a different file, add the signer certificate of the Cloudant server to this truststore, by using the **keytool** command that is contained in the JRE.

Configuring Apache Tomcat:

You must configure a secure JMX connection for Apache Tomcat application server.

About this task

The Server Configuration Tool and the Ant tasks can configure a default secure JMX connection, which includes the definition of a JMX remote port, and the definition of authentication properties. They modify `<tomcatInstallDir>/bin/setenv.bat` and `<tomcatInstallDir>/bin/setenv.sh` to add these options to `CATALINA_OPTS`:

```
-Djava.rmi.server.hostname=localhost
-Dcom.sun.management.jmxremote.port=8686
-Dcom.sun.management.jmxremote.authenticate=false
-Dcom.sun.management.jmxremote.ssl=false
```

Note: 8686 is a default value. The value for this port can be changed if the port is not available on the computer.

- The `setenv.bat` file is used if you start Apache Tomcat with `<tomcatInstallDir>/bin/startup.bat`, or `<tomcatInstallDir>/bin/catalina.bat`.
- The `setenv.sh` file is used if you start Apache Tomcat with `<tomcatInstallDir>/bin/startup.sh`, or `<tomcatInstallDir>/bin/catalina.sh`.

This file might not be used if you start Apache Tomcat with another command. If you installed the Apache Tomcat Windows Service Installer, the service launcher does not use `setenv.bat`.

Important: This configuration is not secure by default. To secure the configuration, you must manually complete steps 2 and 3 of the following procedure.

Procedure

Manually configuring Apache Tomcat:

1. For a simple configuration, add the following options to `CATALINA_OPTS`:
 - Djava.rmi.server.hostname=localhost
 - Dcom.sun.management.jmxremote.port=8686
 - Dcom.sun.management.jmxremote.authenticate=false
 - Dcom.sun.management.jmxremote.ssl=false
2. To activate authentication, see the Apache Tomcat user documentation [SSL Support - BIO and NIO and SSL Configuration HOW-TO](#).
3. For a JMX configuration with SSL enabled, add the following options:
 - Dcom.sun.management.jmxremote=true
 - Dcom.sun.management.jmxremote.port=8686
 - Dcom.sun.management.jmxremote.ssl=true
 - Dcom.sun.management.jmxremote.authenticate=false
 - Djava.rmi.server.hostname=localhost
 - Djavax.net.ssl.trustStore=<key store location>
 - Djavax.net.ssl.trustStorePassword=<key store password>
 - Djavax.net.ssl.trustStoreType=<key store type>
 - Djavax.net.ssl.keyStore=<key store location>
 - Djavax.net.ssl.keyStorePassword=<key store password>
 - Djavax.net.ssl.keyStoreType=<key store type>

Note: The port `8686` can be changed.

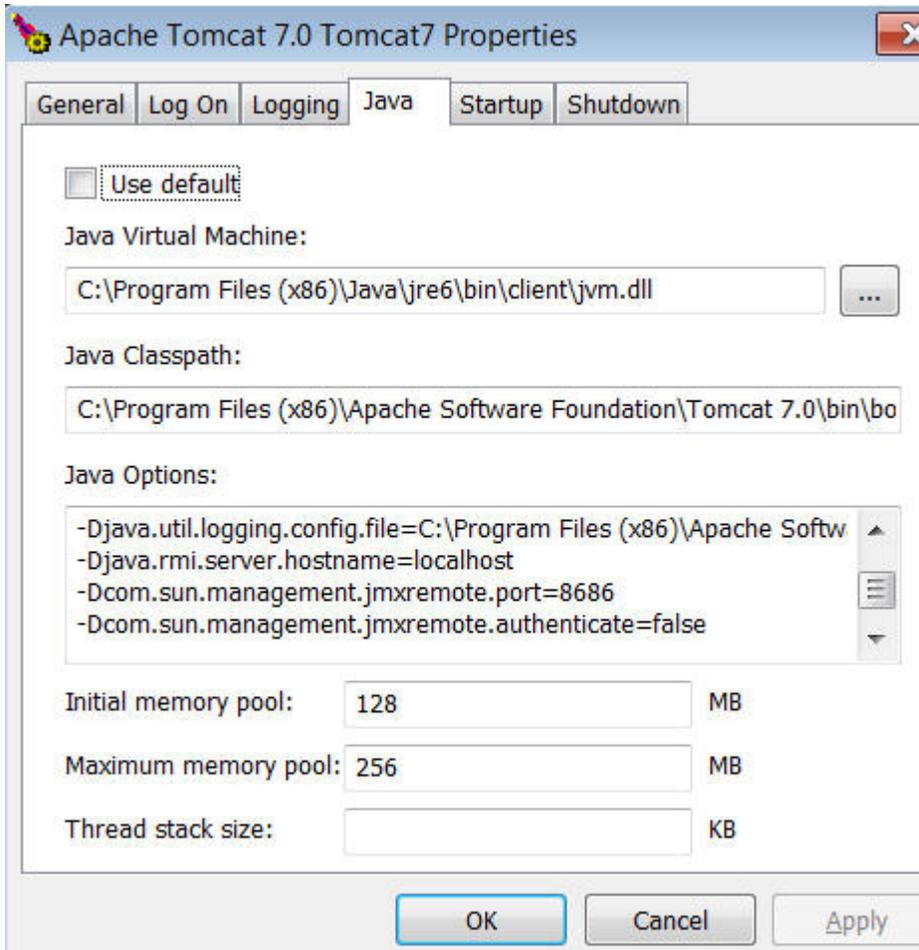

4. If the Tomcat instance is running behind a firewall, the JMX Remote Lifecycle Listener must be configured. See the Apache Tomcat documentation for [JMX Remote Lifecycle Listener](#).

The following environment properties must also be added to the Context section of the Administration Services application in the `server.xml` file, such as in the following example:

```
<Context docBase="worklightadmin" path="/worklightadmin ">
  <Environment name="ibm.worklight.admin.rmi.registryPort" value="registryPort" type="java.lang.Integer"/>
  <Environment name="ibm.worklight.admin.rmi.serverPort" value="serverPort" type="java.lang.Integer"/>
</Context>
```

In the previous example:

- `registryPort` must have the same value as the `rmiRegistryPortPlatform` attribute of the JMX Remote Lifecycle Listener.
 - `serverPort` must have the same value as the `rmiServerPortPlatform` attribute of the JMX Remote Lifecycle Listener.
5. If you are going to use a Cloudant database for the administration or for a deployed project WAR file, configure the application server as described in “Configuring Apache Tomcat for use with Cloudant” on page 6-67.
 6. If you installed Apache Tomcat with the Apache Tomcat Windows Service Installer instead of adding the options to `CATALINA_OPTS`, run `<TomcatInstallDir>/bin/Tomcat7w.exe`, and add the options in the **Java** tab of the Properties window.

What to do next

For more information about the optimization of MobileFirst Server, especially the tuning of the JVM memory allocation, see “Optimization and tuning of MobileFirst Server” on page 6-150.

Configuring Apache Tomcat for use with Cloudant:

You must ensure that the truststore declared for the Apache Tomcat server through JVM properties recognizes the SSL certificate from the Cloudant server.

Procedure

1. Determine the location of the truststore that is declared for the Apache Tomcat server through JVM properties:
 - If the file `TOMCAT_DIR/bin/setenv.sh` (on UNIX and Linux), or `TOMCAT_DIR/bin/setenv.bat` (on Windows) contains an augmentation of the `CATALINA_OPTS` variable with an option of the form `-Djavax.net.ssl.trustStore=...`, the value is the truststore location that you are looking for.
 - Otherwise, if you have a `CATALINA_OPTS` environment variable set, and it contains an option of the form `-Djavax.net.ssl.trustStore=...`, the value is the truststore location that you are looking for.

- If you cannot find the truststore location by any of the previously mentioned ways, then the truststore location is `JRE_DIR/lib/security/cacerts`
2. If the truststore location is a `JRE_DIR/lib/security/cacerts` file:
 - If the Cloudant server is on the internet, such as `account.cloudant.com`, or if it is a Cloudant Local server with a certificate that is signed by a trusted certificate authority, you have nothing to do, because the `cacerts` file already contains the root certificates for most internet servers.
 - Otherwise, do as follows:
 - a. Create a new truststore file that contains both the contents of the `cacerts` file and the signer certificate of the Cloudant server, by using the **keytool** command that is contained in the JRE.
 - b. Augment the file `TOMCAT_DIR/bin/setenv.sh` (on UNIX and Linux), or `TOMCAT_DIR/bin/setenv.bat` (on Windows), with options to set the JVM properties `javax.net.ssl.trustStore`, `javax.net.ssl.trustStoreType`, and `javax.net.ssl.trustStorePassword`, as documented in the JSSE Reference Guide.
 3. If the truststore location is a different file, add the signer certificate of Cloudant server to this truststore, by using the **keytool** command that is contained in the JRE.

Configuring WebSphere Application Server and WebSphere Application Server Network Deployment:

You must configure a secure JMX connection for WebSphere Application Server and WebSphere Application Server Network Deployment.

Procedure

- IBM MobileFirst Platform Foundation requires access to the SOAP port, or the RMI port to perform JMX operations. By default, the SOAP port is active on a WebSphere Application Server. IBM MobileFirst Platform Foundation uses the SOAP port by default. If both the SOAP and RMI ports are deactivated, IBM MobileFirst Platform Foundation does not run.
- RMI is only supported with a WebSphere Application Server Network Deployment. RMI is not supported with a stand-alone profile, or with a WebSphere Application Server server farm.
- You must activate Administrative and Application Security.
- If you are going to use a Cloudant database for the administration or for a deployed project WAR file, configure the application server as described in “Configuring WebSphere Application Server for use with Cloudant.”

What to do next

For more information about the optimization of MobileFirst Server, especially the tuning of the JVM memory allocation, see “Optimization and tuning of MobileFirst Server” on page 6-150.

Configuring WebSphere Application Server for use with Cloudant:

You must ensure that some SSL configuration in the WebSphere Application Server recognizes the SSL certificate from `https://username.cloudant.com`. To do so, you can add the signer of this certificate either to the default SSL configuration, or to an SSL configuration of its own. The second option provides for higher security. Similar instructions apply if you use a Cloudant Local server over HTTPS instead of `cloudant.com`.

To add this certificate to the default SSL configuration

1. Open the WebSphere Application Server console.
2. Go to **Security > SSL Certificates and Key Management**.
3. In **Related Items**, click **Key stores and certificates**
4. Select **NodeDefaultTrustStore**.
5. Select **Additional Properties > Signer certificates**.
6. Click **Retrieve from port**.
 - a. Enter the Cloudant host name *username.cloudant.com*, where *username* is the user name of the Cloudant account, and the port, which is by default 443.

Important: Do not enter the host name *cloudant.com*. This would not work, as it has a different signer certificate than *username.cloudant.com*.
 - b. Select an alias, for example **cloudant certificate signer**.
 - c. Click **Retrieve signer information**.
 - d. Click **OK**.
7. Click **Save**.

To add the certificate signer to a new SSL configuration

1. First, create a truststore that contains only the signer of this certificate:
 - a. Open the WebSphere Application Server console.
 - b. Go to **Security > SSL Certificates and Key Management**.
 - c. In **Related Items**, click **Key stores and certificates**.
 - d. Set the **Keystore usages** combobox to **SSL keystores**.
 - e. Click **New**, and enter the name *CloudantTruststore*, the path *cloudanttruststore* (this path is relative to $\{\text{CONFIG_ROOT}\}/\text{etc}$), and a password.
 - f. Click **OK**.
 - g. Click **Save**.
 - h. Select the **CloudantTruststore** keystore.
 - i. Select **Additional Properties > Signer certificates**.
 - j. Click **Retrieve from port**.
 - 1) Enter the Cloudant host name *username.cloudant.com*, where *username* is the user name of the Cloudant account, and the port, which is by default 443.

Important: Do not enter the host name *cloudant.com*. This would not work, as it has a different signer certificate than *username.cloudant.com*.
 - 2) Select an alias, for example **cloudant certificate signer**.
 - 3) Click **Retrieve signer information**.
 - 4) Click **OK**.
 - k. Click **Save**.
2. If you are using WebSphere Application Server Network Deployment, copy the truststore file to all relevant nodes. In this case, the truststore file is $\{\text{CONFIG_ROOT}\}/\text{etc}/\text{cloudanttruststore}$.
3. Create an SSL configuration that uses this truststore:
 - a. Open the WebSphere Application Server console.
 - b. Go to **Security > SSL Certificates and Key Management**.

- c. In **Related Items**, click **SSL configurations**.
 - d. Click **New**, and enter the name `CloudantConfig`, select as **Trust store name** the **CloudantTruststore**.
 - e. Click **OK**.
 - f. Click **Save**.
4. There are two ways of using this configuration:
- You can define the JNDI property `mfp.db.cloudant.ssl.configuration` in the MobileFirst Server administration and project WAR applications, later.
 - You can create a dynamic outbound configuration:
 - a. Open the WebSphere Application Server console.
 - b. Go to **Security > SSL Certificates and Key Management**.
 - c. In **Related Items**, click **Dynamic outbound endpoint SSL configurations**.
 - d. Click **New**, and enter the name `MyCloudant` and a description.
 - e. Enter a connection information: `HTTP, .cloudant.com, 443`, and click **Add >>**.
 - f. In the SSL configuration combination box, select **CloudantConfig**.
 - g. Click **OK**.
 - h. Click **Save**.

See also

- “Declaring the Cloudant SSL configuration for the MobileFirst Server administration” on page 6-111
- “Declaring the Cloudant SSL configuration for a project WAR file” on page 12-49

Configuring WebSphere Application Server V7.0:

If you use WebSphere Application Server V7.0, you must add a custom property to the web container settings.

Procedure

1. Click **Servers > Server Types > Application Servers**, and select the server for IBM MobileFirst Platform Foundation.
2. Click **Web Container Settings > Web container**.
3. Click **Custom properties**.
4. Click **New**.
5. Add the following property:
 - Name: `com.ibm.ws.webcontainer.invokerequestlistenerfilter`
 - Value: `true`
6. Click **OK**.
7. Click **Save**.

Results

For more information, see the page PK91120: Servlet listeners not getting fired with servlet filters.

Installing MobileFirst Server administration with the Server Configuration Tool

You can use the Server Configuration Tool to install and configure MobileFirst Server administration.

Before you begin

Verify that the user who runs the Server Configuration Tool has the privileges that are described in “File system prerequisites” on page 6-16.

About this task

Restriction:

- The Server Configuration Tool does not support server farms. Therefore, you cannot use this tool to install, upgrade, or configure a server farm.
- MobileFirst Server is not supported for production use on Mac OS X.

Procedure

1. Start the Server Configuration Tool.
 - On Linux: In the desktop menu, click **IBM MobileFirst Platform Server > Server Configuration Tool**.
 - On Windows: In the **Start** menu, click **IBM MobileFirst Platform Server > Server Configuration Tool**.
 - On Mac OS X: In the **Finder**, double-click the file *mf_server_install_dir/shortcuts/configuration-tool.sh*.

Note: The *mf_server_install_dir* placeholder represents the directory where you install MobileFirst Server. *mf_server* is the shortcut for MobileFirst Server.

2. Select **Create a MobileFirst Server Configuration**.
3. Name your configuration.
4. In the Configuration Description window:
 - a. Enter the context root of the MobileFirst Administration REST service.

The context root is used to create the URL to the MobileFirst REST Administration service. This URL is typically in the form `<URL_TO_APPLICATION_SERVER_HTTPS_PORT>/contextroot` or `<URL_TO_APPLICATION_SERVER_HTTP_PORT>/contextroot`.

- b. Enter an **environmentId**.

This ID is optional and is used to distinguish between different deployments of the MobileFirst Server administration components in the same application server environment, for example in the same cell of WebSphere Application Server Network Deployment.

Important: Review carefully this environment ID. It must match the environment ID of all the runtime environments that are managed by this MobileFirst Server administration component. If you install or upgrade the MobileFirst runtime environments with separate Ant files, this verification is particularly important because the **environmentId** attribute must match. For a server farm, all installations must also have the same **environmentId** attribute.

The **environmentId** attribute is an attribute of the following Ant tasks:

- **installworklightadmin**, **updateworklightadmin**, and **uninstallworklightadmin**, which are documented at “Ant tasks for installation of MobileFirst Operations Console and Administration Services” on page 16-34.

- **configureapplicationserver**, **updateapplicationserver**, **unconfigureapplicationserver**, which are documented at “Ant tasks for installation of MobileFirst runtime environments” on page 16-42.
5. In the Console Settings window, enter the context root of the MobileFirst Operations Console.
 6. In the Database Properties window:
 - a. Select your database type: IBM DB2, MySQL, Oracle, or Cloudant.
 - b. In the next window, enter the details to connect to the database instance, or to a valid Cloudant account.
 - c. In the Database itional properties window, enter the parameters to connect to the administration database.
 - d. If the database administrator did not create the databases in step “Optional creation of the administration database” on page 6-58, enter the database administration credentials in the **database creation request** window.

Note: For IBM DB2 and for Oracle, you must have an SSH access to the host where the database management system (DBMS) is installed.

If you selected a relational database, the Server Configuration Tool creates the database for you. If you select Cloudant as the database management system for your MobileFirst runtime environment, the Server Configuration Tool does not create a database.

7. In the Application Server Choice window:
 - a. Select your application server type: WebSphere Application Server, WebSphere Application Server Liberty profile, or Apache Tomcat.
 - b. In the Application Server window, enter the data so that you can deploy IBM MobileFirst Platform Foundation to that application server.
 - c. Depending on your application server, proceed as follows:
 - If the application server is WebSphere Application Server Liberty profile, or Apache Tomcat, select **Create a default user** if you want to declare a user who can log in to the console as administrator to the MobileFirst Operations Console
 - If the application server is WebSphere Application Server, select **Declare the WebSphere Administrator as an administrator of IBM MobileFirst Platform Operations Console** if you want to allow the WebSphere administrator to log in to the MobileFirst Operations Console.

For more information about further configuration of security roles, see “Configuring user authentication for MobileFirst Server administration” on page 6-106.

8. When all the data is entered, click **Deploy**. The following effects take place:
 - For relational databases:
 - If the database administrator did not complete step “Optional creation of the administration database” on page 6-58, the database for the MobileFirst Server administration is created and access rights are granted to the user that is specified in the **database additional properties** window.
 - If the tables for MobileFirst administration do not exist in the database, they are created.
 - The MobileFirst administration components are installed in the application server and are connected to the database.
 - For Cloudant:

- The application server is configured with the required information to connect to your Cloudant account. The database for the MobileFirst Server administration is created when the application server starts.
9. Restart the application server
 10. If you are in an environment where you must protect the password of the user who can log in to the console as administrator to the MobileFirst Operations Console, follow the steps in “Securing the MobileFirst Server administration” on page 6-162.
 11. Open the console.
If the context root of the console was not changed in the Console Settings window, you find it at `<URL_TO_APPLICATION_SERVER_HTTPS_PORT>/worklightconsole`, or if HTTPS is not supported in your application server, at the unsecured URL `<URL_TO_APPLICATION_SERVER_HTTP_PORT>/worklightconsole`.

What to do next

Install a MobileFirst runtime environment. For more information, see “Deploying, updating, undeploying, or upgrading MobileFirst Server by using the Server Configuration Tool” on page 12-11.

Using Ant tasks to install MobileFirst Server administration

Learn about the Ant tasks that you can use to install MobileFirst Server administration.

Creating and configuring the database for MobileFirst Server administration with Ant tasks:

If you did not manually create the database, you can use Ant tasks to create and configure your database for MobileFirst Server administration. If your database exists, you can perform only the configuration steps with Ant tasks.

Before you begin

Make sure that a database management system (DBMS) is installed and running on a database server, which can be the same computer, or a different computer.

Note: Apache Derby is not supported for production use.

If you want to start the Ant task from a computer on which MobileFirst Server is not installed, you must copy the following files to that computer:

- The library `mf_server_install_dir/WorklightServer/worklight-ant-deployer.jar` file.
- The Ant sample files that are in `mf_server_install_dir/WorklightServer/configuration-samples` folder.

Note: The `mf_server_install_dir` placeholder represents the directory where you installed MobileFirst Server.

About this task

Important: You use this procedure to create a relational database, if needed, and to populate it with the required tables. If you deploy with Cloudant as a database, you do not need to perform this procedure. However, you must ensure that you have a valid Cloudant account, as described in “Creating the Cloudant database

for MobileFirst Server administration” on page 6-62. The MobileFirst administration Cloudant database is created, if needed, when the MobileFirst Server administration application is run for the first time.

If you did not create your database manually, as described in “Optional creation of the administration database” on page 6-58, complete steps 1 to 3.

If your relational database exists, you must create only the database tables. To create these tables, follow steps 4 to 7.

Procedure

If you did not create your database manually, complete steps 1 to 3.

1. Copy the Ant file that corresponds to your database. The files for creating a database are named after the following pattern:

```
create-database-<dbms>.xml
```

For more information, see table 1, Table 16-83 on page 16-78, in “Sample configuration files” on page 16-77.

2. Edit the Ant file and replace the placeholder values with the properties at the beginning of the file.
3. Run the following command to create the database.

```
ant -f create-database-dbms.xml admdatabases
```

You can find the Ant command in *mf_server_install_dir/shortcuts*.

If the database exists, then you must create only the database tables by completing the following steps.

4. Copy the sample Ant file that corresponds to both your application server and your DBMS. The files for configuring an existing database are named after this pattern:

```
configure-<appServer>-<dbms>.xml
```

For more information, see table 1, Table 16-83 on page 16-78, in “Sample configuration files” on page 16-77.

5. Edit the Ant file, and replace the placeholder values with the properties at the beginning of the file.
6. Run the following command to create the database.

```
ant -f configure-<appServer>-<dbms>.xml admdatabases
```

You can find the Ant command in *mf_server_install_dir/shortcuts*.

7. Save the Ant file. You need it to deploy the MobileFirst Operations Console and Administration Services with Ant tasks. For more information, see “Deploying the MobileFirst Operations Console and Administration Services with Ant tasks” on page 6-75. If you do not want to save the passwords, you can replace them by “*****” (12 stars) for interactive prompting.

What to do next

Deploy MobileFirst Operations Console and the Administration Services, see “Deploying the MobileFirst Operations Console and Administration Services with Ant tasks” on page 6-75.

See also:

- “Ant **configuredatabase** task reference” on page 16-25
- “Sample configuration files” on page 16-77

Deploying the MobileFirst Operations Console and Administration Services with Ant tasks:

Use Ant tasks to deploy the MobileFirst Operations Console and Administration Services to an application server, and configure data sources, properties, and database drivers that are used by IBM MobileFirst Platform Foundation.

Before you begin

1. Complete the procedure in “Creating and configuring the databases with Ant tasks” on page 12-15.
2. Run the Ant task on the computer where the application server is installed, or the Network Deployment Manager for WebSphere Application Server Network Deployment. If you want to start the Ant task from a computer on which MobileFirst Server is not installed, you must copy the following files to that computer:
 - The library *mf_server_install_dir*/WorklightServer/worklight-ant-deployer.jar file.
 - The Ant sample files that are in *mf_server_install_dir*/WorklightServer/configuration-samples folder.
3. If you use Cloudant via https as a database, and WebSphere Application Server full profile as an application server, declare the Cloudant signer certificate, as described in “Configuring WebSphere Application Server for use with Cloudant” on page 6-68.

Note: The *mf_server_install_dir* placeholder represents the directory where you installed MobileFirst Server.

Procedure

1. Copy the Ant file that corresponds to both your application server and your database management system (DBMS). The files for deploying a project WAR file are named after this pattern:

```
configure-<appServer>-<dbms>.xml
```

For more information, see table 1, Table 16-83 on page 16-78, in “Sample configuration files” on page 16-77.

2. Edit the Ant file, and replace the placeholder values with the properties at the beginning of the file.

For WebSphere Application Server Liberty profile, the administration services require access to the RESTConnector, which is only accessible with Liberty administrator credentials. If you do not modify the <jmx/> tag, a new user named WorklightRESTUser is declared in the basic registry and is given administrator rights by declaring this user in the <administrator-role/> tag. You might have to modify the <jmx/> tag to define the Liberty administrator credentials for example if the Liberty administrator is identified using LDAP. In the Ant file, replace the empty <jmx/> tag by the following line.

```
<jmx libertyAdminUser="demo" libertyAdminPassword="demo" createLibertyAdmin="false"/>
```

Where:

- **libertyAdminUser** is the name of the Liberty administrator.

- **libertyAdminPassword** is the password of the Liberty administrator.

If **createLibertyAdmin** is set to false, the Ant task does not attempt to add the user to the basic registry or to declare the user as a Liberty administrator.

3. To deploy the Administration Services and the MobileFirst Operations Console WAR files, run the following command:

```
ant -f configure-<appServer>-<dbms>.xml admininstall
```

You can find the Ant command in *mf_server_install_dir/shortcuts*

4. Save the Ant file. You might need it later to apply a fix pack or perform an upgrade. For more information, see “Identify the MobileFirst WAR file and prepare the Ant deployment script” on page 7-30. If you do not want to save the passwords, you can replace them by “*****” (12 stars) for interactive prompting.

What to do next

Install a MobileFirst runtime environment. For more information, see “Using Ant tasks to deploy the project WAR file” on page 12-15.

See also:

- “Sample configuration files” on page 16-77
- “Ant tasks for installation of MobileFirst Operations Console and Administration Services” on page 16-34
- “Encrypting database password with Ant tasks for Liberty” on page 16-33

Manually installing MobileFirst Server administration

You can install the MobileFirst Server administration manually instead of using the Ant task or the Server Configuration Tool. You might also want to reconfigure MobileFirst Server so that it uses a different database or schema from the one that was specified during the first installation of MobileFirst Server. This reconfiguration depends on the type of database and the kind of application server.

Configuring the DB2 database manually for the IBM MobileFirst Platform Server administration:

You configure the DB2 database manually by creating the database, creating the database tables, and then configuring the relevant application server to use this database setup.

Procedure

1. Create the database. This step is described in “Creating the DB2 database for MobileFirst Server administration” on page 6-59.
2. Create the tables in the database. This step is described in “Setting up your DB2 database manually for the MobileFirst Server administration.”
3. Perform the application server-specific setup as the following list shows.

Setting up your DB2 database manually for the MobileFirst Server administration:

You can set up your DB2 database for the MobileFirst Server administration manually.

About this task

Set up your DB2 database for the MobileFirst Server administration by creating the database schema.

Procedure

1. Create a system user, **worklight**, in a DB2 admin group such as **DB2USERS**, by using the appropriate commands for your operating system. Give it the password **worklight**. For more information, see the DB2 documentation and the documentation for your operating system.

Important: You can name your user differently, or set a different password, but ensure that you enter the appropriate user name and password correctly across the DB2 database setup. DB2 has a user name and password length limit of 8 characters for UNIX and Linux systems, and 30 characters for Windows.

2. Open a DB2 command line processor, with a user that has **SYSADM** or **SYSCTRL** permissions:

- On Windows systems, click **Start > IBM DB2 > Command Line Processor**.
- On Linux or UNIX systems, go to `~/sql1lib/bin` and enter `./db2`.

3. Enter the following database manager and SQL statements to create a database that is called **WLADMIN**:

```
CREATE DATABASE WLADMIN COLLATE USING SYSTEM PAGESIZE 32768
CONNECT TO WLADMIN
GRANT CONNECT ON DATABASE TO USER worklight
QUIT
```

4. Run DB2 with the following commands to create the **WLADMIN** tables, in a schema named **WLADMSC**. You can change the name of the schema. This command can be run on an existing database whose page size is compatible with the one defined in step 3.

```
db2 CONNECT TO WLADMIN
db2 SET CURRENT SCHEMA = 'WLADMSC'
db2 -vf product_install_dir/WorklightServer/databases/create-worklightadmin-db2.sql -t
```

Configuring Liberty profile for DB2 manually for MobileFirst Server administration:

You can set up and configure your DB2 database manually for MobileFirst Server administration with WebSphere Application Server Liberty profile.

Before you begin

Complete the DB2 Database Setup procedure before continuing.

Procedure

1. Add the DB2 JDBC driver JAR file to `LIBERTY_HOME/wlp/usr/shared/resources/db2`.

If that directory does not exist, create it. You can retrieve the file in one of two ways:

- Download it from DB2 JDBC Driver Versions.
- Fetch it from the `db2_install_dir/java` on the DB2 server directory.

2. Configure the data source in the `LIBERTY_HOME/wlp/usr/servers/worklightServer/server.xml` file as follows:

In this path, you can replace `worklightServer` by the name of your server.

```

<library id="DB2Lib">
  <fileset dir="{shared.resource.dir}/db2" includes="*.jar"/>
</library>

<!-- Declare the administration database. -->
<dataSource jndiName="jdbc/WorklightAdminDS" transactional="false">
  <jdbcDriver libraryRef="DB2Lib"/>
  <properties.db2.jcc databaseName="WLADMIN" currentSchema="WLADMSC"
    serverName="db2server" portNumber="50000"
    user="worklight" password="worklight"/>
</dataSource>

```

The **worklight** value after **user=** is the name of the system user with CONNECT access to the **WLADMIN** database that you have previously created. The **worklight** value after **password=** is this user's password. If you have defined either a different user name, or a different password, or both, replace **worklight** accordingly. Also, replace **db2server** with the host name of your DB2 server (for example, **localhost**, if it is on the same computer).

DB2 has a user name and password length limit of 8 characters for UNIX and Linux systems, and 30 characters for Windows.

3. You can encrypt the database password with the `securityUtility` program in `<liberty_install_dir>/bin`.

Configuring WebSphere Application Server for DB2 manually for MobileFirst Server administration:

You can set up and configure your DB2 database manually for the MobileFirst Server administration with WebSphere Application Server.

About this task

Complete the DB2 database setup procedure before continuing.

Note: The `was_install_dir` and `mf_server_install_dir` placeholders denote the directories where you installed WebSphere Application Server and MobileFirst Server.

Procedure

1. Determine a suitable directory for the JDBC driver JAR file in the WebSphere Application Server installation directory.
 - For a standalone server, you can use a directory such as `WAS_INSTALL_DIR/optionalLibraries/IBM/WorklightAdmin/db2`.
 - For deployment to a WebSphere Application Server Network Deployment cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/WorklightAdmin/db2`.
 - For deployment to a WebSphere Application Server Network Deployment cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/WorklightAdmin/db2`.
 - For deployment to a WebSphere Application Server Network Deployment node, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/WorklightAdmin/db2`.
 - For deployment to a WebSphere Application Server Network Deployment server, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/WorklightAdmin/db2`.

If the directory for the JDBC driver JAR file does not exist, you must create it.

2. Add the DB2 JDBC driver JAR file (download it from DB2 JDBC Driver Versions, or fetch it from the directory *db2_install_dir/java* on the DB2 server) to the directory that you determined in step 1.
3. Set up the JDBC provider:
 - a. In the WebSphere Application Server console, click **Resources > JDBC > JDBC Providers**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Set **Database type** to **DB2**.
 - e. Set **Provider type** to **DB2 Using IBM JCC Driver**.
 - f. Set **Implementation Type** to **Connection pool data source**.
 - g. Set **Name** to **DB2 Using IBM JCC Driver**.
 - h. Click **Next**.
 - i. Set the **Class path** to the set of JAR files in the directory that you determined in step 1, one per line, replacing *WAS_INSTALL_DIR/profiles/profile-name* with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.
 - j. Do not set **Native library path**.
 - k. Click **Next**.
 - l. Click **Finish**.
 - m. The JDBC provider is created.
 - n. Click **Save**.
4. Create a data source for the administration database:
 - a. Click **Resources > JDBC > Data sources**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New** to create a data source.
 - d. Set the **Data source name** to **administration database**.
 - e. Set **JNDI Name** to **jdbc/WorklightAdminDS**.
 - f. Click **Next**.
 - g. Enter properties for the data source, for example:
 - **Driver type:** 4
 - **Database Name:** WLADMIN
 - **Server name:** localhost
 - **Port number:** 50000 (default)
 Leave **Use this data source in (CMP)** selected.
 - h. Click **Next**.
 - i. Create JAAS-J2C authentication data, specifying the DB2 user name and password as its properties. If necessary, go back to the data source creation wizard, by repeating steps 4a to 4h.
 - j. Select the authentication alias that you created in the **Component-managed authentication alias** combination box (not in the **Container-managed authentication alias** combination box).
 - k. Click **Next** and **Finish**.
 - l. Click **Save**.
 - m. In **Resources > JDBC > Data sources**, select the new data source.
 - n. Click **WebSphere Application Server data source properties**.
 - o. Select the **Non-transactional data source** check box.

- p. Click **OK**.
 - q. Click **Save**.
 - r. Click **Custom properties** for the data source, select property **currentSchema**, and set the value to the schema used to create the MobileFirst Server administration tables (WLADMSC in this example).
5. Test the data source connection by selecting **Data Source** and clicking **Test Connection**.
 6. For WebSphere Application Server Network Deployment, click **System administration > Nodes**, select the nodes, and click **Full Synchronize**.

Configuring Apache Tomcat for DB2 manually for MobileFirst Server administration:

You can set up and configure your DB2 database manually for IBM MobileFirst Platform Server administration with the Apache Tomcat application server.

About this task

Before you continue, complete the DB2 database setup procedure.

Procedure

1. Add the DB2 JDBC driver JAR file.

You can retrieve this JAR file in one of the following ways:

- Download it from DB2 JDBC Driver Versions.
- Or fetch it from the directory `db2_install_dir/java` on the DB2 server) to `$TOMCAT_HOME/lib`.

2. Prepare an XML statement that defines the data source, as shown in the following code example.

```
<Resource auth="Container"
  driverClassName="com.ibm.db2.jcc.DB2Driver"
  name="jdbc/WorklightAdminDS"
  username="worklight"
  password="password"
  type="javax.sql.DataSource"
  url="jdbc:db2://server:50000/WLADMIN:currentSchema=WLADMSC;"/>
```

The **worklight** parameter after **username=** is the name of the system user with "CONNECT" access to the **WLADMIN** database that you previously created. The **password** parameter after **password=** is this user's password. If you defined either a different user name, or a different password, or both, replace these entries accordingly.

DB2 enforces limits on the length of user names and passwords.

- For UNIX and Linux systems: 8 characters
 - For Windows: 30 characters
3. Insert this statement in the `server.xml` file, as indicated in "Configuring Apache Tomcat for MobileFirst Server administration manually" on page 6-99.

Configuring the Apache Derby database manually for the IBM MobileFirst Platform Server administration:

You configure the Apache Derby database manually by creating the database and database tables, and then configuring the relevant application server to use this database setup.

Procedure

1. Create the database and the tables within them. This step is described in “Setting up your Apache Derby database manually for the MobileFirst Server administration.”
2. Configure the application server to use this database setup. Go to one of the following topics:
 - “Configuring Liberty profile for Derby manually for MobileFirst Server administration”
 - “Configuring WebSphere Application Server for Derby manually for MobileFirst Server administration” on page 6-82
 - “Configuring Apache Tomcat for Derby manually for the MobileFirst Server administration” on page 6-83

Setting up your Apache Derby database manually for the MobileFirst Server administration:

You can set up your Apache Derby database for the MobileFirst Server administration manually.

About this task

Set up your Apache Derby database for the MobileFirst Server administration by creating the database schema.

Procedure

1. In the location where you want the database to be created, run `ij.bat` on Windows systems or `ij.sh` on UNIX and Linux systems.

Note: The `ij` program is part of Apache Derby. If you do not already have it installed, you can download it from Apache Derby: Downloads.

For supported versions of Apache Derby, see “System requirements” on page 2-15.

The script displays `ij` version number.

2. At the command prompt, enter the following commands:

```
connect 'jdbc:derby:WLADMIN;user=WLADMIN;create=true';
run 'product_install_dir/WorklightServer/databases/create-worklightadmin-derby.sql';
quit;
```

Configuring Liberty profile for Derby manually for MobileFirst Server administration:

If you want to manually set up and configure your Apache Derby database for MobileFirst Server administration with WebSphere Application Server Liberty profile, use the following procedure.

About this task

Complete the Apache Derby database setup procedure before continuing.

Procedure

Configure the data source in the `$LIBERTY_HOME/usr/servers/worklightServer/server.xml` file (`worklightServer` may be replaced in this path by the name of your server) as follows:

```

<!-- Declare the jar files for Derby access through JDBC. -->
<library id="derbyLib">
  <fileset dir="C:/Drivers/derby" includes="derby.jar" />
</library>

<!-- Declare the administration database. -->
<dataSource jndiName="jdbc/WorklightAdminDS" transactional="false" statementCacheSize="10">
  <jdbcDriver libraryRef="derbyLib"
    javax.sql.ConnectionPoolDataSource="org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource"
  <properties.derby.embedded databaseName="DERBY_DATABASES_DIR/WLADMIN" user="WLADMIN"
    shutdownDatabase="false" connectionAttributes="upgrade=true"/>
  <connectionManager connectionTimeout="180"
    maxPoolSize="10" minPoolSize="1"
    reapTime="180" maxIdleTime="1800"
    agedTimeout="7200" purgePolicy="EntirePool"/>
</dataSource>

```

Configuring WebSphere Application Server for Derby manually for MobileFirst Server administration:

You can set up and configure your Apache Derby database manually for the MobileFirst Server administration with WebSphere Application Server.

About this task

Complete the Apache Derby database setup procedure before continuing.

Procedure

1. Determine a suitable directory for the JDBC driver JAR file in the WebSphere Application Server installation directory.
 - For a standalone server, you can use a directory such as `WAS_INSTALL_DIR/optionalLibraries/IBM/WorklightAdmin/derby`.
 - For deployment to a WebSphere Application Server Network Deployment cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/WorklightAdmin/derby`.
 - For deployment to a WebSphere Application Server Network Deployment cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/WorklightAdmin/derby`.
 - For deployment to a WebSphere Application Server Network Deployment node, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/WorklightAdmin/derby`.
 - For deployment to a WebSphere Application Server Network Deployment server, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/WorklightAdmin/derby`.

If the directory for the JDBC driver JAR file does not exist, you must create it.
2. Add the Derby JAR file from `product_install_dir/ApplicationCenter/tools/lib/derby.jar` to the directory that you determined in step 1.
3. Set up the JDBC provider.
 - a. In the WebSphere Application Server console, click **Resources > JDBC > JDBC Providers**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Set **Database Type** to **User-defined**.
 - e. Set **class Implementation name** to `org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource40`.

- f. Set **Name** to **Worklight - Derby JDBC Provider**.
 - g. Set **Description** to **Derby JDBC provider for Worklight**.
 - h. Click **Next**.
 - i. Set the **Class path** to the JAR file in the directory that you determined in step 1, replacing *WAS_INSTALL_DIR/profiles/profile-name* with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.
 - j. Click **Finish**.
4. Create the data source for the administration database.
 - a. In the WebSphere Application Server console, click **Resources > JDBC > Data sources**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Set **Data source Name** to **administration database**.
 - e. Set **JNDI name** to `jdbc/WorklightAdminDS`.
 - f. Click **Next**.
 - g. Select the existing JDBC Provider that is named **Worklight - Derby JDBC Provider**.
 - h. Click **Next**.
 - i. Click **Next**.
 - j. Click **Finish**.
 - k. Click **Save**.
 - l. In the table, click the **administration Database** data source that you created.
 - m. Under **Additional Properties**, click **Custom properties**.
 - n. Click **databaseName**.
 - o. Set **Value** to the path to the WLADMIN database that is created in “Setting up your Apache Derby database manually for the MobileFirst Server administration” on page 6-81.
 - p. Click **OK**.
 - q. Click **Save**.
 - r. Click **administration Database**.
 - s. Under **Additional Properties**, click **WebSphere Application Server data source properties**.
 - t. Select **Non-transactional datasource**.
 - u. Click **OK**.
 - v. Click **Save**.
 - w. In the table, select the **administration Database** data source that you created.
 - x. Optional: Only if you are not on the console of a WebSphere Application Server Deployment Manager, click **test connection**.
 5. For WebSphere Application Server Network Deployment, click **System administration > Nodes**, select the nodes, and click **Full Synchronize**.

Configuring Apache Tomcat for Derby manually for the MobileFirst Server administration:

If you want to manually set up and configure your Apache Derby database for the IBM MobileFirst Platform Server administration with the Apache Tomcat server, use the following procedure.

About this task

Complete the Apache Derby database setup procedure before continuing.

Procedure

1. Add the Derby JAR file from *product_install_dir/WorklightServer/tools/lib/derby.jar* to the directory `$TOMCAT_HOME/lib`.
2. Prepare an XML statement that defines the data source, as shown in the following code example. Insert this statement in the `server.xml` file, as indicated in “Configuring Apache Tomcat for MobileFirst Server administration manually” on page 6-99

```
<Resource auth="Container"
  driverClassName="org.apache.derby.jdbc.EmbeddedDriver"
  name="jdbc/WorklightAdminDS"
  username="WLADMIN"
  password=""
  type="javax.sql.DataSource"
  url="jdbc:derby:DERBY_DATABASES_DIR/WLADMIN"/>
```

Configuring the MySQL database manually for the IBM MobileFirst Platform Server administration:

You configure the MySQL database manually by creating the database, creating the database tables, and then configuring the relevant application server to use this database setup.

Procedure

1. Create the database. This step is described in “Creating the MySQL database for MobileFirst Server administration” on page 6-60.
2. Create the tables in the database. This step is described in “Setting up your MySQL database manually for the MobileFirst Server administration.”
3. Perform the application server-specific setup as the following list shows.

Setting up your MySQL database manually for the MobileFirst Server administration:

You can set up your MySQL database for the MobileFirst Server administration manually.

About this task

Complete the following procedure to set up your MySQL database.

Procedure

1. Create the database schema.
 - a. Run a MySQL command line client with the option `-u root`.
 - b. Enter the following commands:

```
CREATE DATABASE WLADMIN CHARACTER SET utf8 COLLATE utf8_general_ci;
GRANT ALL PRIVILEGES ON WLADMIN.* TO 'worklight'@'Worklight-host' IDENTIFIED BY 'worklight';
GRANT ALL PRIVILEGES ON WLADMIN.* TO 'worklight'@'localhost' IDENTIFIED BY 'worklight';
FLUSH PRIVILEGES;
```

```
USE WLADMIN;
SOURCE product_install_dir/WorklightServer/databases/create-worklightadmin-mysql.sql;
```

Where **worklight** before the "at" sign (@) is the user name, **worklight** after **IDENTIFIED BY** is its password, and **Worklight-host** is the name of the host on which IBM MobileFirst Platform Foundation runs.

2. Add the following property to your MySQL option file: `max_allowed_packet = 256M`

For more information about the option files, see MySQL documentation .

3. Add the following property to your MySQL option file: `innodb_log_file_size = 250M`

For more information about **innodb_log_file_size**, see MySQL documentation: InnoDB Startup Options and System Variables.

Configuring Liberty profile for MySQL manually for MobileFirst Server administration:

If you want to manually set up and configure your MySQL database for MobileFirst Server administration with WebSphere Application Server Liberty profile, use the following procedure.

Before you begin

Complete the MySQL database setup procedure before continuing.

Procedure

1. Add the MySQL JDBC driver JAR file to `$LIBERTY_HOME/wlp/usr/shared/resources/mysql`. If that directory does not exist, create it.
2. Configure the data source in the `$LIBERTY_HOME/usr/servers/worklightServer/server.xml` file (worklightServer may be replaced in this path by the name of your server) as follows:

```
<!-- Declare the jar files for MySQL access through JDBC. -->
<library id="MySQLLib">
  <fileset dir="{shared.resource.dir}/mysql" includes="*.jar"/>
</library>
```

```
<!-- Declare the administration database. -->
<dataSource jndiName="jdbc/WorklightAdminDS" transactional="false">
  <jdbcDriver libraryRef="MySQLLib"/>
  <properties databaseName="WLADMIN"
    serverName="mysqlserver" portNumber="3306"
    user="worklight" password="worklight"/>
</dataSource>
```

where **worklight** after **user=** is the user name, **worklight** after **password=** is this user's password, and **mysqlserver** is the host name of your MySQL server (for example, localhost, if it is on the same machine).

3. You can encrypt the database password with the securityUtility program in `<liberty_install_dir>/bin`.

Configuring WebSphere Application Server for MySQL manually for MobileFirst Server administration:

If you want to manually set up and configure your MySQL database for MobileFirst Server administration with WebSphere Application Server, use the following procedure.

About this task

Complete the MySQL database setup procedure before continuing.

Note: MySQL in combination with WebSphere Application Server Liberty profile or WebSphere Application Server full profile is not classified as a supported

configuration. For more information, see WebSphere Application Server Support Statement. We suggest that you use IBM DB2 or another database supported by WebSphere Application Server to benefit from a configuration that is fully supported by IBM Support.

Procedure

1. Determine a suitable directory for the JDBC driver JAR file in the WebSphere Application Server installation directory.
 - For a standalone server, you can use a directory such as `WAS_INSTALL_DIR/optionalLibraries/IBM/WorklightAdmin/mysql`.
 - For deployment to a WebSphere Application Server Network Deployment cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/WorklightAdmin/mysql`.
 - For deployment to a WebSphere Application Server Network Deployment cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/WorklightAdmin/mysql`.
 - For deployment to a WebSphere Application Server Network Deployment node, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/WorklightAdmin/mysql`.
 - For deployment to a WebSphere Application Server Network Deployment server, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/WorklightAdmin/mysql`.

If the directory for the JDBC driver JAR file does not exist, you must create it.

2. Add the MySQL JDBC driver JAR file that you downloaded from Download Connector/J to the directory determined in step 1.
3. Set up the JDBC provider:
 - a. In the WebSphere Application Server console, click **Resources > JDBC > JDBC Providers**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Create a **JDBC provider** named **MySQL**.
 - e. Set **Database type** to **User defined**.
 - f. Set **Scope** to **Cell**.
 - g. Set **Implementation class** to **com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource**.
 - h. Set the **Class path** to the JAR file in the directory that you determined in step 1, replacing `WAS_INSTALL_DIR/profiles/profile-name` with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.
 - i. Save your changes.
4. Create a data source for the administration database:
 - a. Click **Resources > JDBC > Data sources**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New** to create a data source.
 - d. Type any name (for example, Worklight administration Database).
 - e. Set **JNDI Name** to `jdbc/WorklightAdminDS`.
 - f. Use the existing **JDBC Provider MySQL**, defined in the previous step.
 - g. Set **Scope** to **New**.
 - h. On the **Configuration** tab, select **Non-transactional data source**.
 - i. Click **Next** a number of times, leaving all other settings as defaults.

- j. Save your changes.
5. Set the custom properties of the new data source.
 - a. Select the new data source.
 - b. Click **Custom properties**.
 - c. Set the following properties:

```
portNumber = 3306
relaxAutoCommit=true
databaseName = WLADMIN
serverName = the host name of the MySQL server
user = the user name of the MySQL server
password = the password associated with the user name
```
6. Set the WebSphere Application Server custom properties of the new data source.
 - a. In **Resources > JDBC > Data sources**, select the new data source.
 - b. Click **WebSphere Application Server data source properties**.
 - c. Select **Non-transactional data source**.
 - d. Click **OK**.
 - e. Click **Save**.
7. For WebSphere Application Server Network Deployment, click **System administration > Nodes**, select the nodes, and click **Full Synchronize**.

Configuring Apache Tomcat for MySQL manually for MobileFirst Server administration:

If you want to manually set up and configure your MySQL database for IBM MobileFirst Platform Server administration with the Apache Tomcat server, use the following procedure.

About this task

Complete the MySQL database setup procedure before continuing.

Procedure

1. Add the MySQL Connector/J JAR file to the \$TOMCAT_HOME/lib directory.
2. Prepare an XML statement that defines the data source, as shown in the following code example. Insert this statement in the server.xml file, as indicated in "Configuring Apache Tomcat for MobileFirst Server administration manually" on page 6-99.

```
<Resource name="jdbc/WorklightAdminDS"
  auth="Container"
  type="javax.sql.DataSource"
  maxActive="100"
  maxIdle="30"
  maxWait="10000"
  username="worklight"
  password="worklight"
  driverClassName="com.mysql.jdbc.Driver"
  url="jdbc:mysql://server:3306/WLADMIN"/>
```

Configuring the Oracle database manually for the IBM MobileFirst Platform Server administration:

You configure the Oracle database manually by creating the database, creating the database tables, and then configuring the relevant application server to use this database setup.

Procedure

1. Create the database. This step is described in “Creating the Oracle database for MobileFirst Server administration” on page 6-61.
2. Create the tables in the database. This step is described in “Setting up your Oracle database manually for the MobileFirst Server administration.”
3. Perform the application server-specific setup as the following list shows.

Setting up your Oracle database manually for the MobileFirst Server administration:

You can set up your Oracle database for the MobileFirst Server administration manually.

About this task

Complete the following procedure to set up your Oracle database.

Procedure

1. Ensure that you have at least one Oracle database.

In many Oracle installations, the default database has the SID (name) ORCL. For best results, specify **Unicode (AL32UTF8)** as the character set of the database.

If the Oracle installation is on a UNIX or Linux computer, make sure that the database is started next time the Oracle installation is restarted. To this effect, make sure that the line in `/etc/oratab` that corresponds to the database ends with a Y, not with an N.

2. Create the user WLADMIN, either by using Oracle Database Control, or by using the Oracle SQLPlus command-line interpreter.

- Create the user for the runtime database/schema, by using Oracle Database Control, proceed as follows:

- a. Connect as SYSDBA.
- b. Go to the Users page.
- c. Click **Server**, then **Users** in the Security section.
- d. Create a user, named WLADMIN with the following attributes:

```
Profile: DEFAULT
Authentication: password
Default tablespace: USERS
Temporary tablespace: TEMP
Status: Unlocked
Add system privilege: CREATE SESSION
Add system privilege: CREATE SEQUENCE
Add system privilege: CREATE TABLE
Add quota: Unlimited for tablespace USERS
```

- To create the user by using Oracle SQLPlus, enter the following commands:

```
CONNECT SYSTEM/<SYSTEM_password>@ORCL
CREATE USER WLADMIN IDENTIFIED BY password DEFAULT TABLESPACE USERS QUOTA UNLIMITED ON USERS;
GRANT CREATE SESSION, CREATE SEQUENCE, CREATE TABLE TO WLADMIN;
DISCONNECT;
```

3. Create the database tables for the runtime database and reports database:

- a. Using the Oracle SQLPlus command-line interpreter, create the tables for the IBM administration database by running the `create-worklightadmin-oracle.sql` file:

```
CONNECT WLADMIN/WLADMIN_password@ORCL
@product_install_dir/WorklightServer/databases/create-worklightadmin-oracle.sql
DISCONNECT;
```

4. Download and configure the Oracle JDBC driver:
 - a. Download the JDBC driver from the Oracle website at Oracle: JDBC, SQLJ, Oracle JPublisher and Universal Connection Pool (UCP):
 - b. Ensure that the Oracle JDBC driver is in the system path. The driver file is ojdbc6.jar.

Configuring Liberty profile for Oracle manually for MobileFirst Server administration:

If you want to manually set up and configure your Oracle database for MobileFirst Server administration with WebSphere Application Server Liberty profile, use the following procedure.

Before you begin

Complete the Oracle database setup procedure before continuing.

Procedure

1. Add the Oracle JDBC Driver JAR file to \$LIBERTY_HOME/wlp/usr/shared/resources/oracle. If that directory does not exist, create it.
2. If you are using JNDI, configure the data sources in the \$LIBERTY_HOME/wlp/usr/servers/worklightServer/server.xml file (worklightServer may be replaced in this path by the name of your server) as shown in the following JNDI code example:

```
<!-- Declare the jar files for Oracle access through JDBC. -->
<library id="OracleLib">
  <fileset dir="${shared.resource.dir}/oracle" includes="*.jar"/>
</library>

<!-- Declare the administration database. -->
<dataSource jndiName="jdbc/WorklightAdminDS" transactional="false">
  <jdbcDriver libraryRef="OracleLib"/>
  <properties.oracle driverType="thin"
    serverName="oserver" portNumber="1521"
    databaseName="ORCL"
    user="WLADMIN" password="WLADMIN_password"/>
</dataSource>
```

where **WLADMIN** after **user=** is the user name, **WLADMIN_password** after **password=** is this user's password, and **oserver** is the host name of your Oracle server (for example, localhost, if it is on the same machine).

Note: For more information on how to connect the Liberty server to the Oracle database with a service name, or with a URL, see the WebSphere Application Server Liberty Core 8.5.5 documentation, section **properties.oracle**.

3. You can encrypt the database password with the securityUtility program in <liberty_install_dir>/bin.

Configuring WebSphere Application Server for Oracle manually for the MobileFirst Server administration:

If you want to manually set up and configure your Oracle database for the MobileFirst Server administration with WebSphere Application Server, use the following procedure.

About this task

Complete the Oracle database setup procedure before continuing.

Procedure

1. Determine a suitable directory for the JDBC driver JAR file in the WebSphere Application Server installation directory.
 - For a standalone server, you can use a directory such as `WAS_INSTALL_DIR/optionalLibraries/IBM/WorklightAdmin/oracle`.
 - For deployment to a WebSphere Application Server Network Deployment cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/WorklightAdmin/oracle`.
 - For deployment to a WebSphere Application Server Network Deployment cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/WorklightAdmin/oracle`.
 - For deployment to a WebSphere Application Server Network Deployment node, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/WorklightAdmin/oracle`.
 - For deployment to a WebSphere Application Server Network Deployment server, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/WorklightAdmin/oracle`.

If the directory for the JDBC driver JAR file does not exist, you must create it.

2. Add the Oracle `ojdbc6.jar` file downloaded from JDBC and Universal Connection Pool (UCP) to the directory that you determined in step 1.
3. Set up the JDBC provider:
 - a. In the WebSphere Application Server console, click **Resources > JDBC > JDBC Providers**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Complete the JDBC Provider fields as indicated in the following table:

Table 6-20. JDBC Provider field values

Field	Value
Database type	Oracle
Provider type	Oracle JDBC Driver
Implementation type	Connection pool data source
Name	Oracle JDBC Driver

- e. Click **Next**.
 - f. Set the **Class path** to the JAR file in the directory that you determined in step 1, replacing `WAS_INSTALL_DIR/profiles/profile-name` with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.
 - g. Click **Next**.

The JDBC provider is created.
4. Create a data source for the administration database:
 - a. Click **Resources > JDBC > Data sources**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Set **Data source name** to **Oracle JDBC Driver DataSource**.
 - e. Set **JNDI name** to `jdbc/WorklightAdminDS`.
 - f. Click **Next**.
 - g. Click **Select an existing JDBC provider** and select **Oracle JDBC driver** from the list.

- h. Click **Next**.
 - i. Set the URL value to `jdbc:oracle:thin:@oserver:1521:ORCL`, where **oserver** is the host name of your Oracle server (for example, localhost, if it is on the same machine).
 - j. Click **Next** twice.
 - k. Click **Resources > JDBC > Data sources > Oracle JDBC Driver DataSource > Custom properties**.
 - l. Set `oracleLogPackageName` to `oracle.jdbc.driver`.
 - m. Set `user` = `WLADMIN`.
 - n. Set `password` = `WLADMIN_password`.
 - o. Click **OK** and save the changes.
 - p. In **Resources > JDBC > Data sources**, select the new data source.
 - q. Click **WebSphere Application Server data source properties**.
 - r. Select the **Non-transactional data source** check box.
 - s. Click **OK**.
 - t. Click **Save**.
5. For WebSphere Application Server Network Deployment, click **System administration > Nodes**, select the nodes, and click **Full Synchronize**.

Configuring Apache Tomcat for Oracle manually for MobileFirst Server administration:

If you want to manually set up and configure your Oracle database for IBM MobileFirst Platform Server administration with the Apache Tomcat server, use the following procedure.

About this task

Complete the Oracle database setup procedure before continuing.

Procedure

1. Add the Oracle JDBC driver JAR file to the directory `$TOMCAT_HOME/lib`.
2. Prepare an XML statement that defines the data source, as shown in the following code example. Insert this statement in the `server.xml` file, as indicated in "Configuring Apache Tomcat for MobileFirst Server administration manually" on page 6-99

```
<Resource name="jdbc/WorklightAdminDS"
  auth="Container"
  type="javax.sql.DataSource"
  driverClassName="oracle.jdbc.driver.OracleDriver"
  url="jdbc:oracle:thin:@oserver:1521:ORCL"
  username="WLADMIN"
  password="WLADMIN_password"/>
```

Where **WLADMIN** after `username=` is the name of the system user with "CONNECT" access to the **WLADMIN** database that you have previously created, and **WLADMIN_password** after `password=` is this user's password. If you have defined either a different user name, or a different password, or both, replace these values accordingly.

Configuring the Cloudant database manually for MobileFirst Server administration:

You configure the Cloudant database by setting JNDI properties in the appropriate application server.

There is no manual configuration required for a Cloudant database. If the database for the MobileFirst Server administration does not exist, and if the Cloudant user that is provided to the MobileFirst Server administration is the Cloudant administrator, then the database is automatically created when the MobileFirst Server administration is started. If the user that is provided to the MobileFirst Server administration is not allowed to create a database, you must create a database with the names that are documented at “Creating the Cloudant database for MobileFirst Server administration” on page 6-62.

For more information about the MobileFirst Server administration configuration with Cloudant, see “Deploying the Administration Services and MobileFirst Operations Console and configuring the application server manually”

Deploying the Administration Services and MobileFirst Operations Console and configuring the application server manually:

The procedure to deploy the Administration services and IBM MobileFirst Platform Operations Console manually to an application server depends on your application server.

These manual instructions assume that you are familiar with your application server.

Note: Using the MobileFirst Server installer to install MobileFirst Server administration is more reliable than installing manually and should be used whenever possible.

If you prefer to use the manual process, follow these steps to configure your application server for MobileFirst Server administration. You must deploy the `worklightconsole.war` and `worklightadmin.war` files to your MobileFirst Server administration. The files are located in `product_install_dir/WorklightServer`.

Configuring WebSphere Application Server Liberty profile for MobileFirst Server administration manually:

To configure WebSphere Application Server Liberty profile for MobileFirst Server administration manually, you must modify the `server.xml` file.

About this task

In addition to modifications for the databases, which are described in “Manually installing MobileFirst Server administration” on page 6-76, you must make the following modifications to the `server.xml` file.

Note: In the following procedure, when the example uses the `worklight.war` file name, use the name of your MobileFirst project, for example, `myProject.war`.

As the `server.xml` file contains passwords, you need to protect this file. If you must prevent other users on the same computer from accessing these passwords, remove the read permissions of the file for users other than yourself. You can use a command, such as the following examples:

- On UNIX: `chmod 600 server.xml`
- On Windows: `cacls server.xml /P Administrators:F %USERDOMAIN%\%USERNAME%:F`

You can also encode the passwords with the Liberty profile securityUtility program, which is provided in the *liberty_install_dir/bin* directory.

Procedure

1. Ensure that the <featureManager> element contains at least the following <feature> elements:

- For WebSphere Application Server Liberty profile V8.5.0.x:

```
<feature>ssl-1.0</feature>
<feature>servlet-3.0</feature>
<feature>jdbc-4.0</feature>
<feature>jndi-1.0</feature>
<feature>restConnector-1.0</feature>
<feature>appSecurity-1.0</feature>
```

- For WebSphere Application Server Liberty profile V8.5.5.0 and later:

```
<feature>jdbc-4.0</feature>
<feature>appSecurity-2.0</feature>
<feature>restConnector-1.0</feature>
```

2. Follow the instructions from the IBM WebSphere Application Server Liberty Core user documentation to configure the secure JMX connection.
3. Add the following global JNDI entries in the server.xml file:

```
<jndiEntry jndiName="ibm.worklight.admin.jmx.host" value="localhost"/>
<jndiEntry jndiName="ibm.worklight.admin.jmx.port" value="9443"/>
<jndiEntry jndiName="ibm.worklight.admin.jmx.user" value="WorklightRESTUser"/>
<jndiEntry jndiName="ibm.worklight.admin.jmx.pwd" value="WorklighRESTUserPassword"/>
<jndiEntry jndiName="ibm.worklight.topology.platform" value="Liberty"/>
<jndiEntry jndiName="ibm.worklight.topology.clustermode" value="Standalone"/>
```

Where:

- **ibm.worklight.admin.jmx.host** is the host name for the JMX REST connection.
 - **ibm.worklight.admin.jmx.port** is the HTTPS port. You can find its value in the httpEndpoint element of the server.xml file.
 - **ibm.worklight.admin.jmx.user** is a user with the <administrator-role> that you created in step 2.
 - **ibm.worklight.admin.jmx.pwd** is the password of that user. This password can be encoded with the Liberty profile securityUtility program. The supported encoding types are xor and aes (only with the default key).
4. Modify the web container definition with the following values:
 5. Declare a thread pool: Add the following <executor> declaration, or if the server.xml file has an <executor> declaration already, modify its coreThreads and maxThreads values accordingly.

```
<!-- Thread pool -->
<executor name="LargeThreadPool" id="default"
    coreThreads="200" maxThreads="400" keepAlive="60s"
    stealPolicy="STRICT" rejectedWorkPolicy="CALLER_RUNS"/>
```

6. Copy the following WAR files to the apps directory of the Liberty server: *product_install_dir/WorklightServer/worklightadmin.war* and *product_install_dir/WorklightServer/worklightconsole.war*.

Note: The apps directory is in the same directory as the server.xml file.

7. Declare the Administration Services and MobileFirst Operations Console applications:

```

<!-- Declare the Administration Services application. -->
<application id="worklightadmin" name="worklightadmin" location="worklightadmin.war" type="war">
  <application-bnd>
    <security-role name="worklightadmin">
      <!-- This example adds a user to the worklightadmin security-role <user name="worklightUser"/>
    </security-role>
    <security-role name="worklightdeployer">
    </security-role>
    <security-role name="worklightmonitor">
    </security-role>
    <security-role name="worklightoperator">
    </security-role>
  </application-bnd>
  <classloader delegation="parentLast">
    <commonLibrary>
      <fileset dir="{wlp.install.dir}/lib" includes="com.ibm.ws.crypto.passwordutil_*.jar"/>
    </commonLibrary>
  </classloader>
</application>

<!-- Declare the MobileFirst Operations
Console application. -->
<application id="worklightconsole" name="worklightconsole" location="worklightconsole.war" type="war">
  <application-bnd>
    <security-role name="worklightadmin">
      <!-- This example adds a user to the worklightadmin security-role <user name="worklightUser"/>
    </security-role>
    <security-role name="worklightdeployer">
    </security-role>
    <security-role name="worklightmonitor">
    </security-role>
    <security-role name="worklightoperator">
    </security-role>
  </application-bnd>
</application>

<jndiEntry jndiName="worklightconsole/ibm.worklight.admin.endpoint" value="*://*/worklightadmin/

```

Note: For more information about how to configure a user registry for Liberty profile, see *Configuring a user registry for the Liberty profile*.

The JNDI property **worklightconsole/ibm.worklight.admin.endpoint** is prefixed by the context root of the MobileFirst Operations Console application, in this example `worklightconsole`. The value of this property is the end point to the MobileFirst administration.

The syntax `*://*/worklightadmin` means that the URL is the same as the one that is used to contact the MobileFirst Operations Console. However, the context root of the MobileFirst Operations Console is replaced by `worklightadmin`.

You might also specify the full endpoint, for example: `http://myhostname.mydomain.com:9080/worklightadmin`.

8. If the database is Oracle, add the **commonLibraryRef** attribute to the class loader of the `worklightadmin` application.

```

...
<classloader delegation="parentLast" commonLibraryRef="OracleLib">
  <commonLibrary>
...

```

The name of the library reference (`OracleLib` in this example) must be the ID of the library that contains the JDBC JAR file. This ID is declared in the procedure that is documented in *“Configuring Liberty profile for Oracle manually for MobileFirst Server administration”* on page 6-89.

9. If the database is Cloudant, add the following JNDI properties:

```
<!-- Declare the JNDI properties for the Administration Services application for Cloudant. -  
<jndiEntry jndiName="worklightadmin/mfp.db.cloudant.url" value="https://wuser.cloudant.com:4  
<jndiEntry jndiName="worklightadmin/mfp.db.cloudant.username" value="wuser"'/>  
<jndiEntry jndiName="worklightadmin/mfp.db.cloudant.password" value="password"'/>
```

- a. The JNDI properties are prefixed by the context root of the Administration Services application, in this example `worklightadmin`. If you select another value in a previous step, replace `worklightadmin` with that value.
- b. Replace `https://wuser.cloudant.com:443` with the URL to connect to Cloudant.
- c. Replace `wuser` with the name of the user who accesses the MobileFirst Server administration database. If this user is not allowed to create a database, you must create a database manually, with the names that are documented at “Creating the Cloudant database for MobileFirst Server administration” on page 6-62.
- d. Replace `password` with the password that is associated with this user. This password can be encoded with the Liberty profile `securityUtility` program. The supported encoding types are `xor` and `aes` (only with the default key).

Note: The default database name is `mfp_admin_db`. If you want to change the database name, add the following JNDI property:

```
<jndiEntry jndiName="worklightadmin/mfp.db.cloudant.adminDbName" value="'your_db_name"'/>
```

For a complete list of the JNDI properties that you can set, see “List of JNDI properties for MobileFirst Server administration” on page 6-111.

Configuring WebSphere Application Server for MobileFirst Server administration manually:

To configure WebSphere Application Server for IBM MobileFirst Platform Server administration manually, you must configure variables, custom properties, and class loader policies.

Before you begin

These instructions assume that a stand-alone profile exists with an application server named “Worklight” and that the server is using the default ports.

If you use Cloudant through `https` as a database, and WebSphere Application Server full profile as an application server, declare the Cloudant signer certificate, as described in “Configuring WebSphere Application Server for use with Cloudant” on page 6-68.

Procedure

1. Log on to the WebSphere Application Server administration console for your MobileFirst Server.
The address is of the form `http://server.com:9060/ibm/console`, where *server* is the name of the server.
2. Enable application security.
 - a. Click **Security > Global Security**.
 - b. Ensure that **Enable administrative security** is selected. Application security can be enabled only if administrative security is enabled.
 - c. Ensure that **Enable application security** is selected.

- d. Click **OK**.
- e. Save the changes.

For more information, see Enabling security in WebSphere Application Server user documentation.

3. Review the server class loader policy: Click **Servers > Server Types > WebSphere application servers**, and select the server used for IBM MobileFirst Platform Foundation.
 - If the class loader policy is set to **Multiple**, do nothing.
 - If the class loader policy is set to **Single** and the class loading mode is set to **parent-last**, do nothing.
 - If the class loader policy is set to **Single** and the class loading mode is set to **parent-first**, change the class loader policy to **Multiple**, and set the class loader order of all applications other than MobileFirst applications to **parent-first**.
4. For Derby, DB2, MySQL, or Oracle, create the MobileFirst Server administration JDBC data source and provider. See the instructions in the appropriate subsection in “Manually installing MobileFirst Server administration” on page 6-76.

Note: This step is not relevant for Cloudant.

5. If you install on WebSphere Application Server Network Deployment, find the SOAP port of the deployment manager by clicking System Administration/Deployment manager.
 - a. In **Additional properties**, open **Ports**.
 - b. Take note of the value `SOAP_CONNECTOR_ADDRESS`, because you need it to set the value of the `ibm.worklight.admin.jmx.dmgr.port` environment entry for the Administration Services.
6. Install the Administration Services WAR file:
 - a. Depending on your version of WebSphere Application Server, click one of the following options:
 - **Applications > New > New Enterprise Application**
 - **Applications > New Application > New Enterprise Application**
 - b. Go to the MobileFirst Server installation directory `product_install_dir/WorklightServer`.
 - c. Select **worklightadmin.war**, and then click **Next**.
 - d. On the How do you want to install the application? page, click **Detailed**, and then click **Next**.
 - e. On the Application Security Warnings page, click **Continue**.
 - f. Click **Next** until you reach the Map resource references to resources page, and enter the JNDI name of the data source that you created in step 4. If you want to use Cloudant, select the default data source. The data source is not used in this case.

To enter a default data source, enter `DefaultDatasource` in the **Name** field of the Target Resource JNDI. If the `DefaultDatasource` does not exist in your application server, a message displays the following message when you quit the page: “**Application Resource Warning**”. Ignore the warning and click **Continue**.
 - g. Click **Next** until you reach the Map context roots for web modules page.
 - h. In the **Context Root** field, type `/worklightadmin`.
 - i. Click **Next**.

- j. In Map environment entries for web modules:
 - If you install by using the Deployment Manager in the WebSphere Application Server Network Deployment product, enter the following values:
 - For the entry `ibm.worklight.admin.jmx.dmgr.host`, enter the host name of the deployment manager.
 - For the entry `ibm.worklight.admin.jmx.dmgr.port`, enter the SOAP port of the deployment manager that you noted in step 5.b.
 - For the entry `ibm.worklight.topology.platform`, enter WAS.
 - For the entry `ibm.worklight.topology.clustermode`, enter Cluster.
 - If you install on a stand-alone server:
 - For the entry `ibm.worklight.topology.platform`, enter WAS.
 - For the entry `ibm.worklight.topology.clustermode`, enter Standalone.
 - k. If you want to use Cloudant as the database for the MobileFirst Server administration, set the variables as follows:
 - `mfp.db.cloudant.url`: the URL to connect to Cloudant
 - `mfp.db.cloudant.username`: the Cloudant account user name

Note: If this user is not allowed to create a database, you must create a database manually, with the names that are documented at “Creating the Cloudant database for MobileFirst Server administration” on page 6-62.

 - `mfp.db.cloudant.password`: the Cloudant account password
 - The default database name is `mfp_admin_db`. If you want to change the database name, set the following JNDI property:
`mfp.db.cloudant.adminDbName`
 - For a complete list of the JNDI properties that you can set, see “List of JNDI properties for MobileFirst Server administration” on page 6-111.
 - l. Click **Next** until you reach the last step, and click **Finish**.
 - m. Click **Save**.
7. Configure the class loader policies for the Administration Services and then start the application:
- a. Click the **Manage Applications** link, or click **Applications > Applications Types > WebSphere enterprise applications**.
 - b. From the list of applications, click `worklightadmin_war`.
 - c. In the **Detail Properties** section, click the **Class loading and update detection** link.
 - d. In the **Class loader order** pane, click **Classes loaded with local class loader first (parent last)**.
 - e. Click **OK**.
 - f. In the **Detail Properties** section, click the **Startup behavior** link.
 - g. In **Startup Order**, enter 1, and click **OK**.
 - h. In the **Modules** section, click **Manage Modules**.
 - i. From the list of modules, click the **Worklight Administration Services** module.
 - j. In the **Class loader order** pane, click **Classes loaded with local class loader first (parent last)**.
 - k. Click **OK** twice.
 - l. Click **Save**.

- m. Select **worklightadmin_war** and click **Start**.
8. Install the IBM MobileFirst Platform Operations Console WAR file.
 - a. Depending on your version of WebSphere Application Server, click one of the following options:
 - **Applications > New > New Enterprise Application**
 - **Applications > New Application > New Enterprise Application**
 - b. Go to the MobileFirst Server installation directory *product_install_dir/WorklightServer*.
 - c. Select **worklightconsole.war**, and then click **Next**.
 - d. On the How do you want to install the application? page, click **Detailed**, and then click **Next**.
 - e. On the Application Security Warnings page, click **Continue**.
 - f. Click **Next** until you reach the Map context roots for web modules page.
 - g. In the **Context Root** field, type `/worklightconsole`.
 - h. Click **Next**.
 - i. In Map environment entries for web modules, enter the value `*://*:*/worklightadmin` for the entry `ibm.worklight.admin.endpoint`.
 - j. Click **Next** until you reach the last step, and click **Finish**.
 - k. Click **Save**.
9. Configure the class loader policies for the MobileFirst Operations Console and start the application:
 - a. Click the **Manage Applications** link, or click **Applications > Application Types > WebSphere enterprise applications**.
 - b. From the list of applications, click **worklightconsole_war**.
 - c. In the **Detail Properties** section, click the **Class loading and update detection** link.
 - d. In the **Class loader order** pane, click **Classes loaded with local class loader first (parent last)**.
 - e. Click **OK**.
 - f. In the **Detail Properties** section, click the **Startup behavior** link.
 - g. In **Startup Order**, enter 1, and click **OK**.
 - h. In the **Modules** section, click **Manage Modules**.
 - i. From the list of modules, click the **Worklight Console** module.
 - j. In the **Class loader order** pane, click **Classes loaded with local class loader first (parent last)**.
 - k. Click **OK** twice.
 - l. Click **Save**.
 - m. Click **Applications > Application Types > WebSphere enterprise applications**.
 - n. Select **Select** for **worklightconsole_war** and click **Start**.

What to do next

You must configure user authentication, as described in “Configuring user authentication for MobileFirst Server administration” on page 6-106. Then, you can access the MobileFirst Server administration at `http://<server>:<port>/worklightconsole`, where *server* is the host name of your server and *port* is the port number (by default 9080).

For more steps to configure MobileFirst Server administration, see “Configuring WebSphere Application Server full profile for MobileFirst Server administration” on page 6-108.

Configuring Apache Tomcat for MobileFirst Server administration manually:

To configure Apache Tomcat for the MobileFirst Server administration manually, you must copy JAR and WAR files to Tomcat, add database drivers, edit the `server.xml` file, and then start Tomcat.

Before you begin

Prerequisites:

- Configure the database for MobileFirst Server administration. For more information about various databases configuration, see “Manually installing MobileFirst Server administration” on page 6-76.
- Define the `CATALINA_OPTS` options to enable Java Management Extensions (JMX) as described in “Configuring Apache Tomcat” on page 6-65.

Procedure

1. Edit `tomcat_install_dir/conf/server.xml` file.

a. Uncomment the following element, which is initially commented out:

```
<Valve className="org.apache.catalina.authenticator.SingleSignOn" />
```

b. Declare the MobileFirst Operations Console and Administration Services applications and a user registry:

```
<!-- Declare the Administration Services application. -->  
<Context docBase="worklightadmin" path="/worklightadmin">
```

```
    <!-- Declare the JNDI environment entries for the Administration Services. -->  
    <Environment name="ibm.worklight.topology.platform" value="Tomcat" type="java.lang.String" />  
    <Environment name="ibm.worklight.topology.clusterMode" value="Standalone" type="java.lang.String" />
```

```
    <!-- Declare the administration database. -->  
    <!-- <Resource name="jdbc/WorklightAdminDS" type="javax.sql.DataSource" ... /> -->
```

```
</Context>
```

```
<!-- Declare the MobileFirst Platform Operations Console application. -->  
<Context docBase="worklightconsole" path="/worklightconsole">
```

```
    <!-- Declare the JNDI environment entries for the Operations Console. -->  
    <Environment name="ibm.worklight.admin.endpoint" value="*:*:*/*worklightadmin" type="java.lang.String" />  
</Context>
```

```
<!-- Declare the user registry for the MobileFirst Server administration.  
    The MemoryRealm recognizes the users defined in conf/tomcat-users.xml.  
    For other choices, see Apache Tomcat "Realm Configuration HOW-TO"  
    http://tomcat.apache.org/tomcat-7.0-doc/realms-howto.html . -->  
<Realm className="org.apache.catalina.realm.MemoryRealm"/>
```

Where, for Derby, DB2, MySQL, and Oracle, you must uncomment and complete the `<Resource>` element to declare the administration database as described in one of the following sections:

- “Configuring Apache Tomcat for DB2 manually for MobileFirst Server administration” on page 6-80
- “Configuring Apache Tomcat for Derby manually for the MobileFirst Server administration” on page 6-83

- “Configuring Apache Tomcat for MySQL manually for MobileFirst Server administration” on page 6-87
 - “Configuring Apache Tomcat for Oracle manually for MobileFirst Server administration” on page 6-91
- c. If you want to use Cloudant as the database for the MobileFirst Server administration, add the following JNDI properties inside the <Context docBase="worklightadmin" path="/worklightadmin"> element:

```
<Environment name="mfp.db.cloudant.url" value="https://wuser.cloudant.com:443" type="java.lang.String" override="false"/>
<Environment name="mfp.db.cloudant.username" value="wuser" type="java.lang.String" override="false"/>
<Environment name="mfp.db.cloudant.password" value="password" type="java.lang.String" override="false"/>
```

- Replace `https://wuser.cloudant.com:443` with the URL to connect to Cloudant.
- Replace `wuser` with the name of the user who accesses the MobileFirst Server administration database.

Note: If this user is not allowed to create a database, you must create a database manually, with the names that are documented at “Creating the Cloudant database for MobileFirst Server administration” on page 6-62.

- Replace `password` with the password that is associated with this user.

Note: The default database name is `mfp_admin_db`. If you want to change the database name, add a JNDI property:

```
<Environment name="mfp.db.cloudant.adminDbName" value="your_db_name" type="java.lang.String" override="false"/>
```

For a complete list of the JNDI properties that you can set, see “List of JNDI properties for MobileFirst Server administration” on page 6-111.

2. Copy the MobileFirst Server administration WAR files to Tomcat.

- On UNIX and Linux systems:

```
cp product_install_dir/WorklightServer/*.war tomcat_install_dir/webapps
```

- On Windows systems:

```
copy /B product_install_dir\WorklightServer\worklightconsole.war tomcat_install_dir\webapps\worklightconsole.war
copy /B product_install_dir\WorklightServer\worklightadmin.war tomcat_install_dir\webapps\worklightadmin.war
```

3. Start Tomcat.

What to do next

For more steps to configure the MobileFirst Server administration, see “Configuring Apache Tomcat for MobileFirst Server administration” on page 6-110.

Installations that are not stand alone: information for experts:

You can configure a clustered installation or a server-farm installation.

The other topics in “Deploying the Administration Services and MobileFirst Operations Console and configuring the application server manually” on page 6-92 explain how to configure MobileFirst Server administration for stand-alone web servers. Other options are a clustered installation or a server farm installation. In these installations, MobileFirst Server administration runs on several servers with a load balancer in front.

For installation of server farms, see “Installing a server farm” on page 6-138.

Clustered installations are currently only supported for WebSphere Application Server full profile.

Cluster mode

The JNDI property **ibm.worklight.topology.clusterMode** specifies the type of installation. You can set it to:

- Standalone
- Cluster
- Farm

If cluster mode is not set, the system tries to determine the cluster mode automatically, but the heuristic might fail. Therefore, you should specify this property correctly.

The lock master for the Cloudant database

In a server farm or a clustered installation, several servers run MobileFirst Server administration in parallel. For some operations, synchronization, among all servers in the farm or among all nodes in a cluster, is required. For example, when an application or adapter is deployed through MobileFirst Operations Console on one server, the other servers are not allowed to have the same operation done at the same time.

Synchronization is implemented through a lock mechanism similar to Java locks. Cloudant does not support database locks, so the chosen lock mechanism depends on the database and the cluster mode.

- • If the database is Derby, DB2, MySQL, or Oracle, a database lock mechanism is used. This mechanism does not require extra configuration.
- • If the database is Cloudant and the cluster mode is Standalone, an in-memory lock mechanism is used. This mechanism does not require extra configuration.
- • If the database is Cloudant and the cluster mode is Cluster or Farm, a distributed lock mechanism is used that requires one of the servers to be the lock master.

When the database is Cloudant and the lock master is required, the system tries to detect the lock master automatically. In a farm, if the server that acts as current lock master is shut down, then another server in the farm automatically takes the role of lock master.

Optionally, you can specify the lock master through the property **ibm.worklight.admin.lock.master** with the possible value true or false. In this case, it must be specified with true for only one of the servers and with false for all the other servers. The property can be specified as a JNDI property for the servers of a farm or as a Java Virtual Machine (JVM) property in a WebSphere Application Server full profile cluster, because, in such a cluster, all cluster members have the same JNDI properties.

If the property **ibm.worklight.admin.lock.master** is specified, note that:

- When the farm or cluster is started, the other servers wait until the lock master is started. In a server farm, you should start the lock master first.
- The lock master must be running to permit any deployment operations in MobileFirst Operations Console.
- The other servers do not automatically take the role of lock master when the lock master is shut down.

Defining the endpoint of the MobileFirst Administration services

If circumstances require the parameters of the endpoint definition to be changed, you must configure properties of the web application server appropriately.

MobileFirst Operations Console must be able to locate the MobileFirst Administration REST services and must be able to generate various URI for the entry points of web applications or for the download of audit log files.

By default, the URI protocol, host name, and port are the same as those defined in the web application server used to access MobileFirst Operations Console; the context root of the MobileFirst Administration REST services is `wrklightadmin`. When the context root of the MobileFirst Administration REST services is changed or when the internal URI of the web application server is different from the external URI, and the external URI is used to access MobileFirst Operations Console, the externally accessible endpoint (protocol, host name, and port) must be defined by configuring the web application server. Reasons for separating internal and external URI could be, for example, a firewall or a secured reverse proxy that uses HTTP redirection.

The following figure shows a configuration with a secured reverse proxy that hides the internal address (192.168...) when MobileFirst Operations Console is accessed with the external address (`wrklight.net`).

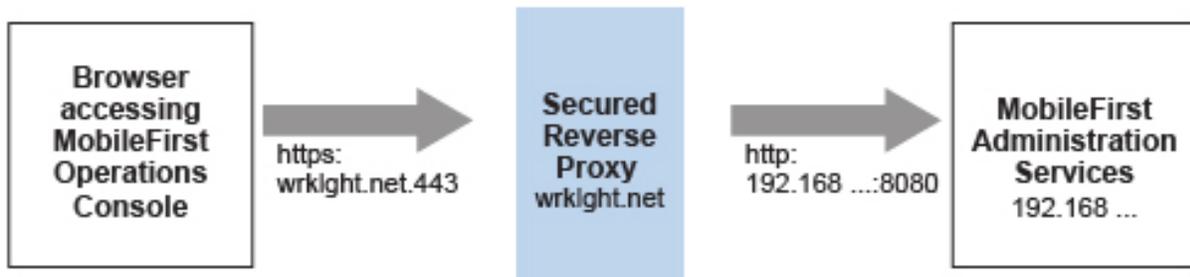

Figure 6-9. Configuration with secured reverse proxy

Table 6-21. The endpoint properties

Property name	Purpose	Example
ibm.worklight.admin.endpoint	This property enables MobileFirst Operations Console to locate the MobileFirst Administration REST services. The value of this property must be specified as the external address and context root of the worklightadmin.war web application. You can use the asterisk (*) character as wildcard for specifying that the MobileFirst Administration services use the same value as MobileFirst Operations Console. For example: <code>*://*:*/*/wladmin</code> means use the same protocol, host, and port as MobileFirst Operations Console, but use <code>wladmin</code> as context root. This property must be specified for the MobileFirst Operations Console application.	<code>https://wrk1ght.net:443/worklightadmin</code>
ibm.worklight.admin.proxy.protocol	If external access is required, this property specifies the protocol for external browsers to access the MobileFirst Administration services. This property must be specified for the MobileFirst Administration services application.	<code>https</code>
ibm.worklight.admin.proxy.host	If external access is required, this property specifies the host name for external browsers to access the MobileFirst Administration services. This property must be specified for the MobileFirst Administration services application.	<code>wrk1ght.net</code>
ibm.worklight.admin.proxy.port	If external access is required, this property specifies the port for external browsers to access the MobileFirst Administration services. This property must be specified for the MobileFirst Administration services application.	<code>443</code>

Configuring the endpoint (WebSphere Application Server full profile):

Configure the endpoint of the application resources in the environment entries of MobileFirst Operations Console and the MobileFirst Administration services application.

About this task

Follow this procedure when you must change the endpoint of the MobileFirst Administration services.

Procedure

1. Log in to the WebSphere Application Server console.
2. Select **Applications > Application Types > WebSphere enterprise applications**.
3. Click **Worklight Administration Services**.
4. In the “Web Module Properties” section, select “Environment entries for Web modules”.
5. Assign the appropriate values for the following environment entries:
 - a. For **ibm.worklight.admin.proxy.host**, assign the host name.
 - b. For **ibm.worklight.admin.proxy.port**, assign the port number.
 - c. For **ibm.worklight.admin.proxy.protocol**, assign the external protocol.
6. Click **OK** and save the configuration.
7. Select **Applications > Application Types > WebSphere enterprise applications**.
8. Click **Worklight Console**.
9. In the “Web Module Properties” section, select “Environment entries for Web modules”.
10. For **ibm.worklight.admin.endpoint**, assign the full URI of the MobileFirst Administration services; That is, the URI of the `worklightadmin.war` file.
 - In a scenario with a firewall or a secured reverse proxy, this URI must be the external URI and not the internal URI inside the local LAN.
 - You can use the asterisk (*) character as wildcard for specifying that the MobileFirst Administration services use the same value as MobileFirst Operations Console. For example, `*://*/*/wladmin` means use the same protocol, host, and port as MobileFirst Operations Console, but use `wladmin` as context root.
11. Click **OK** and save the configuration. For a complete list of JNDI properties that you can set, see “List of JNDI properties for MobileFirst Server administration” on page 6-111.

Configuring the endpoint (Liberty profile):

For the Liberty profile, configure the endpoint of the application resources through the JNDI environment.

About this task

Follow this procedure when you must change the endpoint of MobileFirst Administration services. The appropriate entries in the `server.xml` file must be correctly defined.

Procedure

1. Ensure that the <feature> element in the server.xml file is correctly defined to be able to define JNDI entries.

```
<feature>jndi-1.0</feature>
```

2. In the <server> section of the server.xml file, add an entry for each required property. Each such entry should have the following syntax:

```
<jndiEntry jndiName="JNDI_property_name" value="property_value"/>
```

Where:

- *JNDI_property_name* is the name of the property that you are adding.
- *property_value* is the value of the property that you are adding.

For a complete list of JNDI properties that you can set, see “List of JNDI properties for MobileFirst Server administration” on page 6-111.

Example of setting properties for configuring the endpoint

This example shows the settings of the properties in the server.xml file that are required for configuring the endpoint of the application resources.

```
<jndiEntry jndiName="worklightconsole/ibm.worklight.admin.endpoint"
  value="https://wrklght.net:443/worklightadmin" />
<jndiEntry jndiName="worklightadmin/ibm.worklight.admin.proxy.protocol"
  value="https" />
<jndiEntry jndiName="worklightadmin/ibm.worklight.admin.proxy.host"
  value="wrklght.net" />
<jndiEntry jndiName="worklightadmin/ibm.worklight.admin.proxy.port"
  value="443" />
```

In this example, assume that the context root of MobileFirst Operations Console is `worklightconsole` and that the context root of the Administration Services is `worklightadmin`. You can prefix the JNDI properties with the context root of the corresponding web application. If multiple instances of MobileFirst Server are running in the same web application server, this technique is particularly useful. If you have only one instance of MobileFirst Server, you can omit the context root prefix; for example:

```
<jndiEntry jndiName="ibm.worklight.admin.endpoint"
  value="https://wrklght.net:443/worklightadmin" />
<jndiEntry jndiName="ibm.worklight.admin.proxy.protocol"
  value="https" />
<jndiEntry jndiName="ibm.worklight.admin.proxy.host"
  value="wrklght.net" />
<jndiEntry jndiName="ibm.worklight.admin.proxy.port"
  value="443"/>
```

For **ibm.worklight.admin.endpoint**, you can use the asterisk (*) character as wildcard for specifying that the MobileFirst Administration services use the same value as MobileFirst Operations Console. For example, `*://*:*/wladmin` means use the same protocol, host, and port as MobileFirst Operations Console, but use `wladmin` as context root.

Configuring the endpoint (Apache Tomcat):

For the Apache Tomcat server, configure the endpoint of the application resources in the server.xml file.

About this task

Follow this procedure when you must change the endpoint of the MobileFirst Administration services. You must edit the `server.xml` file in the `conf` directory of your Apache Tomcat installation.

Procedure

In the `server.xml` file in the `conf` directory of your Apache Tomcat installation, add an entry for each property in the `<context>` section of the corresponding application. Each entry should have the following syntax:

```
<Environment name="JNDI_property_name" value="property_value" type="property_type" override="false"/>
```

Where:

- *JNDI_property_name* is the name of the property that you are adding.
- *property_value* is the value of the property that you are adding.
- *property_type* is the value of the type of property that you are adding.

For a complete list of JNDI properties that you can set, see “List of JNDI properties for MobileFirst Server administration” on page 6-111.

Example of setting `server.xml` properties for configuring the endpoint

This example shows the settings of the properties in the `server.xml` file that are required for configuring the endpoint of the application resources.

In the `context` section of the MobileFirst Operations Console application:

```
<Environment name="ibm.worklight.admin.endpoint" value="https://wrklight.net:443/worklightadmin" type="java.lang.String" override="false"/></p>
```

For **`ibm.worklight.admin.endpoint`**, you can use the asterisk (*) character as wildcard for specifying that the MobileFirst Administration services use the same value as MobileFirst Operations Console. For example, `*://*:*/*/wladmin` means use the same protocol, host, and port as MobileFirst Operations Console, but use `wladmin` as context root.

In the `<context>` section of the MobileFirst Administration Services application, you can write:

```
<Environment name="ibm.worklight.admin.proxy.protocol" value="https" type="java.lang.String" override="false"/>
<Environment name="ibm.worklight.admin.proxy.host" value="wrklight.net" type="java.lang.String" override="false"/>
<Environment name="ibm.worklight.admin.proxy.port" value="443" type="java.lang.Integer" override="false"/>
```

Configuring user authentication for MobileFirst Server administration

You configure user authentication and choose an authentication method. The configuration procedure depends on the web application server that you use.

The MobileFirst Server administration requires user authentication.

You configure user authentication after the installer deploys the MobileFirst Server administration web applications in the web application server.

The MobileFirst Server administration has the following Java Platform, Enterprise Edition (Java EE) security roles defined:

worklightadmin
worklightdeployer
worklightoperator
worklightmonitor

You must map the roles to the corresponding sets of users. The **worklightmonitor** role can view data but cannot change any data. The purpose of the roles is illustrated by the following table.

Table 6-22. MobileFirst Roles and Functionality - Production Server

	Administrator	Deployer	Operator	Monitor
Java EE security role.	worklightadmin	worklightdeployer	worklightoperator	worklightmonitor
Deployment				
Deploy an application.	Yes	Yes	No	No
Deploy an adapter.	Yes	Yes	No	No
MobileFirst Server Management				
Configure runtime settings.	Yes	Yes	No	No
Application Management				
Upload new MobileFirst application.	Yes	Yes	No	No
Remove MobileFirst application.	Yes	Yes	No	No
Upload new MobileFirst adapter.	Yes	Yes	No	No
Remove MobileFirst adapter.	Yes	Yes	No	No
Turn on or off application authenticity testing for an application.	Yes	Yes	No	No
Change properties on MobileFirst application status: Active, Active Notifying, and Disabled.	Yes	Yes	Yes	No

Table 6-22. MobileFirst Roles and Functionality - Production Server (continued)

	Administrator	Deployer	Operator	Monitor
Lock an application so the new artifacts cannot be used for a version.	Yes	Yes	Yes	No
Notifications				
Unsubscribe a device from SMS notification.	Yes	Yes	Yes	Yes
Configure Push.	Yes	Yes	Yes	Yes
Logging				
Enable and disable device logging remotely.	Yes	Yes	Yes	No
Configure log levels.	Yes	Yes	Yes	No
Disable the specific device, marking the state as lost or stolen so that access from any of the applications on that device is blocked.	Yes	Yes	Yes	No
Disable a specific application, marking the state as disabled so that access from the specific application on that device is blocked.	Yes	Yes	No	No

If you choose to use an authentication method through a user repository such as LDAP, you can configure the MobileFirst Server administration so that you can use users and groups with the user repository to define the Access Control List (ACL) of the MobileFirst Server administration. This procedure is conditioned by the type and version of the web application server that you use.

Configuring WebSphere Application Server full profile for MobileFirst Server administration:

Configure security by mapping the MobileFirst Server administration Java EE roles to a set of users for both web applications.

Procedure

You define the basics of user configuration in the WebSphere Application Server console. Access to the console is usually by this address:
<https://localhost:9043/ibm/console/>

1. Select **Security > Global Security**.
2. Select **Security Configuration Wizard** to configure users.
You can manage individual user accounts by selecting **Users and Groups > Manage Users**.
3. Map the roles **worklightadmin**, **worklightdeployer**, **worklightmonitor**, and **worklightoperator** to a set of users.
 - a. Select **Servers > Server Types > WebSphere application servers**.
 - b. Select the server.
 - c. In the **Configuration** tab, select **Applications > Enterprise applications**.
 - d. Select **IBM_Worklight_Administration_Services**.
 - e. In the **Configuration** tab, select **Details > Security role to user/group mapping**.
 - f. Perform the necessary customization.
 - g. Click **OK**.
 - h. Repeat steps c to g to map the roles for the console web application. In step d, select **IBM_Worklight_Console**.
 - i. Click **Save** to save the changes.

Configuring WebSphere Application Server Liberty profile for MobileFirst Server administration:

Configure the Java EE security roles of the MobileFirst Server administration and the data source in the `server.xml` file.

Before you begin

In WebSphere Application Server Liberty profile, you configure the roles of **worklightadmin**, **worklightdeployer**, **worklightmonitor**, and **worklightoperator** in the `server.xml` configuration file of the server.

About this task

To configure the security roles, you must edit the `server.xml` file. In the `<application-bnd>` element of each `<application>` element, create `<security-role>` elements. Each `<security-role>` element is for each roles: **worklightadmin**, **worklightdeployer**, **worklightmonitor**, and **worklightoperator**. Map the roles to the appropriate user group name, in this example: **worklightadmingroup**, **worklightdeployergroup**, **worklightmonitorgroup**, or **worklightoperatorgroup**. These groups are defined through the `<basicRegistry>` element. You can customize this element or replace it entirely with an `<ldapRegistry>` element or a `<safRegistry>` element.

Then, to maintain good response times with a large number of installed applications, for example with 80 applications, you should configure a connection pool for the administration database.

Procedure

1. Edit the server.xml file.

For example:

```
<security-role name="worklightadmin">
  <group name="worklightadmingroup"/>
</security-role>
<security-role name="worklightdeployer">
  <group name="worklightdeployergroup"/>
</security-role>
<security-role name="worklightmonitor">
  <group name="worklightmonitorgroup"/>
</security-role>
<security-role name="worklightoperator">
  <group name="worklightoperatorgroup"/>
</security-role>
```

```
<basicRegistry id="worklightadmin">
  <user name="admin" password="admin"/>
  <user name="guest" password="guest"/>
  <user name="demo" password="demo"/>
  <group name="worklightadmingroup">
    <member name="guest"/>
    <member name="demo"/>
  </group>
  <group name="worklightdeployergroup">
    <member name="admin" id="admin"/>
  </group>
  <group name="worklightmonitorgroup"/>
  <group name="worklightoperatorgroup"/>
</basicRegistry>
```

2. Edit the server.xml file to define the **AppCenterPool** size.

```
<connectionManager id="AppCenterPool" minPoolSize="10" maxPoolSize="40"/>
```

3. In the <dataSource> element, define a reference to the connection manager:

```
<dataSource id="WLADMIN" jndiName="jdbc/WorklightAdminDS" connectionManagerRef="AppCenterPool">
  ...
</dataSource>
```

Configuring Apache Tomcat for MobileFirst Server administration:

You must configure the Java EE security roles for the MobileFirst Server administration on the Apache Tomcat web application server.

Procedure

1. If you installed the MobileFirst Server administration manually, declare the following roles in the conf/tomcat-users.xml file.

```
<role rolename="worklightadmin"/>
<role rolename="worklightmonitor"/>
<role rolename="worklightdeployer"/>
<role rolename="worklightoperator"/>
```

2. Add roles to the selected users, for example:

```
<user name="demo" password="demo" roles="worklightadmin"/>
```

3. You can define the set of users as described in the Apache Tomcat documentation, Realm Configuration HOW-TO.

Declaring the Cloudant SSL configuration for the MobileFirst Server administration

If you install the MobileFirst Server administration into WebSphere Application Server or WebSphere Application Server Network Deployment, you use a Cloudant database, and meet specific criteria described in this topic, you must declare the Cloudant SSL configuration.

About this task

You must perform this procedure if you meet all of the following criteria:

- You are installing the MobileFirst Server administration into WebSphere Application Server or WebSphere Application Server Network Deployment.
- You use a Cloudant database for the MobileFirst Server administration.
- The Cloudant database server URL uses the https protocol.
- You created a separate SSL configuration for Cloudant, as described in “Configuring WebSphere Application Server for use with Cloudant” on page 6-68, but did not create a dynamic outbound configuration for it.

Procedure

1. Log in to the WebSphere Application Server console.
2. Select **Applications > Application Types > WebSphere enterprise applications**.
3. Click **Worklight Administration Services**.
4. In the **Web Module Properties** section, select **Environment entries for Web modules**.
5. Set the value of the property `mfp.db.cloudant.ssl.configuration` to the name of the SSL configuration that you created.
6. Click **OK**.
7. Click **Save**.

List of JNDI properties for MobileFirst Server administration

When you configure MobileFirst Server Administration Services and MobileFirst Operations Console for your application server, you set optional or mandatory JNDI properties, in particular for Java Management Extensions (JMX).

JNDI properties for MobileFirst Administration Services

The following properties can be set on the Administration Services web application `worklightadmin.war`.

Table 6-23. JNDI properties for Administration Services: JMX

Property	Optional or mandatory	Description	Restrictions
<code>ibm.worklight.admin.jmx.connector</code>	Optional	The Java Management Extensions (JMX) connector type. The possible values are SOAP and RMI. The default value is SOAP.	WebSphere Application Server only.

Table 6-23. JNDI properties for Administration Services: JMX (continued)

Property	Optional or mandatory	Description	Restrictions
ibm.worklight.admin.jmx.host	Optional	Host name for the JMX REST connection.	Liberty profile only.
ibm.worklight.admin.jmx.port	Optional	Port for the JMX REST connection.	Liberty profile only.
ibm.worklight.admin.jmx.user	Optional	User name for the JMX REST connection.	<p>WebSphere Application Server Liberty profile: User name for the JMX REST connection.</p> <p>WebSphere Application Server Farm: User name for the SOAP connection.</p> <p>WebSphere Application Server Network Deployment: user name of the WebSphere administrator if the virtual host mapped to the MobileFirst server administration application is not the default host.</p>

Table 6-23. JNDI properties for Administration Services: JMX (continued)

Property	Optional or mandatory	Description	Restrictions
ibm.worklight.admin.jmx.pwd	Optional	User password for the JMX REST connection.	WebSphere Application Server Liberty profile: User password for the JMX REST connection. WebSphere Application Server Farm: User password for the SOAP connection. WebSphere Application Server Network Deployment: User password of the WebSphere administrator if the virtual host that is mapped to the MobileFirst Server server administration application is not the default host.
ibm.worklight.admin.rmi.registryPort	Optional	RMI registry port for the JMX connection through a firewall.	Tomcat only.
ibm.worklight.admin.rmi.serverPort	Optional	RMI server port for the JMX connection through a firewall.	Tomcat only.
ibm.worklight.admin.jmx.dmgr.host	Mandatory	Deployment manager host name.	WebSphere Application Server Network Deployment only.
ibm.worklight.admin.jmx.dmgr.port	Mandatory	Deployment manager RMI or SOAP port.	WebSphere Application Server Network Deployment only.

Table 6-24. JNDI properties for Administration Services: time out

Property	Optional or mandatory	Description
ibm.worklight.admin.actions.prepareTimeOut	Optional	Timeout in milliseconds to transfer data from the management service to the runtime during a deployment transaction. If the runtime cannot be reached within this time, an error is raised and the deployment transaction ends. Default value: 1800000 ms (30 min)

Table 6-24. JNDI properties for Administration Services: time out (continued)

Property	Optional or mandatory	Description
<code>ibm.worklight.admin.actions.commitRejectTimeout</code>	Optional	Timeout in milliseconds, when a runtime is contacted, to commit or reject a deployment transaction. If the runtime cannot be reached within this time, an error is raised and the deployment transaction ends. Default value: 120000 ms (2 min)
<code>ibm.worklight.admin.lockTimeoutInMs</code>	Optional	Timeout in milliseconds for obtaining the transaction lock. Because deployment transactions run sequentially, they use a lock. Therefore, a transaction must wait until a previous transaction is finished. This timeout is the maximal time during which a transaction waits. Default value: 1200000 ms (20 min)
<code>ibm.worklight.admin.maxLockTimeInMs</code>	Optional	The maximal time during which a process can take the transaction lock. Because deployment transactions run sequentially, they use a lock. If the application server fails while a lock is taken, it can happen in rare situations that the lock is not released at the next restart of the application server. In this case, the lock is released automatically after the maximum lock time so that the server is not blocked forever. Set a time that is longer than a normal transaction. Default value: 1800000 (30 min)

Table 6-25. JNDI properties for Administration Services: logging

Property	Optional or mandatory	Description
<code>ibm.worklight.admin.logging.formatjson</code>	Optional	Set this property to true to enable pretty formatting (extra blank space) of JSON objects in responses and log messages. Setting this property is helpful when you debug the server. Default value: false.
<code>ibm.worklight.admin.logging.toSystemError</code>	Optional	Specifies whether all logging messages are also directed to System.Error. Setting this property is helpful when you debug the server.

Table 6-26. JNDI properties for Administration Services: proxies

Property	Optional or mandatory	Description
ibm.worklight.admin.proxy.port	Optional	If the MobileFirst Administration server is behind a firewall or reverse proxy, this property specifies the address of the host. Set this property to enable a user outside the firewall to reach the MobileFirst Administration server. Typically, this property is the port of the proxy, for example 443. It is necessary only if the protocol of the external and internal URIs are different.
ibm.worklight.admin.proxy.protocol	Optional	If the MobileFirst Administration server is behind a firewall or reverse proxy, this property specifies the protocol (HTTP or HTTPS). Set this property to enable a user outside the firewall to reach the MobileFirst Administration server. Typically, this property is set to the protocol of the proxy. For example, wl.net. This property is necessary only if the protocol of the external and internal URIs are different.
ibm.worklight.admin.proxy.scheme	Optional	This property is just an alternative name for ibm.worklight.admin.proxy.protocol .
ibm.worklight.admin.proxy.host	Optional	If the MobileFirst Administration server is behind a firewall or reverse proxy, this property specifies the address of the host. Set this property to enable a user outside the firewall to reach the MobileFirst Administration server. Typically, this property is the address of the proxy.

Table 6-27. JNDI properties for Administration Services: topologies

Property	Optional or mandatory	Description
ibm.worklight.admin.audit	Optional.	Set this property to false to disable the audit feature of the MobileFirst Operations Console. The default value is true.
ibm.worklight.admin.environmentid	Optional.	Environment identifier for the registration of the MBeans. Use this identifier when different instances of the MobileFirst Server are installed on the same application server. The identifier determines which Administration Services, which console, and which runtimes belong to the same installation. The Administration Services manage only the runtimes that have the same environment identifier.
ibm.worklight.admin.serverid	Optional.	Server identifier. Must be different for each server in the farm. For server farms only.

Table 6-27. JNDI properties for Administration Services: topologies (continued)

Property	Optional or mandatory	Description
ibm.worklight.admin.hsts	Optional.	Set to true to enable HTTP Strict Transport Security according to RFC 6797.
ibm.worklight.topology.platform	Mandatory	Server type. Valid values: <ul style="list-style-type: none"> • Liberty • WAS for WebSphere Application Server • Tomcat If you do not set the value, the application tries to guess the server type.
ibm.worklight.topology.clustermode	Mandatory	In addition to the server type, specify here the server topology. Valid values: <ul style="list-style-type: none"> • Standalone • Cluster • Farm The default value is Standalone.

Table 6-27. JNDI properties for Administration Services: topologies (continued)

Property	Optional or mandatory	Description
ibm.worklight.admin.lock.master	Optional	<p>In cluster and farm topologies, this property determines which server is the lock master when the Cloudant database is used.</p> <p>For synchronization, the system requires a locking mechanism that works across all servers in the farm or cluster.</p> <p>SQL data bases have native locking facilities, but Cloudant has none. Therefore, with Cloudant only one of the servers in the farm or cluster provides the locking mechanism. This server is called the lock master.</p> <p>Alternative ways of using this property are available:</p> <ul style="list-style-type: none"> • You set this property to auto on all servers. The locking master is chosen and updated dynamically, depending on server availability. • You set this property to true on one server only and to false on all the other servers. In this configuration, the server where the property has the value true is the lock master. <p>In WebSphere Application Server Network Deployment topologies, setting the property to true must be done through a JVM property of the server.</p> <p>Note: This use creates a single point of failure. When the lock master is unavailable, MobileFirst Administration does not function.</p> <p>The default value is auto.</p>

Table 6-27. JNDI properties for Administration Services: topologies (continued)

Property	Optional or mandatory	Description
ibm.worklight.admin.lock.master.detection.delay	Optional	<p>This property determines the time in milliseconds to wait on startup until Cloudant is ready, before any locking operation can take place. This property is only needed in cluster or farm topology when the database is Cloudant. For synchronization, the system requires a locking mechanism that works across all servers in the farm or cluster.</p> <p>SQL databases have native locking facilities, but Cloudant has none. Therefore, with Cloudant one of the servers in the farm or cluster provides the locking mechanism.</p> <p>This lock master server can be selected automatically with the help of the database. This automatic selection requires a small delay, similar to the setting of mfp.db.cloudant.afterWrite.delay, to ensure that the Cloudant database is in a consistent state. This delay occurs only once when the server starts. Reasonable values are between 1 and 10 seconds. Negative values are ignored. The default value is 3000 (three seconds).</p>
ibm.worklight.admin.lock.master.detection.timeout	Optional	<p>This property determines the timeout in seconds for the detection of the lock master. This property is only needed in cluster or farm topology when the database is Cloudant. For synchronization, the system requires a locking mechanism that works across all servers in the farm or cluster.</p> <p>SQL databases have native locking facilities, but Cloudant has none. Therefore, with Cloudant one of the servers in the farm or cluster provides the locking mechanism.</p> <p>During startup, the lock master server must come alive before all the other servers. Therefore, the other servers wait for this server before they complete their startup.</p> <p>This timeout value specifies the maximum time another server waits for the lock master to come alive. Negative values are ignored. The default value is 120 (two minutes).</p>

Table 6-27. JNDI properties for Administration Services: topologies (continued)

Property	Optional or mandatory	Description
ibm.worklight.admin.lock.master.connection.timeout	Optional	<p>This property determines the timeout in seconds for the connection to the lock master. This property is only needed in cluster or farm topology when the database is Cloudant. For synchronization, the system requires a locking mechanism that works across all servers in the farm or cluster.</p> <p>SQL databases have native locking facilities, but Cloudant has none. Therefore, with Cloudant one of the servers in the farm or cluster provides the locking mechanism. That server is called the lock master.</p> <p>The timeout value specifies the maximum time another server waits for the lock master to respond to requests to take a lock. Negative values are ignored. The default value is 10 (seconds).</p>
ibm.worklight.admin.farm.heartbeat	Optional	<p>This property enables you to set in minutes the heartbeat rate that is used in server farm topologies.</p> <p>The default value is 2 minutes.</p> <p>In a server farm, all members must use the same heartbeat rate. If you set or change this JNDI value on one server in the farm, you must also set the same value on every other server in the farm.</p> <p>For more information, see “Lifecycle of a server farm node” on page 6-145.</p>
ibm.worklight.admin.farm.missed.heartbeat.timeout	Optional	<p>This property enables you to set the number of missed heartbeats of a farm member before the status of the farm member is considered to be failed or down.</p> <p>The default value is 2.</p> <p>In a server farm all members must use the same missed heartbeat value. If you set or change this JNDI value on one server in the farm, you must also set the same value on every other server in the farm.</p> <p>For more information, see “Lifecycle of a server farm node” on page 6-145.</p>
ibm.worklight.admin.farm.reinitialization	Optional	<p>A Boolean value (true or false) for re-registering or re-initializing the farm member.</p>

Table 6-27. JNDI properties for Administration Services: topologies (continued)

Property	Optional or mandatory	Description
ibm.worklight.admin.cloudant.dashboard.url	Optional	This property defines the URL of the Cloudant dashboard, such as the dashboard of the Cloudant account that you use for the MobileFirst data proxy. If this property is set, a link will be displayed in the header of MobileFirst Operations Console.

Table 6-28. JNDI properties for Administration Services: relational database

Property	Optional or mandatory	Description
ibm.worklight.admin.db.jndi.name	Optional	The JNDI name of the database. This parameter is the normal mechanism to specify the database. The default value is <code>java:comp/env/jdbc/WorklightAdminDS</code> .
ibm.worklight.admin.db.openjpa.connectionDriverName	Conditionally mandatory	The fully qualified name of the database connection driver class. Mandatory only when the data source that is specified by the ibm.worklight.admin.db.jndi.name property is not defined in the application server configuration.
ibm.worklight.admin.db.openjpa.connectionURL	Conditionally mandatory	The URL for the database connection. Mandatory only when the data source that is specified by the ibm.worklight.admin.db.jndi.name property is not defined in the application server configuration.
ibm.worklight.admin.db.openjpa.connectionUserName	Conditionally mandatory	The user name for the database connection. Mandatory only when the data source that is specified by the ibm.worklight.admin.db.jndi.name property is not defined in the application server configuration.
ibm.worklight.admin.db.openjpa.connectionPassword	Conditionally mandatory	The password for the database connection. Mandatory only when the data source that is specified by the ibm.worklight.admin.db.jndi.name property is not defined in the application server configuration.

Table 6-28. JNDI properties for Administration Services: relational database (continued)

Property	Optional or mandatory	Description
<code>ibm.worklight.admin.db.openjpa.logging</code>	Optional	This property is passed to OpenJPA and enables JPA logging. For more information, see the Apache OpenJPA User's Guide.
<code>ibm.worklight.admin.db.type</code>	Optional	This property defines the type of database. The default value is inferred from the connection URL.

Table 6-29. JNDI properties for Administration Services: IBM Cloudant database.

Property	Optional or mandatory	Description
<code>mfp.db.cloudant.url</code>	Optional	This property defines the URL of the Cloudant account used to store the database. The default value is <code>https://username.cloudant.com</code> .
<code>mfp.db.cloudant.username</code>	Optional Conditionally mandatory	This property defines the user name of the Cloudant account used to store the database. If this property is not defined, a relational database is used.
<code>mfp.db.cloudant.password</code>	Optional Conditionally mandatory	This property defines the password of the Cloudant account used to store the database. This property must be set when <code>mfp.db.cloudant.username</code> is set.
<code>mfp.db.cloudant.ssl.authentication</code>	Optional	This property specifies whether the SSL certificate chain validation and host name verification are enabled for HTTPS connections to the Cloudant database. The value is a Boolean value (true or false). The default value is true. Note: Setting this property to false creates security risks.

Table 6-29. JNDI properties for Administration Services: IBM Cloudant database (continued).

Property	Optional or mandatory	Description
mfp.db.cloudant.ssl.configuration	Optional	This property applies to WebSphere Application Server full profile only. For HTTPS connections to the Cloudant database, it specifies the name of an SSL configuration in the WebSphere Application Server configuration to use when no configuration is specified for the host and port.
mfp.db.cloudant.proxyHost	Optional	This property defines the host name of an HTTP proxy for the connection to the Cloudant database server.
mfp.db.cloudant.proxyPort	Optional	This property defines the port of an HTTP proxy for the connection to the Cloudant database server.
mfp.db.cloudant.adminDbName	Optional	This property defines the name of the database for MobileFirst Administration Services in the Cloudant account. The name must start with a lowercase letter and contain only lowercase letters and any of the following characters: 0-9 , \$ - _ The default name is <code>mfp_admin_db</code> .
mfp.db.cloudant.connectTimeout	Optional	This property defines the timeout in milliseconds for establishing a network connection for Cloudant. A value of zero means an infinite timeout. A negative value means the default value (no override).
mfp.db.cloudant.socketTimeout	Optional	This property defines the timeout in milliseconds for detecting the loss of a network connection for Cloudant. A value of zero means an infinite timeout. A negative value means the default value (no override).
mfp.db.cloudant.maxConnections	Optional	This property defines the maximum number of simultaneous connections to the Cloudant database.

Table 6-29. JNDI properties for Administration Services: IBM Cloudant database (continued).

Property	Optional or mandatory	Description
mfp.db.cloudant.afterWrite.fullCommit	Optional	This property specifies whether an "ensure full commit" operation is used after every write operation to the Cloudant database. The possible values are: true, false. The default value is false.
mfp.db.cloudant.afterWrite.delay	Optional	This property specifies in milliseconds how long to wait after every write operation to the Cloudant database. A value of zero means no wait. The default value is 0.
mfp.db.cloudant.retry.count	Optional	This property specifies the number of times to retry a Cloudant database query operation until it satisfies the expectations known from the context. The default value is 2.
mfp.db.cloudant.retry.delay	Optional	This property specifies in milliseconds how long to wait before retrying a Cloudant database query operation. A value of 0 means no wait. The default value is 0.
mfp.db.cloudant.documentOperationTimeout	Optional	This property specifies in seconds the timeout for the completion of operations on Cloudant documents. A value of zero means an infinite timeout. A negative value means the default value (no override). The default value is 30 seconds.
mfp.db.cloudant.attachmentOperationTimeout	Optional	This property specifies in seconds the timeout for the completion of operations on Cloudant attachments. A value of zero means an infinite timeout. A negative value means the default value (no override). The default value is 600 seconds (10 minutes).

Table 6-30. JNDI properties for Administration Services: licensing.

Property	Optional or mandatory	Description
<code>ibm.worklight.admin.license.key.server.host</code>	Optional (For Perpetual license) • Mandatory (For Token license)	Host name of the Rational License Key Server.
<code>ibm.worklight.admin.license.key.server.port</code>	Optional (For Perpetual license) • Mandatory (For Token license)	Port number of the Rational License Key Server.

JNDI properties for MobileFirst Operations Console

The following properties can be set on the web application (`worklightconsole.war`) of MobileFirst Operations Console.

Table 6-31. JNDI properties for the MobileFirst Operations Console

Property	Optional or mandatory	Description
<code>ibm.worklight.admin.endpoint</code>	Optional	Enables the MobileFirst Operations Console to locate the MobileFirst Server Administration REST services. Specify the external address and context root of the <code>worklightadmin.war</code> web application. In a scenario with a firewall or a secured reverse proxy, this URI must be the external URI and not the internal URI inside the local LAN. For example, <code>https://wl.net:443/worklightadmin</code> .
<code>ibm.worklight.admin.global.logout</code>	Optional	Clears the WebSphere user authentication cache during the console logout. This property is useful only for WebSphere Application Server V7. The default value is false.
<code>ibm.worklight.admin.hsts</code>	Optional	Set this property to true to enable HTTP Strict Transport Security according to RFC 6797. For more information, see the W3C Strict Transport Security page. The default value is false.
<code>ibm.worklight.admin.ui.cors.enabled</code>	Optional	The default value is true. For more information, see the W3C Cross-Origin Resource Sharing page.
<code>ibm.worklight.admin.ui.cors.originals1</code>	Optional	Set to false to allow CORS situations where the MobileFirst Operations Console is secured with SSL (HTTPS protocol) while the MobileFirst Server Administration services are not, or conversely. This property takes effect only if the <code>ibm.worklight.admin.ui.cors.enabled</code> property is enabled.

Configuring the JNDI properties

For more information about how to configure the JNDI properties, see the topic “JNDI environment entries for MobileFirst projects in production” on page 12-68.

To configure the properties with Ant tasks, you must use the Ant task **installworklightadmin**, instead of **configureapplicationserver**.

For the console, the property element should be under the console element.

For more information, see “Ant tasks for installation of MobileFirst Operations Console and Administration Services” on page 16-34.

Related information:

JNDI environment entries for MobileFirst projects in production

Verifying the installation of MobileFirst Server administration

You must log in to the MobileFirst Operations Console to verify that the installation was successful.

Procedure

1. Open a web browser.
2. Enter the following URL in the address bar: `http://hostname:9083/worklightconsole/`.

Note:

- In this URL, *hostname* is the host name of the computer that runs your application server.
 - You must replace *9083* by the HTTP port of your application server.
3. Log in with a **worklightadmin** user role.
 4. The console displays the following message: **No runtime can be found..** To install a MobileFirst runtime environment that you can manage with the MobileFirst Operations Console, see “Installing the MobileFirst runtime environment.”

Note: If the Application Center and MobileFirst Operations Console are installed in the same Tomcat instance, you cannot log in to the Application Center console and to the MobileFirst Operations Console at the same time in the same browser. If you try to log in at the same time, you get a 404 Page Not Found error message.

For example, you get this error message if you open your browser, successfully log in to the Application Center console, open a new tab in the browser, and log in to the MobileFirst Operations Console.

This is a technical limitation of Tomcat. The implementation of single sign-on in Tomcat does not allow to use the same browser to log in to the Application Center console and to the MobileFirst Operations Console at the same time. But the Application Center and MobileFirst Server require single sign-on. You must exit the browser after your work is done in the Application Center console and restart the browser to log in to the MobileFirst Operations Console. You can then successfully log in to the MobileFirst Operations Console.

Installing the MobileFirst runtime environment

About this task

For more information about the MobileFirst runtime environment, see “Deploying the project WAR file” on page 12-5.

Installing and configuring for token licensing

If you plan to use token licensing for MobileFirst Server, you must install the Rational Common Licensing library and configure your application server to connect MobileFirst Server to the Rational License Key Server.

The following topics describe the installation overview, the manual installation of Rational Common Licensing library, the configuration of the application server, and the platform limitations for token licensing.

Installation overview for token licensing

The installation process overview for the use of IBM MobileFirst Platform Foundation with token licensing enabled

About this task

If you intend to use token licensing with IBM MobileFirst Platform Foundation, make sure that you go through the following preliminary steps in this order.

Important:

- The ability to activate token licensing is not available in IBM MobileFirst Platform Foundation V7.1.0 and the interim fixes that are delivered before 14 September 2015. If the graphic mode installation does not display the **Token Licensing** panel, or if the silent installation with `imcl` does not confirm that token licensing is activated, then the token licensing is not activated. The installation is then not compliant with token licensing. To resolve the problem, you need to download IBM MobileFirst Platform Foundation V7.1.0 from Passport Advantage, or the interim fix 7.1.0.0-MFPF-IF201509132345 dated 15 September 2015.
- Your choice about token licensing (activating it or not) as part of an installation or upgrade that supports token licensing cannot be modified. If later you need to change the token licensing option, you must uninstall IBM MobileFirst Platform Foundation and reinstall it. If the product is installed with an installer without token licensing support, you can activate the feature at the first upgrade with an interim fix or a release that supports token licensing. The choice to activate token licensing is provided when you make the first upgrade with the interim fix 7.1.0.0-MFPF-IF201509132345 dated 15 September 2015, or a release that has token licensing support.

Procedure

1. Review “Planning for the use of token licensing” on page 6-34 before you start the installation of the product.
2. When you run IBM Installation Manager to install IBM MobileFirst Platform Foundation, you must activate token licensing. For more information about running IBM Installation Manager, see “Running IBM Installation Manager” on page 6-43. To enable token licensing, do the following steps:

Graphic mode installation

If you install the product in graphic mode, select **Activate token licensing with the Rational License Key Server** option in the **Token Licensing** section during the installation.

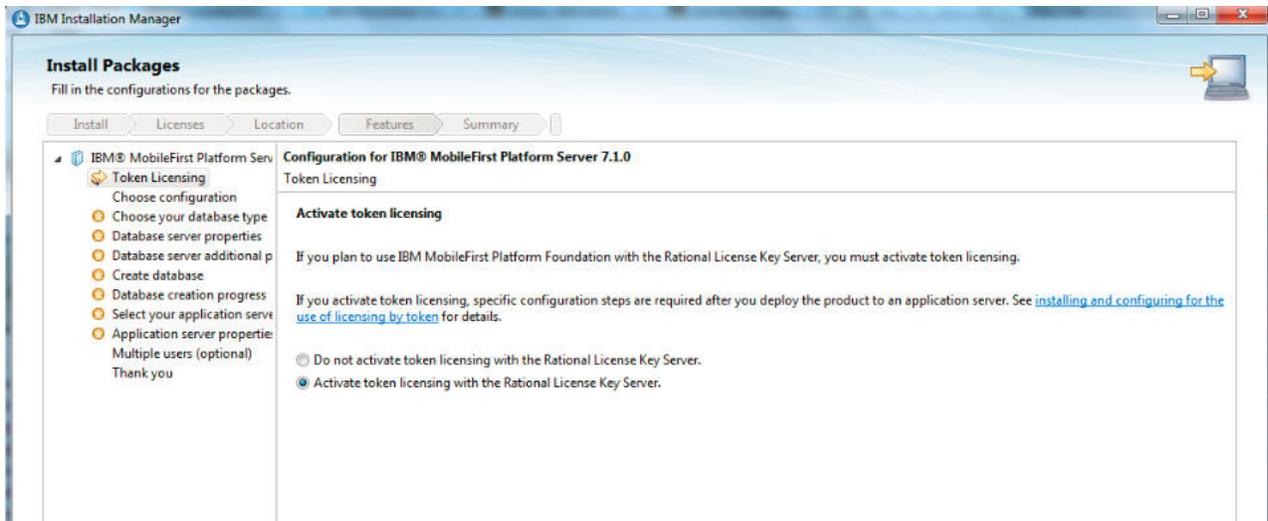

Figure 6-10. Activating token licensing during the installation of the product.

Silent mode installation

If you install in silent mode, set the value as true to the **user.licensed.by.tokens** parameter in the response file. For more information, see “Command-line (silent installation) parameters” on page 6-49.

3. Install the MobileFirst Server administration after the product installation is complete. For more information, see “Installing the MobileFirst Server administration” on page 6-58.
4. Configure MobileFirst Server for token licensing. The steps depend on your application server and the details are given for Apache Tomcat, WebSphere Application Server Liberty profile, and WebSphere Application Server full profile. For more information, see “Installing and configuring for token licensing” on page 6-126.

Connecting MobileFirst Server installed on Apache Tomcat to the Rational License Key Server

You must install the Rational Common Licensing native and Java libraries on the Apache Tomcat application server before you connect MobileFirst Server to the Rational License Key Server.

Before you begin

- Rational License Key Server 8.1.4.8 or later must be installed and configured. The network must allow communication to and from MobileFirst Server by opening the two-way communication ports (**1mrgd** and **ibmrat1**). For more information, see Rational License Key Server Portal and How to serve a license key to client machines through a firewall.
- MobileFirst Server must be installed and configured with the option Activate token licensing with the Rational License Key Server on your Apache Tomcat as indicated in “Installation overview for token licensing” on page 6-126.

Installing Rational Common Licensing libraries: Procedure

1. Choose the Rational Common Licensing native library. Depending on your operating system and the bit version of the Java Runtime Environment (JRE) on which your Apache Tomcat is running, you must choose the correct native

library in *product_install_dir/WorklightServer/tokenLibs/bin/your_corresponding_platform/the_native_library_file*. For example, for Linux x86 with a 64-bit JRE, the library can be found in *product_install_dir/WorklightServer/tokenLibs/bin/Linux_x86_64/librc1_ibmrat1.so*.

2. Copy the native library to the computer that runs MobileFirst Server administration service. The directory might be `${CATALINA_HOME}/bin`.

Note: `${CATALINA_HOME}` is the installation directory of your Apache Tomcat.

3. Copy `rc1_ibmrat1.jar` file to `${CATALINA_HOME}/lib`. The `rc1_ibmrat1.jar` file is a Rational Common Licensing Java library that can be found in *product_install_dir/WorklightServer/tokenLibs* directory. The library uses the native library that is copied in Step 2, and can be loaded only once by Apache Tomcat. This file must be placed in the `${CATALINA_HOME}/lib` directory or any directory in the path of Apache Tomcat common class loader.

Important: The Java virtual machine (JVM) of Apache Tomcat needs read and execute privileges on the copied native and Java libraries. Both copied files must also be readable and executable at least for the application server process in your operating system.

4. Configure the access to the Rational Common Licensing library by the JVM of your application server. For any operating systems, configure the `${CATALINA_HOME}/bin/setenv.bat` file (or `setenv.sh` file on UNIX) by adding the following line:

Windows:

```
set CATALINA_OPTS=%CATALINA_OPTS%  
-Djava.library.path=absolute_path_to_the_previous_bin_directory
```

UNIX: `CATALINA_OPTS="$CATALINA_OPTS`

```
-Djava.library.path=absolute_path_to_the_previous_bin_directory"
```

Note: If you move the configuration folder of the server on which the administration service is running, you must update the `java.library.path` with the new absolute path.

5. Configure MobileFirst Server to access Rational License Key Server. In `${CATALINA_HOME}/conf/server.xml` file, look for the `<Context>` element of the administration service application, and add in these JNDI configuration lines.

```
<Environment name="ibm.worklight.admin.license.key.server.host" value="rlks_hostname" type="java.  
<Environment name="ibm.worklight.admin.license.key.server.port" value="rlks_port" type="java.lang
```

- `rlks_hostname` is the host name of the Rational License Key Server.
- `rlks_port` is the port of the Rational License Key Server. By default, the value is 27000.

For more information, see JNDI properties for Administration Services: licensing.

Installing on Apache Tomcat server farm:

About this task

For configuring the connection of MobileFirst Server on Apache Tomcat server farm, you must follow all the steps that are described in “Installing Rational Common Licensing libraries” on page 6-127 for each node of your server farm where the MobileFirst Server administration service is running. For more information about server farm, see “Installing a server farm” on page 6-138.

Connecting MobileFirst Server installed on WebSphere Application Server Liberty profile to the Rational License Key Server

You must install the Rational Common Licensing native and Java libraries on the Liberty profile before you connect MobileFirst Server to the Rational License Key Server.

Before you begin

- Rational License Key Server 8.1.4.8 or later must be installed and configured. The network must allow communication to and from MobileFirst Server by opening the two-way communication ports (**lmgd** and **ibmratl**). For more information, see Rational License Key Server Portal and How to serve a license key to client machines through a firewall.
- You must have WebSphere Application Server Liberty profile 8.5.5.x. WebSphere Application Server Liberty profile 8.5.0.x is not supported.
- MobileFirst Server must be installed and configured with the option `Activate token licensing` with the Rational License Key Server on your Liberty profile as indicated in “Installation overview for token licensing” on page 6-126.

Installing Rational Common Licensing libraries: Procedure

1. Define a shared library for the Rational Common Licensing client. This library uses native code and can be loaded only once by the application server. Thus, the applications that use it must reference it as a common library.
 - a. Choose the Rational Common Licensing native library. Depending on your operating system and the bit version of the Java Runtime Environment (JRE) on which your Liberty profile is running, you must choose the correct native library in `product_install_dir/WorklightServer/tokenLibs/bin/your_corresponding_platform/the_native_library_file`. For example, for Linux x86 with a 64-bits JRE, the library can be found in `product_install_dir/WorklightServer/tokensLibs/bin/Linux_x86_64/librcl_ibmratl.so`.
 - b. Copy the native library to the computer that runs MobileFirst Server administration service. The directory might be `${shared.resource.dir}/rcllib`. For more information about standard location of `${shared.resource.dir}`, see WebSphere Application Server Liberty Core - Directory locations and properties. If the `rcllib` folder does not exist, create this folder and then copy the native library file over.

Note: Ensure that the Java virtual machine (JVM) of the application server has both read and execute privileges on the native library. On Windows, the following exception appears in the application server log if the JVM of the application server does not have the executable rights on the copied native library.

```
com.ibm.rcl.ibmratl.LicenseConfigurationException: java.lang.UnsatisfiedLinkError: rcl_ibm
```

- c. Copy `rcl_ibmratl.jar` file to `${shared.resource.dir}/rcllib`. The `rcl_ibmratl.jar` file is a Rational Common Licensing Java library that can be found in `product_install_dir/WorklightServer/tokenLibs` directory.

Note: The Java virtual machine (JVM) of Liberty profile must have the privilege to read the copied Java library. This file must also have readable privilege (at least for the application server process) in your operating system.

- d. Declare a shared library that uses the `rcl_ibmrat1.jar` file in the `${server.config.dir}/server.xml` file.

```
<!-- Declare a shared Library for the RCL client. -->
<!-- This library can be loaded only once because it uses native code. -->
<library id="RCLLibrary">
  <fileset dir="${shared.resource.dir}/rcllib" includes="rcl_ibmrat1.jar"/>
</library>
```

- e. Declare the shared library as a common library for the MobileFirst Server administration service application by adding an attribute (**commonLibraryRef**) to the class loader of the application. As the library can be loaded only once, it must be used as a common library, and not as a private library.

```
<application id="wladmin" name="wladmin" location="worklightadmin.war" type="war">
  [...]
  <!-- Declare the shared library as an attribute commonLibraryRef to the class loader of the application. -->
  <classloader delegation="parentLast" commonLibraryRef="RCLLibrary">
    <commonLibrary id="worklightlib_wladmin">
      <fileset dir="${wlp.install.dir}/lib" includes="com.ibm.ws.crypto.passwordutil_*.jar"/>
    </commonLibrary>
  </classloader>
</application>
```

- f. Configure the access to the Rational Common Licensing library by the JVM of your application server. For any operating systems, configure the `${wlp.user.dir}/servers/server_name/jvm.options` file by adding the following line:

```
-Djava.library.path=Absolute_path_to_the_previously_created_rcllib_folder
```

Note: If you move the configuration folder of the server on which the administration service is running, you must update the **java.library.path** with the new absolute path.

2. Configure MobileFirst Server to access Rational License Key Server.

In the `${server.config.dir}/server.xml` file, add these JNDI configuration lines.

```
<jndiEntry jndiName="ibm.worklight.admin.license.key.server.host" value="rlks_hostname"/>
<jndiEntry jndiName="ibm.worklight.admin.license.key.server.port" value="rlks_port"/>
```

- `rlks_hostname` is the host name of the Rational License Key Server.
- `rlks_port` is the port of the Rational License Key Server. By default, the value is 27000.

For more information, see [JNDI properties for Administration Services: licensing](#).

Installing on Liberty profile server farm:

About this task

For configuring the connection of MobileFirst Server on Liberty profile server farm, you must follow all the steps that are described in [Installing Rational Common Licensing libraries for each node of your server farm where the MobileFirst Server administration service is running](#). For more information about server farm, see ["Installing a server farm"](#) on page 6-138.

Connecting MobileFirst Server installed on WebSphere Application Server to the Rational License Key Server

You must configure a shared library for the Rational Common Licensing libraries on WebSphere Application Server before you connect MobileFirst Server to the Rational License Key Server.

Before you begin

- Rational License Key Server 8.1.4.8 or later must be installed and configured. The network must allow communication to and from MobileFirst Server by opening the two-way communication ports (**1mrgd** and **ibmrat1**). For more information, see Rational License Key Server Portal and How to serve a license key to client machines through a firewall.
- MobileFirst Server must be installed and configured with the option Activate token licensing with the Rational License Key Server on your WebSphere Application Server as indicated in “Installation overview for token licensing” on page 6-126.

Installing Rational Common Licensing library on a stand-alone server:

Procedure

1. Define a shared library for the Rational Common Licensing library. This library uses native code and can be loaded only once by a class loader during the application server lifecycle. For this reason, the library is declared as a shared library and associated to all the application servers that run the MobileFirst Server administration service. For more information about the reasons to declare this library as a shared library, see Configuring native libraries in shared libraries.
 - a. Choose the Rational Common Licensing native library. Depending on your operating system and the bit version of the Java Runtime Environment (JRE) on which your WebSphere Application Server is running, you must choose the correct native library in *product_install_dir/WorklightServer/tokenLibs/bin/your_corresponding_platform/the_native_library_file*. For example, for Linux x86 with a 64-bits JRE, the library can be found in *product_install_dir/WorklightServer/tokensLibs/bin/Linux_x86_64/librcl_ibmrat1.so*.

To determine the bit version of the Java Runtime Environment for a stand-alone WebSphere Application Server or WebSphere Application Server Network Deployment installation, run the `versionInfo.bat` on Windows or `versionInfo.sh` on UNIX from the `bin` directory. The `versionInfo.sh` file is in `/opt/IBM/WebSphere/AppServer/bin`. Look at the Architecture value in the **Installed Product** section. The Java Runtime Environment is 64-bit if the Architecture value mentions it explicitly or if it is suffixed with 64 or `_64`.
 - b. Place the native library that corresponds to your platform in a folder of your operating system. For example, `/opt/IBM/RCL_Native_Library/`.
 - c. Copy `rcl_ibmrat1.jar` file to `/opt/IBM/RCL_Native_Library/`. The `rcl_ibmrat1.jar` file is a Rational Common Licensing Java library that can be found in *product_install_dir/WorklightServer/tokenLibs* directory.

Important: The Java virtual machine (JVM) of the application server needs read and execute privileges on the copied native and Java libraries. Both copied files must also be readable and executable at least for the application server process in your operating system.

- d. Declare a shared library in WebSphere Application Server administrative console.
 - 1) Log in to WebSphere Application Server administrative console.
 - 2) Expand **Environment > Shared Libraries**.
 - 3) Select a scope that is visible by all servers that run the MobileFirst Server administration service. For example, a cluster.
 - 4) Click **New**.

- 5) Enter a name for the library in the **Name** field. For example, RCL Shared Library.
 - 6) In the **Classpath** field, enter the path to the `rcl_ibmrat1.jar` file. For example, `/opt/IBM/RCL_Native_Library/rcl_ibmrat1.jar`.
 - 7) Click **OK** and save the changes. This setting takes effect when the server is restarted.
- e. Associate the shared library with all servers that run the MobileFirst Server administration service.

Associating the shared library to a server allows the shared library to be used by several applications. If you need the Rational Common Licensing client only for the MobileFirst Server administration service, you can create a shared library with an isolated class loader and associate it with the administration service application.

The following instruction is to associate the library with a server. For WebSphere Application Server Network Deployment, you must complete this instruction for all the servers that run the MobileFirst Server administration service.

- 1) Set the class loader policy and mode.
 - a) In WebSphere Application Server administrative console, click **Servers > Server Types > WebSphere application servers > *server_name*** to access the application server setting page.
 - b) Set the values for the application class-loader policy and class loading mode of the server:
 - **Classloader policy:** Multiple
 - **Class loading mode:** Classes loaded with parent class loader first
 - c) In **Server Infrastructure** section, click **Java and Process Management > Class loader**.
 - d) Click **New** and ensure that class loader order is set to **Classes loaded with parent class loader first**.
 - e) Click **Apply** to create a new class loader ID.
 - 2) Create a library reference for each shared library file that your application needs.
 - a) Click the name of the class loader that is created in the previous step.
 - b) In **Additional properties** section, click **Shared library references**.
 - c) Click **Add**.
 - d) At the **Library reference settings** page, select the appropriate library reference. The name identifies the shared library file that your application uses. For example, RCL Shared Library.
 - e) Click **Apply** and then save the changes.
2. Configure the environment entries for MobileFirst Server administration service web application.
- a. In WebSphere Application Server administrative console, click **Applications > Application Types > WebSphere enterprise applications** and select the administration service application: `Worklight_Administration_Service`.
 - b. In **Web Module Properties** section, click **Environment entries for web modules**.
 - c. Enter the values for `ibm.worklight.admin.license.key.server.host` and `ibm.worklight.admin.license.key.server.port`.

- **ibm.worklight.admin.license.key.server.host** is the host name of the Rational License Key Server.
 - **ibm.worklight.admin.license.key.server.port** is the port of the Rational License Key Server. By default, the value is 27000.
- d. Click **OK** and save the changes.
3. Configure the access to the Rational Common Licensing library by the application server JVM.
 - a. In WebSphere Application Server administrative console, click **Servers > Server Types > WebSphere Application Servers** and select your server.
 - b. In **Server Infrastructure** section, click **Java and Process Management > Process Definition > Java Virtual Machine > Custom Properties > New** to add a custom property.
 - c. In the **Name** field, type the name of the custom property as `java.library.path`.
 - d. In the **Value** field, enter the path of the folder where you place the native library file in Step 1b. For example, `/opt/IBM/RCL_Native_Library/`.
 - e. Click **OK** and save the changes.
 4. Restart your application server.

Installing Rational Common Licensing library on WebSphere Application Server Network Deployment:

About this task

For installing the native library on a WebSphere Application Server Network Deployment, you must follow all the steps that are described in “Installing Rational Common Licensing library on a stand-alone server” on page 6-131. The servers or clusters that you configure must be restarted in order for the changes to take effect.

Each node of your WebSphere Application Server Network Deployment must have a copy of the Rational Common Licensing native library.

Each server where the MobileFirst Server administration service runs must be configured to have access to the native library copied on your local computer. These servers must also be configured to connect to Rational License Key Server.

Important:

- If you use a cluster with WebSphere Application Server Network Deployment, your cluster can change. You must configure each newly added server in your cluster, where the administration services are running.
- Asymmetric deployment with runtimes and administration services in different server or cluster is not supported on WebSphere Application Server Network Deployment. For more information, see “Planning for the use of token licensing” on page 6-34.

Limitations of supported platforms for token licensing

The list of operating system, its version, and the hardware architecture that supports MobileFirst Server with token licensing enabled.

For token licensing, the MobileFirst Server needs to connect to the Rational License Key Server by using the Rational Common Licensing library.

This library is composed of a Java library and also native libraries. These native libraries depend on the platform where MobileFirst Server is running. Thus, the token licensing by MobileFirst Server is supported only on platforms where the Rational Common Licensing library can be run.

The following table describes the platforms that support MobileFirst Server with the token licensing.

Table 6-32. Supported Operating System, Operating System version, and hardware architecture.

Operating System	Operating System version	Hardware architecture
AIX	6.1	POWER7® (64-bit only)
AIX	7.1	POWER7 (64-bit only)
AIX	7.1	POWER8® (64-bit only)
Red Hat Server Editions	6	x86-64 only
Solaris	10	SPARC (64-bit only)
SUSE Linux Enterprise Server	11	x86-64 only
Windows Server	2012	x86-64 only

Token licensing does not support 32-bit Java Runtime Environment (JRE). Make sure that the application server uses a 64-bit JRE.

If you intend to use token licensing with WebSphere Application Server Liberty profile, make sure that the version is 8.5.5.x. WebSphere Application Server Liberty profile 8.5.0.x is not supported.

Troubleshooting token licensing problems

Find information to help resolve issues that you might encounter with token licensing if you activated this feature when you installed MobileFirst Server.

When you start the MobileFirst Server administration services after you complete “Installing and configuring for token licensing” on page 6-126, some errors or exceptions can be emitted in the application server log or on MobileFirst Operations Console. These exceptions might be due to incorrect installation of the Rational Common Licensing library and configuration of the application server.

Apache Tomcat

Check `catalina.log` or `catalina.out` file, depending on your platform.

WebSphere Application Server Liberty profile

Check `messages.log` file.

WebSphere Application Server full profile

Check `SystemOut.log` file.

Important: If token licensing is installed on WebSphere Application Server Network Deployment or a cluster, you must check the log of each server.

Here is a list of exceptions that might occur after the installation and configuration for token licensing:

- “Rational Common Licensing native library is not found”
- “Rational Common Licensing shared library is not found” on page 6-136
- “The Rational License Key Server connection is not configured” on page 6-136
- “The Rational License Key Server is not accessible” on page 6-137
- “Failed to initialize Rational Common Licensing API” on page 6-137
- “Insufficient token licenses” on page 6-138
- “Invalid rcl_ibmratl.jar file” on page 6-138

Rational Common Licensing native library is not found

FWLSE3125E: The Rational Common Licensing native library is not found. Make sure the JVM property (`java.library.path`) is defined with the right path and the native library can be executed. Restart IBM MobileFirst Platform Server after taking corrective action.

For WebSphere Application Server full profile

Possible causes to this error might be:

- No common property with name **java.library.path** is defined at server level.
- The path that is given as the value for the **java.library.path** property does not contain the Rational Common Licensing native library.
- The native library does not have appropriate permissions. The library must have the read and execute privileges on UNIX and Windows for the user who accesses it with the Java Runtime Environment of the application server.

For WebSphere Application Server Liberty profile and Apache Tomcat

Possible causes to this error might be:

- The path to the Rational Common Licensing native library given as the value of **java.library.path** property is either not set or incorrect.
 - For Liberty profile, check `${wlp.user.dir}/servers/server_name/jvm.options` file.
 - For Apache Tomcat, check `${CATALINA_HOME}/bin/setenv.bat` file or `setenv.sh` file, depending on your platform.
- The native library is not found in the path that is defined to the **java.library.path** property. Check that the native library exists in the defined path with the expected name.

- The native library does not have appropriate permissions. The error might be preceded by this exception:

```
com.ibm.rcl.ibmratl.LicenseConfigurationException:
java.lang.UnsatisfiedLinkError: {0}\rcl_ibmratl.dll: Access is
denied
```

The Java Runtime Environment of the application server needs read and execute privileges on this native library. The library file must also be readable and executable at least for the application server process in your operating system.

- The shared library that uses the `rcl_ibmratl.jar` file is not defined in the `${server.config.dir}/server.xml` file for Liberty profile. The `rcl_ibmratl.jar` might also not in the correct directory or the directory does not have the appropriate permissions.

- The shared library that used the `rcl_ibmratl.jar` file is not declared as a common library for the MobileFirst Server administration service application in the `${server.config.dir}/server.xml` file for the Liberty profile.
- There is a mix of 32-bit and 64-bit objects between the Java Runtime Environment of the application server and the native library. For example, a 32-bit Java Runtime Environment is used with a 64-bit native library. This mix is not supported.

Rational Common Licensing shared library is not found

FWLSE3126E: The Rational Common Licensing shared library is not found. Make sure the shared library is configured. Restart IBM MobileFirst Platform Server after taking corrective action.

Possible causes to this error might be:

- The `rcl_ibmratl.jar` file is not in the expected directory.
 - For Apache Tomcat, check that this file is in `${CATALINA_HOME}/lib` directory.
 - For WebSphere Application Server Liberty profile, check that this file is in the directory as defined in the `server.xml` file for the shared library of the Rational Common Licensing client. For example, `${shared.resource.dir}/rcllib`. In the `server.xml` file, ensure that this shared library is correctly referenced as a common library for MobileFirst Server administration service application.
 - For WebSphere Application Server, make sure that this file is in the directory that is specified in the class path of the WebSphere Application Server shared library. Check that the class path of that shared library contains this entry: `absolute_path/rcl_ibmratl.jar` whereas `absolute_path` is the absolute path of the `rcl_ibmratl.jar` file.
- The **java.library.path** property is not set for the application server. Define a property with name **java.library.path** and set the path to the Rational Common Licensing native library as the value. For example, `/opt/IBM/RCL_Native_Library/`.
- The native library does not have the expected permissions. On Windows, the Java Runtime Environment of the application server must have the read and executable rights on the native library.
- There is a mix of 32-bit and 64-bit objects between the Java Runtime Environment of the application server and the native library. For example, a 32-bit Java Runtime Environment is used with a 64-bit native library. This mix is not supported.

The Rational License Key Server connection is not configured

FWLSE3127E: The Rational License Key Server connection is not configured. Make sure the admin JNDI properties `"ibm.worklight.admin.license.key.server.host"` and `"ibm.worklight.admin.license.key.server.port"` are set. Restart IBM MobileFirst Platform Server after taking corrective action.

Possible causes to this error might be:

- The Rational Common Licensing native library and the shared library that uses the `rcl_ibmratl.jar` file are correctly configured but the value of JNDI properties (**ibm.worklight.admin.license.key.server.host** and **ibm.worklight.admin.license.key.server.port**) is not set in the MobileFirst Server administration services application.

- The Rational License Key Server is down.
- The host computer on which Rational License Key Server is installed cannot be reached. Check the IP address or host name with the specified port.

The Rational License Key Server is not accessible

FWLSE3128E: The Rational License Key Server "{port}@{IP address or hostname}" is not accessible. Make sure that license server is running and accessible to IBM MobileFirst Platform Server. If this error occurs at runtime startup, restart IBM MobileFirst Platform Server after taking corrective action.

Possible causes to this error might be:

- The Rational Common Licensing shared library and the native library are correctly defined but there is no valid configuration to connect to the Rational License Key Server. Check the IP address, the host name, and the port of the license server. Make sure that the license server is started and accessible from the computer where the application server is installed.
- The native library is not found in the path that is defined to the **java.library.path** property.
- The native library does not have appropriate permissions.
- The native library is not in the defined directory.
- The Rational License Key Server is behind a firewall. The error might be preceded by this exception: [ERROR] Failed to get license for application 'WorklightStarter' because Rational Licence Key Server ({port}@{IP address or hostname}) is either down or not accessible com.ibm.rcl.ibmratl.LicenseServerUnreachableException. All license files searched for features: {port}@{IP address or hostname}
Ensure that the license manager daemon (**lmgrd**) port and the vendor daemon (**ibmratl**) port are open in your firewall. For more information, see How to serve a license key to client machines through a firewall.

Failed to initialize Rational Common Licensing API

Failed to initialize Rational Common Licensing (RCL) API because its native library could not be found or loaded
com.ibm.rcl.ibmratl.LicenseConfigurationException:
java.lang.UnsatisfiedLinkError: rcl_ibmratl (Not found in java.library.path)

Possible causes to this error might be:

- The Rational Common Licensing native library is not found in the path that is defined to the **java.library.path** property. Check that the native library exists in the defined path with the expected name.
- The **java.library.path** property is not set for the application server. Define a property with name **java.library.path** and set the path to the Rational Common Licensing native library as the value. For example, /opt/IBM/RCL_Native_Library/.
- There is a mix of 32-bit and 64-bit objects between the Java Runtime Environment of the application server and the native library. For example, a 32-bit Java Runtime Environment is used with a 64-bit native library. This mix is not supported.

Insufficient token licenses

FWLSE3129E: Insufficient token licenses for feature "{0}".

This error occurs when the remaining number of token licenses on the Rational License Key Server is not enough to deploy a new MobileFirst application.

Invalid rcl_ibmrat1.jar file

UTLS0002E: The shared library RCL Shared Library contains a classpath entry which does not resolve to a valid jar file, the library jar file is expected to be found at {0}/rcl_ibmrat1.jar.

Note: For WebSphere Application Server and WebSphere Application Server Network Deployment only

Possible causes to this error might be:

- The rcl_ibmrat1.jar Java library does not have the appropriate permissions. The error might be followed by another exception: java.util.zip.ZipException: error in opening zip file.

Check that the rcl_ibmrat1.jar file has the read permission for the user who installs WebSphere Application Server.

- If there is no other exception, the rcl_ibmrat1.jar file that is referenced in the class path of the shared library might be invalid or does not exist. Check that the rcl_ibmrat1.jar file is valid or exists in the defined path.

You must install the Rational Common Licensing native and Java libraries on the Apache Tomcat application server before you connect MobileFirst Server to the Rational License Key Server.

“Connecting MobileFirst Server installed on WebSphere Application Server Liberty profile to the Rational License Key Server” on page 6-129

You must install the Rational Common Licensing native and Java libraries on the Liberty profile before you connect MobileFirst Server to the Rational License Key Server.

“Connecting MobileFirst Server installed on WebSphere Application Server to the Rational License Key Server” on page 6-130

You must configure a shared library for the Rational Common Licensing libraries on WebSphere Application Server before you connect MobileFirst Server to the Rational License Key Server.

Installing a server farm

MobileFirst Server provides a specific plug-in so that instances of application servers can become server farm nodes. After you have prepared the installation depending on your work environment, you can install your server farm manually or by running Ant tasks.

Planning the configuration of a server farm

To plan the configuration of a server farm, choose the application server, write the configuration file, and deploy the WAR files.

When you intend to plan a server farm installation, you should first see “Planning deployment of administration components and runtimes” on page 6-19, and in particular see “Server farm topology” on page 6-22.

In IBM MobileFirst Platform Foundation, a server farm is composed of multiple stand-alone application servers that are not federated or administered by a managing component of an application server. MobileFirst Server internally provides a farm plug-in as the means to enhance an application server so that it can be part of a server farm.

When to declare a server farm

Declare a server farm in the following cases:

- MobileFirst Server is installed on multiple Tomcat application servers.
- MobileFirst Server is installed on multiple WebSphere Application Server servers but not on WebSphere Application Server Network Deployer.
- MobileFirst Server is installed on multiple WebSphere Application Server Liberty servers.

Do not declare a server farm in the following cases:

- Your application server is stand-alone.
- Multiple application servers are federated by WebSphere Application Server Network Deployment.

Why it is mandatory to declare a farm

Each time a management operation is performed through the MobileFirst Operations Console or through the MobileFirst Administration Services application, the operation needs to be replicated to all instances of a runtime environment. Examples of such management operations are the uploading of a new version of a wlap or of an adapter. The replication is done via JMX calls performed by the MobileFirst Administration Services application instance that handles the operation. The Administration Service needs to contact all runtime instances in the cluster. In environments listed under “When to declare a server farm,” the runtime can be contacted through JMX only if a farm is configured. If a server is added to a cluster without proper configuration of the farm, the runtime in that server will be in an inconsistent state after each management operation, and until it is restarted again.

Configuring a server farm

You must configure each server in the farm according to the requirements of the single type of application server used for each member of the server farm.

About this task

When you plan a server farm, first create stand-alone servers that communicate with the same database instance. Then, modify the configuration of these servers to make them members of a server farm.

Procedure

1. Choose the type of application server to use to configure the members of the server farm. IBM MobileFirst Platform Foundation supports these application servers in server farms:

- WebSphere Application Server full profile.

Note: In a farm topology, you cannot use the RMI JMX connector. In this topology, IBM MobileFirst Platform Foundation supports only the SOAP connector.

- WebSphere Application Server Liberty profile.

- Apache Tomcat.

To know which versions of application servers are supported, see “System requirements” on page 2-15.

Note: IBM MobileFirst Platform Foundation supports only homogeneous server farms. A server farm is homogeneous when it connects application servers of the same type. Attempting to associate different types of application servers might lead to unpredictable behavior at run time. For example, a farm with a mix of Apache Tomcat servers and WebSphere Application Server full profile servers is an invalid configuration.

2. Decide which database that you want to use. You can choose from:

- DB2
- MySQL
- Oracle

MobileFirst databases are shared between the application servers in a farm, which means:

- You create the database only once, whatever the number of servers in the farm.
- You cannot use the Derby database in a farm topology, because the Derby database allows only a single connection at a time.

For more information about databases, see “Planning the creation of the databases” on page 6-30.

3. Set up as many stand-alone servers as the number of members that you want in the farm. Each of these stand-alone servers must communicate with the same database. You must make sure that any port used by any of these servers is not also used by another server configured on the same host. This constraint applies to the ports used by http, https, REST, SOAP, and RMI protocols.

To set up the servers, you can choose one of the following methods of installation:

- Install them by using the Server Configuration Tool.
- Install them by using configuration Ant scripts.
- Install them manually.

Each of these servers must have the MobileFirst Administration Services and one or more MobileFirst runtime environments deployed on it.

For more information about setting up a server, see “Planning the installation of MobileFirst Server” on page 6-14.

When each of these servers is working properly in a stand-alone topology, you can transform them into nodes of a server farm.

4. Stop all the servers that are intended to become members of the farm.
5. Configure each server appropriately for the type of application server. You must set some JNDI properties correctly. For Apache Tomcat, you must also check that the JVM arguments are properly defined.

- **WebSphere Application Server Liberty profile**

In the server.xml file, set the JNDI properties shown in the following sample code.

```
<jndiEntry jndiName="ibm.worklight.topology.clustermode" value="Farm"/>
<jndiEntry jndiName="ibm.worklight.admin.serverid" value="farm_member_1"/>
<jndiEntry jndiName="ibm.worklight.admin.jmx.user" value="myRESTConnectorUser"/>
<jndiEntry jndiName="ibm.worklight.admin.jmx.pwd" value="password-of-rest-connector-user"/>
<jndiEntry jndiName="ibm.worklight.admin.jmx.host" value="93.12.0.12"/>
```

These properties must be set with appropriate values:

- **ibm.worklight.admin.serverid**: The identifier that you defined for this farm member. This identifier must be unique across all farm members.
- **ibm.worklight.admin.jmx.user** and **ibm.worklight.admin.jmx.pwd**: These values must match the credentials of a user as declared in the <administrator-role/> element.
- **ibm.worklight.admin.jmx.host**: Set this parameter to the IP or the host name that is used by remote members to access this server. Therefore, do not set it to localhost. This host name is used by the other members of the farm and must be accessible to all farm members.
- **ibm.worklight.admin.jmx.port**: Set this parameter to the server HTTPS port that is used for the JMX REST connection. You can find the value in the <httpEndpoint> element of the server.xml file.

- **Apache Tomcat**

Modify the conf/server.xml file to set the following JNDI properties in the MobileFirst administration context and in every MobileFirst runtime context.

```
<Environment name="ibm.worklight.topology.clustermode" value="Farm" type="java.lang.String"
<Environment name="ibm.worklight.admin.serverid" value="farm_member_1" type="java.lang.String"
```

The **ibm.worklight.admin.serverid** property must be set to the identifier that you defined for this farm member. This identifier must be unique across all farm members.

You must make sure that the -Djava.rmi.server.hostname JVM argument is set to the IP or the host name that is used by remote members to access this server. Therefore, do not set it to localhost. This argument is set in the CATALINA_OPTS environment variable.

- **WebSphere Application Server full profile**

You must declare the following environment variables in the MobileFirst Administration Services and in every MobileFirst runtime application deployed on the server.

- *ibm.worklight.topology.clustermode*
- *ibm.worklight.admin.serverid*

- a. In the WebSphere Application Server console, select **Applications > Application Types > WebSphere Enterprise applications**.
 - b. Select the MobileFirst Administration Service application.
 - c. In Web Module Properties, click **Environment entries for Web Modules** to display the JNDI properties.
 - d. Set the values of the following properties.
 - Set **ibm.worklight.topology.clustermode** to Farm.
 - Set **ibm.worklight.admin.serverid** to the identifier that you chose for this farm member.
 - Set **ibm.worklight.admin.jmx.user** to a user name that has access to the SOAP connector.
 - Set **ibm.worklight.admin.jmx.pwd** to the password of the user declared in **ibm.worklight.admin.jmx.user**.
 - e. Verify that **ibm.worklight.admin.jmx.connector** is set to SOAP.
 - f. Click **OK** and save the configuration.
 - g. Make similar changes for every MobileFirst runtime application deployed on the server.
6. Exchange the server certificates in their truststores. Exchanging the server certificates in their truststores is mandatory for farms that use WebSphere

Application Server full profile and WebSphere Application Server Liberty profile, because in these farms communications between the servers is secured by SSL.

- **WebSphere Application Server Liberty profile**

You can configure the truststore by using IBM utilities such as Keytool or iKeyman.

- For more information about Keytool, see Keytool in the IBM SDK, Java Technology Edition.
- For more information about iKeyman, see iKeyman in the IBM SDK, Java Technology Edition.

The locations of keystore and truststore are defined in the `server.xml` file. See the `keyStoreRef` and `trustStoreRef` attributes in SSL configuration attributes. By default, the keystore of Liberty profile is at `${server.config.dir}/resources/security/key.jks`. If the truststore reference is missing or not defined in the `server.xml` file, the keystore that is specified by `keyStoreRef` is used. The server uses the default keystore and the file is created the first time that the server runs. In that case, a default certificate is created with a validity period of 365 days. For production, you might consider using your own certificate (including the intermediate ones if needed) or changing the expiration date of the generated certificate.

Note: If you want to confirm the location of the truststore, you can do so by adding the following declaration to the `server.xml` file:

```
<logging traceSpecification="SSL=all:SSLChannel=all"/>
```

Then, start the server and look for lines that contain `com.ibm.ssl.trustStore` in the `${wlp.install.dir}/usr/servers/server_name/logs/trace.log` file.

- a. Import the certificates of the other servers in the farm into the truststore that is referenced by the `server.xml` configuration file of the server.

If you are using the Keytool utility, do the following steps for each server of the farm:

- 1) In the `${wlp.user.dir}/servers/server_name/resources/security` directory, enter the command: **keytool -list -keystore key.jks**.

This command shows the certificates in the keystore and their corresponding alias names. You are prompted for the password of the keystore before you can see the truststore entries. This is the case for all the next commands with Keytool utility. If you do not use a custom keystore, the server must be started once to generate a default truststore `key.jks` in the mentioned directory. The password of the default keystore is `worklight`.

Note: If you replace the default `key.jks` by your own truststore, you might have to append the option **-storetype** to every Keytool command you enter to match your truststore type.

- 2) Export all the certificates in the truststore with the command: **keytool -exportcert -keystore key.jks -alias cert_entry -file cert_entry.cert** where `cert_entry` must be replaced with each certificate alias name.
- 3) Copy all the extracted certificates to the other servers of the farm so that they can be imported in their respective truststores. This step assumes that you copy them in the remote directories: `${wlp.user.dir}/servers/server_name/resources/security`.
- 4) Import the certificates in the truststore of the other servers of the farm.

On each server, change the directory to `${wlp.user.dir}/servers/
server_name/resources/security`. Import each certificate in the
truststore in turn by using the command: **keytool -importcert
-keystore key.jks -alias new_alias_name -file cert_entry.cert**
where `cert_entry.cert` is to be replaced with the name of each
certificate that you copied at previous step. The `new_alias_name` is the
name of the entry that is created in the truststore to store this certificate.
You are prompted to explicitly trust the certificate.

Note: Each alias in the truststore must be unique. You are warned by
the tool if a certificate is already present but stored with a different alias.

- b. Restart each instance of WebSphere Application Server Liberty profile to
make the security configuration take effect.

The following steps are required for single sign-on (SSO) to work:

- c. Start one member of the farm if not already done. In the default LTPA
configuration, after the Liberty server starts successfully, it generates an
LTPA keystore as `${wlp.install.dir}/usr/servers/server_name/resources/
security/ltpa.keys`.
- d. Copy the `ltpa.keys` file to the `${wlp.install.dir}/usr/servers/
server_name/resources/security` directory of each farm member to
replicate the LTPA keystores across the farm members.
- e. Start the other members of the farm.

For more information about LTPA configuration, see *Configuring LTPA on
the Liberty profile*.

- **WebSphere Application Server full profile**

Configure the truststore in the WebSphere Application Server administration
console.

- a. Log in to WebSphere Application Server administration console.
- b. Select **Security > SSL certificate and key management**.
- c. In Related Items, select **Keystores and certificates**.
- d. In the **Keystore usages** field, make sure that **SSL keystores** is selected. You
can now import the certificates from all the other servers in the farm.
- e. Click **NodeDefaultTrustStore**.
- f. In **Additional Properties**, select **Signer certificates**.
- g. Click **Retrieve from port**. You can now enter communication and security
details of each of the other servers in the farm. Follow the next steps for
each of the other farm members.
- h. In the **Host** field, enter the server host name or IP address.
- i. In the **Port** field, enter the HTTPS transport (SSL) port.
- j. In “SSL configuration for outbound connection”, select
NodeDefaultSSLSettings.
- k. In the **Alias** field, enter an alias for this signer certificate.
- l. Click **Retrieve signer information**.
- m. Review the information that is retrieved from the remote server and then
click **OK**.
- n. Click **Save**.
- o. Restart the server.

What to do next

If you are creating a farm whose members use WebSphere Application Server Liberty profile, you can now set up an IBM HTTP Server for Liberty. For more information, see “Setting up HTTP Server in a WebSphere Application Server Liberty profile farm” on page 6-339.

Verifying a farm configuration

To verify a server farm configuration, start all the servers, deploy an application to one of the servers of the farm, and then check the log files of each server to confirm that all servers have been updated.

About this task

The purpose of this task is to verify that a farm is configured properly and that administration operations are propagated on all servers of a farm.

Procedure

1. Start all the servers of the farm.
2. Deploy a MobileFirst application to one of the servers of the farm. You can use the MobileFirst Operations Console or the wladm program with the deploy app command. For more information about the deploy app command, see “Commands for apps” on page 13-45.
3. Once the operation is completed, review the log file of the application server and search for the entries of class BaseTransaction. Verify that all servers have been updated.

This is the example of a Liberty log file:

```
$ grep BaseTransaction messages.log
```

```
[9/22/14 1:03:17:032 CEST] 0000006d com.ibm.worklight.admin.actions.BaseTransaction
[9/22/14 1:03:17:251 CEST] 0000006e com.ibm.worklight.admin.actions.BaseTransaction
[9/22/14 1:03:19:123 CEST] 00000072 com.ibm.worklight.admin.actions.BaseTransaction
[9/22/14 1:03:19:123 CEST] 00000072 com.ibm.worklight.admin.actions.BaseTransaction
[9/22/14 1:03:19:138 CEST] 00000071 com.ibm.worklight.admin.actions.BaseTransaction
[9/22/14 1:03:19:138 CEST] 00000071 com.ibm.worklight.admin.actions.BaseTransaction
```

Troubleshooting

- If you use an environment ID (see “List of JNDI properties for MobileFirst Server administration” on page 6-111 and “JNDI environment entries for MobileFirst projects in production” on page 12-68), for each server, verify that the **environmentId** value for the MobileFirst Administration Service is the same as the **environmentId** value for the runtime.
- If you have several servers on the same computer, you must verify that all servers are using a different JMX port:
 - For WebSphere Application Server, the port that is used for JMX is the SOAP port.
 - For WebSphere Application Server Liberty, the port that is used for JMX is the HTTPS port.
 - For Apache Tomcat, the port that is used for JMX is the RMI port, which is specified in the Ant tasks or in the setenv file for a manual installation.

If the JMX port is not available for a server, the MobileFirst runtime environment cannot start.

Lifecycle of a server farm node

You can configure heartbeat rate and timeout values to indicate possible server problems among farm members by triggering a change in status of an affected node.

When a server configured as a farm node is started, the Administration Service on that server automatically registers it as a new farm member.

When a farm member is shut down, it automatically unregisters from the farm.

A heartbeat mechanism exists to keep track of farm members that might become unresponsive, for example, because of a power outage or a server failure. In this heartbeat mechanism, MobileFirst runtimes send periodically at a given rate a heartbeat to MobileFirst administration services. If the MobileFirst administration services register that too long a time has elapsed since a farm member sent a heartbeat, then the farm member is considered to be down.

Farm members considered to be down do not serve any more requests to mobile applications.

Having one or more nodes down does not prevent the other members of the farm from:

- Serving requests correctly to mobile applications
- Accepting new management operations triggered through MobileFirst Operations Console

Configuring the heartbeat rate and timeout values

You can configure the heartbeat rate and timeout values by defining the following JNDI properties:

- **ibm.worklight.admin.farm.heartbeat**
- **ibm.worklight.admin.farm.missed.heartbeats.timeout**

For more information, see “List of JNDI properties for MobileFirst Server administration” on page 6-111

You can check the status of farm members from MobileFirst Operations Console by clicking **Server Farm Nodes**.

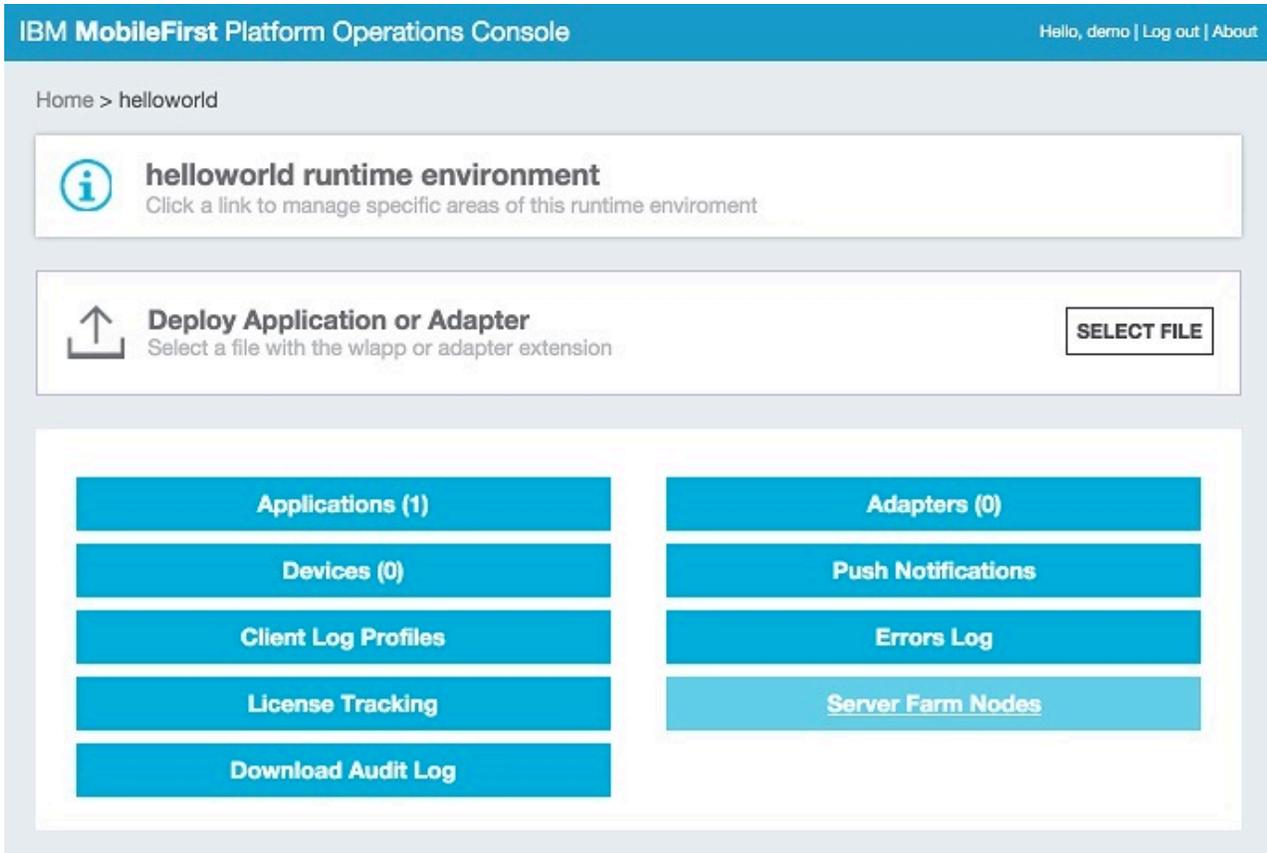

Figure 6-11. Checking the status of farm nodes

Clicking **Server Farm Nodes** enables you to access the list of registered farm members and their status.

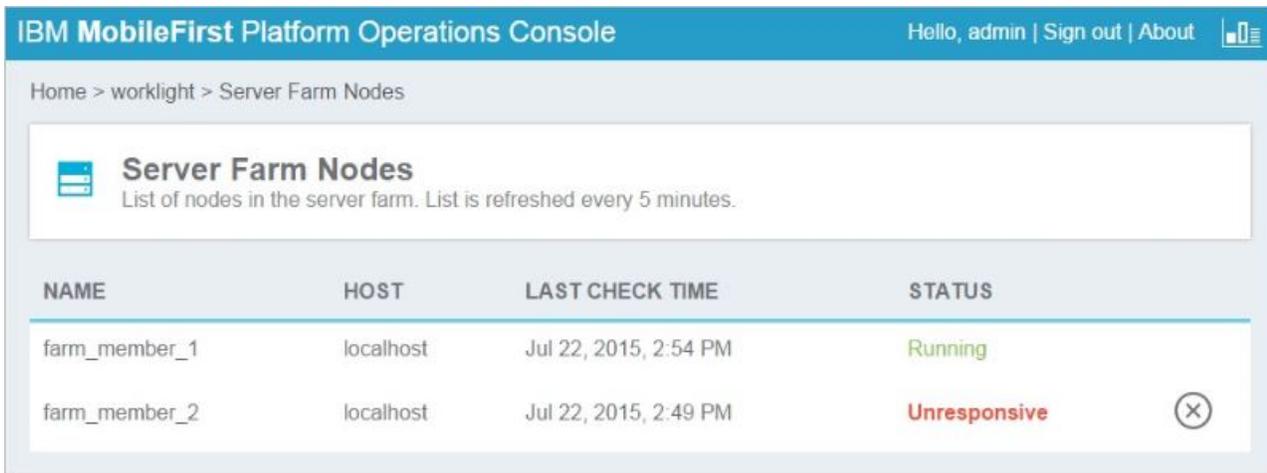

Figure 6-12. List of server farm nodes

The node identified as “farm_member_2” is considered to be down, which indicates that this server has probably failed and requires some maintenance.

Configuring MobileFirst Server

Consider your backup and recovery policy, optimize your MobileFirst Server configuration, and apply access restrictions and security options.

Backup and recovery

You can back up the customization and the content (adapters and applications) outside the MobileFirst instance, for example in a source control system.

It is advisable to back up the runtime database as-is. When reports are enabled, the database can become quite large. Consider the benefits of backing them up separately. Report tables can be configured to be stored on a different database instance.

Disaster recovery: active-active topology

How to enable disaster recovery and high availability with IBM MobileFirst Platform Foundation by deploying an active-active topology.

Overview

When a mobile application is widely used around the world, in many cases the application servers are located in several data centers.

Starting from V7.1.0 of IBM MobileFirst Platform Foundation, if your system is operating in session-independent mode, you can provide high availability and disaster recovery to your distributed network. One possible topology to achieve this is active-active. The topology involves several instances of IBM MobileFirst Platform Server that are deployed in two or more active data centers, in combinations with IBM Cloudant and IBM WebSphere eXtreme scale. Optionally, these configuration might use a load-balancer to determine which site handles the client requests.

Session-independence

A prerequisite for enabling an active-active topology is to have IBM MobileFirst Platform Server operating in session-independent mode.

For more information, see “Session-independent mode” on page 8-324.

Topologies for achieving high availability

Topologies that deliver active-active features must work with the same IBM MobileFirst Platform Foundation attribute store. Starting with V7.1.0, the attribute store in IBM MobileFirst Platform Server persists, by default, to the runtime database. There are two supported persistency configurations:

Cloudant

In this configuration, there is one administration database per data center. The runtime database is shared between both data centers on Cloudant, which provides high availability support. See Figure 1.

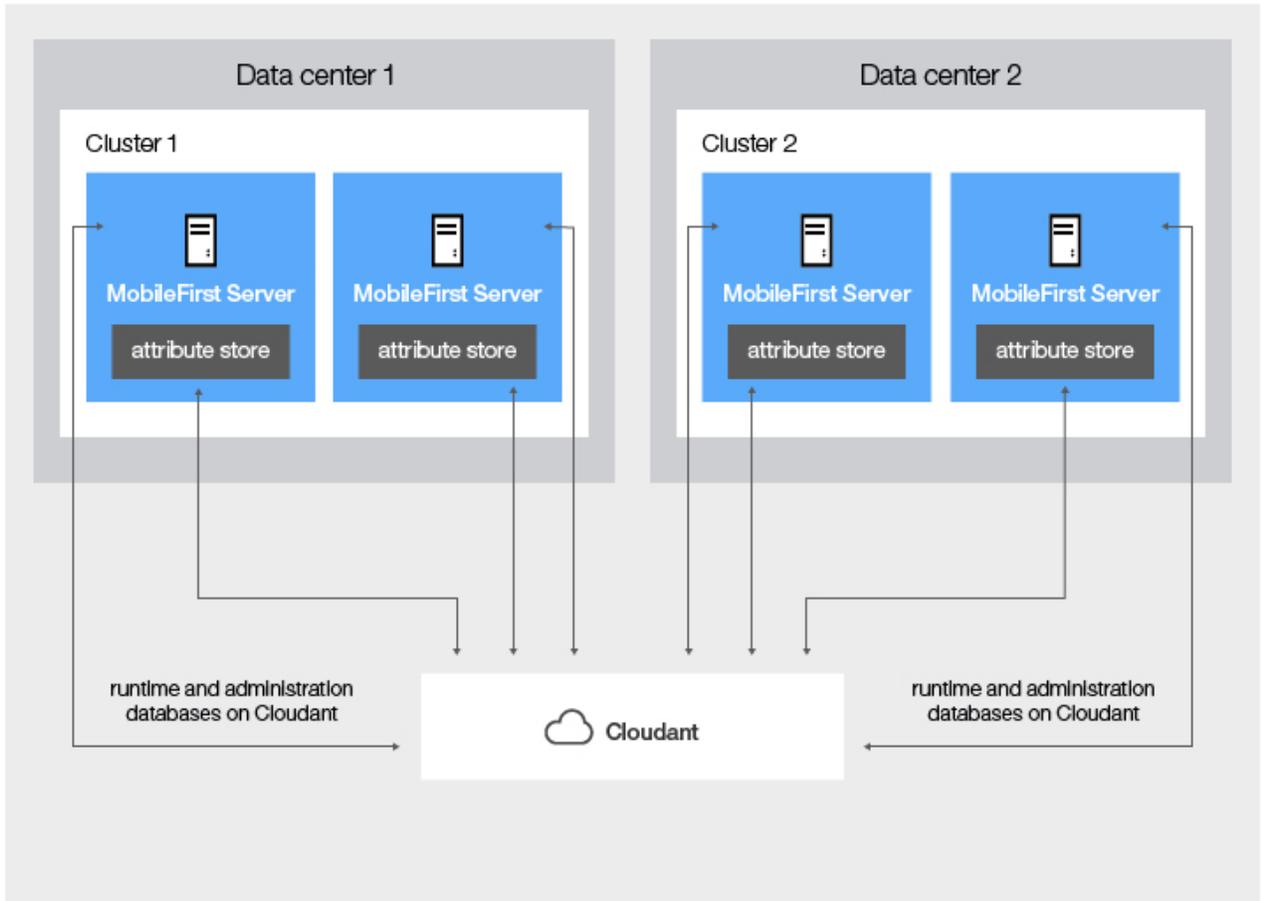

Figure 6-13. Active-active topology using Cloudant

Important:

- Ensure that runtime servers in all data centers are using the same Cloudant database.
- Because the administration console and database are not shared between data centers, MobileFirst artifacts such as applications and adapters must be deployed in each data center.

IBM WebSphere eXtreme Scale, persisted to Cloudant

In this configuration, eXtreme Scale provides an additional caching layer for increased performance. The layer is used to cache the attribute store, which is the most extensively used object in MobileFirst client login flows. The usage of eXtreme Scale alone does not provide built-in active-active functionality, as eXtreme Scale writes nothing to disk. All data in eXtreme Scale is managed in-memory. There are several ways to achieve active-active using eXtreme Scale. This page describes the configuration that involves eXtreme Scale and a built-in write-behind Loader plug-in that is provided with MobileFirst Server. The Loader persists the data in eXtreme Scale to a Cloudant database, as illustrated in Figure 2. When the attribute store data is persisted, even if one data center crashes along with its eXtreme Scale server(s), the eXtreme Scale server(s) in other data centers can restore their lost state from Cloudant and keep serving the mobile clients transparently.

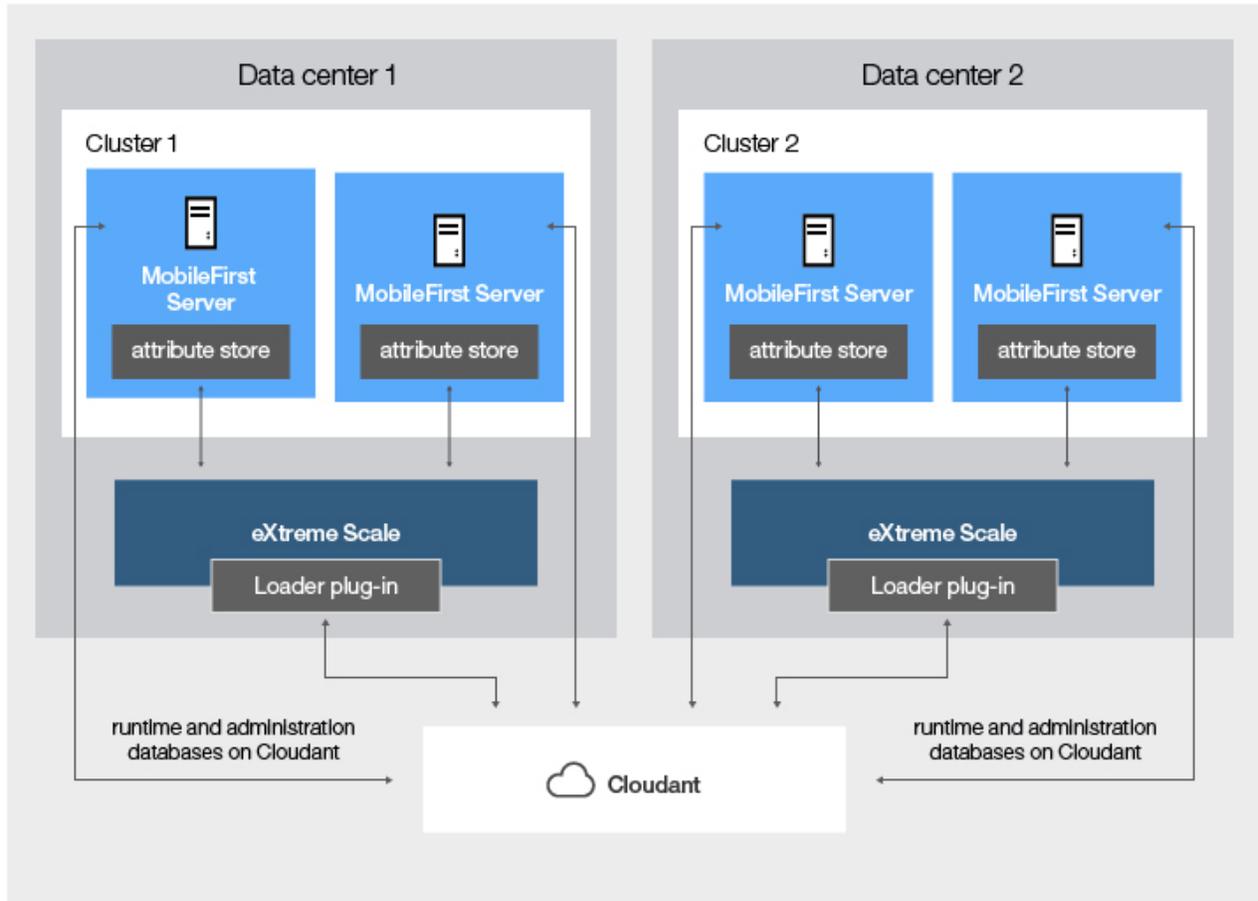

Figure 6-14. Active-active topology using eXtreme Scale and Cloudant

Configuring two data centers to work on Cloudant

There are two ways to configure two data centers to work in an active-active topology: with the Server Configuration Tool, or with an Ant task.

Server configuration tool

For each data center, run the Server Configuration Tool on all machines using the same Cloudant account.

1. For the administration services database, specify a name that is unique for the data center. For example, `admin_db_datacenter1` for the first data center and `admin_db_datacenter2` for the second data center.
2. For the runtime, specify the same prefix for the database name in all data centers.

Ant task

The relevant sample Ant file is located at `<installDir>/WorklightServer/configuration-samples`. You must specify values for the following properties:

- `worklight.contextroot`
- `database.cloudant.url`
- `database.cloudant.username`
- `database.cloudant.worklight.dbprefix`
- `database.cloudant.wladmin.dbname`

Specify the same value for the first four properties in all data centers. For the last property, specify a unique value for each data center. For example, `admin_db_datacenter1` and `admin_db_datacenter2`.

Configuring IBM MobileFirst Platform Foundation to work with eXtreme Scale and Cloudant

For more information, see “Attribute store over IBM WebSphere eXtreme Scale” on page 8-327.

Optimization and tuning of MobileFirst Server

Optimize the MobileFirst Server configuration by tuning the allocation of Java virtual machine (JVM) memory, HTTP connections, back-end connections, and internal settings.

The MobileFirst Server works with three application servers: Apache Tomcat, WebSphere Application Server and Liberty profile. For best results, install MobileFirst Server on a 64-bit operating system, and use only 64-bit software.

JDK

The MobileFirst Server can run on IBM JDK or Oracle JDK.

JVM memory allocation

The Java instance of the application server allocates memory. Consider the following general guidelines for JVM memory allocations:

- Set the JVM memory to at least 2 GB. This means you can not use less than 2GB, but that might not be enough and you will have to specify more, based on the requirements.
- For a production environment, setting the minimum heap size and maximum heap size to the same value can provide the best performance, as it avoids heap expansion and contraction.
- Set the required memory size of the application server:
 - Liberty: See the `jvm.options` section in Customizing the Liberty profile environment. You must create this file if it does not exist.
 - WebSphere Application Server: proceed as follows.
 1. Log in to the administration console.
 2. Go to **Servers > Server types > WebSphere application servers**.
 3. Select each server and set Java memory settings under **Java Process definition > JVM arguments**.
 - Apache Tomcat: find the `catalina` script and set `JAVA_OPTS` to inject memory.

For information about how to calculate memory size, see the Scalability and Hardware Sizing document and the hardware calculator spreadsheet at the Developer Center website for IBM MobileFirst Platform Foundation.

Tuning HTTP connections

This configuration defines threading and execution settings for the application server.

Each incoming request requires a thread for the duration of that request. If more simultaneous requests are received than can be handled by the currently available request processing threads, then additional threads will be created up to the configured maximum.

Specific application server configuration:

- Liberty: See the executor section in Liberty profile: Configuration elements in the `server.xml` file.

By default, the maximum number of threads is unlimited.

- WebSphere Application Server: Proceed as follows:
 1. Log in to the administration console.
 2. Go to **Servers > Server types > WebSphere application servers > *server_name* > Web container.**

By default, the maximum number of threads is 50.

- Apache Tomcat: See The HTTP Connector page in the Apache Tomcat website.
By default, the maximum number of threads is 200.

Bear in mind the following points when you configure HTTP threads:

- If, for example, the longest call takes 500 milliseconds and you configure a maximum of 50 threads, you can handle approximately 100 requests per second.
- If your environment includes a back-end system that runs slowly, increase the number of default threads. In addition, increase the number of back-end connection threads. For more information, see “Tuning database connections.”
- If you expect a high number of concurrent users, increase the number of default threads.
- Liberty specific: Even though the maximum number of threads is unlimited, the executor service makes informed choices whether adding another thread will actually be useful.

Tuning database connections

In tuning database connections, the most important parameter is the number of connection threads from the server to the database. This configuration is made in the data source. This is mostly important when working in session-independent mode, where the attribute store is kept in the runtime database (that is, `mfp.attrStore.type` has been set to `true`). In this mode, the server makes extensive use of the database. In addition, there are two IBM MobileFirst Platform Foundation features that rely heavily on the database: SSO (single sign-on) and reports. When using these features, you must ensure that you have enough database connection threads. The only limitation is that each node in the MobileFirst Server cluster can have no more than **MAX_DB_INCOMING_CONNECTIONS/NUM_OF_CLUSTER_NODES** connection threads, where **MAX_DB_INCOMING_CONNECTIONS** is the maximum incoming connections defined in the database server and **NUM_OF_CLUSTER_NODES** is the number of MobileFirst Server nodes in the cluster. A rough rule of thumb is to set the number of database connections to be the number of HTTP threads in the application server, as long as you maintain the limitation above.

Each incoming request uses a thread. If more simultaneous requests are received than can be handled by the currently available request-processing threads, more threads are created up to the configured maximum.

For data source configuration, check the following topics:

- WebSphere Application Server: See Connection pool settings.
- Apache Tomcat: See JNDI Datasource HOW-TO.
- Liberty Server: See the Datasource section in Liberty profile: Configuration elements in the server.xml file.
- Cloudant: See Property keys and values for Cloudant configuration.

Tuning back-end connections

maxConcurrentConnectionsPerNode

The **maxConcurrentConnectionsPerNode** parameter defines the maximum number of concurrent calls to the back-end service from the MobileFirst Server node. This **maxConcurrentConnectionsPerNode** parameter is set in the **<connectionPolicy>** element of the adapter XML file.

Starting from IBM MobileFirst Platform Foundation V6.3, all requests to the back-end remain on the HTTP thread. The MobileFirst Server does NOT allocate a new thread for the backend request. The only use of **maxConcurrentConnectionsPerNode** is for blocking the number of connections to the HTTP back-end. The implication is that you can specify a large value for **maxConcurrentConnectionsPerNode** (for example, 5000), so as not to limit the back-end calls.

Handling slow backend servers

If your backend server is slow, increase the values for your server settings, in particular the following values:

- Number of HTTP threads in the application server: For a backend that responds in 750 ms, for example, 3000 HTTP threads is recommended.
- **maxConcurrentConnectionsPerNode** in the adapter XML file: For a backend that responds in 750 ms, for example, 3000 is recommended.
- OS settings: Increase the number of open files. 4096 is the recommended number.
- Clients threads: A good rule of thumb is 2900 JMETER clients threads.
- Backend server: 3000 threads is recommended.

Push Notifications

For push notification information see the Push Notification section in the Scalability and Hardware Sizing document and the hardware calculator spreadsheet at the Developer Center website for IBM MobileFirst Platform Foundation.

Analytics

For Analytics Server configuration see the Analytics section in the Scalability and Hardware Sizing document and the hardware calculator spreadsheet at the Developer Center website for IBM MobileFirst Platform Foundation.

MobileFirst Server internal configuration

When working in “Session-dependent mode” on page 8-326, consider the following factors:

- The **serverSessionTimeout** property defines client inactivity timeout, after which the session is invalidated. A session is an object stored in the server memory for each connecting device. Among other data, it stores authentication information.

Active sessions are determined by the number of sessions opened versus the sessions timing out due to lack of activity. The default session timeout is 10 minutes, but it can and should be configured. Users typically set the timeout to anywhere from 5 to 10 minutes. This parameter affects the server memory consumption. Note that in session-independent mode, no data is stored in the session, therefore the session timeout is irrelevant.

- In addition, the mobile client has a “heartbeat” property that allows the mobile client to ping the server while the app is in the foreground, so that the server session will not time out.

Note:

When a mobile app has moved into the background, it no longer interacts with the server, nor sends a “heartbeat”. The result is that the server session drops after the specified server session timeout.

- For example, suppose every minute 1,000 users start a session against the server. Even if they exit the application after 3 minutes, their sessions will remain active on the server for 10 minutes, leaving $10 \times 1,000 = 10,000$ sessions.

Intervals for background tasks

The following **worklight.properties** parameters control the intervals at which background tasks. Background tasks perform several actions on the database and/or file system:

sso.cleanup.taskFrequencyInSeconds

The SSO (single sign-on) mechanism stores session data in a database table. This parameter is the interval for the SSO cleanup task to check if there are inactive accounts in the SSO table. If any are found, it deletes them. The default value is 5 seconds, meaning that every 5 seconds, the database is checked for inactive accounts. An inactive account is one that has remained idle for longer than the value of the **serverSessionTimeout** property.

push.cleanup.taskFrequencyInSeconds

Deletes inactive push notification subscriptions. The default is 60 minutes. This parameter is currently implemented only for Apple APNS.

mfp.attrStore.db.cleanupFrequency.minutes

Deletes stale attributes from the attribute store database table. The default is 60 minutes.

Optimization of MobileFirst Server project databases

You can improve the performance of the project databases or schemas that support MobileFirst Server.

Note: The Reports database and the associated APP_ACTIVITY_REPORT table described below are deprecated in IBM MobileFirst Platform Foundation V7.1.0. Use “Operational analytics” on page 14-9 instead. Note that setting up the Reports database is optional in this release and earlier releases.

The following sections provide general information about database tuning, and techniques you can use to optimize your database performance for IBM MobileFirst Platform Foundation. In the following sections, the examples that are provided are for the IBM DB2 database. If you use MySQL, Oracle, or Cloudant, consult the vendor's documentation for the corresponding procedures.

Database disks

You can find some overview information about the MobileFirst Server project databases in the **Database usage and size** section of the Scalability and Hardware Sizing document and its accompanying hardware calculator spreadsheet at the Developer Center website for IBM MobileFirst Platform Foundation. The spreadsheet can aid you in computing the hardware configuration that is best suited to your planned server environment.

When you compute your hardware needs, consider servers that offer multiple disks because performance increases significantly if you use disks correctly when you set up your MobileFirst Server project databases. For example, whether you use DB2, MySQL, or Oracle, you can almost always speed up database performance by configuring the database to use separate disks to store database logs, index, and data. Multidisk configuration results in faster access to your data with every transaction because there is no contention resulting from the same disk attempting to write to its log files or access its index at the same time it processes the data transaction.

Database compression

By using the compression feature set by your database vendor, you can decrease database size and input/output (I/O) time.

For example, in tests that were performed on IBM DB2, adding `COMPRESS YES` to the SQL that creates the `APP_ACTIVITY_REPORT` table decreased the size of that table on the disk by a factor of 3 and decreased its I/O time by a factor of 2.

CPU time might increase as a result of this compression, but it was not observed in the tests on the `APP_ACTIVITY_REPORT` table, possibly because most of the activity was INSERTs and the aggregation task was not monitored deeply.

On DB2, LOB data size

If your database is DB2, consider using the `INLINE_LENGTH` option when you create tables for SSO information. This option is also appropriate for tables that contain data that is stored as large objects (LOBs), but that are only a few kilobytes in size. To improve performance of LOB data access, you can constrain the LOB size by placing the LOB data within the formatted rows on data pages rather than in the LOB storage object. For more information about this technique, see [Inline LOBs improve performance](#).

Database table partitions

A partition is a division of a logical database table into distinct independent parts. You can improve performance and the purging accumulated data by mapping each table partition to a different table space. This suggestion applies only to the `APP_ACTIVITY_REPORT` table, which holds most of the row data.

Note: Partitioned tables are different from a partitioned database (DPF) environment, which is not suggested for use with IBM MobileFirst Platform Foundation.

To show how to use database partitions can be used, here is an example from DB2:

- A partition is defined on the `ACTIVITY_TIMESTAMP` column in the `APP_ACTIVITY_REPORT` table.

- Each partition contains the data for one day.
- The number of partitions is the number of days of data that you want to save.
- Each partition is created in a different table space.
- Thus in the SQL example that follows, you create seven partitions in DB2:

```
CREATE TABLESPACE app_act_rep_1;
CREATE TABLESPACE app_act_rep_2;
CREATE TABLESPACE app_act_rep_3;
CREATE TABLESPACE app_act_rep_4;
CREATE TABLESPACE app_act_rep_5;
CREATE TABLESPACE app_act_rep_6;
CREATE TABLESPACE app_act_rep_7;

CREATE TABLE "APP_ACTIVITY_REPORT" (
    "ID" BIGINT NOT NULL ,
    "ACTIVITY" CLOB(1048576) LOGGED NOT COMPACT ,
    "ACTIVITY_TIMESTAMP" TIMESTAMP ,
    "ADAPTER" VARCHAR(254) ,
    "DEVICE_ID" VARCHAR(254) ,
    "DEVICE_MODEL" VARCHAR(254) ,
    "DEVICE_OS" VARCHAR(254) ,
    "ENVIRONMENT" VARCHAR(254) ,
    "GADGET_NAME" VARCHAR(254) ,
    "GADGET_VERSION" VARCHAR(254) ,
    "IP_ADDRESS" VARCHAR(254) ,
    "PROC" VARCHAR(254) ,
    "SESSION_ID" VARCHAR(254) ,
    "SOURCE" VARCHAR(254) ,
    "USER_AGENT" VARCHAR(254) )
    IN app_act_rep_1, app_act_rep_2, app_act_rep_3, app_act_rep_4,
    app_act_rep_5, app_act_rep_6, app_act_rep_7
    PARTITION BY RANGE (ACTIVITY_TIMESTAMP)
    (STARTING FROM ('2013-02-25-00.00.00.000000')
    ENDING AT ('2013-03-04-00.00.00.000000') EXCLUSIVE
    EVERY (1 DAY)
);
```

Database purge

After high-volume data is allocated to separate table spaces, the task of periodically purging the data is simplified. This suggestion is also primarily relevant only to the APP_ACTIVITY_REPORT table that holds most of the row data. The process in this DB2 example is as follows:

- Aggregate data either with a MobileFirst process or with a client external process.
- When the data is no longer needed (the aggregation task should successfully process the data), it can be deleted.
- The most effective way to delete the data is to delete the partition. In DB2, you purge the data by detaching the partition to a temp table, then truncating that temp table and attaching a new day to the partition. You can implement the process as a scheduled stored procedure in the database, as in the following example:

```
ALTER TABLE "APP_ACTIVITY_REPORT"
    DETACH PARTITION part0
    INTO temptable;

TRUNCATE TABLE temptable;

ALTER TABLE "APP_ACTIVITY_REPORT"
```

```
ATTACH PARTITION part0
STARTING FROM ('2013-02-25-00.00.00.000000')
ENDING AT ('2013-03-26-00.00.00.000000') EXCLUSIVE
FROM temptable;
```

Testing MobileFirst Server performance

You can run performance tests on the different features of the MobileFirst Server. This section describes how to run the Apache jMeter performance test tool, but the procedure is similar for other tools.

Note: The procedures described in this page apply only to a scenario that involves a propriety JavaScript adapter that is running in **session-dependent** mode. It is not applicable in a scenario that involves the OAuth security framework. For more information about session independency, see “Session-independent mode” on page 8-324. For more information about OAuth, see “OAuth-based security model” on page 8-527.

The following features can have an impact on MobileFirst Server performance:

- Authentication flow
- Back-end invocation
- Database reporting
- Single sign-on (SSO)
- Direct update
- Push notification
- Geolocation

This section focuses on testing the impact of authentication flow and back-end invocation on MobileFirst Server performance.

Testing authentication flow performance

The following realms, which are part of the default security test for Android, iOS, and Windows Phone Silverlight 8, are tested:

Remote disable realm

Check on every request that the application is not blocked.

AntiXSRF realm

Check on every request that WL-Instance-Id is equal to the one sent in the init response.

Anonymous User realm

Generate a random user ID that is used for such things as reports and identifying the user.

Device no provisioning

Check that the token value inside the authorization header is equal to the one sent in the initialization response.

For more information about the realms, see “The authentication configuration file” on page 8-603.

When you run a performance test, your first step is to complete the authentication flow. If you do not do so, security challenges are raised and your requests are rejected with “401” errors. This step involves sending an init request to the MobileFirst Server and extracting the relevant data from the response. The init

request has the following structure: `http://{Host}:{Port}/{Context}/apps/services/api/{AppName}/{environment}/init`

Table 6-33. Initialization parameters

Parameter	Description
x-wl-app-version	Application version.
x-wl-platform-version	Version of the product that built the application.

This is an example of a jMeter test:

```

x Headers Preview Response Cookies Timing
Request URL: http://192.168.1.104:10080/worklight/apps/services/api/DummyApp/common/init
Request Method: POST
Status Code: 401 Unauthorized
Request Headers
Accept: text/javascript, text/html, application/xml, text/xml, */*
Accept-Encoding: gzip, deflate, sdch
Accept-Language: en-US
Cache-Control: max-age=0
Connection: keep-alive
Content-Length: 65
Content-type: application/x-www-form-urlencoded; charset=UTF-8
Cookie: WL_PERSISTENT_COOKIE=9b52c92f-20ee-4c39-b346-f7d2d3f5e135; JSESSIONID=0000s6n4z1i557LbsL5Mh5uAyTH:0c75f839-48c4-4f6b-87b2-d36dc2b52d60; testcookie=oreo
Host: 192.168.1.104:10080
Origin: http://192.168.1.104:10080
Referer: http://192.168.1.104:10080/worklight/apps/services/preview/DummyApp/common/0/default/DummyApp.html
User-Agent: Mozilla/5.0 (Windows NT 6.1; WOW64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/32.0.1700.107 Safari/537.36
X-Requested-With: XMLHttpRequest
x-wl-app-version: 1.0
x-wl-platform-version: 6.0.0
Form Data
skin:
skinLoaderChecksum:
isAjaxRequest: true
x: 0_s00389923991412
  
```

The dynamic parameters in the Form Data (`skinLoaderChecksum`, `isAjaxRequest`, and `x`) are appended to the URL. During performance testing, the `skin` and `skinLoaderChecksum` parameters are not needed because jMeter does not really run the app: jMeter only simulates the client app. The parameter `x` aims to prevent response data from being returned from cache. As a result, you do not need to append the parameters during performance testing or you can generate a random value for the dynamic parameter `x`. A better option is always to clean cookies in your performance testing tool before you start loading test threads.

Response data from MobileFirst initialization service

The response data from the MobileFirst `init` request differs depending on the security test you apply on your MobileFirst application environment. By default, if you have no additional security test, the response data structure for the common and iPhone environment are shown in the following figures. (The data structure for the Android and Windows Phone Silverlight 8 environment is the same as that for the iPhone environment.)

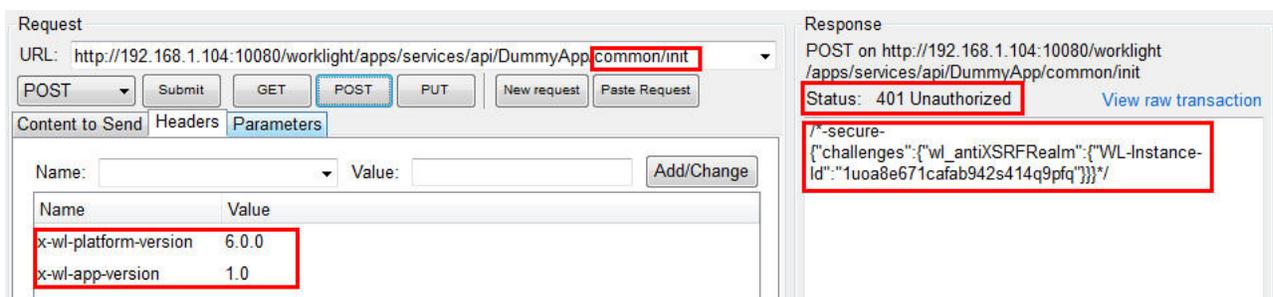

Figure 6-15. Response data from common environment

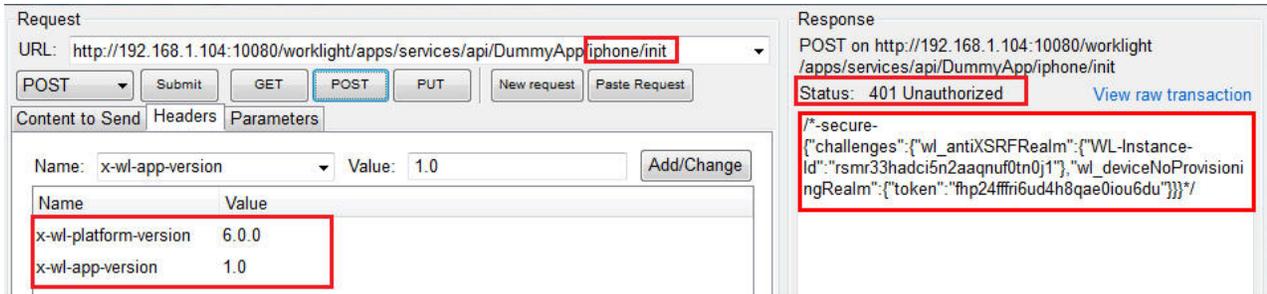

Figure 6-16. Response data from iPhone environment

The difference between the common and iPhone environment data structures is that the common environment has no `wl_deviceNoProvisioningRealm` challenge by default.

Extracting the init response data

You need to extract the `WL-Instance-Id` and the token from the `init` response and send them as headers in all requests to the MobileFirst Server. If you do not do so, the authentication check fails and the request is rejected. Challenge data is different for each session, so you need to extract and store the challenge data for each thread. For more information, see “Testing back-end invocation” later in this section.

Changing the response status to HTTP 200

When the performance testing thread runs the initialization for the first time, MobileFirst Server responds to challenge data with an HTTP 401 status. This is to be expected, so the performance tool should treat this HTTP status as a success. The HTTP status can be changed to HTTP 200 by using the performance testing tool's script. In this way, the performance testing tool will record the request as a success, otherwise the performance testing report might mark this request as having failed and might record it as an error. This would greatly impact the performance testing report.

Testing back-end invocation

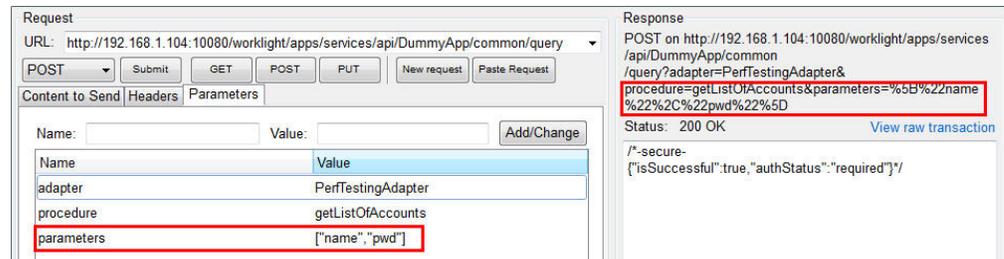

You should start testing back-end invocation only after you have finished testing authentication flow. You can choose any type of back end that you want. The request for the back-end invocation has the following structure:

```
http://{Host}:{Port}/{Context}/apps/services/api/{AppName}/{environment}/query.
```

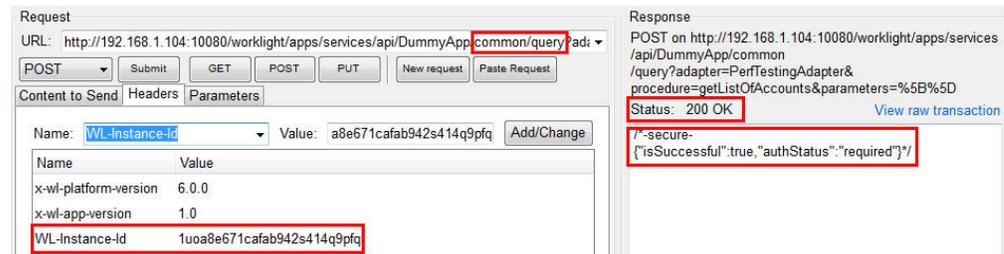

Table 6-34. Backend invocation parameters

Parameter	Description
adapter	MobileFirst Adapter name.
procedure	MobileFirst procedure name
parameters	Procedure parameters should be an array.

The following figure shows an example array of parameters:

The following figure shows an example of request headers:

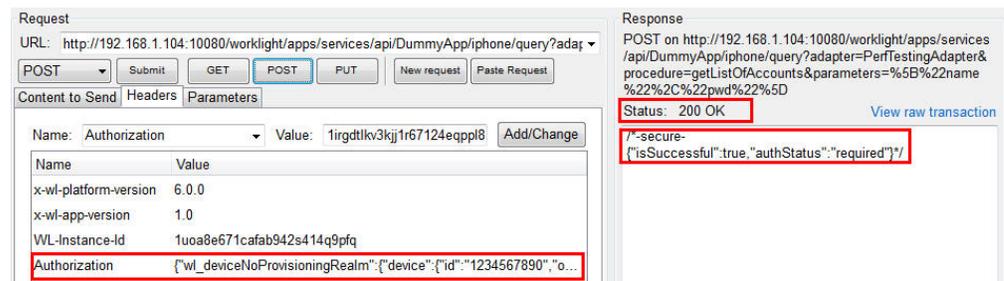

By default, the jMeter tool encodes the URL. If your performance testing tool does not support URL encoding, you must use encoded parameter values.

For the Android, iPhone, and Windows Phone Silverlight 8 environments, since they contain `wl_deviceNoProvisioningRealm` by default, you need to send the Authorization header. The format for HTTP Authorization header is shown as follows. You need to replace `#{device-token}` with the token you extracted in the initialization phase.

```
{\"wl_deviceNoProvisioningRealm\":{\"device\":{\"id\":\"1234567890\",\"os\":\"5.0\",\"model\":\"testMod
```

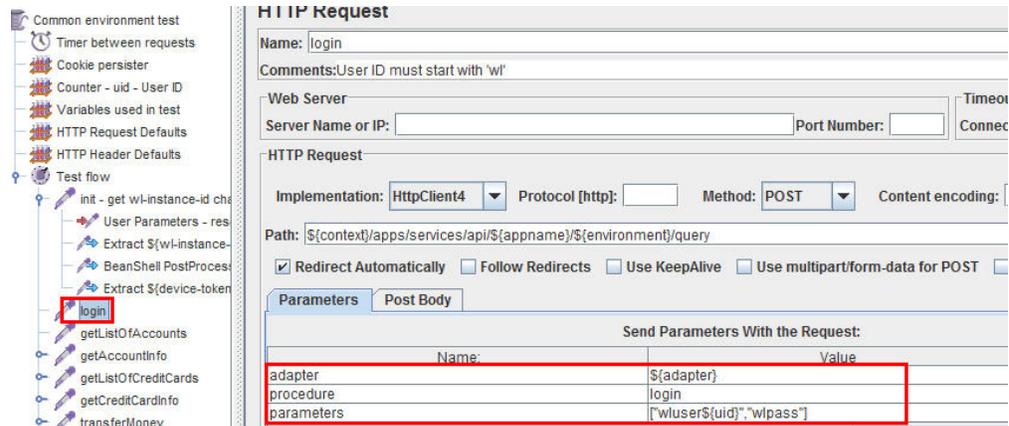

When the response data `isSuccessful` is true, this indicates that the response data from the MobileFirst Adapter procedure was successfully received and now you can continue with your back-end testing.

Logging in

When the MobileFirst adapter procedure is protected by a security test or the `connectAs` property is set to `endUser`, you need to log in to the MobileFirst Server before calling this procedure. To check if the MobileFirst adapter procedure needs a login, you can call the procedure followed by the steps described earlier, and check the response data from the MobileFirst Server. If the response data includes `isSuccessful:true` and `authStatus:required`, you should log in to the MobileFirst Server first, otherwise the requests to this procedure are rejected by MobileFirst Server. The way you log in to the MobileFirst Server depends on the authentication

type. If the app is protected by form-based authentication or adapter-based authentication, you can call the login procedure after successfully completing initialization. In general, the login procedure should not be protected by a security test; it can be directly called after initialization is completed. For other authentication types, you can capture the network traffic on MobileFirst Server by using network traffic capture tools (for example, Fiddler or Wireshark). The network traffic data shows the detailed URL and parameters that you can use to log in to the MobileFirst Server. The following screen image shows an example of a login function that calls the setActiveUser API with the supplied user ID and password:

Logging out

The following options are available for logging out of the MobileFirst Server:

Not logging out for each iteration

MobileFirst Server automatically logs the user out when the session times out. This option consumes more memory than logging out, but is useful if you want to maximize memory usage during performance testing. To adopt this option, you need to clean cookies for each iteration in the performance testing tool.

Logging out after each iteration by using the MobileFirst logout service

It is recommended to clean cookies for each iteration to avoid sharing data between iterations. The logout request has the following structure:
`http://{Host}:{Port}/{Context}/apps/services/api/{AppName}/{environment}/logout`

For more information about the parameters, see “HTTP Interface of the production server” on page 6-364.

Database reporting

To activate database reporting, you need to specify `reports.exportRowData=true` in your `worklight.properties` file. You also need to set up the reports database. For more information, see “(deprecated) Reports database” on page 14-99. After you enable database reporting, you can use the back-end invocation step described earlier. See the database reporting section in the Scalability and Hardware Sizing document at the Developer Center website for IBM MobileFirst Platform Foundation.

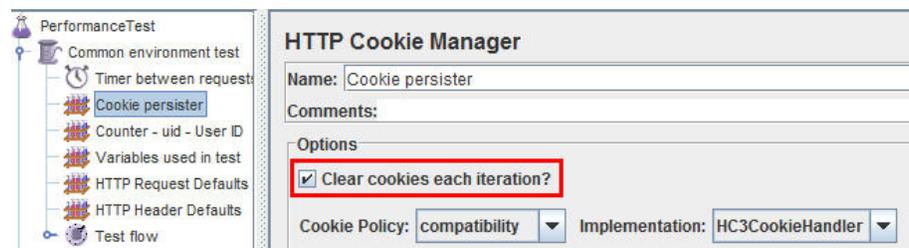

Single sign-on (SSO), direct update, push notification, and geolocation

See the relevant section in the Scalability and Hardware Sizing document at the Developer Center website for IBM MobileFirst Platform Foundation.

General example: Using jMeter as a performance testing tool

HTTP cookie management

Cleaning the cookies on every thread iteration ensures that no data and user information is being cached during this iteration. If you want to keep cookie information, you need to clean the user information at the end of the iteration to avoid unexpected errors during load testing. For example, if the user does not log out during the previous iteration, the next iteration might be affected by that user.

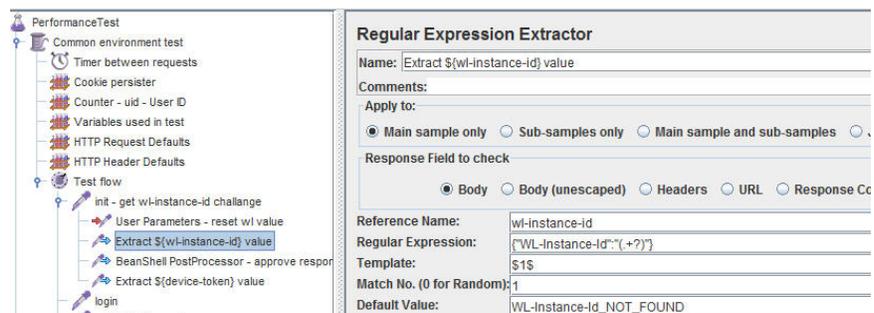

HTTP Header Management

The necessary x-wl-platform-version and x-wl-app-version that were described earlier can be defined here; you can also define the WL-Instance-Id and WL_deviceNoProvisioningRealm token placeholders. You can use a jMeter script to extract the real challenge data and replace the placeholders for each thread iteration as shown in the following image:

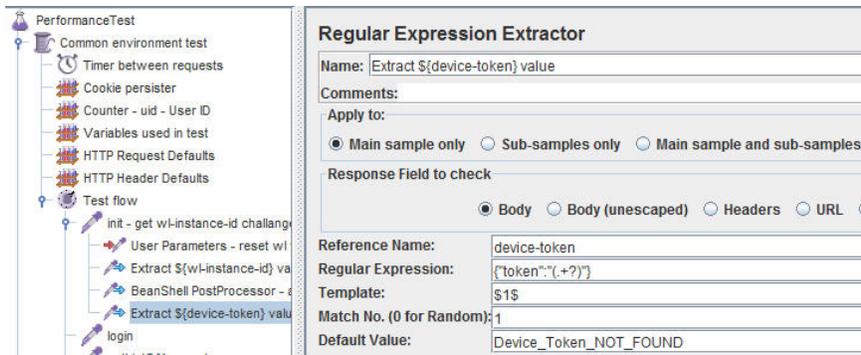

Initialization phase

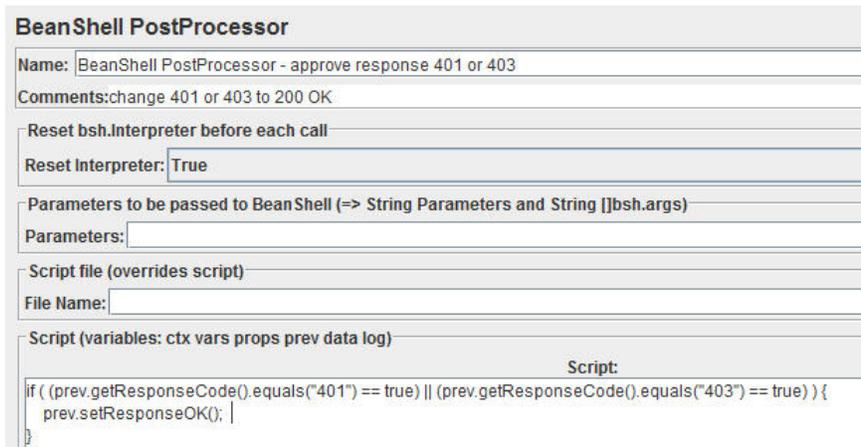

1. Extract and replace the WL-Instance-Id placeholder:

2. Extract and replace the WL_deviceNoProvisioningRealm token placeholder:

3. Change initialization HTTP status 401 and 403 to HTTP status 200:

Security configuration

Configure the security of the MobileFirst Server as detailed here.

Securing the MobileFirst Server administration

No unauthorized person can perform MobileFirst Server administration operations. This is particularly important in a production environment.

The security threat is that any person who can install mobile applications in a production environment can modify the behavior of these apps on the mobile devices. The apps are served to the clients through the MobileFirst runtime environments, which get these apps from the Administration Services through JMX. The Administration Services fetch these apps from the administration database. The Administration Services and the IBM MobileFirst Platform Operations Console allow any user in the roles of worklightadmin or worklightdeployer to deploy applications. A similar threat exists for adapters.

Enabling https in the application server

The ability to use https with the application server is a prerequisite.

For WebSphere Application Server Liberty profile:

- Verify that the server.xml file contains either <feature>ssl-1.0</feature> or <feature>restConnector-1.0</feature>, or both features. The restConnector-1.0 feature implies that the ssl-1.0 feature is enabled.

- Verify that the HTTPS port is enabled, by ensuring that the `server.xml` file does not have an `<httpEndpoint>` element with a negative `httpsPort` attribute. If the HTTPS port is disabled, SSL is also disabled, and the JMX connections that the MobileFirst Server requires do not work.
- Verify that the `server.xml` file contains `<keyStore id="defaultKeyStore" .../>`, or an equivalent declaration, otherwise the JMX connections that the MobileFirst Server requires do not work. For more information, see Liberty profile: SSL configuration attributes.

For Apache Tomcat:

Enable an `https` port as documented in SSL support and SSL Configuration HOW-TO.

Enabling application security in the application server

Without this step, anyone can connect to the web applications without credentials.

For WebSphere Application Server full profile:

- Verify that Administrative Security is enabled.
- Verify that Application Security is enabled.

For WebSphere Application Server Liberty profile:

Verify that the `server.xml` file contains `<feature>appSecurity-1.0</feature>`.

Protecting the passwords of users in the roles `worklightadmin` and `worklightdeployer`

If the password of any user who is mapped to the roles `worklightadmin` or `worklightdeployer` is compromised, that is, becomes potentially known to an unauthorized person, unauthorized MobileFirst administration operations are possible. Here are steps to mitigate this risk.

- Minimize the number of users that you map to the `worklightadmin` and `worklightdeployer` roles. For more information, see “Configuring user authentication for MobileFirst Server administration” on page 6-106.
- Map different users to the `worklightadmin` or `worklightdeployer` roles in development and test environments than you do in the production environment. If the password of the administrator of the development or test environment is compromised (for example, by use of `secure="false"`), mapping users and roles differently helps secure the password of the administrator of the production environment.
- If these users are authenticated through LDAP, secure the connection to the LDAP server.
- Never use the MobileFirst Operations Console or the MobileFirst Administration REST services over `http`. Always use `https`. You can prevent such use in the following ways:
 - Configure the application server to respond only to an `https` port, not to an `http` port.
 - Modify the `worklightconsole.war` and `worklightadmin.war` files to activate the Java EE 6 transport security of type `CONFIDENTIAL`. This setting redirects from `http` to `https` before the application server requests a user and password.
 1. Unpack `worklightconsole.war` (as a `.zip` file).

2. Edit its WEB-INF/web.xml file, changing `<transport-guarantee>NONE</transport-guarantee>` to `<transport-guarantee>CONFIDENTIAL</transport-guarantee>`.
 3. Repack `worklightconsole.war`.
 4. Unpack `worklightadmin.war` (as a .zip file).
 5. Edit its WEB-INF/web.xml file, changing `<transport-guarantee>NONE</transport-guarantee>` to `<transport-guarantee>CONFIDENTIAL</transport-guarantee>`.
 6. Repack `worklightadmin.war`.
 7. Redeploy these WAR files, either manually, or through the Ant task `<installworklightadmin>` or `<updateworklightadmin>`. For more information, see “Deploying the MobileFirst Operations Console and Administration Services with Ant tasks” on page 6-75.
- Never use the `<wladm>` Ant task with the attribute `secure="false"`, and never use the `wladm` command with the option `-secure=false`. For this purpose:
 - Ensure that your application server uses an SSL certificate signed by a CA, not a self-signed certificate, and that the host name that is mentioned in this certificate matches the host name of the application server host.
 - Ensure that this SSL certificate is contained in the truststore of the JVM that runs the `<wladm>` Ant task or the `wladm` command.
 - Change the file access permissions of the file that contains the password that is used by the `<wladm>` Ant task or the `wladm` command to be as restrictive as possible. To do so, you can use a command, such as the following examples:
 - On UNIX: `chmod 600 adminpassword.txt`
 - On Windows: `cacls adminpassword.txt /P Administrators:F %USERDOMAIN%\%USERNAME%:F`
 - Additionally, you might want to obfuscate the password, to hide it from an occasional glimpse. To do so, use the `wladm config password` command to store the obfuscated password in a configuration file. Then, you can copy and paste the obfuscated password to the Ant script or to the password file that you want.
 - In the configuration of the MobileFirst Operations Console web application, set the JNDI property `ibm.worklight.admin.ui.cors.strictssl` to `true`. This property helps rejecting unsecure SSL certificates.
 - In the configuration of the MobileFirst Operations Console web application, set the JNDI property `ibm.worklight.admin.hsts` to `true`. This property implements HTTP Strict Transport Security and helps the administrator's browser remember to access the MobileFirst Operations Console through `https` instead of `http`.

Protecting the administration database

If the password of the administration database (or of the user who owns the corresponding schema of that database) is compromised, that is, becomes potentially known to an unauthorized person, unauthorized deployments of apps and adapters are possible. Here are steps to mitigate this risk.

- Do not host other services than the database management system on the computers that serve this database.
- If you use Ant tasks to configure the MobileFirst Server administration (see “Using Ant tasks to install MobileFirst Server administration” on page 6-73), you must do one of the following actions:
 - Change the file access rights of the Ant XML file to be as restrictive as possible before you store passwords in it. For more information, see step 2 in “Sample configuration files” on page 16-77.

- Write ***** (12 asterisks) in place of the password, so the Ant XML file does not contain the password. Instead, the Ant task queries the password interactively when it is invoked.
- Minimize the number of users who have login access to the computers that run MobileFirst Server.
- Change the file access rights of the application server configuration files that contain the jdbc/WorklightAdminDS data source password to be as restrictive as possible. For more information, see step 3 in “Sample configuration files” on page 16-77.

Protecting the JMX communication

If the JMX communication between Administration Services and the MobileFirst runtime environments are not secured, unauthorized persons who have local access to the MobileFirst Server computers can play man-in-the-middle attacks and thus activate tampered apps and adapters. Here are steps to mitigate this risk.

- For WebSphere Application Server Liberty, follow the procedure of Configuring secure JMX connection to the Liberty profile.
- For Apache Tomcat, use a JMX configuration with SSL, as described in “Configuring Apache Tomcat” on page 6-65.

For WebSphere Application Server Liberty, encode the password of the user who is granted the administrator role that is required for the JMX communication. This password is declared in the Liberty profile `server.xml` file, both in the `ibm.worklight.admin.jmx.pwd` JNDI property and inside the `<user>` element of the basic registry in case you use this registry type. Both passwords can be encoded with the Liberty profile `securityUtility` program. The supported encoding types are `xor` and `aes` (only with the default key).

Protecting the apps and adapters to deploy

If the source from which the MobileFirst administrator receives apps and adapters is not secured, tampered apps and adapters can be submitted to the MobileFirst administrator, who then deploys them. Here are steps to mitigate this risk.

- Ensure that the MobileFirst administrator receives apps and adapters only through channels that guarantee the integrity of the sender and of the sent artifacts. For example, use emails with digital signature, or web-based tools with the need to log in through `https`.
- Ensure that the development teams that create these apps and adapters use a version control system that guarantees the integrity of each modification and disallows modifications by unauthorized persons. Examples of version control systems in this category are `RTC/jazz` and `Git`. In contrast, `CVS` does not belong to this category.

Protecting against attacks from the internet

Attackers from the internet might attempt to search for security flaws in the MobileFirst Operations Console and Administration Services and try to circumvent the security measures. Here is a tip to mitigate this risk. It assumes that mobile application users connect to MobileFirst Server from the internet, but all legitimate uses of the MobileFirst Operations Console and Administration Services are from an intranet.

- Configure your internet gateway or firewall (for example, IBM DataPower) to block access to URLs under the context roots of the MobileFirst Operations

Console (default: /worklightconsole) and of the Administration Services (default: /worklightadmin). At the same time, keep the access to the MobileFirst runtime web applications open.

Database and certificate security passwords

When you configure a MobileFirst Server, you must typically configure database and certificate passwords for security.

Configuration of a IBM MobileFirst Platform Server typically includes the following credentials:

- User name and password to the runtime database
- User name and password to other custom databases
- User name and password to certificates that enable the stamping of apps

All credentials are stored in the in JNDI properties of the application server. Defaults can be stored in the `worklight.properties` file. See “Configuration of MobileFirst applications on the server” on page 12-50 for information about individual properties.

You can encrypt any or all of these passwords. For more information, see “Storing properties in encrypted format” on page 12-62.

Apache Tomcat security options

An optimal Apache Tomcat security balances ease of use and access with strengthening of security and hardening of access.

You must harden the Tomcat Server according to your company policy. Information on how to harden Apache Tomcat is available on the Internet. All other out-of-the-box services provided by Apache Tomcat are unnecessary and can be removed.

Running MobileFirst Server in WebSphere Application Server with Java 2 security enabled

You can run IBM MobileFirst Platform Server in WebSphere Application Server with Java 2 security enabled.

About this task

To enable Java 2 security in WebSphere Application Server, complete the following procedure to modify the `app.policy` file and then restart WebSphere Application Server for the modification to take effect.

Procedure

1. Install MobileFirst Server on a WebSphere Application Server instance. The installation contains all the necessary libraries to support WebSphere Application Server security.
2. Enable Java 2 security in WebSphere Application Server.
 - a. In the WebSphere Application Server console, click **Security > Global security**
 - b. Select **Use Java 2 security to restrict application access to local resources**.
3. Modify the `app.policy` file, `<ws.install.root>/profiles/<server_name>/config/cells/<cell_name>/node/<node_name>/app.policy`.

The app.policy file is a default policy file that is shared by all of the WebSphere Application Server enterprise applications. For more information, see *app.policy file permissions* in the WebSphere Application Server documentation.

Add the following content into the app.policy file.

```
grant codeBase "file:${was.install.root}/worklight-jee-library-xxx.jar" {
    permission java.security.AllPermission;
};

// The war file is your WL server war.
grant codeBase "file:worklight.war" {
    //permission java.security.AllPermission;
    //You can use all permission for simplicity, however, it might
    // cause security problems.
    permission java.lang.RuntimePermission "*";
    permission java.io.FilePermission "${was.install.root}${/}-", "read,write,delete";
    // In Linux need to set TEMP folder of Linux.
    permission java.io.FilePermission "C:/Windows/TEMP/${/}-", "read,write,delete";
    permission java.util.PropertyPermission "*", "read, write";
    permission java.lang.reflect.ReflectPermission "suppressAccessChecks";
    permission com.ibm.tools.attach.AttachPermission "createAttachProvider";
    permission com.ibm.tools.attach.AttachPermission "attachVirtualMachine";
    permission com.sun.tools.attach.AttachPermission "createAttachProvider";
    permission com.sun.tools.attach.AttachPermission "attachVirtualMachine";
    permission java.net.SocketPermission "*", "accept,resolve";
};
```

4. Restart WebSphere Application Server for the modification of the app.policy file to take effect.

Transmitting MobileFirst data on the BlackBerry Enterprise Server MDS channel

If you install IBM MobileFirst Platform Foundation in an environment that includes a BlackBerry Enterprise Server, you can use the BlackBerry MDS channel to transmit MobileFirst data.

About this task

Figure 6-17 on page 6-168 shows an environment in which apps that are installed on BlackBerry devices transmit data by using the BlackBerry MDS channel. When you install IBM MobileFirst Platform Foundation in environments such as these, you can configure MobileFirst data to use the same channel.

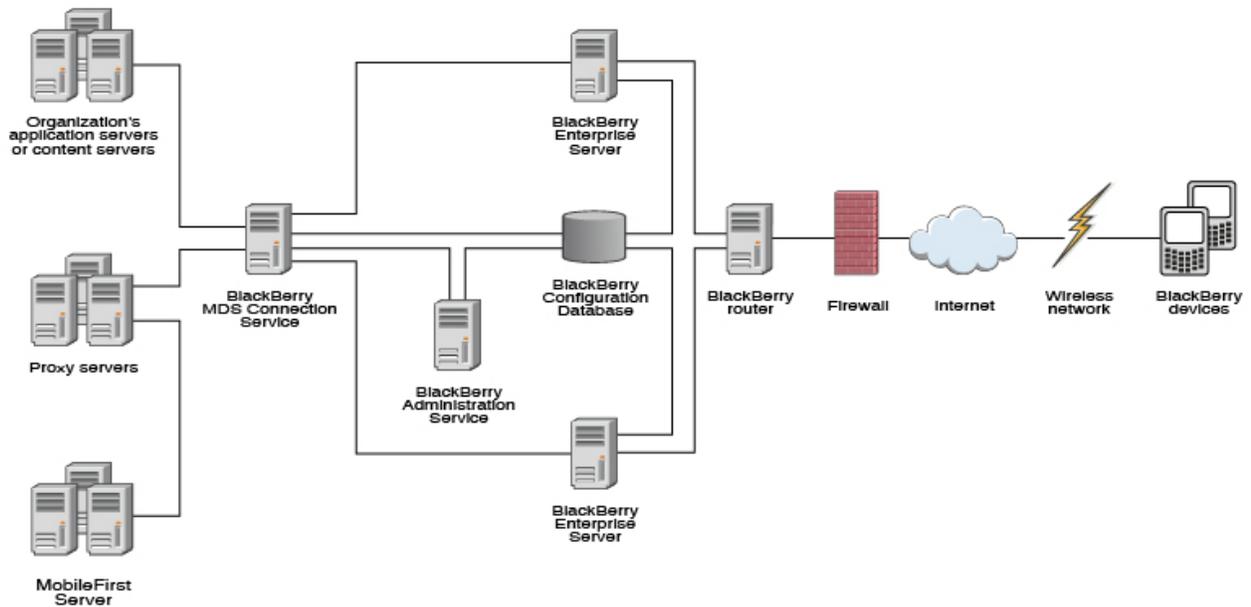

Figure 6-17. IBM MobileFirst Platform Foundation with BlackBerry Enterprise Server

Procedure

On the BlackBerry Enterprise Server, configure an MDS connection service to the MobileFirst Server or to its intermediary proxy server. For information about how to configure an MDS connection service, see the BlackBerry Enterprise Server documentation.

Integration with IBM WebSphere DataPower as a security gateway and reverse proxy

Protect your mobile-application traffic by using IBM WebSphere DataPower as a reverse proxy and security gateway in the DMZ between client applications and MobileFirst Server.

Protecting mobile-application traffic that enter your network from customer and employee devices involves preventing data from being altered, authenticating users, and allowing only authorized users to access applications. You can use the DataPower security-gateway features of to protect mobile-application traffic that is initiated by client MobileFirst applications.

Enterprise topologies are designed to include different protection zones so that specific processes can be secured and optimized. You can use DataPower in different ways in the DMZ (a firewall configuration for securing local area networks) and in other zones within your network to protect enterprise resources. When you start to build MobileFirst applications to be delivered to the devices of your customers and employees, you can apply these methods to protect the mobile-application traffic.

You can use DataPower as a front-end reverse proxy and security gateway. DataPower uses a multiprotocol gateway (MPGW) service to proxy and secure access to MobileFirst mobile applications. You can select the method that DataPower will use to authenticate the mobile client, such as HTTP basic

authentication or HTML forms-based authentication. The following topics demonstrate how to implement this topology by using either HTTP basic authentication or HTML forms-based authentication. You can adjust the procedure, as needed, to use a different authentication method. For more information about configuring DataPower, see the WebSphere DataPower documentation.

Consider adopting the following phased approach to establishing DataPower as a reverse proxy and security gateway:

1. Install and configure a MobileFirst environment, and test the installation with a simple application without DataPower acting as the reverse proxy.
2. Test your application logic and verify that it works.
3. Configure your MobileFirst project to work with your preferred reverse-proxy DataPower gateway configuration.
4. Configure a multi-protocol gateway on your DataPower appliance to use DataPower as a proxy for your MobileFirst mobile application or MobileFirst Operations Console. As part of the configuration select your preferred authentication method for the DataPower AAA (authentication, authorization, audit) policy.
5. Run your application and attempt to access a protected resource to test the implementation.

Note: To integrate your application with DataPower by using LTPA and DataPower HTML forms-based authentication, follow the specialized procedure “Integrating with DataPower as a reverse proxy using LTPA and form-based authentication” on page 6-181. This procedure includes a DataPower configuration pattern and MobileFirst samples that eliminate much of the manual configuration described in the more generic procedure “Integrating with DataPower as a security gateway and reverse proxy.”

Integrating with DataPower as a security gateway and reverse proxy

Learn how to integrate with IBM WebSphere DataPower as a reverse proxy and security gateway.

Before you begin

Note: To integrate your application with DataPower by using LTPA and DataPower HTML forms-based authentication, follow the specialized procedure at “Integrating with DataPower as a reverse proxy using LTPA and form-based authentication” on page 6-181. The specialized procedure includes a DataPower configuration pattern that eliminates much of the manual configuration described in the following generic procedure, including the need for the manual rule definitions outlined in the topic “DataPower configuration rules” on page 6-175.

- Read the topic “Integration with IBM WebSphere DataPower as a security gateway and reverse proxy” on page 6-168.
- Install IBM WebSphere DataPower by following the instructions in the WebSphere DataPower documentation.
- Install IBM MobileFirst Platform Foundation with interim fix 7.1.0.00-20160513-1006 or later.
Ensure that the installation includes MobileFirst Studio.
- Establish a stand-alone MobileFirst Server environment that uses WebSphere Application Server.

Procedure

1. Configuring your MobileFirst applications

- a. For each application that you are configuring, modify the authenticationConfig.xml file on the server to include the following security test, realm, and login module declarations:

```
<securityTests>
  <mobileSecurityTest name="WASLTPARealm">
    <testDeviceId provisioningType="none"/>
    <testUser realm="WASLTPARealm"/>
  </mobileSecurityTest>
  <webSecurityTest name="WASLTPARealm">
    <testUser realm="WASLTPARealm"/>
  </webSecurityTest>
</securityTests>

<realms>
  <!-- For websphere -->
  <realm name="WASLTPARealm" loginModule="WASLTPAModule">
    <className>com.worklight.core.auth.ext.WebSphereFormBasedAuthenticator</className>
    <parameter name="login-page" value="/login.html"/>
    <parameter name="error-page" value="/loginError.html"/>
  </realm>
</realms>

<loginModules>
  <!-- For websphere -->
  <loginModule name="WASLTPAModule">
    <className>com.worklight.core.auth.ext.WebSphereLoginModule</className>
  </loginModule>
</loginModules>
```

By default, the authenticationConfig.xml file is usually available in this directory: `<WAS_INSTALL_DIR>/profiles/<WAS_PROFILE>/installedApps/<WAS_CELL>/IBM_Worklight_Console.ear/worklight.war/WEB-INF/classes/conf.`

- b. Restart the MobileFirst Operations Console enterprise application.
- ### 2. Update your client mobile app.
- a. In your client mobile app, add the following JavaScript code to your HTML MobileFirst application:

```
function showLoginScreen() {
  $("#index").hide();
  $("#authPage").show();
}

function showMainScreen() {
  $("#authPage").hide();
  $("#index").show();
}

var myChallengeHandler = WL.Client.createChallengeHandler("WASLTPARealm");
```

```

var lastRequestURL;

myChallengeHandler.isCustomResponse = function(response) {

    //A normal login form has been returned
    var findError = response.responseText.search("DataPower/Worklight Error");
    if(findError >= 0) {
        return true;
    }

    //A normal login form has been returned
    var findLoginForm = response.responseText.search("DataPower/Worklight Form Login");
    if(findLoginForm >= 0) {
        lastRequestURL = response.request.url;
        return true;
    }

    //This response is a MobileFirst Server response, handle it normally
    return false;
};

myChallengeHandler.handleChallenge = function(response) {
    showLoginScreen();
};

challengeHandler1.handleFailure = function(response) {
    console.log("Error during WL authentication.");
};

myChallengeHandler.submitLoginFormCallback = function(response) {
    var isCustom = myChallengeHandler.isCustomResponse(response);
    if(isCustom) {
        myChallengeHandler.handleChallenge(response);
    }
    else {
        //hide the login screen, you are logged in
        showMainScreen();

        myChallengeHandler.submitSuccess();
    }
};

//When the login button is pressed, submit a login form
$("#loginButton").click(function() {
    var reqURL = "/j_security_check";
    alert(lastRequestURL);
    var options = {method: "POST"};
    options.parameters = {
        j_username: $("#username").val(),
        j_password: $("#password").val(),
        originalUrl : lastRequestURL,
        login: "Login"
    };

    options.headers = {};
    myChallengeHandler.submitLoginForm(reqURL, options, myChallengeHandler.submitLoginFormCallback);
});

```

- b. If you want to retrieve the LTPA key file that is used for authentication from MobileFirst Server, you can also use the login method of the MobileFirst WL.Client class: `WL.Client.login("WASLTPARealm");` This call triggers the `myChallengeHandler.isCustomResponse` method with a JSON response from which you can retrieve the LTPA key file:

```
if (response.responseJSON.WASLTPARealm && response.responseJSON.WASLTPARealm.isUserAuthenticated)
var sessionKey = response.responseJSON.WASLTPARealm.attributes.LtpaToken;
```

For any subsequent adapter call that needs to be proxied through the reverse proxy, you can include the extracted LTPA key file (stored in the *sessionKey* variable in the code sample) as a header within the request.

Ensure that the HTML body for your MobileFirst application reflects the login information that is to be handled by DataPower.

- c. To add the authentication test to an application or device, add a **securityTest** attribute to the environment tag in the project application-descriptor.xml file.

Set the value of this attribute to the name of the security test that you declared in the authenticationConfig.xml file in substep 1a. Here is an iPad example:

```
<ipad bundleId="com.Datapower" securityTest="WASSTest-securityTest" version="1.0">
  <worklightSettings include="false"/>
  <security>
    <encryptWebResources enabled="false"/>
    <testWebResourcesChecksum enabled="false" ignoreFileExtensions="png, jpg, jpeg, gif, mp4, mp3"/>
  </security>
</ipad>
```

3. Define a multiprotocol gateway.
 - a. In the IBM DataPower WebGUI, in the search box under Control Panel, enter Multi-Protocol and select **New Multi-Protocol Gateway**.
 - b. On the General Configuration page, define the following settings:

Table 6-35. General Configuration

Field	Description
Multi-Protocol Gateway Name	Provide a name for your gateway.
Response Type	Select Non-XML . With this value, HTTP web application traffic (including JSON, JavaScript, and CSS) passes through the appliance.
Request Type	Select Non-XML . With this value, HTTP web application requests are handled by the appliance.

Table 6-35. General Configuration (continued)

Field	Description
Front Side Protocol	<p>Select HTTPS (SSL). For this type of interaction in which user credentials are passed between client and server, HTTPS is appropriate. Also provide the following front-side handler details:</p> <p>Name Enter a name for the configuration.</p> <p>Port Number Enter a number for the listening port. This port number must match the port number that you specify if you define an AAA policy that uses HTML forms-based authentication. See Table 6-37 on page 6-174.</p> <p>Allowed Methods and Versions Select GET method to enable support for HTTP Get.</p> <p>SSL Proxy Select an SSL Reverse Proxy profile to identify the SSL server.</p>
Multi-Protocol Gateway Policy	<p>Click +, and then create rules to define the policies that are listed in the following topics, depending on the type of authentication that you decide to use:</p> <ul style="list-style-type: none"> • Policy worklight-basicauth for HTTP basic authentication. See “Rules for HTTP basic authentication” on page 6-175. • Policy mpgw-form for HTML forms-based login authentication. See “Rules for HTML forms-based authentication” on page 6-176.
Backend URL	Specify the address and port of the MobileFirst Server that is hosted on WebSphere Application Server.

4. Create an AAA policy that supports the HTTP basic authentication or HTML forms-based login policy that you defined in the previous step.
 - a. In the IBM DataPower WebGUI, in the search box under Control Panel, enter AAA, and then click **Add**.
 - b. Depending on the type of authentication that you want to use, define the following settings.
 - For HTTP basic authentication, specify the settings as listed in the following table.

Table 6-36. AAA policy for HTTP basic authentication

Phase	Description
Extract Identity	In the Methods field, select HTTP Authentication Header .

Table 6-36. AAA policy for HTTP basic authentication (continued)

Phase	Description
Authenticate	Choose the authentication method. If WebSphere Application Server is using LDAP, configure LDAP here.
Extract Resource	Select URL Sent by Client .
Post processing	Generate an LTPA token. Specify LTPA Token Expiry , LTPA Key File , and LTPA Key File Password .

- For HTML forms-based authentication, specify the settings as listed in the following table.

Table 6-37. AAA policy for HTML forms-based authentication

Phase	Description
Extract Identity	In the Methods field, select HTML Forms-based Authentication . Select or create an HTML forms-based policy that has the Use SSL for Login option enabled, assigns SSL Port to the port number on which the MPGWS is listening (that was specified in step 3), and has the Enable Session Migration option disabled.
Authenticate	Choose the authentication method. If WebSphere Application Server is using LDAP, configure LDAP here.
Extract Resource	Select URL Sent by Client .
Post processing	Generate an LTPA token. Specify LTPA Token Expiry , LTPA Key File , and LTPA Key File Password .

5. On the Advanced page, specify the advanced settings as listed in the following table.

Table 6-38. Advanced settings

Field	Value
Persistent Connections	On .
Allow Cache-Control Header	Off
Loop Detection	Off
Follow Redirects	Off . This value prevents the DataPower back-end user agent from resolving redirects from the back end. Web applications typically require a client browser to resolve redirects so that they can maintain the context for "directory" along with setting an LTPA cookie on the client.
Allow Chunked Uploads	Off
MIME Back Header Processing	Off
MIME Front Header Processing	Off

Results

Your MobileFirst application traffic is now protected by a secure DataPower gateway. User authentication is enforced by the DataPower appliance, which forwards the user credentials to MobileFirst Server either as an HTTP header or as an LTPA token, depending on the selected authentication method.

DataPower configuration rules:

Learn how to add the required authentication rules to your IBM WebSphere DataPower configuration.

Note: The following topics document how to perform specific types of manual DataPower configuration to complete the configuration steps outlined in the “Integrating with DataPower as a security gateway and reverse proxy” on page 6-169 procedure. If you use a preconfigured DataPower pattern, for example if you follow the specialized “Integrating with DataPower as a reverse proxy using LTPA and form-based authentication” on page 6-181 procedure, you do not need typically to perform these manual configurations.

Rules for HTTP basic authentication:

Add rules to define an HTTP basic authentication policy that is named `worklight-basicauth`.

You create the `worklight-basicauth` policy as part of the process of defining a multiprotocol gateway. See “Integrating with DataPower as a security gateway and reverse proxy” on page 6-169, Table 6-35 on page 6-172.

Table 6-39. HTTP Basic Authentication properties

Property	Value
Policy Name	<code>worklight-basicauth</code>
Order of configured rules	<ol style="list-style-type: none"><code>worklight-basicauth_rule_0</code>: see Table 6-40<code>worklight-basicauth_rule_3</code>: see Table 6-43 on page 6-176<code>worklight-basicauth_rule_1</code>: see Table 6-41 on page 6-176<code>worklight-basicauth_rule_2</code>: see Table 6-42 on page 6-176

Table 6-40. Properties of `worklight-basicauth_rule_0`. When processing HTML content, skip processing with the icon that is associated with the website or the web page.

Property	Value
Direction	Client to Server or Both Directions.
Match	<ul style="list-style-type: none">Type = URLPattern = <code>/favicon.ico</code>
Advanced	"Set Variable" -> <code>var://service/mpgw/skip-backside = 1</code>
Result	Not applicable.

Table 6-41. Properties of *worklight-basicauth_rule_1*. Handle end-user authentication if an LTPA token does not exist.

Property	Value
Direction	Client to Server.
Match	<ul style="list-style-type: none"> Type = URL Pattern = *
AAA	BasicAuth2LTPA <ul style="list-style-type: none"> Output: NULL
Result	Not applicable.

Table 6-42. Properties of *worklight-basicauth_rule_2*. Handle both the redirect and content-type reset on the response side.

Property	Value
Direction	Server to Client.
Match	<ul style="list-style-type: none"> Type = URL Pattern = *
Filter	Provide a custom stylesheet that handles redirect and content-type rewrite. For a sample redirect stylesheet, see “Sample redirect stylesheet” on page 6-180. <ul style="list-style-type: none"> Output: NULL
Result	Not applicable.

Table 6-43. Properties of *worklight-basicauth_rule_3*. Because the policy is applied to each request, the rules must be ordered such as to ensure that an LTPA token is verified if it exists in the HTTP request. If no token is available, proceed to the next rule and authenticate the user.

Property	Value
Direction	Client to Server.
Match	<ul style="list-style-type: none"> Type = HTTP HTTP header tag = Cookie HTTP value match = *LtpaToken*
AAA	VerifyLTPA <ul style="list-style-type: none"> Output: NULL
Result	Not applicable.

Rules for HTML forms-based authentication:

Add rules to define an HTML forms login policy named `mpgw-form` for HTML forms-based authentication.

You create the `mpgw-form` policy as part of the process of defining a multi-protocol gateway. See “Integrating with DataPower as a security gateway and reverse proxy” on page 6-169, Table 6-35 on page 6-172.

Table 6-44. HTTP Form-Based Login properties

Property	Value
Policy Name	mpgw-form
Order of configured rules	<ol style="list-style-type: none"> 1. mpgw-form_rule_0: see Table 6-45 2. mpgw-form_rule_1: see Table 6-46 3. mpgw-form_rule_2: see Table 6-47 4. mpgw-form_rule_3: see Table 6-48 on page 6-178 5. mpgw-form_rule_6: see Table 6-49 on page 6-178

Table 6-45. Properties of mpgw-form_rule_0. This rule skips processing with the icon that is associated with the web site or the web page.

Property	Value
Direction	Client to Server or Both Directions.
Match	<ul style="list-style-type: none"> • Type = URL • Pattern = /favicon.ico
Advanced	“Set Variable” -> var://service/mpgw/skip-backside = 1
Result	Not applicable.

Table 6-46. Properties of mpgw-form_rule_1. This rule verifies an LTPA token if it exists in the HTTP request.

Property	Value
Direction	Client to Server.
Match	<ul style="list-style-type: none"> • Type = HTTP • HTTP header tag = Cookie • HTTP value match = *LtpaToken*
AAA	VerifyLTPA • Output: NULL
Result	Not applicable.

Table 6-47. Properties of mpgw-form_rule_2. This rule generates the HTML form login page.

Property	Value
Direction	Client to Server.
Match	<ul style="list-style-type: none"> • Match with PCRE = on • Type = URL • Pattern = /(Login Error)Page\.htm(1)?(\?originalUrl=.*)?
Transform	<p>Provide a custom stylesheet that builds either a Login or Error HTML page. For a sample stylesheet, see “Sample form login stylesheet” on page 6-178.</p> <p>Note: The HTML Login Form policy allows you to specify whether you retrieve the login and error pages from DataPower or from the back-end application server.</p>

Table 6-47. Properties of *mpgw-form_rule_2* (continued). This rule generates the HTML form login page.

Property	Value
Advanced	Select the set-var action and specify the service variable: <code>var://service/routing-url</code> and value with the endpoint of your login page.
Result	Not applicable.

Table 6-48. Properties of *mpgw-form_rule_3*. This rule handles end-user authentication if an LTPA token does not exist.

Property	Value
Direction	Client to Server.
Match	<ul style="list-style-type: none"> Type = URL Pattern = *
Advanced	"Convert Query Parameter to XML". Accept default values for other selections.
AAA	Form2LTPA

Table 6-49. Properties of *mpgw-form_rule_6*. This rule handles both the redirect and content-type reset on the response side.

Property	Value
Direction	Server to Client.
Match	<ul style="list-style-type: none"> Type = URL Pattern = *
Filter	Provide a custom stylesheet that handles redirect and content-type rewrite. For a sample redirect stylesheet, see "Sample redirect stylesheet" on page 6-180. <ul style="list-style-type: none"> Output: NULL
Result	Not applicable.

Sample form login stylesheet:

You can use this sample stylesheet to generate the HTML form login page or error page when creating rules to define an HTML forms-based authentication policy.

You provide a custom stylesheet when defining rule *mpgw-form_rule_2*. See "Rules for HTML forms-based authentication" on page 6-176, Table 6-47 on page 6-177.

```

Integrating with DataPower as a reverse proxy using LTPA and form-based authentication

Use the provided MobileFirst samples and IBM WebSphere DataPower configuration pattern and to integrate your application with a DataPower gateway that uses lightweight third-party authentication (LTPA) and HTML forms-based authentication.

Before you begin

- Read the topic “Integration with IBM WebSphere DataPower as a security gateway and reverse proxy” on page 6-168.
- Install IBM WebSphere DataPower by following the instructions in the WebSphere DataPower documentation.
The following procedure and the sample DataPower configuration pattern (MFP_LTPA_Integration) were tested with DataPower Service Gateway XG45 version 7.0.0.10.
- Install IBM MobileFirst Platform Foundation with interim fix 7.1.0.00-20160513-1006 or later.
Ensure that the installation includes MobileFirst Studio.
- Establish a stand-alone MobileFirst Server environment that uses WebSphere Application Server with LTPA.
- Download the MobileFirst LTPA DataPower integration package or the specific components that you require. The package contains the following artifacts:
 - pattern contains a sample DataPower pattern (MFP_LTPA_Integration) that is preconfigured to integrate with IBM MobileFirst Platform Foundation using LTPA with HTML forms-based authentication. This pattern is used in the following procedure.
 - DataPower contains a MobileFirst project with common platform-independent components, which you can import to MobileFirst Studio, and a sample MobileFirst hybrid application (apps/HybridDataPower).
 - DataPowerSwift contains a sample Xcode project for a native iOS MobileFirst application.
 - DataPowerAndroid contains a sample Android Studio project for a native Android application.

Note: The outlined procedure and the provided samples are targeted at native and cross-platform (hybrid) Android and iOS applications. The procedure was not tested on other platforms.

About this task

Following is a specialized procedure for protecting mobile-application traffic by integrating your MobileFirst application with a DataPower gateway that uses LTPA and DataPower HTML forms-based login authentication. The procedure uses a sample MobileFirst DataPower configuration pattern (MFP_LTPA_Integration) that simplifies the required configuration of the DataPower gateway.

- Configuring your MobileFirst client application
- Configuring your MobileFirst Server
- Protecting your resources
- Configuring DataPower
- Customization notes
- Results and flow diagrams

Procedure

• Configuring your MobileFirst client application

1. Create a MobileFirst application with your required application logic. See “Developing MobileFirst applications” on page 8-1. Start with a simple application that does not include security tests, and run the application to test your installation. You can also start out by using the sample project from the MobileFirst LTPA DataPower integration package.
2. Add a challenge handler to your client application: When the application attempts to access a protected resource, the sample MFP_LTPA_Integration DataPower pattern sends a login forum to the application. Add a custom challenge handler to your application to detect the incoming login form by searching the response for a known string, such as `j_security_check`.

The challenge-handler requirements for handling a DataPower login forum are the same as for handling MobileFirst form-based authentication. See “Implementing form-based authenticators” on page 8-629, Code the client side step. Note the following points:

- The login forum's submit-action URL is `/j_security_check`.
- The login forum that you submit back needs to contain `j_username` and `j_password` fields.

The sample client application code in the MobileFirst LTPA DataPower integration package defines the required challenge handler for integrating with the sample DataPower MFP_LTPA_Integration pattern.

Following is an explanation of the provided sample-application challenge handler, using the code from the sample hybrid application (DataPower/apps/HybridDataPower/common/js/main.js):

The sample creates a challenge-handler object (DataPowerChallengeHandler); see the `WL.Client.createChallengeHandler` method:

```
var DataPowerChallengeHandler = WL.Client.createChallengeHandler();
```

Clicking the form-submission button in the login forum triggers a call to the `submitLoggingForm` method of the challenge-handler object with the provided authentication credentials, which are stored in the `j_username` and `j_password` parameters:

```
$('#AuthSubmitButton').bind('click', function () {  
    busyIndicator.show();  
    var reqURL = '/j_security_check';
```

```

var options = {};
options.parameters = {
    j_username : $('#AuthUsername').val(),
    j_password : $('#AuthPassword').val()
};
options.headers = {};
DataPowerChallengeHandler.submitLoginForm(reqURL, options,
    DataPowerChallengeHandler.submitLoginFormCallback);
});

```

When the login response returns, the security framework calls the challenge-handler's login-form submission callback method, `submitLoginFormCallback`. The callback method calls the handler's `isCustomResponse` method to check whether a custom login response was received. When this method returns true, the callback method calls the challenge handler's `handleChallenge` method:

```

DataPowerChallengeHandler.isCustomResponse = function(response){
    if (!response || response.responseText === null) {
        return false;
    }
    var indicatorIdx = response.responseText.search('j_security_check');

    if (indicatorIdx >= 0){
        return true;
    }

    return false;
};

DataPowerChallengeHandler.submitLoginFormCallback = function(response) {
    var isLoginFormResponse = DataPowerChallengeHandler.isCustomResponse(response);
    if (isLoginFormResponse){
        DataPowerChallengeHandler.handleChallenge(response);
    } else {
        $('#result').show();
        $('#auth').hide();
        DataPowerChallengeHandler.submitSuccess();
    }
}

```

The challenge handler's `handleChallenge` method can be used to display your custom login form, provided that `#auth` contains the HTML code for collecting the user credentials:

```

DataPowerChallengeHandler.handleChallenge = function(response){
    $('#result').hide();
    $('#auth').show();
    busyIndicator.hide();
};

```

3. On Android, consider adding a workaround for failed requests due to circular redirects: A known limitation might cause some requests, such as post-logout requests, to fail on Android platforms with errors such as `org.apache.http.client.CircularRedirectException: Circular redirect.....` The workaround is to add the following call in the native Java code of your application before making any request:

```

HttpClientManager.getInstance().getHttpClient().getParams().setBooleanParameter(ClientPNames.ALLOW_CIRCULAR_REDIRECTS, true);

```

In native applications, you can use the following shorthand form instead:

```

WLClient.getInstance().setAllowHttpClientCircularRedirect(true);

```

For example, in a hybrid application you can add the workaround code in the `onInitWebFrameworkComplete` method of the

WLInitWebFrameworkListener interface. This method is called when the IBM MobileFirst Platform Foundation web initialization is completed and web resources are ready to be used:

```
public void onInitWebFrameworkComplete(WLInitWebFrameworkResult result){
    if (result.getStatusCode() == WLInitWebFrameworkResult.SUCCESS) {
        HttpClientManager.getInstance().getHttpClient().getParams().setBooleanParameter(ClientPNames.ALLOW_CIRCULAR_REDIRECTS, true);
        super.loadUrl(WL.getInstance().getMainHtmlFilePath());
    } else {
        handleWebFrameworkInitFailure(result);
    }
}
```

4. On Android, using the send method of the WLResourceRequest class with a custom WLHttpResponseListener response listener is currently not supported in gateway topologies. If your application uses WLHttpResponseListener, call WLClient.connect or WLAuthorizationManager.obtainAuthorizationHeader before sending the resource request, to ensure that your challenge is handled.

- **Configuring your MobileFirst Server**

1. Configure the user registry in your application-server configuration file (server.xml):
 - a. Open the LTPA keys file of your application server: ltpa.keys. (This file is typically found in the <server_configuration_directory>/servers/worklight/resources/security directory of your MobileFirst Server.) Find the com.ibm.websphere.ltpa.Realm key in the file, and copy and save its value (for example, worklightRealm).
 - b. Open the configuration file of your application server: server.xml. (This file is typically found in the <server_configuration_directory>/servers/worklight directory of your MobileFirst Server.) Look for a <basicRegistry> or <ldapRegistry> element in the file. If neither element exists, create the element that matches your required configuration (see the documentation of your application server).
 - c. Set the **realm** attribute of your user-registry element to the value of the com.ibm.websphere.ltpa.Realm LTPA key that you copied and saved in Step 1a (if it is not already set).
 - d. When using the <basicRegistry> element, ensure that the element defines all the authorized users for your application. For example, the following basic-registry definition includes the credentials of two of the authorized users that are configured in the sample MFP_LTPA_Integration pattern:

```
<basicRegistry realm="worklightRealm">
  <user name="admin" password="admin"/>
  <user name="fred" password="smith"/>
</basicRegistry>
```

Note: You need to set the **password** attribute of each contained <user> element, even though these passwords will not be used because DataPower will handle the credentials authentication.

For LDAP configuration, see the documentation of your application server.

Note: When moving from development to production or when connecting to an untrusted network, modify the authorized users or the authentication method of the sample pattern, and edit your server configuration to match the pattern. See the authorized-users credentials and authentication method customization note.

2. Configure the authentication-configuration file of your MobileFirst Server: authenticationConfig.xml. (This file is typically found in the server/conf directory of your MobileFirst project.) DataPower will be responsible for authenticating the client, and will use LTPA to communicate the results to

MobileFirst Server. However, to represent the user to DataPower you need to define a MobileFirst LTPA form-based authentication realm and LTPA login module. The realm must be of the LTPA authenticator class (com.worklight.core.auth.ext.WebSphereFormBasedAuthenticator) and use the WASLTPAModule login module for LTPA integration of the security framework with WebSphere Application Server. Then, define a security test that uses your realm. You will use this security test in the next step to protect your resources.

The DataPower/server/conf/authenticationConfig.xml file of the sample MobileFirst DataPower integration project includes the required configurations that are explained here.

- WASLTPAModule login module

```
<loginModules>
...
<loginModule name="WASLTPAModule" expirationInSeconds="30">
  <className>com.worklight.core.auth.ext.WebSphereLoginModule</className>
</loginModule>
</loginModules>
```

- WASLTPARealm realm that uses the WASLTPAModule login module

```
<realms>
...
<realm name="WASLTPARealm" loginModule="WASLTPAModule">
  <className>com.worklight.core.auth.ext.WebSphereFormBasedAuthenticator</className>
  <parameter name="login-page" value="/login.html"/>
  <parameter name="error-page" value="/loginError.html"/>
</realm>
</realms>
```

Note: You need to assign values to the **login-page** and **error-page** parameters in the realm definition, even though these parameters will not be used because DataPower will be responsible for sending the login form.

- Security test (DataPowerTest in the following example) that uses the WASLTPARealm realm

```
<securityTests>
...
<customSecurityTest name="DataPowerTest">
  <test realm="wl_antixSRFRealm" step="1"/>
  <test realm="WASLTPARealm" isInternalUserID="true" step="1"/>
</customSecurityTest>
</securityTests>
```

For more information about the authentication-configuration file and the related security elements, see the following topics:

- "The authentication configuration file" on page 8-603
- "MobileFirst security configuration" on page 12-92
- "Implementing form-based authenticators" on page 8-629
- "Configuring the MobileFirst LTPA realm" on page 12-95
- "LTPA authenticator" on page 8-644
- "WASLTPAModule login module" on page 8-620
- "Security tests" on page 8-569
- **Protecting your resources** Protect your selected resources (such as adapter procedures or your application) with the form-based LTPA security test that you created in Step 2 on page 6-184 of the server configuration. See "Security configurations of protected resources" on page 8-571.

For example, the provided sample MobileFirst project contains a JavaScript HTTP adapter with a simple `getSecretData` procedure (defined in `DataPower/adapter/Protected-impl.js`). This procedure is protected by the `DataPowerTest` security test that is defined in the sample project (see Step 2 on page 6-184 of the server configuration). The procedure is protected by adding the **securityTest** attribute to the `<procedure>` element of the `getSecretData` procedure in the adapter descriptor file (`DataPower/adapter/Protected.xml`):

```
<procedure name="getSecretData" securityTest="DataPowerTest"/>
```

- **Configuring DataPower**

Configure your DataPower appliance with the sample `MFP_LTPA_Integration` configuration pattern.

Note: The procedure was tested with DataPower Service Gateway XG45 version 7.0.0.10, and the included DataPower graphical user interface (GUI) references match this product version.

1. Download the `MFP_LTPA_Integration` MobileFirst DataPower configuration pattern (`MFP_LTPA_Integration.zip`). The pattern is included in the MobileFirst LTPA DataPower integration package, and can also be downloaded directly here.
2. Create a new application domain for your DataPower appliance.
3. Configure the SSL proxy profile that will be used by DataPower to support HTTPS requests from the client application: The sample configuration pattern uses HTTPS (SSL) to communicate between the mobile device and the DataPower gateway. To support this communication, you need to define an SSL proxy profile. If you do not already have such a profile definition, define an SSL proxy profile in the DataPower WebGUI:

Note: The SSL proxy profile is deprecated beginning with version 7.2.0 of IBM WebSphere DataPower. For information on how to migrate your DataPower configuration from an SSL proxy profile to an SSL client profile, see [Migration from SSL Proxy Profile](#).

- a. In the search field of the navigation sidebar, search for SSL and select **SSL Proxy Profile** from the results list.
 - b. In the profile configuration page, select **Add**.
 - c. Enter the required configuration input for your profile. As part of the configuration you might need to upload an SSL certificate and private keys. The configuration of an SSL profile and the creation of a related certificate are outside the scope of the current documentation. For more information, see the IBM WebSphere DataPower documentation. You can see a sample configuration procedure that uses a self-signed CA root certificate in the following video: [Protecting IBM MobileFirst Platform using DataPower](#).
- Note:** Keep in mind that most mobile devices reject self-signed certificates. The workaround is outside the scope of the current documentation.
- d. Select **Apply** to apply your changes to the running configuration, and then select **Save Configuration** to save the changes to the startup configuration.
4. Import the `MFP_LTPA_Integration` pattern:
 - a. In the navigation bar of the DataPower WebGUI, select **BluePrint Console**, and make sure that you are logged in to the same application domain that you created in Step 2.
 - b. Select the **Patterns** tab.
 - c. Select the import graphic button (next to the **New pattern** button): 

- d. In the **Pattern file** field of the Import pattern window, browse to the location of the MFP_LTPA_Integration.zip pattern archive file that you downloaded in Step 1 on page 6-186. Then, select **Import** to import the pattern.
5. Deploy the MFP_LTPA_Integration pattern to your DataPower appliance to create a service from the pattern:
 - a. Select the **Deploy** button in the pattern heading line.
 - b. In the Deploy pattern window, enter the required information for deploying the pattern and creating your service.
 - **Service name** is the service name that you want to display.
 - **Description** is an optional description of your service.
 - **Step 2: Destinations** configures the connection between the DataPower gateway and the MobileFirst Server back-end server:
 - **URL** is the full URL of your MobileFirst Server instance, of the format `<http or https>://<host_name>:<port>/<project_name>`.
 - **SSL proxy profile** is the name of the SSL profile that is used by your MobileFirst Server instance to communicate with the DataPower gateway. Configure this field only if your server uses SSL to communicate with the gateway.
 - **Step 3: HTTPS connection** configures the HTTPS (SSL) connection between the DataPower gateway and your client mobile application:
 - **IP address** is the IP address that is the entry point to your application. A value of 0.0.0.0 indicates that any IP address can be used.
 - **Port** is the port number for connecting to your application.
 - **SSL proxy profile** is the SSL proxy profile that you set up in Step 3 on page 6-186. Select this profile from the list.
 - **Step 4: Authenticate with LTPA** and **Step 5** configure the gateway's LTPA keys. Provide the same configuration input in both steps:

Note: Due to a known issue in versions 7.2 and later of the DataPower firmware, the LTPA steps might not appear when you deploy the pattern. If this is the case, configure the LTPA key manually after you deploy the pattern.

- **LTPA key file** is your application server's LTPA keys file: ltpa.keys (typically found in the `<server_configuration_directory>/servers/worklight/resources/security` directory of your MobileFirst Server).
 - **Key file password** is the password of the MobileFirst Server LTPA keys file. The default keys-file password for WebSphere is WebAS.
- c. Select **Deploy pattern** to deploy the pattern to your DataPower appliance and create the service.
 - d. Verify that the pattern was deployed successfully: go to the Control Panel of the DataPower WebGUI, select **Multi-Protocol Gateway**, and verify that the gateway's **Op-State** value is up.

- **Customization notes**

Edit the DataPower pattern and MobileFirst configurations, as needed, for your specific needs. Note the following points:

Changing the authorized-users credentials or the authentication method of the DataPower AAA policy

By default, the sample MFP_LTPA_Integration pattern checks the user credentials against a `local:///MyAAA.xml` file. The file path is hardcoded in the pattern's `pattern/config/local/MyAAA.xml` file, which also defines test credentials of several authorized users. To use the pattern, your server-configuration file must contain a `<basicRegistry>` element with

one or more of the users that are configured in the pattern, as outlined in Step 1d on page 6-184 of the server configuration.

You can modify the pattern's authorized-users credentials or authentication method, provided that you adjust the definition of the user-registry element in your server-configuration file to match the pattern. The default configuration is designed for testing during the development stage, and should be modified when connecting to an untrusted network or when moving from development to production. You can modify the configuration, for example, to integrate with an external user register or with any selected security system.

To modify the authentication method, follow these steps in the DataPower WebGUI:

1. In the search field of the navigation bar, search for AAA Policy. Select the **MFPIntegrationWebHTTPSFormLTPAForm2LTPA** policy from the displayed results.
2. Select the **Authentication** tab. In the **Method** field, select your preferred authentication method. For example, you can choose **Bind to LDAP server** to bind against a lightweight directory access protocol (LDAP) server. Then, complete the required configuration for your selected method. The pattern can use any valid authentication method of the DataPower AAA policy, provided that the user identities that are returned by this method also exist in the application server's user registry.

Configuring an HTTP (non-SSL) port

The sample MFP_LTPA_Integration DataPower pattern is configured only for HTTPS (SSL) communication between the mobile device and the DataPower gateway. Therefore, you are required to configure an SSL proxy profile for this interface, as outlined in Step 3 on page 6-186 of the DataPower configuration. However, during development, you can modify the DataPower configuration to open a non-SSL (HTTP) port:

1. In the Control Panel of the DataPower WebGUI, select **Multi-Protocol Gateway**, and look for **Front side settings**.
2. Add an **HTTP Front side handler**, choose a port for HTTP requests, and make sure to check GET in the list of allowed methods.

Results

Your MobileFirst application traffic is now protected by a secure DataPower gateway. User authentication is enforced by the DataPower appliance, which forwards the user credentials to MobileFirst Server. When using the sample DataPower MFP_LTPA_Integration pattern, the user credentials are passed as an LTPA token that is contained within a cookie, as demonstrated in the following initial-login, logout, and expired-authentication flow diagrams.

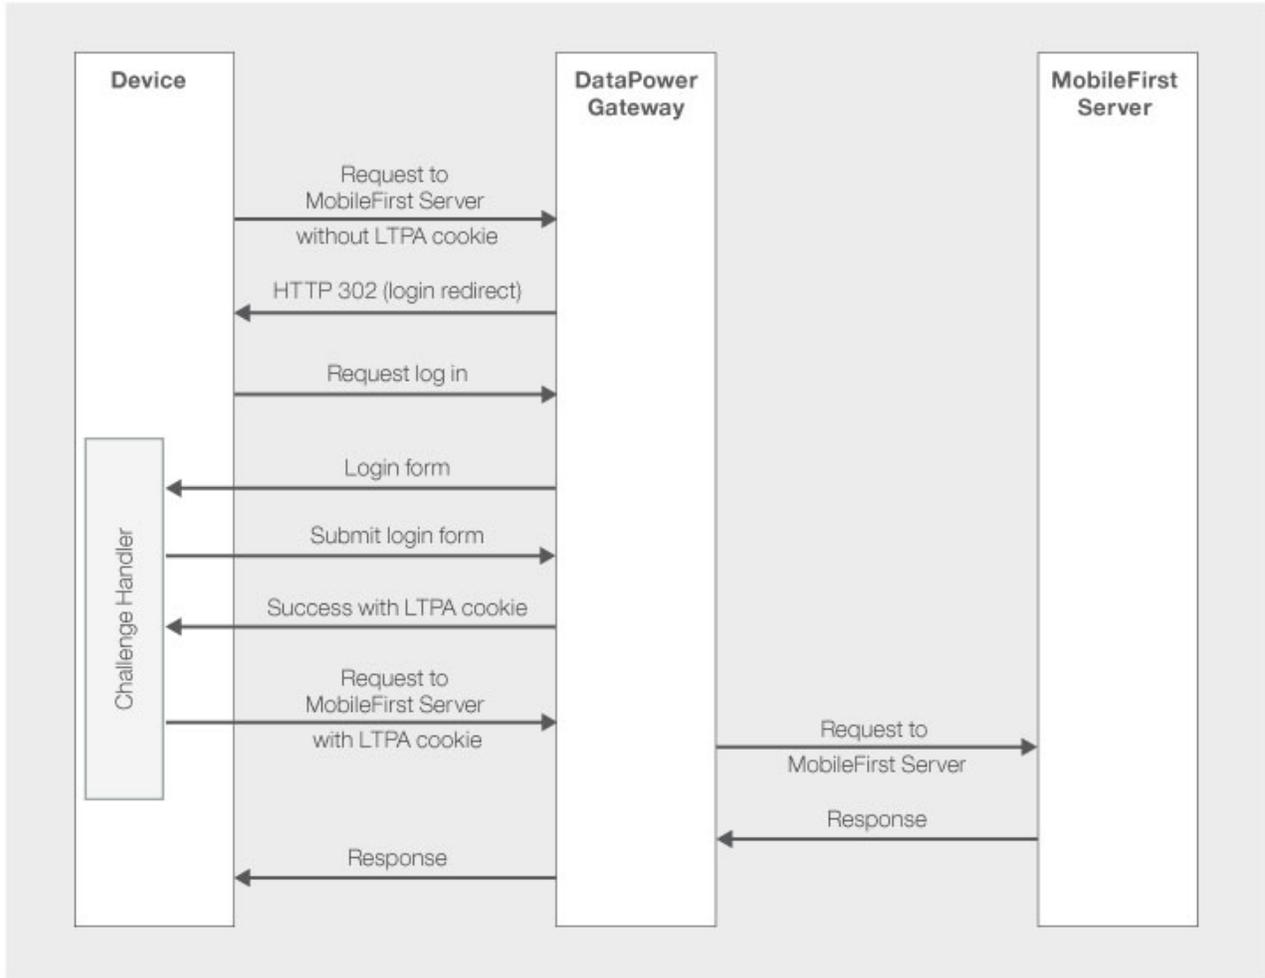

Figure 6-18. Initial-login flow

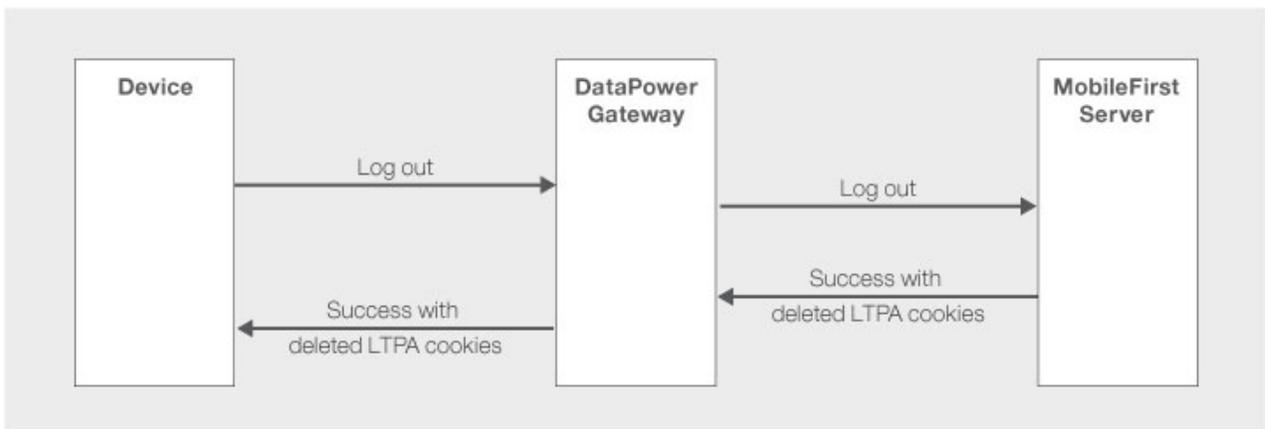

Figure 6-19. Logout flow

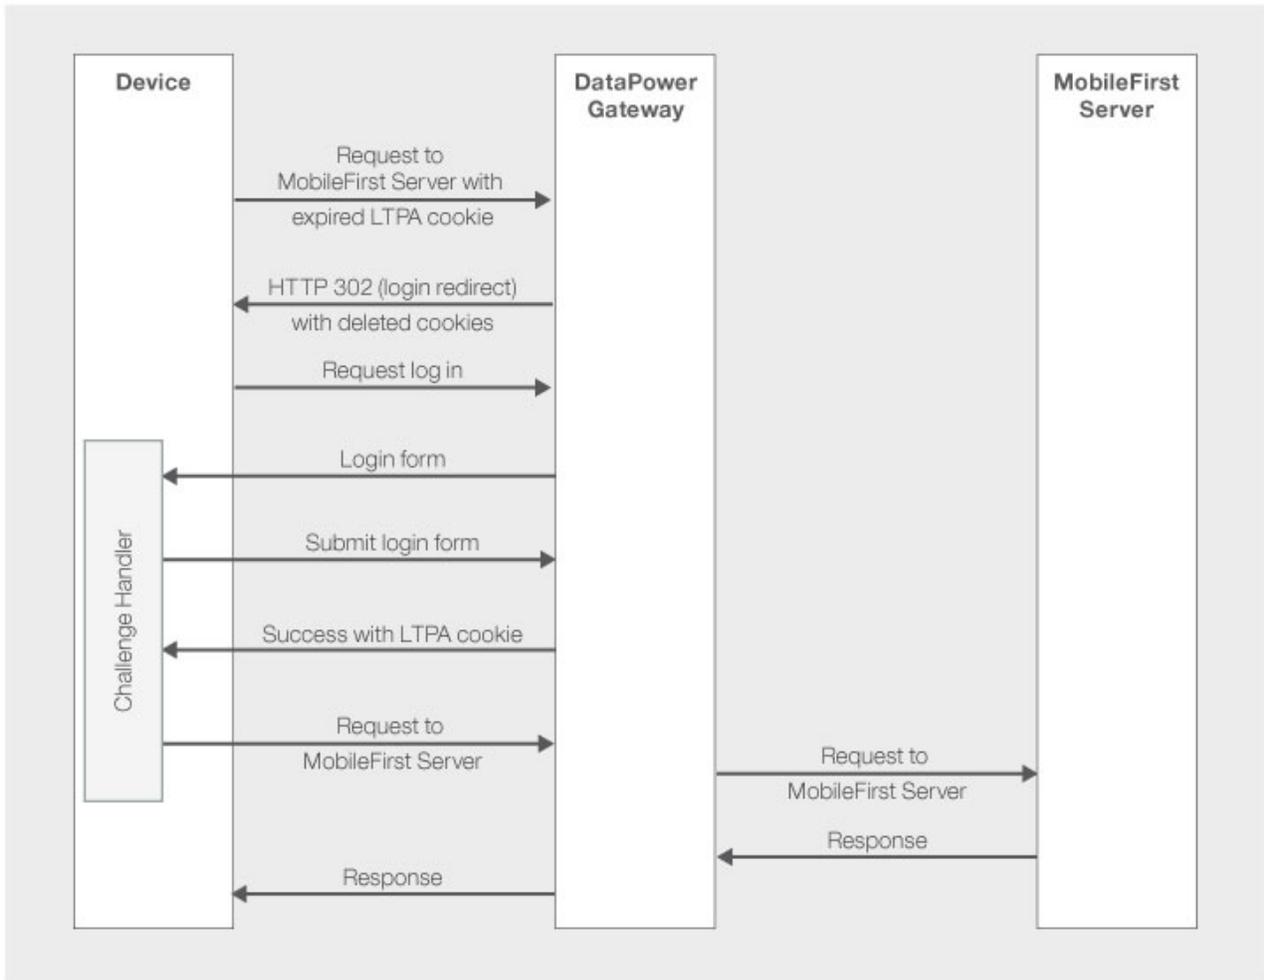

Figure 6-20. Expired-authentication flow

Configuring MobileFirst Server to enable TLS V1.2

For MobileFirst Server to communicate with devices that support only TLS V1.2, among the SSL protocols, you must complete the following instructions.

About this task

The steps to configure MobileFirst Server to enable Transport Layer Security (TLS) V1.2 depend on how MobileFirst Server connects to devices.

If MobileFirst Server is behind a reverse proxy that decrypts SSL-encoded packets from devices before passing the packets to the application server, you must enable TLS V1.2 support on your reverse proxy. If you are using IBM HTTP Server as your reverse proxy, see *Securing IBM HTTP Server* for instructions.

If MobileFirst Server communicates directly with devices, the steps to configure MobileFirst Server to enable TLS V1.2 depend on the application server that you use. The following sections provide you with the specific instructions for Apache Tomcat, WebSphere Application Server Liberty profile, and WebSphere Application Server full profile.

Apache Tomcat Procedure

1. Confirm that the Java Runtime Environment (JRE) supports TLS V1.2.
Ensure that you have one of the following JRE versions, depending on your version of IBM MobileFirst Platform Foundation.

For MobileFirst Server V7.1 or later:

Use one of the following JRE versions.

- Oracle JRE 1.7.0_75 or later
- Oracle JRE 1.8.0_31 or later

For MobileFirst Server V7.0 or earlier:

Use Oracle JRE 1.7.0_75 or later.

2. Edit the `conf/server.xml` file and modify the `<Connector>` element that declares the HTTPS port so that the `sslEnabledProtocols` attribute has the following value:

```
sslEnabledProtocols="TLSv1.2,TLSv1.1,TLSv1,SSLv2Hello"
```

WebSphere Application Server Liberty profile Procedure

1. Confirm that the Java Runtime Environment (JRE) supports TLS V1.2.
 - If you use an IBM Java SDK, ensure that your IBM Java SDK is patched for the POODLE vulnerability. You can find the minimum IBM Java SDK versions that contain the patch for your version of WebSphere Application Server in Security Bulletin: Vulnerability in SSLv3 affects IBM WebSphere Application Server (CVE-2014-3566).

Note: You can use the versions that are listed in the security bulletin or later versions.

- If you use an Oracle Java SDK, ensure that you have one of the following versions, depending on your version of IBM MobileFirst Platform Foundation.

For MobileFirst Server V7.1 or later:

Use one of the following JRE versions.

- Oracle JRE 1.7.0_75 or later
- Oracle JRE 1.8.0_31 or later

For MobileFirst Server V7.0 or earlier:

Use Oracle JRE 1.7.0_75 or later.

2. If you use an IBM Java SDK, edit the `server.xml` file.
 - a. Add the following line:

```
<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore" sslProtocol="SSL_TLSv2"/>
```

- b. Add the `sslProtocol="SSL_TLSv2"` attribute to all existing `<ssl>` elements.

WebSphere Application Server full profile Procedure

1. Confirm that the Java Runtime Environment (JRE) supports TLS V1.2.
Ensure that your IBM Java SDK is patched for the POODLE vulnerability. You can find the minimum IBM Java SDK versions that contain the patch for your version of WebSphere Application Server in Security Bulletin: Vulnerability in SSLv3 affects IBM WebSphere Application Server (CVE-2014-3566).

Note: You can use the versions that are listed in the security bulletin or later versions.

2. Log in to WebSphere Application Server administrative console, and click **Security > SSL certificate and key management > SSL configurations**.
3. For each SSL configuration listed, modify the configuration to enable TLS V1.2.
 - a. Select an SSL configuration and then, under **Additional Properties**, click **Quality of protections (QoP) settings**.
 - b. From the **Protocol** list, select **SSL_TLSv2**.
 - c. Click **Apply** and then save the changes.

Configuring SSL between MobileFirst adapters and back-end servers by using self-signed certificates

You can configure SSL between MobileFirst adapters and back-end servers by importing the server self-signed SSL certificate to the MobileFirst keystore.

Procedure

1. Check the configuration in the `worklight.properties` file. The configuration might look like this example (the password will be different for each project):

```
#####  
# MobileFirst SSL keystore  
#####  
#SSL certificate keystore location.  
ssl.keystore.path=conf/mfp-default.keystore  
#SSL certificate keystore type (jks or PKCS12)  
ssl.keystore.type=jks  
#SSL certificate keystore password.  
ssl.keystore.password=oW523Mes0b241qAXc5F7
```

2. Make sure that the keystore file exists in the `server/conf` folder of the MobileFirst project.
3. Export the server public certificate from the back-end server keystore.

Note: Export back-end public certificates from the back-end keystore by using `keytool` or `openssl` lib. Do not use the export feature in a web browser.

4. Import the back-end server certificate into the MobileFirst keystore.
5. Restart the MobileFirst Server.

Example

The CN name of the back-end certificate must match what is configured in the `adapter.xml` file. For example, consider an `adapter.xml` file that is configured as follows:

```
<protocol>https</protocol>  
<domain>mybackend.com</domain>
```

The back-end certificate must be generated with `CN=mybackend.com`.

As another example, consider the following adapter configuration:

```
<protocol>https</protocol>  
<domain>123.124.125.126</domain>
```

The back-end certificate must be generated with `CN=123.124.125.126`.

The following example demonstrates how you complete the configuration by using the `Keytool` program.

1. Create a back-end server keystore with a private certificate for 365 days.

```
keytool -genkey -alias backend -keyalg RSA -validity 365 -keystore backend.keystore -storetype JKS
```

Note: The **First and Last Name** field contains your server URL, which you use in theadapter.xml configuration file, for example mydomain.com or localhost.

2. Configure your back-end server to work with the keystore. For example, in Apache Tomcat, you change the server.xml file:

```
<Connector port="443" SSLEnabled="true" maxHttpHeaderSize="8192"
  maxThreads="150" minSpareThreads="25" maxSpareThreads="200"
  enableLookups="false" disableUploadTimeout="true"
  acceptCount="100" scheme="https" secure="true"
  clientAuth="false" sslProtocol="TLS"
  keystoreFile="backend.keystore" keystorePass="password" keystoreType="JKS"
  keyAlias="backend"/>
```

3. Check the connectivity configuration in the adapter.xml file:

```
<connectivity>
  <connectionPolicy xsi:type="http:HTTPConnectionPolicyType">
    <protocol>https</protocol>
    <domain>mydomain.com</domain>
    <port>443</port>
    <!-- The following properties are used by adapter's key manager for choosing
a specific certificate from the key store
    <sslCertificateAlias></sslCertificateAlias>
    <sslCertificatePassword></sslCertificatePassword>
    -->
  </connectionPolicy>
  <loadConstraints maxConcurrentConnectionsPerNode="2"/>
</connectivity>
```

4. Export the public certificate from the created back-end server keystore:

```
keytool -export -alias backend -keystore backend.keystore -rfc -file backend.crt
```

5. Import the exported certificate into your MobileFirst Server mfp-default.keystore file in the server/conf directory of the MobileFirst project:

```
keytool -import -alias backend -file backend.crt -storetype JKS -keystore mfp-default.keystore
```

6. Check that the certificate is correctly imported in the keystore:

```
keytool -list -keystore mfp-default.keystore
```

Configuring SSL by using untrusted certificates

Making SSL work between instances of IBM MobileFirst Platform Server and clients with certificates that are not signed by a known public certificate authority (CA) can be challenging. Each mobile platform has its own peculiarities and enforces different portions of the transport layer security (TLS) standard at different times.

The following recommendations focus mostly on the iOS and Android environments. Support for X.509 certificates comes from the individual platforms, not from IBM MobileFirst Platform Foundation. For more information about specific requirements for X.509 certificates, see the documentation of each mobile platform.

If you have difficulties with getting your application to access a MobileFirst Server because of SSL-related issues, the likely cause is a bad server certificate. Another likely cause is a client that is not properly configured to trust your server. Many other reasons can cause an SSL handshake to fail, so not all possibilities are covered. Some hints and tips are provided to troubleshoot the most basic issues

that are sometimes forgotten or overlooked. These issues are important when you deal with the mobile world and X.509 certificates.

Basic concepts

Certificate authority (CA)

An entity that issues certificates. A CA can issue (sign) other certificates or other CA certificates (intermediate CA certificates).

In a public key infrastructure (PKI), certificates are verified by a hierarchical chain of trust. The topmost certificate in this tree is the root CA certificate.

You can purchase your certificates from a public Internet CA or operate your own private (local) CA to issue private certificates for your users and applications. A CA is meant to be an authority that is well-trusted by your clients. Most commercial CAs issue certificates that are automatically trusted by most web browsers and mobile platforms. Using private CAs means that you must take certain actions to ensure that the client trusts certificates that are signed by your root CA.

A certificate can be signed (issued) by one of the many public CAs that are known by your mobile platforms, a private CA, or by itself.

Self-signed certificate

A certificate that is signed by itself and has no CA that attests to its validity.

Using self-signed certificates is not recommended because most mobile platforms do not support their use.

Self-signed CA

A CA that is signed by itself. It is both a certificate and a CA. Because it is the topmost certificate in a tree, it is also the root CA.

Using certificates that are signed by private CAs is not recommended for production use on external Internet-facing servers because of security concerns. However, they might be the preferred option for development and testing environments due to their low cost. They are also often appropriate for internal (intranet) servers as they can be deployed quickly and easily.

Certificate types that are supported by different mobile platforms

Table 6-50. Certificate types that are supported by different mobile platforms

Platform	self-signed certificates	self-signed CA certificates	certificates that are signed by a private CA	certificates that are signed by a public CA
iOS	-	△	△	△
Android	-	△	△	△
Windows Phone	-	△	△	△
Blackberry	-	△	△	△
Windows 8	-	△	△	△

Self-signed certificates versus self-signed CAs

When you are dealing with mobile clients, the use of self-signed certificates is not recommended because mobile platforms do not allow the installation of these

types of certificates onto the device truststore. This restriction makes it impossible for the client to ever trust the server's certificate. Although self-signed certificates are often recommended for development and testing purposes, they will not work when the client is a mobile device.

The alternative is to use self-signed CA certificates instead of self-signed certificates. Self-signed CA certificates are as easy to acquire and are also as cost-effective of a solution.

You can create a self-signed CA with most tools. For example, the following command uses the `openssl` tool to create a self-signed CA:

```
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout privateKey.key -out certificate.crt -r
```

Note: X.509 version 1 certificates are not allowed by some mobile platforms. You must use X.509 version 3 certificates instead. If you are generating self-signed CA certificates, ensure that they are of the type X.509 version 3, and have the following extension defined: `basicConstraints = CA:TRUE`. See the appropriate tool's documentation for how to specify the required version and certificate extensions. For `openssl` commands, you can specify the `-reqexts v3_req` flag to indicate version 3 X.509 certificates, and the `-extensions v3_ca` flag to indicate that the certificate is also a CA.

You can check the certificate version and extensions by running the following `openssl` command:

```
openssl x509 -in certificate.crt -text -noout
```

Establishing trust on the client

When you open a web page on your mobile browser or connect directly to your MobileFirst Server on an HTTPS port, a client receives a server certificate in the SSL handshake. The client then evaluates the server certificate against its list of known and trusted CAs to establish trust. Each mobile platform includes a set of trusted CAs that are deemed trustworthy for issuing SSL certificates. Trust is established if your server certificate is signed by a CA that is already trusted by the device. After trust is established, the SSL handshake is successful and you are allowed to open the web page on a browser or connect directly to your server.

However, if your server uses a certificate that is signed by a CA that is unknown to the client, the trust cannot be established, and your SSL handshake fails. To ensure your client device trusts your server's certificate, you must install the trust anchor certificate (root CA) on the client device.

Note: Only the root CA certificate (trust anchor) needs to be installed. You do not need to install any other certificates, such as intermediaries, on the device.

For iOS, see "Installing the root CA on iOS" on page 6-200.

For Android, see "Installing the root CA on Android" on page 6-203.

For Windows Phone, see "Installing the root CA on Windows Phone" on page 6-204.

For Windows 8, see "Installing the root CA on Windows 8" on page 6-208.

Configuring Android

It is important to note that if the following flag is set to true in your application, Android ignores SSL errors under certain conditions:

```
android:debuggable="true"
```

The use of this flag is highly discouraged for production environments. It is not necessary if you properly configured your server with a certificate that is signed by a CA that is trusted by your client device.

Handling the certificate chain

If you are using a server certificate that is not signed by itself, you must ensure that the server sends the full certificate chain to the client.

For the client to validate the certificate path, it must have access to the full certificate chain. To ensure that the client has access to the full certificate chain, including intermediate certificates, ensure that all the certificates in the chain are in the server-side keystore file.

For the WebSphere Application Server Liberty, see “Updating your keystore and Liberty profile configuration to use a certificate chain” on page 6-212.

Handling certificate extensions

RFC 5280 (and its predecessors) defines a number of certificate extensions that provide extra information about the certificate. Certificate extensions provide a means of expanding the original X.509 certificate information standards.

When an extension is specified in an X.509 certificate, the extension must specify whether it is a critical or non-critical extension. A client that is processing a certificate with a critical extension that the client does not recognize, or which the client cannot process, must reject the certificate. A non-critical extension can be ignored if it is not recognized.

Not all mobile platforms recognize or process certain certificate extensions in the same manner. For this reason, you must follow the RFC as closely as possible. Avoid certificate extensions unless you know that all of your targeted mobile platforms can handle them as you expect.

CRL support

If your certificate supports certificate revocation lists (CRLs), ensure that the CRL URL is valid and accessible. Otherwise, certificate chain validation fails.

Tools to use to verify the server certificate

To debug certificate path validation problems, try the `openssl s_client` command line tool. This tool generates good diagnostic information that is helpful in debugging SSL issues.

The following example shows how to use the `openssl s_client` command line tool:

```
openssl s_client -CApath $HOME/CAdir -connect hostname:port
```

The following example shows how to inspect a certificate:

```
openssl x509 -in certificate.crt -text -noout
```

Troubleshooting problems with server certificates that are not signed by a trusted certificate authority

Table 6-51. Troubleshoot problems with server certificates

Problem	Actions to take
Unable to install the root CA on iOS. Certificate installs, but after installation, iOS shows the certificate as not trusted.	The certificate is not identified as a certificate authority. Ensure that the certificate specifies a certificate extension: <code>basicConstraints = CA:TRUE</code> For more information, see “Self-signed certificates versus self-signed CAs” on page 6-194. Ensure that the certificate is in PEM format. Ensure that the certificate has a .crt file extension.
Unable to install the root CA on Android. After installation, the certificate does not show up in the system trusted credentials.	The certificate is an X.509 version 1 certificate or does not have the following certificate extension: <code>basicConstraints = CA:TRUE</code> For more information, see “Self-signed certificates versus self-signed CAs” on page 6-194. Ensure that the certificate is in PEM or DER format. Ensure that the certificate has a .crt file extension.

Table 6-51. Troubleshoot problems with server certificates (continued)

Problem	Actions to take
<p>"errorCode":"UNRESPONSIVE_HOST","errorMsg": "service is currently not available."</p>	<p>This error usually indicates an SSL handshake failure.</p> <p>The client cannot establish trust for the server certificate.</p> <ol style="list-style-type: none"> 1. Ensure that you installed the server's root CA on the client device. For more information, see "Establishing trust on the client" on page 6-195. 2. Ensure that the server sends the complete certificate chain and in the right order. For more information, see "Handling the certificate chain" on page 6-196. <p>The server certificate is invalid.</p> <ol style="list-style-type: none"> 1. Check the validity of the server certificate. For more information, see "Tools to use to verify the server certificate" on page 6-196. 2. Ensure that the CRL URL is valid and reachable. For more information, see "CRL support" on page 6-196. 3. The server certificate contains a critical certificate extension that is not recognized by the client platform. For more information, see "Handling certificate extensions" on page 6-196.
<p>SSL works on Android, but does not work on iOS.</p>	<p>When Android is in debuggable mode, Cordova ignores most SSL errors. This behavior gives the impression that things are working. Android is in debuggable mode when the APK is unsigned, or when you explicitly set the mode in the manifest. Verify that the debuggable flag is set to false (debuggable:false) in the Android manifest file, or sign the APK. Make sure that there is no explicit declaration in the manifest that sets it to debuggable mode. For more information about configuring Android, see "Configuring Android" on page 6-196.</p>

RFC 5280 - Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile

Specifying a trusted SSL certificate

While the certificates from several certificate authorities (CA) are already recognized and trusted by the MobileFirst Platform Command Line Interface, you can authorize an untrusted CA by adding its certificate path as an environment variable.

About this task

The Node.js system contains several CAs whose signed certificates are trusted by default. If you try to connect a server with a certificate from an untrusted source by using the MobileFirst Platform Command Line Interface, the operating system displays the following message:

Failed to retrieve runtime information: CERT_UNTRUSTED

This can happen when you are using a self-signed certificate, one from a private certificate authority, or a public CA that is not recognized as a trusted source by Node.js.

You can add up to 10 certificates to be trusted to your environment variables. To add a certificate, complete the following steps:

Procedure

1. Copy the path to the certificate file that you want to add to the list of trusted certificates. The certificate file must be in the .PEM format.
2. Add the environment variable.
 - For a Unix-based operating system, complete the following steps:
 - a. Open a terminal window.
 - b. Enter the following command to add the environment variable:

```
$ set MFP_HTTPS_SSL_TRUSTSTORE_0=path_to_certificate/certificate_file.cer
```

Where *path_to_certificate* is the path to your certificate, and *certificate_file* is the filename of the certificate.
 - c. Enter the following command to integrate the environment variable:

```
$ export MFP_HTTPS_SSL_TRUSTSTORE_0
```
 - **Note:** These steps must be completed for the untrusted certificates whenever you start a new shell.
 - For the Windows operating system, complete the following steps:
 - a. Open your environment variables by selecting **Start > Control Panel > System and Security > Advanced Settings > Environment Variables....**
 - **Important:** Use caution when you add the new Environment Variables. Accidentally modifying an existing Environment Variable can cause problems for other programs on your system.
 - b. In System Variables, select **New...**
 - c. Enter `MFP_HTTPS_SSL_TRUSTSTORE_0` for your Variable name.
 - d. Enter `/path_to_certificate.cer` for your Variable value.
 - e. Restart the operating system.
3. Repeat these steps for any other untrusted certificates that you need to add. You can add up to nine more certificates by changing the 0 in the variable to a digit that is 1-9, inclusive.

Installing the root CA on iOS

The root CA must be installed on the client device to ensure that the client trusts server certificates that are signed by your private CAs.

About this task

To establish trust for your server certificate, you must install the trust anchor certificate (root CA) on the client device.

Note: Only the root CA certificate (trust anchor) must be installed. You do not need to install any other certificates, such as intermediaries, on the device.

Procedure

1. Ensure that the root CA is in PEM file format and has a .crt file extension. Convert as needed.
2. Run the following command to view the certificate details.

```
openssl x509 -in certificate.crt -text -noout
```
3. Ensure that the certificate is of version X.509 v3. The certificate details must show Version 3.

Note: The following openssl flag generates X.509 v3 certificates:

```
-reqexts v3_req
```

4. Ensure that the certificate is a certificate authority. The certificate details must show X509v3 Basic Constraints: CA:TRUE

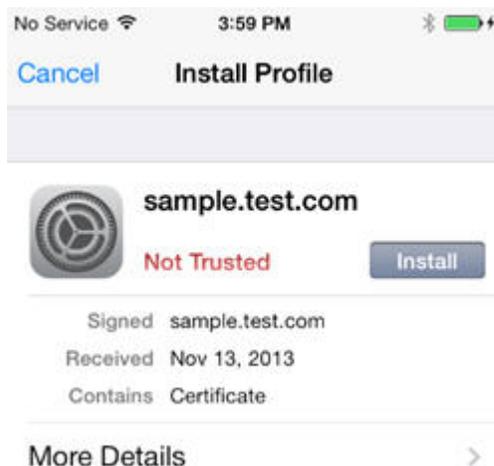

Note: The following openssl flag generates the CA extension:

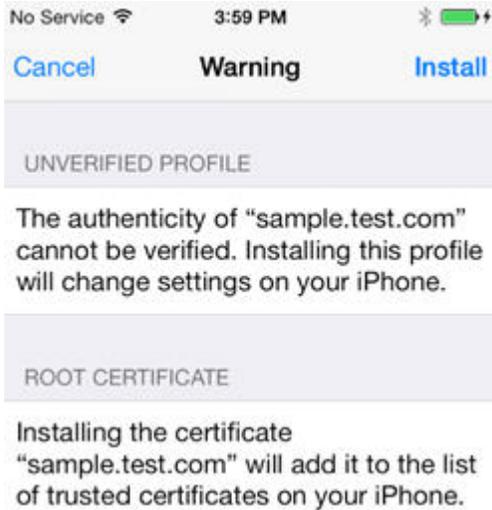

```
-extensions v3_ca
```

5. To download the certificate file on the device, send it as an email attachment or host it on a secure website.

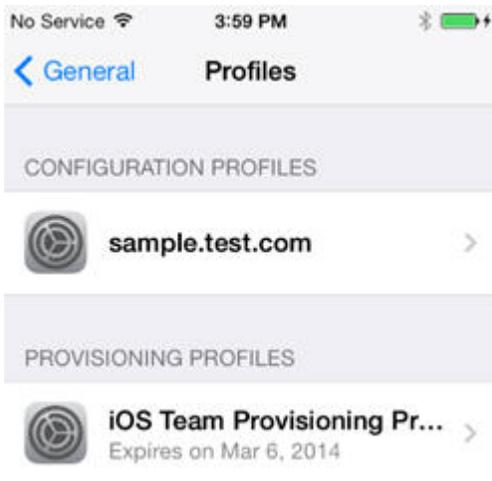

Note: Do not install the server certificate by accessing the protected resource directly from your browser. This action imports the certificate only into the browser space and not into the device system truststore.

6. After you have the certificate file on the device, click the file to allow the iOS system to install the certificate.

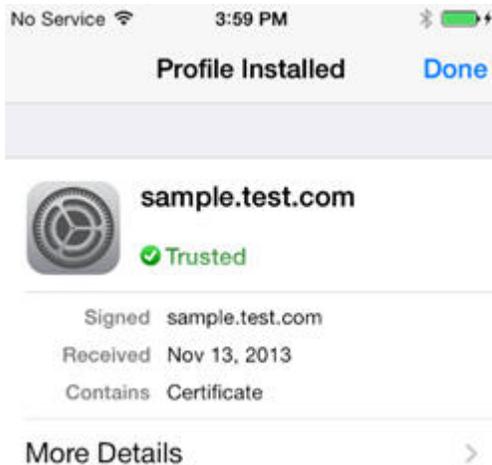

7. Check that the certificate was properly installed under **Settings > General > Profiles > Configuration Profiles**.

8. Ensure that the iOS device lists the CA as a trusted certificate authority.

Installing the root CA on Android

The root CA must be installed on the client device to ensure that the client trusts server certificates that are signed by your private CAs.

About this task

To establish trust for your server certificate, you must install the trust anchor certificate (root CA) on the client device.

Note: Only the root CA certificate (trust anchor) must be installed. You do not need to install any other certificates, such as intermediaries, on the device.

Procedure

1. Ensure that the root CA is in PEM or DER file format and has a `.crt` file extension. Convert as needed.
2. Run the following command to view the certificate details.

```
openssl x509 -in certificate.crt -text -noout
```
3. Ensure that the certificate is of version X.509 v3. The certificate details must show Version 3.

Note: The following `openssl` flag generates X.509 v3 certificates:

```
-reqexts v3_req
```

4. Ensure that the certificate is a certificate authority. The certificate details must show X509v3 Basic Constraints: CA:TRUE

Note: The following `openssl` flag generates the CA extension:

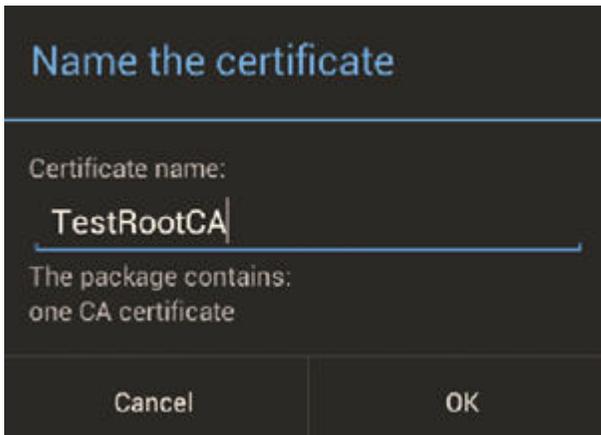

```
-extensions v3_ca
```

5. To download the certificate file on the device, send it as an email attachment or host it on a secure website.

Note: Do not install the server certificate by accessing the protected resource directly from your browser. This action imports the certificate only into the browser space and not into the device system truststore.

6. After you have the file on the device, click the file to allow the Android system to install the certificate.

7. Provide an alias name for the certificate when you are prompted.

8. Check that the certificate was properly installed under **Settings > Security > Trusted Credentials > User**.

Installing the root CA on Windows Phone

The root CA must be installed on the client device to ensure that the client trusts server certificates that are signed by your private CAs.

About this task

To establish trust for your server certificate, you must install the trust anchor certificate (root CA) on the client device.

Note: Only the root CA certificate (trust anchor) must be installed. You do not need to install any other certificates, such as intermediaries, on the device.

Procedure

1. Ensure that the root CA is in DER file format and has a .cer file extension. The PEM with a .crt file extension is not supported. Convert as needed.
2. Run the following command to view the certificate details.
`openssl x509 -inform DER -in certificate.crt -text -noout`
3. Ensure that the certificate is of version X.509 v3. The certificate details must show Version 3.

Note: The following openssl flag generates X.509 v3 certificates:

`-reqexts v3_req`

4. Ensure that the certificate is a certificate authority. The certificate details must show X509v3 Basic Constraints: CA:TRUE

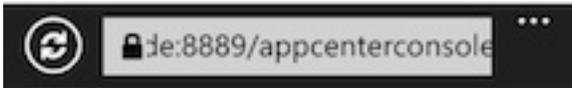

Note: The following openssl flag generates the CA extension:

`-extensions v3_ca`

5. To download the certificate file on the device, send it as an email attachment or host it on a secure website.
6. Click the link in your email or on the website, and then click **Tap to open** and confirm the installation.

Tap to open

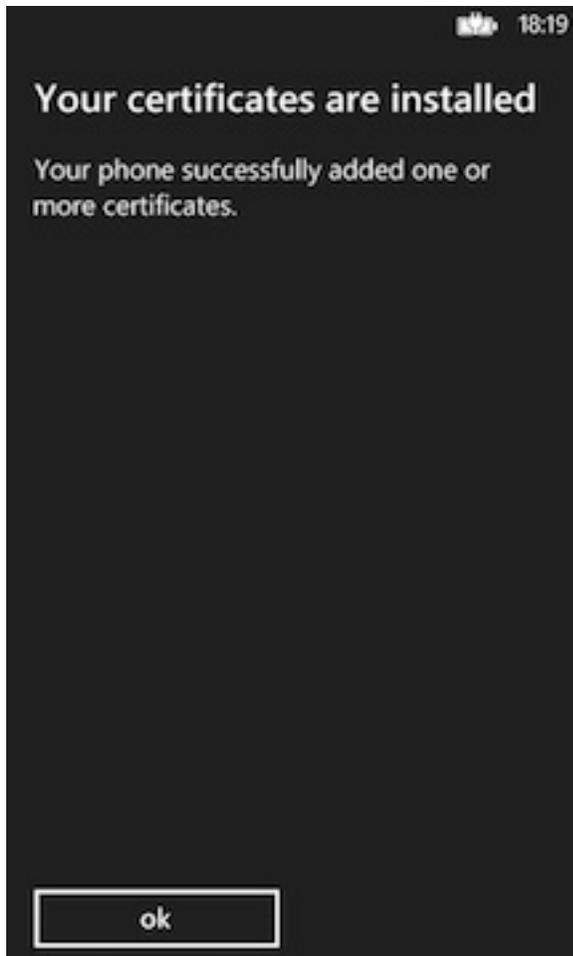

Install certificate?

A certificate is confirmation of identity and contains information that's used to establish or protect secure network connections.

www.myappcntr.net

install

cancel

Results

You can now use web servers that are secured with certificates that are based on this root CA.

Note: There is no way on Windows Phone to check whether the certificate was properly installed. Furthermore, after you install the certificate, Windows Phone provides no way to remove the certificate from the device.

Installing the root CA on Windows 8

The root CA must be installed on the client device to ensure that the client trusts server certificates that are signed by your private CAs.

About this task

To establish trust for your server certificate, you must install the trust anchor certificate (root CA) on the client device.

Note: Only the root CA certificate (trust anchor) must be installed. You do not need to install any other certificates, such as intermediaries, on the device.

Procedure

1. Ensure that the root CA is in DER file format and has a .cer file extension. The PEM with a .crt file extension is not supported. Convert as needed.

2. Run the following command to view the certificate details.
`openssl x509 -inform DER -in certificate.crt -text -noout`
3. Ensure that the certificate is of version X.509 v3. The certificate details must show Version 3.

Note: The following openssl flag generates X.509 v3 certificates:

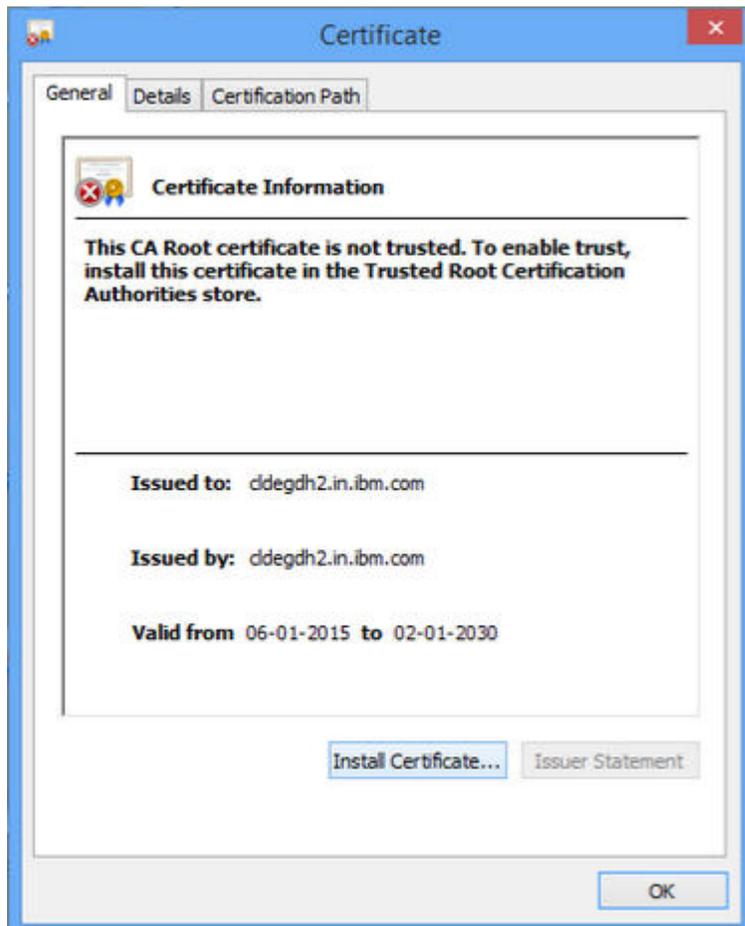

`-reqexts v3_req`

4. Ensure that the certificate is a certificate authority. The certificate details must show X509v3 Basic Constraints: CA:TRUE

Note: The following openssl flag generates the CA extension:

`-extensions v3_ca`

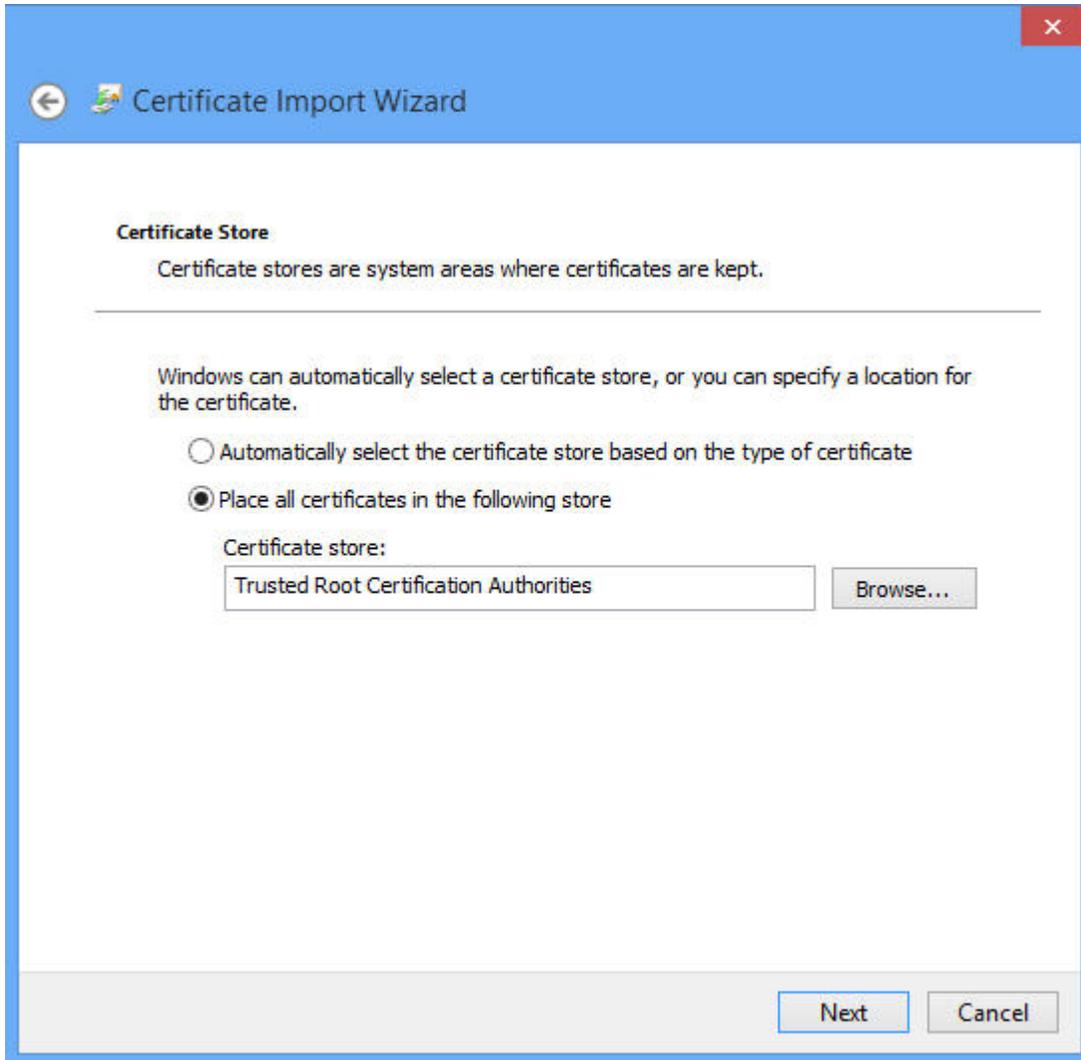

5. To download the certificate file on the device, send it as an email attachment or host it on a secure website.
6. Click the link in your email or on the website, and on the General tab in the certificate window, select **Install Certificate** and click **OK** to confirm the installation.

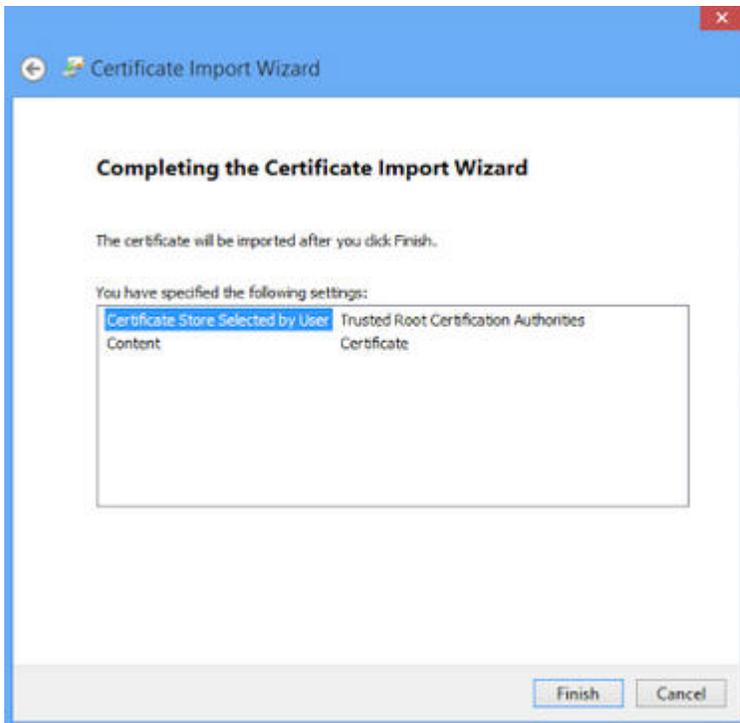

7. In the Certificate Import Wizard welcome screen, select **Local Machine** as the Store Location and click **Next**.

8. Choose **Place all certificates in the following store** option and select **Trusted Root Certification Authorities** as the certificate store. Click **Next**.

9. Choose **Certificate Store Selected by User** and click **Finish**.

10. You will receive a **Import successful** message, select **OK**. The certificate is now installed.

Results

You can now use web servers that are secured with certificates that are based on this root CA.

Note: There is no way on Windows 8 to check whether the certificate was properly installed. Furthermore, after you install the certificate, Windows 8 provides no method to remove the certificate from the device.

Updating your keystore and Liberty profile configuration to use a certificate chain

You must ensure that your server sends the whole certificate chain to client devices on an SSL handshake.

About this task

For the client to validate the certificate path, it must have access to the full certificate chain. To ensure that the client has access to the full certificate chain (including intermediate certificates), ensure that all the certificates in the chain are in the server-side keystore file.

Assuming that you have a root CA certificate, intermediate certificates, and a server certificate, the whole chain must be sent on the HTTPS connection. These certificates must be concatenated in one file, by concatenating in the following order: server certificate, intermediate CA certificates (if any exist, and if so, in the order in which they were signed), and finally the root CA.

The following example assumes that you have a server certificate (SERVER_IDENTITY_CERT_NAME), one intermediate CA certificate

(INTERMEDIATE_CA_CERT_NAME), and a root CA (ROOT_CA_CERT_NAME).

Procedure

1. Open a terminal and navigate to a temporary working directory.
2. Concatenate your certificates to form the certificate chain.
 - a. Concatenate the intermediate and the root CA certificates.

```
cat INTERMEDIATE_CA_CERT_NAME ROOT_CA_CERT_NAME > INTERMEDIATE_CA_CHAIN_CERT_NAME
```
 - b. Add the server certificate to the chain.

```
cat .SERVER_IDENTITY_CERT_NAME INTERMEDIATE_CA_CHAIN_CERT_NAME > server_chain.crt
```
3. Export the private key and certificate chain into a .p12 keystore.

```
openssl pkcs12 -export -in server_chain.crt -inkey server/server_key.pem -out server/server.p12 -passout pass:passServerP12 -passin pass:passServer
```
4. Update your Liberty profile server.xml file.
 - a. Enable the SSL feature.

```
<featureManager>
...
  <feature>ssl-1.0</feature>
...
</featureManager>
```
 - b. Create an SSL configuration.

```
<ssl id="mySSLSettings" keyStoreRef="myKeyStore" />
  <keyStore id="myKeyStore"
    location="server/server.p12"
    type="PKCS12"
    password="passServer12" />
```
 - c. Configure your HTTP endpoint to use this SSL configuration or set the configuration as the default.

```
<sslDefault sslRef="mySSLSettings" />
```

What to do next

For more information, see [Enabling SSL communication for the Liberty profile](#).

Handling MySQL stale connections

You can configure your application server to avoid MySQL timeout issues.

The MySQL database closes its connections after a period of non-activity on a connection. This timeout is defined by the system variable called `wait_timeout`. The default is 28000 seconds (8 hours).

When an application tries to connect to the database after MySQL closes the connection, the following exception is generated:

```
com.mysql.jdbc.exceptions.jdbc4.MySQLNonTransientConnectionException: No operations allowed after
```

You can configure your application server so as to avoid this exception if you use MySQL databases.

Apache Tomcat configuration

Edit the `server.xml` and `context.xml` files, and for every `<Resource>` element add the following properties:

- `testOnBorrow="true"`
- `validationQuery="select 1"`

For example:

```

<Resource name="jdbc/AppCenterDS"
  type="javax.sql.DataSource"
  driverClassName="com.mysql.jdbc.Driver"
  ...
  testOnBorrow="true"
  validationQuery="select 1"
/>

```

WebSphere Application Server Liberty profile configuration

Note: MySQL in combination with a WebSphere Application Server Liberty profile or WebSphere Application Server full profile is not classified as a supported configuration. For more information, see WebSphere Application Server Support Statement. Use IBM DB2 or another database that is supported by WebSphere Application Server to benefit from a configuration that is fully supported by IBM Support.

Edit the `server.xml` file and for every `<dataSource>` element (runtime and Application Center databases) add a `<connectionManager>` element with the **agedTimeout** property:

```
<connectionManager agedTimeout="timeout"/>
```

For example:

```

<dataSource jndiName="jdbc/AppCenterDS" transactional="false">
  <connectionManager agedTimeout="7h30m"/>
  <jdbcDriver libraryRef="MySQLLib"/>
  ...
</dataSource>

```

WebSphere Application Server full profile configuration

Note: MySQL in combination with WebSphere Application Server Liberty profile or WebSphere Application Server full profile is not classified as a supported configuration. For more information, see WebSphere Application Server Support Statement. Use IBM DB2 or another database that is supported by WebSphere Application Server to benefit from a configuration that is fully supported by IBM Support.

1. Log in to the WebSphere Application Server console.
2. Select **Resources > JDBC > Data sources**.
3. For each MySQL data source:
 - a. Click the data source.
 - b. Select **Connection pool properties** under **Additional Properties**.
 - c. Modify the value of the **Aged timeout** property. The value must be lower than the MySQL `wait_timeout` system variable so that the connections are purged before MySQL closes these connections.
 - d. Click **OK**.

Handling DB2 and Oracle stale connections

You can configure your application server to avoid DB2 and Oracle timeout issues.

A `StaleConnectionException` is an exception that is generated by the WebSphere Application Server or the WebSphere Application Server Liberty profile database connection code when a JDBC driver returns an unrecoverable error from a connection request or operation. The `StaleConnectionException` is raised when the database vendor issues an exception to indicate that a connection currently in the

connection pool is no longer valid. This exception can happen for many reasons. The most common cause of `StaleConnectionException` is due to retrieving connections from the database connection pool and finding out that the connection has timed out or dropped when it was unused for a long time.

You can configure your application server to avoid this exception.

WebSphere Application Server full profile configuration

To minimize the stale connection issues, check the connection pools configuration on each data source in WebSphere Application Server administration console.

1. Log in to the WebSphere Application Server administration console.
2. Select **Resources > JDBC Providers > *database_jdbc_provider* > Data Sources > *your_data_source* > Connection pool properties.**
3. Set the **Minimum connections** value to 0.
4. Set the **Reap time** value to be lesser than the **Unused timeout** value.
5. Make sure that the **Purge policy** property is set to `EntirePool` (default).

For more information, see [Connection pool settings](#).

WebSphere Application Server Liberty profile configuration

Edit the `server.xml` file. For every `<dataSource>` element, add a `<connectionManager>` element with the **agedTimeout** attribute:

```
<connectionManager agedTimeout="timeout_value" />
```

For example:

```
<dataSource jndiName="jndi_name" transactional="false">  
  <connectionManager agedTimeout="10m" />  
  ...  
</dataSource>
```

The timeout value depends mainly on the number of opened connections in parallel but also on the minimum and maximum number of the connections in the pool. Hence, you must tune the different `connectionManager` attributes to identify the most adequate values. For more information about the `connectionManager` element, see [Liberty: Configuration elements in the server.xml file](#).

Managing the DB2 transaction log size

When you deploy an application that is at least 40 MB with IBM MobileFirst Platform Operations Console, you might receive a transaction log full error.

About this task

The following system output is an example of the transaction log full error code.

```
DB2 SQL Error: SQLCODE=-964, SQLSTATE=57011
```

The content of each application is stored in the MobileFirst administration database.

The active log files are defined in number by the **LOGPRIMARY** and **LOGSECOND** database configuration parameters, and in size by the **LOGFILSIZ** database

configuration parameter. A single transaction cannot use more log space than `LOGFILSZ * (LOGPRIMARY + LOGSECOND) * 4096 KB`.

The `DB2 GET DATABASE CONFIGURATION` command includes information about the log file size, and the number of primary and secondary log files.

Depending on the largest size of the MobileFirst application that is deployed, you might need to increase the DB2 log space.

Procedure

Using the `DB2 update db cfg` command, increase the `LOGSECOND` parameter. Space is not allocated when the database is activated. Instead, the space is allocated only as needed.

Installing the IBM MobileFirst Platform Operational Analytics

The IBM MobileFirst Platform Operational Analytics is delivered as two separate WAR files. For convenience in deploying on WebSphere Application Server or WebSphere Application Server Liberty, the IBM MobileFirst Platform Operational Analytics is also delivered as an EAR file that contains the two WAR files.

Note: Do not install more than one instance of IBM MobileFirst Platform Operational Analytics on a single host machine. For more information about managing your cluster, see the Elasticsearch documentation.

When you develop within MobileFirst Studio, the WAR files that contain the IBM MobileFirst Platform Operational Analytics are automatically deployed. The MobileFirst Server forwards data to the MobileFirst tools with no additional required configurations.

The analytics WAR and EAR files are included with the MobileFirst Server installation. For more information, see “Distribution structure of MobileFirst Server” on page 6-53.

The following sections describe the required steps for successfully deploying the WAR file to the application server.

When you deploy the WAR file, the MobileFirst Analytics Console is available at:
`http://<hostname>:<port>/analytics/console`

Example:

`http://localhost:9080/analytics/console`

Installing MobileFirst Operational Analytics with Ant tasks

Learn how to use Ant tasks to deploy MobileFirst Operational Analytics to your application server.

Before you begin

You must run the Ant task on the computer where the application server is installed, or the Network Deployment Manager for WebSphere Application Server Network Deployment. If you want to start the Ant task from a computer on which MobileFirst Server is not installed, you must copy the file `mf_server_install_dir/WorklightServer/worklight-ant-deployer.jar` to that computer.

Note: The `mf_server_install_dir` placeholder is the directory where you installed MobileFirst Server.

For more information, see “Production deployment and clustering” on page 14-76.

Procedure

1. Edit the Ant script that you use later to deploy MobileFirst Operational Analytics WAR files.
 - a. Review the sample configuration files in “Sample configuration files for MobileFirst Operational Analytics” on page 16-82.
 - b. Replace the placeholder values with the properties at the beginning of the file.

Note: The following special characters must be escaped when they are used in the values of the Ant XML scripts:

- The dollar sign (\$) must be written as \$\$, unless you explicitly want to reference an Ant variable through the syntax `${variable}`, as described in Properties section of the Apache Ant Manual.
- The ampersand character (&) must be written as `&`, unless you explicitly want to reference an XML entity.
- Double quotation marks (") must be written as `"`, except when it is inside a string that is enclosed in single quotation marks.

2. If you install a cluster of nodes on several servers:
 - a. You must uncomment the property `wl.analytics.masters.list`, and set its value to the list of host name and transport port of the master nodes. For example:

```
node1.mycompany.com:96000,node2.mycompany.com:96000
```
 - b. Add the attribute `mastersList` to the `elasticsearch` elements in the tasks `installanalytics`, `updateanalytics`, and `uninstallanalytics`.

Note: If you install on a cluster on WebSphere Application Server Network Deployment, and you do not set the property, the Ant task computes the data end points for all the members of the cluster at the time of installation, and set the `masternodes JNDI` property to that value.

Alternatively, you can configure the cluster after installation. For more information, see “Properties and configurations” on page 14-95.

3. To deploy the WAR files, run the following command:

```
ant -f configure-appServer-analytics.xml install
```

You can find the Ant command in `mf_server_install_dir/shortcuts`. This installs a node of MobileFirst Operational Analytics, with the default type master and data, on the server, or on each member of a cluster if you install on WebSphere Application Server Network Deployment.

4. Save the Ant file. You might need it later to apply a fix pack or perform an upgrade. For more information, see “Applying a fix pack to IBM MobileFirst Platform Operational Analytics” on page 7-94.

If you do not want to save the passwords, you can replace them by “*****” (12 stars) for interactive prompting.

Note: If you add a node to a cluster of MobileFirst Operational Analytics, you must update the `analytics/masternodes JNDI` property, so that it contains the ports of all the master nodes of the cluster.

What to do next

- “Securing the Operational Analytics server” on page 14-74
- To configure Analytics, see “Properties and configurations” on page 14-95

See also :

- “Ant tasks for installation of MobileFirst Operational Analytics” on page 16-65

Installing IBM MobileFirst Platform Operational Analytics manually

You can manually install IBM MobileFirst Platform Operational Analytics, by running an Analytics EAR file on your application server.

Installing IBM MobileFirst Platform Operational Analytics for WebSphere Application Server Liberty

You can install the IBM MobileFirst Platform Operational Analytics for WebSphere Application Server Liberty.

About this task

The following steps describe how to install and run the Analytics EAR file on WebSphere Application Server Liberty.

The IBM MobileFirst Platform Operational Analytics is protected with role-based security, so you must bind the security roles to the application to be able to access the console.

Procedure

1. Add the Analytics EAR file to the apps folder of your WebSphere Application Server Liberty application server.
2. Modify the server.xml file to set the class loading delegation and bind the security roles.

```
<basicRegistry id="worklight" realm="worklightRealm">
  <user name="demo" password="demo"/>
  <user name="monitor" password="demo"/>
  <user name="deployer" password="demo"/>
  <user name="operator" password="demo"/>
  <user name="admin" password="admin"/>
</basicRegistry>
```

```
<application location="analytics.ear"
  name="analytics-ear"
  type="ear">
  <application-bnd>
    <security-role name="worklightadmin">
      <user name="admin"/>
    </security-role>
    <security-role name="worklightdeployer">
      <user name="deployer"/>
    </security-role>
    <security-role name="worklightmonitor">
      <user name="monitor"/>
    </security-role>
    <security-role name="worklightoperator">
      <user name="operator"/>
    </security-role>
  </application-bnd>
</application>
```

3. Add the following features to the WebSphere Application Server Liberty server in the feature manager.

```
<feature>jsp-2.2</feature>  
<feature>jndi-1.0</feature>  
<feature>appSecurity-1.0</feature>
```

4. Start the application server and view the console in the browser.

<http://localhost:9080/analytics/console>

Results

The analytics console is deployed and can now be viewed in the browser.

Installing IBM MobileFirst Platform Operational Analytics for WebSphere Application Server

You can install the IBM MobileFirst Platform Operational Analytics for WebSphere Application Server.

About this task

The following steps describe how to install and run the Analytics EAR file on WebSphere Application Server. If you are installing the individual WAR files on WebSphere Application Server, follow only steps 2 - 6 on the `analytics-service` WAR file after you deploy both WAR files. The class loading order must not be altered on the `analytics-ui` WAR file.

Procedure

1. Deploy the EAR file to the application server, but do not start it. For more information about the analytics files, see “Distribution structure of MobileFirst Server” on page 6-53. For more information about how to install an EAR file on WebSphere Application Server, see Installing enterprise application files with the console.
2. Select the **IMF Operational Analytics** application from the **Enterprise Applications** list.

3. Click **Class loading and update detection**.

Security role to user/group mapping

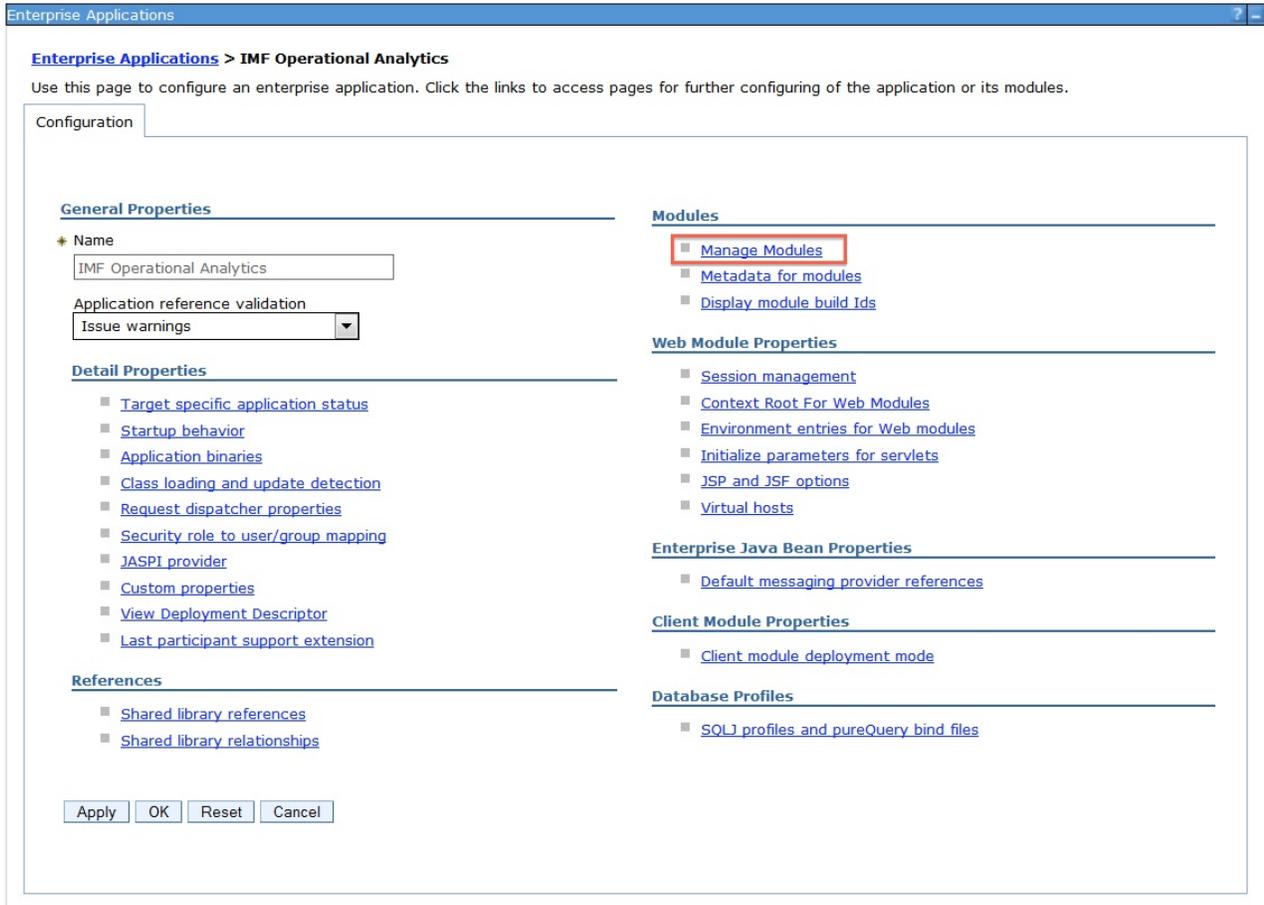

Each role that is defined in the application or module must map to a user or group from the domain user registry. accessIds: The accessIds are required only when using cross realm communication in a multi domain scenario. For all other scenarios the accessId will be determined during the application start based on the user or group name. The accessIds represent the user and group information that is used for Java Platform, Enterprise Edition authorization when using the WebSphere default authorization engine. The format for the accessIds is user:realm/uniqueUserID, group:realm/uniqueGroupID. Entering wrong information in these fields will cause authorization to fail. AllAuthenticatedInTrustedRealms: This indicates that any valid user in the trusted realms be given the access. AllAuthenticated: This indicates that any valid user in the current realm be given the access.

http://<hostname>:<port>/analytics-service/data

Results

The analytics EAR file is now ready to accept incoming analytics data.

Installing IBM MobileFirst Platform Operational Analytics for Apache Tomcat

To configure Apache Tomcat for MobileFirst Operational Analytics manually, you must copy WAR files to Tomcat, edit the `server.xml` file, add the required users, and start Tomcat..

1. Edit the file `tomcat_install_dir/conf/tomcat-users.xml`.

- a. Add the security roles:

```
<role rolename="worklightadmin"/>
<role rolename="worklightdeployer"/>
<role rolename="worklightmonitor"/>
<role rolename="worklightoperator"/>
```

- b. Add roles to the selected users, for example:

```
<user name="admin" password="admin" roles="worklightadmin"/>
```

Note: You can define the set of users as described in the Apache Tomcat documentation, at Realm Configuration HOW-TO.

2. Edit the file `tomcat_install_dir/conf/server.xml`:

- a. Uncomment the following element, which is initially commented out, or add the element if it is not present:

```
<!-- SingleSignOn valve, share authentication between web applications. Documentation at: https://tomcat.apache.org/tomcat-8.0-doc/config/valves.html -->
<Valve className="org.apache.catalina.authenticator.SingleSignOn"/>
```

- b. Declare the MobileFirst Operational Analytics Services and the MobileFirst Operational Analytics Console, as well as a user registry:

```
<!-- Declare the MobileFirst Operational Analytics Service application. -->
<Context docBase="analytics-service" path="/analytics-service">
```

```
    <!-- Declare the JNDI environment entries for the MobileFirst Operational Analytics Service application. -->
    <Environment name="analytics/masternodes" value="hostname:9600" type="java.lang.String"/>
</Context>
```

```
<!-- Declare the MobileFirst Operational Analytics Console application. -->
<Context docBase="analytics" path="/analytics"></Context>
```

```
<!-- Declare the user registry for the IBM Application Center. The MemoryRealm recognizes the user registry. -->
<Realm className="org.apache.catalina.realm.MemoryRealm"/>
```

Note: You must change the value of the JNDI property `analytics/masternodes` to reflect the host name or IP address of the machine on which you are installing MobileFirst Operational Analytics. By default, the port for ElasticSearch is 9600.

3. Copy the `analytics-service.war` file to `tomcat_install_dir/webapp` by using the following commands, according to your operating system.

- On UNIX and Linux systems:

```
cp product_install_dir/Analytics/analytics-service.war tomcat_install_dir/webapps
```

- On Windows systems:

```
copy /B product_install_dir\Analytics\analytics-service.war tomcat_install_dir\webapps\analytics
```

4. Copy the `analytics-ui.war` file to `tomcat_install_dir/webapp` and rename the file to `analytics.war` by using the following commands, according to your operating system.

- On UNIX and Linux systems:
`cp product_install_dir/Analytics/analytics-service.war tomcat_install_dir/webapps/analytics.war`
- On Windows systems:
`copy /B product_install_dir\Analytics\analytics-ui.war tomcat_install_dir\webapps\analytics.war`

Configuring the MobileFirst Server for the IBM MobileFirst Platform Operational Analytics

You must configure the MobileFirst Server for the IBM MobileFirst Platform Operational Analytics.

About this task

The following steps describe how to configure the MobileFirst Server for the IBM MobileFirst Platform Operational Analytics.

Procedure

1. In the `worklight.properties` file, set the `wl.analytics.url` property to point to the deployed WAR file.

```
wl.analytics.url=http://<hostname>:<port>/analytics-service/data
```

For example, if the Liberty server is at `host.ibm.com` on port 8080, then the `wl.analytics.url` property is as follows:

```
wl.analytics.url=http://host.ibm.com:8080/analytics-service/data
```

2. In the `worklight.properties` file, set the `wl.analytics.username` and the `wl.analytics.password` properties.
3. Optional: If you want to access the MobileFirst Analytics Console from the MobileFirst Operations Console, set the `wl.analytics.console.url` property in the `worklight.properties` file.

```
wl.analytics.console.url=http://<hostname>:<port>/analytics/console
```

For example, if the Liberty server is at `host.ibm.com` on port 8080 and the context root is `analytics`, then the `wl.analytics.console.url` property is as follows:

```
wl.analytics.console.url=http://host.ibm.com:8080/analytics/console
```

4. Optional: If you want to send logging information from a package other than the `worklight` package, in the `worklight.properties` file, set the `wl.analytics.logs.packages` property to the relevant package name, for example:

```
#Capture logs from the user defined packages (by default logs captured only from the "com.worklight" package)
```

```
wl.analytics.logs.package=my.package.com
```

Results

The MobileFirst Server now forwards data to the IBM MobileFirst Platform Operational Analytics.

Note: All properties in the `worklight.properties` file can also be set by using JNDI. For more information about JNDI settings, see “Configuration of MobileFirst applications on the server” on page 12-50.

Installing the MobileFirst Data Proxy

You install the MobileFirst Data Proxy to serve as a proxy between your MobileFirst Server and your Cloudant database.

Planning the installation of MobileFirst Data Proxy

Before you install the MobileFirst Data Proxy, you must plan your installations and verify the prerequisites for your system.

Installation overview of the MobileFirst Data Proxy

With the MobileFirst Data Proxy, the data from your mobile applications can be saved on the server side.

To develop applications with this feature, use the MobileFirst Data Proxy SDK that is documented at “Storing mobile data in Cloudant” on page 8-471.

The MobileFirst Data Proxy service requires an installed IBM MobileFirst Platform runtime, and access to a Cloudant database.

IBM MobileFirst Platform Foundation bundles a limited-use Virtual Server entitlement to IBM MobileFirst Platform Cloudant Data Layer Local Edition. This Virtual Server, or node, provides development and test with full API support, and tools. This node can be used for production with appropriate planning for availability, performance, and backup. For more information about the use limitation, see the IBM MobileFirst Platform Foundation license. By purchasing additional entitlements to IBM MobileFirst Platform Cloudant Data Layer Local Edition, customers can cluster multiple nodes together and gain horizontal and geographic scalability, fault tolerance, and continuous availability. You might want to deploy in a clustered topology for applications that require the availability, elasticity, and reach of possibly massive amounts of mobile data and devices. It is best suited for applications that require an operational data store to handle a massively concurrent mix of low-latency reads and writes.

Attention: You can install only one instance of an MobileFirst Data Proxy in an application server. That instance can authenticate incoming requests with only one MobileFirst project runtime.

Installation prerequisites for the MobileFirst Data Proxy

Review the system requirements, and perform the required installations of MobileFirst Server and the Cloudant database before installing the MobileFirst Data Proxy. Some restrictions apply about the type of application server that you can use.

For more information about the supported hardware and pre-required software, see “System requirements” on page 2-15.

Before installing the MobileFirst Data Proxy, you must perform the following actions:

- Install an instance of MobileFirst Server. For more information about the installation process, see “Installing MobileFirst Server” on page 6-14.
- Deploy a project WAR file. For more information about the deployment process, see “Deploying the project WAR file” on page 12-5.

- Install IBM MobileFirst Platform Cloudant Data Layer Local Edition, or get access to the Cloudant database. For more information about the installation process, see the IBM MobileFirst Platform Cloudant Data Layer Local Edition user documentation.

Application server restrictions

You can install the MobileFirst Data Proxy on the following application servers:

- WebSphere Application Server Liberty profile V8.5.5.0 and later
- WebSphere Application Server full profile
- WebSphere Application Server Network Deployment

You cannot install MobileFirst Data Proxy on the following application server:

- Apache Tomcat
- WebSphere Application Server Liberty profile V8.5.0.x

File System prerequisites for MobileFirst Data Proxy

Review the file system privileges and the specific rights for WebSphere Application Server and WebSphere Application Server Network Deployment that you must have before you install the MobileFirst Data Proxy.

The file system prerequisites are the same as for installing the MobileFirst Server, which are described in “File system prerequisites” on page 6-16.

In addition, to install on WebSphere Application Server or WebSphere Application Server Network Deployment, you must have the right to create files in the WebSphere Application Server installation directory: `<was_install_dir>/lib/ext`.

For WebSphere Application Server Network Deployment, you must do this operation on every node of the WebSphere Application Server Network Deployment cell, even if they do not run the MobileFirst Data Proxy service. This is required to install a Trust Association Interceptor (TAI) that is declared at the cell level.

Installing and configuring the MobileFirst Data Proxy

You can choose to install the MobileFirst Data Proxy with Ant tasks, or manually. For more information about the procedures to follow for each case, see the appropriate topics in this section.

Installing the MobileFirst Data Proxy with Ant tasks

Learn about the Ant tasks that you can use to install the MobileFirst Data Proxy.

Before you begin

Make sure that Cloudant is installed and running. It can be on the same computer, or a different computer. The Ant task verifies the connectivity to Cloudant before proceeding with the installation.

To deactivate that verification, see “Ant tasks for installation of MobileFirst Data Proxy” on page 16-60.

You must install the MobileFirst Server, as described in “Installing MobileFirst Server” on page 6-14, and deploy a project WAR file, as described in “Deploying the project WAR file” on page 12-5.

You must have the URL of the deployed project WAR file to complete the installation of the MobileFirst Data Proxy. If you want to start the Ant task from a computer on which MobileFirst Server is not installed, you must copy the following files on that computer:

- *mf_server_install_dir*/WorklightServer/worklight-ant-deployer.jar
- *mf_server_install_dir*/Datastore/imf-data-proxy.jar
- *mf_server_install_dir*/WorklightServer/external-server-libraries/*

About this task

Procedure

1. On WebSphere Application Server Network Deployment, you must install the Trust Association Interceptor (TAI) manually on every node of the WebSphere Application Server Network Deployment cell. For more information on the installation instructions, see “Installing the MobileFirst OAuth Trust Association Interceptor (TAI)” on page 6-230.

2. Review the sample configuration files, and copy the Ant file that corresponds to your application server.

The following list of sample configuration files are in *product_install_dir*/Datastore/configuration-samples:

- *configure-liberty.xml*: to install on a Liberty server.
- *configure-was.xml*: to install on a WebSphere Application Server stand-alone server.
 - *configure-wasnd-cluster.xml*: to install on WebSphere Application Server Network Deployment, on a cluster.
 - *configure-wasnd-server.xml*: to install on WebSphere Application Server Network Deployment, on a managed server.

3. Edit the Ant file and replace the placeholder values for the properties at the beginning of the file.

4. Run the following command to install the MobileFirst Data Proxy:

```
ant -f configure-<appserver>.xml install
```

You can find the Ant command in *mf_server_install_dir*/shortcuts.

Note: With these Ant files, you can also:

- Uninstall a MobileFirst Data Proxy, with the target *uninstall*.
 - Update a MobileFirst Data Proxy with the target *minimal-update* to apply a fix pack.
5. Save the Ant file. You might need it later to apply a fix pack or perform an upgrade. For more information, see “Identify the MobileFirst WAR file and prepare the Ant deployment script” on page 7-30. If you do not want to save the passwords, you can replace them by “*****” (12 stars) for interactive prompting.

Manually installing the MobileFirst Data Proxy

You can install the MobileFirst Data Proxy manually, and configure your application server accordingly.

Configuring WebSphere Application Server Liberty profile for MobileFirst Data Proxy manually:

To configure WebSphere Application Server Liberty profile for MobileFirst Data Proxy manually, you must modify the *server.xml* file. You must also install a

feature in the `usr/extension` directory that is shared between servers, and add an environment variable in a `server.env` file that specifies the MobileFirst runtime, which provides the authentication service for the MobileFirst Data Proxy.

Procedure

1. Install the OAuthTai feature that implements the Trust Association Interceptor (TAI) for IBM MobileFirst Platform Foundation.
 - a. Ensure that the Liberty `usr` directory (see note) contains a subdirectory `extension/lib`. If this subdirectory does not exist, you must create it.
 - b. Copy the file `product_install_dir/WorklightServer/external-server-libraries/com.ibm.worklight.oauth.tai_1.0.0.jar` to `usr/extension/lib/`.
 - c. Copy the file `product_install_dir/WorklightServer/external-server-libraries/OAuthTai-1.0.mf` to `usr/extension/lib/`.

Note:

Where `usr` is the `usr` directory for WebSphere Application Server Liberty profile. For more information, see the Directory locations and properties page in the WebSphere Application Server Liberty Core user documentation. It is typically in `liberty_install_dir/usr` but its location can be redefined with a variable in `liberty_install_dir/etc/server.env`.

`product_install_dir` is the installation directory for MobileFirst Server.

2. Install the MobileFirst Data Proxy WAR file.
 - a. Copy the following WAR file to the apps directory of the Liberty server: `product_install_dir/Datastore/imf-data-proxy.war`.

Note: the apps directory is in the same directory as the `server.xml` file.

3. Edit the `server.xml` file.
 - a. Ensure that the `<featureManager>` element contains at least the following `<feature>` elements:

```
<feature>jaxrs-1.1</feature>
<feature>restConnector-1.0</feature>
<feature>jndi-1.0</feature>
<feature>appSecurity-2.0</feature>
<feature>usr:OAuthTai-1.0</feature>
```

- b. Modify the web container definition with the following values:

```
<webContainer invokeFlushAfterService="false" deferServletLoad="false"/>
```
- c. Configure the Trust Association Interceptor:

```
<usr_OAuthTAI id="myOAuthTAI" cacheSize="1000">
  <securityConstraint securedURLs="/datastore/*"
    scope="cloudant"
    httpMethods="All"/>
</usr_OAuthTAI>
```
- d. If your server is not configured with a **basicRegistry** or an **ldapRegistry**, add an empty **basicRegistry**:

```
<basicRegistry> </basicRegistry>
```

Note: There can be only one **basicRegistry** per `server.xml` file. You must perform this step only if there is no other **basicRegistry** or **ldapRegistry** defined in your server.

- e. Declare the MobileFirst Data Proxy application:

```

<application id="datastore" name="datastore" location="imf-data-proxy.war" type="war">
  <application-bnd>
    <security-role name="TAIUserRole">
      <special-subject type="ALL_AUTHENTICATED_USERS" />
    </security-role>
  </application-bnd>
  <classloader delegation="parentLast">
    <commonLibrary id="worklightlib_datastore">
      <fileset dir="{wlp.install.dir}/lib" includes="com.ibm.ws.crypto.passwordutil_
    </commonLibrary>
  </classloader>
</application>

<!-- Declare the JNDI properties for the MobileFirst Data Proxy. -->
<jndiEntry jndiName="datastore/CloudantProxyDbAccount" value="hostname"/>
<jndiEntry jndiName="datastore/CloudantProtocol" value="http"/>
<jndiEntry jndiName="datastore/CloudantPort" value="80"/>
<jndiEntry jndiName="datastore/CloudantProxyDbAccountUser" value="cloudantuser"/>
<jndiEntry jndiName="datastore/CloudantProxyDbAccountPassword" value="cloudantpassword"/>

```

Where:

- datastore is the context root for the application. datastore is used in the application name and ID, and as a prefix for the jndiName values, and in the securityConstraint of the MobileFirst Data Proxy.
- The values for the following parameters correspond to:
 - CloudantProxyDbAccount is the Cloudant database account or host name of the Cloudant Local server.
 - CloudantProtocol is the protocol to connect to the Cloudant HAProxy (http or https).
 - CloudantPort is the port number to connect to the Cloudant HAProxy.
 - CloudantProxyDbAccountUser is the login of the Cloudant user.
 - CloudantProxyDbAccountPassword is the password of the Cloudant user. This password can be encrypted with the securityUtility feature of WebSphere Application Server Liberty profile.

4. Edit or create a file server.env in the Liberty server directory, and add this content:

```
publicKeyServerUrl=http://hostname:9080/worklight
```

Where the value of the **publicKeyServerUrl** environment variable is the URL to the MobileFirst runtime that runs the mobile apps which use the MobileFirst Data Proxy.

Configuring WebSphere Application Server full profile and WebSphere Application Server Network Deployment for MobileFirst Data Proxy manually:

To configure WebSphere Application Server full profile or WebSphere Application Server Network Deployment for MobileFirst Data Proxy manually, you must follow these steps.

About this task

First, you must select a context root for the MobileFirst Data Proxy application. In the following topics, the context root is referred to as /datastore.

Then you must install the MobileFirst OAuth Trust Association Interceptor (TAI). To install this component, you have two choices, which are described in the section “Installing the MobileFirst OAuth Trust Association Interceptor (TAI)” on page 6-230.

Finally, you must install the MobileFirst Data Proxy application, as described in the section “Installing the MobileFirst Data Proxy application” on page 6-232.

Installing the MobileFirst OAuth Trust Association Interceptor (TAI):

It is mandatory to install the MobileFirst OAuth Trust Association Interceptor to run the MobileFirst Data Proxy. You can either install the TAI on the default security domain of a cell, or on a specific security domain.

About this task

There are two options to install MobileFirst OAuth Trust Association Interceptor. Review the following topics to learn about the procedures for each option.

Installing the MobileFirst OAuth Trust Association Interceptor on the default security domain:

You can choose to install the TAI on the default security domain of a cell. This is convenient for a standalone web server, but on WebSphere Application Server Network Deployment, this means that the TAI is active on all servers and clusters of the cell. It must also be installed, and maintained for fix packs, on all nodes of the cell.

Procedure

1. Copy the file `product_install_dir/WorklightServer/external-server-libraries/com.ibm.worklight.oauth.tai_1.0.0.jar` to `${WAS_INSTALL_ROOT}/lib/ext`.

Note: On WebSphere Application Server Network Deployment, you must perform this operation on every node of the WebSphere Application Server cell.

2. Create a configuration file with this content:

```
<?xml version="1.0" encoding="UTF-8"?>

<OAuthTAI >
  <!-- Security constraint. -->
  <securityConstraint securedURLs="/datastore/*" scope="cloudant" httpMethods="All"/>
</OAuthTAI>
```

Where `datastore` is the context root of the application, as defined in the section *About this task* of the topic “Configuring WebSphere Application Server full profile and WebSphere Application Server Network Deployment for MobileFirst Data Proxy manually” on page 6-229.

3. Copy this configuration file in the `config` directory of the WebSphere Application Server profile, or the WebSphere Application Server Deployment Manager profile for WebSphere Application Server Network Deployment (this directory is synchronized with the nodes). For example:

```
${USER_INSTALL_ROOT}/config/cells/<cellName>/com.worklight.oauth.tai.0AuthTAI.conf
```

Where `USER_INSTALL_ROOT` is the profile directory, and `<cellName>` must be replaced by the actual name of the WebSphere Application Server cell. The directory should already exist.

4. Open the WebSphere Application Server Console.
5. Go to **Security > Global Security > Authentication**, and select **Enable LTPA**.
6. Go to **Security > Global Security > Web and SIP security > Trust association**.
 - a. Enable trust association.
 - b. In the **Interceptors** tab, create a new interceptor by clicking **New**.

- c. Set the following settings for this interceptor:
 - Interceptor class name: `com.worklight.oauth.tai.OAuthTAI`.
 - Custom properties:
 - Name: `configFileLocation`
 - Value: `${USER_INSTALL_ROOT}/config/cells/<cellName>/com.worklight.oauth.tai.OAuthTAI.conf`

Note: Keep `${USER_INSTALL_ROOT}` as a variable, especially if you install on WebSphere Application Server Network Deployment. The `${USER_INSTALL_ROOT}` variable is defined in WebSphere Application Server.

You must replace `<cellName>` by the actual cell name.

7. From the WebSphere Application Server console, define an environment variable for each server of the cell that points to the MobileFirst project runtime which provides the authentication service.
 - a. From the WebSphere Application Server Console, go to **Servers > Server Types > WebSphere application servers > *your_server* > Java and Process Management > Process Definition > Environment Entries > New**.
 - b. Create an environment with the following settings:

```
publicKeyServerUrl=url_to_mfp_server
```

Where `url_to_mfp_server` is the URL to the MobileFirst project runtime that provides the public key for decrypting MFP OAuth tokens. For example, it can be `http://localhost:9080/worklight` if a project runtime is installed on the same server, the port is 9080, and the context root is `/worklight`.

The TAI will not be active before you restart the application server. For WebSphere Application Server Network Deployment, the nodes must also be synchronized.

What to do next

Follow the steps in “Installing the MobileFirst Data Proxy application” on page 6-232

Installing the MobileFirst OAuth Trust Association Interceptor on a specific security domain:

You can choose to install the TAI on a specific security domain. In this case, only servers or clusters that use that security domain can run the MobileFirst Data Proxy.

Procedure

1. Open the WebSphere Application Server Console.
 - a. Create a security domain by clicking **Security > Global Security > Security domains > New**.
 - b. Configure the security domain as follows:
 - Name: `MobileFirstOAuthDomain`
 - Description: `Security Domain with MobileFirst Platform Foundation TAI Enabled`
 - c. Click the security domain that you created.
 - d. Go to **Security Attributes > Trust Association**, and select **Enable Trust Association**.

e. Go to **Security Attributes > Trust Association > Interceptors** and set the properties as follows:

- Interceptor class name: `com.worklight.oauth.tai.OAuthTAI`.
- Custom properties:
 - Name: `configFileLocation`
 - Value: `${USER_INSTALL_ROOT}/config/cells/<cellName>/com.worklight.oauth.tai.OAuthTAI.conf`

Note: Keep `${USER_INSTALL_ROOT}` as a variable, especially if you install on WebSphere Application Server Network Deployment. The `${USER_INSTALL_ROOT}` variable is defined in WebSphere Application Server.

You must replace `<cellName>` by the actual cell name.

f. In **Assigned Scopes**, assign the security domain to the server or cluster that runs the MobileFirst Data Proxy.

2. Copy the file `product_install_dir/WorklightServer/external-server-libraries/com.ibm.worklight.oauth.tai_1.0.0.jar` to `${WAS_INSTALL_ROOT}/lib/ext`.

Note: You must perform this operation on every node that hosts a server with the `MobileFirstOAuthDomain` security domain.

3. Create the TAI configuration file and copy it in the config directory of the WebSphere Application Server profile. For more information, see steps 1 on page 6-230 and 2 on page 6-230 of “Installing the MobileFirst OAuth Trust Association Interceptor on the default security domain” on page 6-230.

4. From the WebSphere Application Server console, define an environment variable for each server with the `MobileFirstOAuthDomain` security domain.

a. Go to **Servers > Server Types > WebSphere application servers > your_server > Java and Process Management > Process Definition > Environment Entries > New**.

b. Create an environment with the following settings:

```
publicKeyServerUrl=url_to_mfp_server
```

Where `url_to_mfp_server` is the URL to the MobileFirst project runtime that provides the public key for decrypting MFP OAuth tokens. For example, it can be `http://localhost:9080/worklight` if a project runtime is installed on the same server, the port is 9080, and the context root is `/worklight`.

The TAI will not be active before you restart the application server. For WebSphere Application Server Network Deployment, the nodes must also be synchronized.

What to do next

Follow the steps in “Installing the MobileFirst Data Proxy application”

Installing the MobileFirst Data Proxy application:

When the previous configuration steps of your application server are done, you must install, then start the MobileFirst Data Proxy application.

Procedure

1. Enable application security.
 - a. Click **Security > Global Security**.

- b. Ensure that **Enable administrative security** is selected. Application security can be enabled only if administrative security is enabled.
 - c. Click **OK**.
 - d. Save the changes.

For more information, see Enabling security in WebSphere Application Server user documentation.
2. Review the server class loader policy:
 - a. Click **Servers > Server Types > WebSphere application servers**.
 - b. Select the server that is used for the MobileFirst Data Proxy.
 - If the class loader policy is set to **Multiple**, do nothing.
 - If the class loader policy is set to **Single** and the class loading mode is set to **parent-last**, do nothing.
 - If the class loader policy is set to **Single** and the class loading mode is set to **parent-first**, change the class loader policy to **Multiple**, and set the class loader order of all applications other than MobileFirst applications to **parent-first**.
 3. Install the Administration Services WAR file:
 - a. Depending on your version of WebSphere Application Server, click one of the following options:
 - **Applications > New > New Enterprise Application**
 - **Applications > New Application > New Enterprise Application**
 - b. Go to the MobileFirst Server installation directory: `product_install_dir/` `Datastore`.
 - c. Select `imf-data-proxy.war`, and click **Next**.
 - d. On the **How do you want to install the application?** page, click **Detailed**, and then click **Next**.
 - e. On the **Application Security Warnings** page, click **Continue**.
 - f. Click **Next** until you reach the **Map context roots for web modules** page.
 - g. In the **Context Root** field, type `/datastore`. This is defined in the section *About this task* of the topic “Configuring WebSphere Application Server full profile and WebSphere Application Server Network Deployment for MobileFirst Data Proxy manually” on page 6-229
 - h. Click **Next**.
 - i. In **Map environment entries for web modules**, enter the following values:
 - for the `CloudantProxyDbAccount` entry, enter the host name of the Cloudant database.
 - for the `CloudantProtocol` entry, enter the protocol used to connect to Cloudant. The possible values are `http` or `https`.
 - for the `CloudantPort` entry, enter the port of the Cloudant database, which is by default `80` for `http` and `443` for `https`.
 - for the `CloudantProxyDbAccountUser` entry, enter the Cloudant user that can log to Cloudant.
 - for the `CloudantProxyDbAccountPassword` entry, enter the Cloudant user's password.
 - j. Click **Next**.
 - k. In **Map security roles to users or groups**, select **TAIUserRole**.
 - l. Select **Map Special Subjects > All Authenticated Users in Application's Realm**.

- m. Click **Next** until you reach the last step, and click **Finish**.
 - n. Click **Save**.
4. Configure the class loader policies for the Administration Services and then start the application:
 - a. Click the **Manage Applications** link, or click **Applications > Applications Types > WebSphere enterprise applications**.
 - b. From the list of applications, click `imf-data-proxy_war`.
 - c. In the **Detail Properties** section, click the **Class loading and update detection** link.
 - d. In the **Class loader order** pane, click **Classes loaded with local class loader first (parent last)**.
 - e. Click **OK**.
 - f. In the **Detail Properties** section, click the **Startup behavior** link.
 - g. In **Startup Order**, enter 1, and click **OK**.
 - h. In the **Modules** section, click **Manage Modules**.
 - i. From the list of modules, click the `imfdata` module.
 - j. In the **Class loader order** pane, click **Classes loaded with local class loader first (parent last)**.
 - k. Click **OK** twice.
 - l. Click **Save**.
 - m. Select `imf-data-proxy_war` and click **Start**.

Configuring the application server to access the Cloudant database through HTTPS

Whether you installed the MobileFirst Data Proxy manually or with Ant tasks, if you access the Cloudant database through HTTPS, and your application server is WebSphere Application Server full profile, you must configure your certificates. If your application server is WebSphere Application Server Liberty profile, and a self-signed certificate is used to access the Cloudant database, an extra configuration step is required.

Procedure

For WebSphere Application Server full profile, you must import the Cloudant signer certificate in the WebSphere Application Server truststore to access the Cloudant database through HTTPS. If you connect to Cloudant through the HTTPS protocol, follow steps 1 to 7.

1. Open the WebSphere Application Server console.
2. Go to **Security > SSL Certificates and Key Management**.
3. In **Related Items**, click **Key stores and certificates**.
4. Select **NodeDefaultTrustStore**.
5. Select **Additional Properties > Signer certificates**.
6. Click **Retrieve from port**.
 - a. Enter the Cloudant host name and the port, which is by default 443.
 - b. Select an alias, for example Cloudant trust store.
 - c. Click **Retrieve signer information**.
 - d. Click **OK**.
7. Click **Save**.

For WebSphere Application Server Liberty profile, if you access the Cloudant database through HTTPS with a self-signed certificate, you must import this

certificate in the cacerts truststore of the JVM that is used by your Liberty server, which you find in: `JAVA_INSTALL_DIR\jre\lib\security\cacerts`.

8. Use the **keytool** command that is available in both IBM JRE and Oracle JRE, as of Java 6.
9. For more information, see the Keytool section of the IBM SDK, Java Technology Edition user documentation.

Note: The password to access this truststore is `changeit`.

Configuring the connection between the MobileFirst Data Proxy and the Analytics server

If you installed MobileFirst Operational Analytics on a server, you can optionally configure the MobileFirst Data Proxy so that it can send events to this server.

To configure the connection between the MobileFirst Data Proxy and the Analytics server, you must follow the instructions from the section *Reporting analytics*, in the page “Protecting resources on WebSphere Application Server or WebSphere Application Server Liberty” on page 8-537.

Installing and configuring the Application Center

You install the Application Center as part of the MobileFirst Server installation.

The Application Center is part of MobileFirst Server. You can install the Application Center with one of the following methods:

- Installation with IBM Installation Manager
- Installation with Ant tasks
- Manual installation

Optionally, you can create the database of your choice before you install MobileFirst Server with the Application Center.

After you installed the Application Center in the web application server of your choice, you have additional configuration to do. For more information, see “Configuring Application Center after installation” on page 6-269.

If you chose a manual setup in the installer, see the documentation of the server of your choice.

If you intend to install applications on iOS devices through the Application Center, you must first configure the Application Center server with SSL.

For a list of installed files and tools, see “Distribution structure of MobileFirst Server” on page 6-53.

Installing Application Center with IBM Installation Manager

With IBM Installation Manager, you can install Application Center, create its database, and deploy it on an Application Server.

Before you begin

Verify that the user who runs IBM Installation Manager has the privileges that are described in “File system prerequisites” on page 6-16.

Procedure

To install IBM Application Center with IBM Installation Manager, complete the following steps.

1. Optional: You can manually create databases for Application Center, as described in “Optional creation of databases.” IBM Installation Manager can create the Application Center databases for you with default settings.
2. Run IBM Installation Manager, as described in “Running IBM Installation Manager” on page 6-43.
3. Select **Yes** to the question **Install IBM Application Center**.

Optional creation of databases

If you want to activate the option to install the Application Center when you run the MobileFirst Server installer, you need to have certain database access rights that entitle you to create the tables that are required by the Application Center.

If you have sufficient database administration credentials, and if you enter the administrator user name and password in the installer when prompted, the installer can create the databases for you. Otherwise, you need to ask your database administrator to create the required database for you. The database needs to be created before you start the MobileFirst Server installer.

The following topics describe the procedure for the supported database management systems.

Creating the DB2 database for Application Center:

During IBM MobileFirst Platform Foundation installation, the installer can create the Application Center database for you.

About this task

The installer can create the Application Center database for you if you enter the name and password of a user account on the database server that has the DB2 SYSADM or SYSCTRL privilege, and the account can be accessed through SSH. Otherwise, the database administrator can create the Application Center database for you. For more information, see the DB2 Solution user documentation.

When you manually create the database, you can replace the database name (here APPCNTR) and the password with a database name and password of your choosing.

Important: You can name your database and user differently, or set a different password, but ensure that you enter the appropriate database name, user name, and password correctly across the DB2 database setup. DB2 has a database name limit of 8 characters on all platforms, and has a user name and password length limit of 8 characters for UNIX and Linux systems, and 30 characters for Windows.

Procedure

1. Create a system user, for example, named `wuser` in a DB2 admin group such as `DB2USERS`, using the appropriate commands for your operating system. Give it a password, for example, `wuser`. If you want multiple instances of IBM MobileFirst Platform Server to connect to the same database, use a different user name for each connection. Each database user has a separate default

schema. For more information about database users, see the DB2 documentation and the documentation for your operating system.

2. Open a DB2 command line processor, with a user that has SYSADM or SYSCTRL permissions:
 - On Windows systems, click **Start > IBM DB2 > Command Line Processor**
 - On Linux or UNIX systems, navigate to `~/sqllib/bin` and enter `./db2`.
 - Enter database manager and SQL statements similar to the following example to create the Application Center database, replacing the user name `wluser` with your chosen user names:

```
CREATE DATABASE APPCNTR COLLATE USING SYSTEM PAGESIZE 32768
CONNECT TO APPCNTR
GRANT CONNECT ON DATABASE TO USER wluser
DISCONNECT APPCNTR
QUIT
```
3. The installer can create the database tables and objects for Application Center in a specific schema. This allows you to use the same database for Application Center and for a MobileFirst project. If the `IMPLICIT_SCHEMA` authority is granted to the user created in step 1 (the default in the database creation script in step 2), no further action is required. If the user does not have the `IMPLICIT_SCHEMA` authority, you need to create a `SCHEMA` for the Application Center database tables and objects.

Creating the MySQL database for Application Center:

During the MobileFirst installation, the installer can create the Application Center database for you.

About this task

The installer can create the database for you if you enter the name and password of the superuser account. For more information, see *Securing the Initial MySQL Accounts* on your MySQL database server. Your database administrator can also create the databases for you. When you manually create the database, you can replace the database name (here `APPCNTR`) and password with a database name and password of your choosing. Note that MySQL database names are case-sensitive on Unix.

Procedure

1. Start the MySQL command-line tool.
2. Enter the following commands:

```
CREATE DATABASE APPCNTR CHARACTER SET utf8 COLLATE utf8_general_ci;
GRANT ALL PRIVILEGES ON APPCNTR.* TO 'worklight'@'Worklight-host' IDENTIFIED BY 'password';
GRANT ALL PRIVILEGES ON APPCNTR.* TO 'worklight'@'localhost' IDENTIFIED BY 'password';
FLUSH PRIVILEGES;
```

Here, you need to replace *Worklight-host* with the name of the host on which IBM MobileFirst Platform Foundation runs.

Creating the Oracle database for Application Center:

During the installation, the installer can create the Application Center database, except for the Oracle 12c database type, or the user and schema inside an existing database for you.

About this task

The installer can create the database, except for the Oracle 12c database type, or the user and schema inside an existing database if you enter the name and password of the Oracle administrator on the database server, and the account can be accessed through SSH. Otherwise, the database administrator can create the database or user and schema for you. When you manually create the database or user, you can use database names, user names, and a password of your choosing. Note that lowercase characters in Oracle user names can lead to trouble.

Procedure

1. If you do not already have a database named ORCL, use the Oracle Database Configuration Assistant (DBCA) and follow the steps in the wizard to create a new general-purpose database named ORCL:
 - a. Use global database name `ORCL_our_domain`, and system identifier (SID) ORCL.
 - b. On the **Custom Scripts** tab of the step **Database Content**, do not run the SQL scripts, because you must first create a user account.
 - c. On the **Character Sets** tab of the step **Initialization Parameters**, select **Use Unicode (AL32UTF8) character set and UTF8 - Unicode 3.0 UTF-8 national character set**.
 - d. Complete the procedure, accepting the default values.
2. Create a database user either by using Oracle Database Control, or by using the Oracle SQLPlus command-line interpreter.
 - Using Oracle Database Control.
 - a. Connect as SYSDBA.
 - b. Go to the **Users** page: click **Server**, then **Users** in the **Security** section.
 - c. Create a user, for example, named APPCENTER. If you want multiple instances of IBM MobileFirst Platform Server to connect to the same general-purpose database you created in step 1, use a different user name for each connection. Each database user has a separate default schema.
 - d. Assign the following attributes:
 - Profile: **DEFAULT**
 - Authentication: **password**
 - Default tablespace: **USERS**
 - Temporary tablespace: **TEMP**
 - Status: **Unlocked**
 - Add system privilege: **CREATE SESSION**
 - Add system privilege: **CREATE SEQUENCE**
 - Add system privilege: **CREATE TABLE**
 - Add quota: **Unlimited for tablespace USERS**
 - Using the Oracle SQLPlus command-line interpreter.

The commands in the following example create a user named APPCENTER for the database:

```
CONNECT SYSTEM/<SYSTEM_password>@ORCL
CREATE USER APPCENTER IDENTIFIED BY password DEFAULT TABLESPACE USERS QUOTA UNLIMITED ON USERS;
GRANT CREATE SESSION, CREATE SEQUENCE, CREATE TABLE TO APPCENTER;
DISCONNECT;
```

Installing Application Center in WebSphere Application Server Network Deployment

To install Application Center in a set of WebSphere Application Server Network Deployment servers, run IBM Installation Manager on the machine where the deployment manager is running.

Procedure

1. When IBM Installation Manager prompts you to specify the database type, select any option other than **Apache Derby**. IBM MobileFirst Platform Foundation supports Apache Derby only in embedded mode, and this choice is incompatible with deployment through WebSphere Application Server Network Deployment.
2. In the installer panel in which you specify the WebSphere Application Server installation directory, select the deployment manager profile.

Attention: Do not select an application server profile and then a single managed server: doing so causes the deployment manager to overwrite the configuration of the server regardless of whether you install on the machine on which the deployment manager is running or on a different machine.

3. Select the required scope depending on where you want Application Center to be installed. The following table lists the available scopes:

Table 6-52. Selecting the required scope.

Scope	Explanation
Cell	Installs Application Center in all application servers of the cell.
Cluster	Installs Application Center in all application servers of the specified cluster.
Node (excluding clusters)	Installs Application Center in all application servers of the specified node that are not in a cluster.
Server	Installs Application Center in the specified server, which is not in a cluster.

4. Restart the target servers by following the procedure in “Completing the installation” on page 6-240.

Results

The installation has no effect outside the set of servers in the specified scope. The JDBC providers and JDBC data sources are defined with the specified scope. The entities that have a cell-wide scope (the applications and, for DB2, the authentication alias) have a suffix in their name that makes them unique. So, you can install Application Center in different configurations or even different versions of Application Center, in different clusters of the same cell.

Note: Because the JDBC driver is installed only in the specified set of application servers, the **Test connection** button for the JDBC data sources in the WebSphere Application Server administration console of the deployment manager might not work.

What to do next

You need to complete the following additional configuration:

- If you use a front-end HTTP server, you need to configure the public URL

Completing the installation

When installation is complete, you must restart the web application server in certain cases.

You must restart the web application server in the following circumstances:

- When you are using WebSphere Application Server with DB2 as database type.
- When you are using WebSphere Application Server and have opened it without the application security enabled before you installed IBM MobileFirst Platform Application Center or MobileFirst Server.

The MobileFirst installer must activate the application security of WebSphere Application Server (if not active yet) to install Application Center. Then, for this activation to take place, restart the application server after the installation of MobileFirst Server completed.

- When you are using WebSphere Application Server Liberty or Apache Tomcat.
- After you upgraded from a previous version of MobileFirst Server.

If you are using WebSphere Application Server Network Deployment and chose an installation through the deployment manager:

- You must restart the servers that were running during the installation and on which the MobileFirst Server web applications are installed.

To restart these servers with the deployment manager console, select **Applications > Application Types > WebSphere enterprise applications > IBM_Application_Center_Services > Target specific application status.**

- You do not have to restart the deployment manager or the node agents.

Note: Only the Application Center is installed in the application server. A MobileFirst Operations Console is not installed by default. To install a MobileFirst Operations Console, you need to follow the steps in “Deploying MobileFirst projects” on page 12-1.

Default logins and passwords created by IBM Installation Manager for the Application Center

IBM Installation Manager creates the logins by default for the Application Center, according to your application server. You can use these logins to test the Application Center.

WebSphere Application Server full profile

The login `appcenteradmin` is created with a password that is generated and displayed during the installation.

All users authenticated in the application realm are also authorized to access the `appcenteradmin` role. This is not meant for a production environment, especially if WebSphere Application Server is configured with a single security domain.

For more information about how to modify these logins, see “Configuring the Java EE security roles on WebSphere Application Server full profile” on page 6-271.

WebSphere Application Server Liberty profile

- The login `demo` is created in the `basicRegistry` with the password `demo`.
- The login `appcenteradmin` is created in the `basicRegistry` with the password `admin`.

For more information about how to modify these logins, see “Configuring the Java EE security roles on WebSphere Application Server Liberty profile” on page 6-272.

Apache Tomcat

- The login demo is created with the password demo.
- The login guest is created with the password guest.
- The login appcenteradmin is created with the password admin.

For more information about how to modify these logins, see “Configuring the Java EE security roles on Apache Tomcat” on page 6-274.

Installing the Application Center with Ant tasks

Learn about the Ant tasks that you can use to install Application Center.

Creating and configuring the database for Application Center with Ant tasks

If you did not manually create the database, you can use Ant tasks to create and configure your database for Application Center. If your database already exists, you can perform only the configuration steps with Ant tasks.

Before you begin

Make sure that a database management system (DBMS) is installed and running on a database server, which can be on the same computer, or a different one.

The Ant tasks for Application Center are in the `ApplicationCenter/configuration-samples` directory of the MobileFirst Server distribution.

If you want to start the Ant task from a computer where MobileFirst Server is not installed, you must copy the following files to that computer:

- The library `mf_server_install_dir/WorklightServer/worklight-ant-deployer.jar`
- The directory that contains binary files of the `aapt` program, from the Android SDK platform-tools package: `mf_server_install_dir/ApplicationCenter/tools/android-sdk`
- The Ant sample files that are in `mf_server_install_dir/ApplicationCenter/configuration-samples`

Note: The `mf_server_install_dir` placeholder represents the directory where you installed MobileFirst Server.

About this task

- If you did not create your database manually, as described in “Optional creation of databases” on page 6-236, follow steps 1 to 3 on page 6-242.
- If your database already exists, you must create only the database tables. Follow steps 4 on page 6-242 to 7 on page 6-242.

Procedure

If you did not create your database manually, as described in “Optional creation of databases” on page 6-236, complete the following steps:

1. Copy the sample Ant file that corresponds to your DBMS. The files for creating a database are named after the following pattern:

```
create-appcenter-database-<dbms>.xml
```

2. Edit the Ant file, and replace the placeholder values with the properties at the beginning of the file.
3. Run the following commands to create the Application Center database:
ant -f create-appcenter-database-<dbms>.xml databases

You can find the Ant command in *mf_server_install_dir/shortcuts*.

If the database already exists, then you must create only the database tables by completing the following steps:

4. Copy the sample Ant file that corresponds to both your application server, and your DBMS. The files for configuring an existing database are named after this pattern:

```
configure-appcenter-<appServer>-<dbms>.xml
```

5. Edit the Ant file, and replace the placeholder values with the properties at the beginning of the file.
6. Run the following commands to configure the database:
ant -f configure-appcenter-<appServer>-<dbms>.xml databases

You can find the Ant command in *mf_server_install_dir/shortcuts*.

7. Save the Ant file. You might need it later to apply a fix pack, or perform an upgrade.

For more information, see “Deploying the Application Center console and services with Ant tasks.”

If you do not want to save the passwords, you can replace them by “*****” (12 stars) for interactive prompting.

What to do next

Follow the procedure at “Deploying the Application Center console and services with Ant tasks.”

See also:

- “Ant tasks for installation of Application Center” on page 16-56
- “Sample configuration files” on page 16-77

Deploying the Application Center console and services with Ant tasks

Use Ant tasks to deploy the Application Center Console and Services to an application server, and configure data sources, properties, and database drivers that are used by Application Center.

Before you begin

- Complete the procedure at “Creating and configuring the database for Application Center with Ant tasks” on page 6-241.
- You must run the Ant task on the computer where the application server is installed, or the Network Deployment Manager for WebSphere Application Server Network Deployment. If you want to start the Ant task from a computer where MobileFirst Server is not installed, you must copy the following files and directories to that computer:
 - The library *mf_server_install_dir/WorklightServer/worklight-ant-deployer.jar*

- The web applications (WAR and EAR files) in *mf_server_install_dir*/ApplicationCenter/console
- The directory that contains the binary files of the aapt program, from the Android SDK platform-tools package: *mf_server_install_dir*/ApplicationCenter/tools/android-sdk
- The Ant sample files that are in *mf_server_install_dir*/ApplicationCenter/configuration-samples

Note: The *mf_server_install_dir* placeholder represents the directory where you installed MobileFirst Server.

Procedure

1. Copy the Ant file that corresponds both to your application server, and your DBMS. The files for configuring Application Center are named after the following pattern:

```
configure-appcenter-<appserver>-<dbms>.xml
```

2. Edit the Ant file, and replace the placeholder values with the properties at the beginning of the file.
3. Run the following command to deploy the Application Center Console and Services to an application server:

```
ant -f configure-appcenter-<appserver>-<dbms>.xml install
```

You can find the Ant command in *mf_server_install_dir*/shortcuts.

Note: With these Ant files, you can also do the following actions:

- Uninstall Application Center, with the target `uninstall`.
 - Update Application Center with the target `minimal-update`, to apply a fix pack.
4. Save the Ant file. You might need it later to apply a fix pack or perform an upgrade. If you do not want to save the passwords, you can replace them by "*****" (12 stars) for interactive prompting.
 5. If you installed on WebSphere Application Server Liberty profile, or Apache Tomcat, check that the aapt program is executable for all users. If needed, you must set the proper user rights. For example, on UNIX/Linux systems:

```
$ chmod a+x mf_server_install_dir/ApplicationCenter/tools/android-sdk/*/aapt*
```

Manually installing Application Center

A reconfiguration is necessary for the MobileFirst Server to use a database or schema that is different from the one that was specified during its installation. This reconfiguration depends on the type of database and on the kind of application server.

On application servers other than Apache Tomcat, you can deploy Application Center from two WAR files or one EAR file.

Restriction: Whether you install Application Center with IBM Installation Manager as part of the MobileFirst Server installation or manually, remember that "rolling updates" of Application Center are not supported. That is, you cannot install two versions of Application Center (for example, V5.0.6 and V6.0.0) that operate on the same database. See "In-place upgrade or rolling upgrade to MobileFirst Server V7.1.0" on page 7-37.

Configuring the DB2 database manually for IBM MobileFirst Platform Application Center

You configure the DB2 database manually by creating the database, creating the database tables, and then configuring the relevant application server to use this database setup.

Procedure

1. Create the database. This step is described in “Creating the DB2 database for Application Center” on page 6-236.
2. Create the tables in the database. This step is described in “Setting up your DB2 database manually for Application Center.”
3. Perform the application server-specific setup as the following list shows.

Setting up your DB2 database manually for Application Center:

You can set up your DB2 database for Application Center manually.

About this task

Set up your DB2 database for Application Center by creating the database schema.

Procedure

1. Create a system user, **worklight**, in a DB2 admin group such as **DB2USERS**, by using the appropriate commands for your operating system. Give it the password **worklight**. For more information, see the DB2 documentation and the documentation for your operating system.

Important: You can name your user differently, or set a different password, but ensure that you enter the appropriate user name and password correctly across the DB2 database setup. DB2 has a user name and password length limit of 8 characters for UNIX and Linux systems, and 30 characters for Windows.

2. Open a DB2 command line processor, with a user that has **SYSADM** or **SYSCTRL** permissions:
 - On Windows systems, click **Start > IBM DB2 > Command Line Processor**.
 - On Linux or UNIX systems, go to `~/sql/lib/bin` and enter `./db2`.
3. Enter the following database manager and SQL statements to create a database that is called **APPCNTR**:

```
CREATE DATABASE APPCNTR COLLATE USING SYSTEM PAGESIZE 32768
CONNECT TO APPCNTR
GRANT CONNECT ON DATABASE TO USER worklight
QUIT
```

4. Run DB2 with the following commands to create the **APPCNTR** tables, in a schema named **APPSCHM** (the name of the schema can be changed). This command can be run on an existing database that has a page size compatible with the one defined in step 3.

```
db2 CONNECT TO APPCNTR
db2 SET CURRENT SCHEMA = 'APPSCHM'
db2 -vf product_install_dir/ApplicationCenter/databases/create-appcenter-db2.sql -t
```

Configuring Liberty profile for DB2 manually for Application Center:

You can set up and configure your DB2 database manually for Application Center with WebSphere Application Server Liberty profile.

Before you begin

Complete the DB2 Database Setup procedure before continuing.

Procedure

1. Add the DB2 JDBC driver JAR file to `$LIBERTY_HOME/wlp/usr/shared/resources/db2`.

If that directory does not exist, create it. You can retrieve the file in one of two ways:

- Download it from DB2 JDBC Driver Versions.
- Fetch it from the `db2_install_dir/java` on the DB2 server directory.

2. Configure the data source in the `$LIBERTY_HOME/wlp/usr/servers/worklightServer/server.xml` file as follows:

In this path, you can replace `worklightServer` by the name of your server.

```
<library id="DB2Lib">
  <fileset dir="{shared.resource.dir}/db2" includes="*.jar"/>
</library>

<!-- Declare the IBM Application Center database. -->
<dataSource jndiName="jdbc/AppCenterDS" transactional="false">
  <jdbcDriver libraryRef="DB2Lib"/>
  <properties.db2.jcc databaseName="APPCNTR" currentSchema="APPSCHM"
    serverName="db2server" portNumber="50000"
    user="worklight" password="worklight"/>
</dataSource>
```

The `worklight` placeholder after `user=` is the name of the system user with CONNECT access to the **APPCNTR** database that you have previously created. The `worklight` placeholder after `password=` is this user's password. If you have defined either a different user name, or a different password, or both, replace `worklight` accordingly. Also, replace `db2server` with the host name of your DB2 server (for example, `localhost`, if it is on the same computer).

DB2 has a user name and password length limit of 8 characters for UNIX and Linux systems, and 30 characters for Windows.

3. You can encrypt the database password with the `securityUtility` program in `<liberty_install_dir>/bin`.

Configuring WebSphere Application Server for DB2 manually for Application Center:

You can set up and configure your DB2 database manually for Application Center with WebSphere Application Server.

About this task

Complete the DB2 database setup procedure before continuing.

Procedure

1. Determine a suitable directory for the JDBC driver JAR file in the WebSphere Application Server installation directory.
 - For a stand-alone server, you can use a directory such as `was_install_dir/optionalLibraries/IBM/Worklight/db2`.
 - For deployment to a WebSphere Application Server ND cell, use `was_install_dir/profiles/profile-name/config/cells/cell-name/Worklight/db2`.

- For deployment to a WebSphere Application Server ND cluster, use *was_install_dir/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/Worklight/db2*.
- For deployment to a WebSphere Application Server ND node, use *was_install_dir/profiles/profile-name/config/cells/cell-name/nodes/node-name/Worklight/db2*.
- For deployment to a WebSphere Application Server ND server, use *was_install_dir/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/Worklight/db2*.

If this directory does not exist, create it.

2. Add the DB2 JDBC driver JAR file and its associated license files, if any, to the directory that you determined in step 1.

You can retrieve the driver file in one of two ways:

- Download it from DB2 JDBC Driver Versions.
- Fetch it from the *db2_install_dir/java* directory on the DB2 server.

3. Set up the JDBC provider:

- a. In the WebSphere Application Server console, click **Resources > JDBC > JDBC Providers**.

- b. Select the appropriate scope from the **Scope** combination box.

- c. Click **New**.

- d. Set **Database type** to **DB2**.

- e. Set **Provider type** to **DB2 Using IBM JCC Driver**.

- f. Set **Implementation Type** to **Connection pool data source**.

- g. Set **Name** to **DB2 Using IBM JCC Driver**.

- h. Click **Next**.

- i. Set the class path to the set of JAR files in the directory that you determined in step 1, replacing *was_install_dir/profiles/profile-name* with the WebSphere Application Server variable reference **\${USER_INSTALL_ROOT}**.

- j. Do not set **Native library path**.

- k. Click **Next**.

- l. Click **Finish**.

- m. The JDBC provider is created.

- n. Click **Save**.

4. Create a data source for the Application Center database:

- a. Click **Resources > JDBC > Data sources**.

- b. Select the appropriate scope from the **Scope** combination box.

- c. Click **New** to create a data source.

- d. Set the **Data source name** to **Application Center Database**.

- e. Set **JNDI Name** to **jdbc/AppCenterDS**.

- f. Click **Next**.

- g. Enter properties for the data source, for example:

- **Driver type:** 4
- **Database Name:** APPCNTR
- **Server name:** localhost
- **Port number:** 50000 (default)

Leave **Use this data source in (CMP)** selected.

- h. Click **Next**.

- i. Create JAAS-J2C authentication data, specifying the DB2 user name and password as its properties. If necessary, go back to the data source creation wizard, by repeating steps 4a on page 6-246 to 4h on page 6-246.
 - j. Select the authentication alias that you created in the **Component-managed authentication alias** combination box (not in the **Container-managed authentication alias** combination box).
 - k. Click **Next** and **Finish**.
 - l. Click **Save**.
 - m. In **Resources > JDBC > Data sources**, select the new data source.
 - n. Click **WebSphere Application Server data source properties**.
 - o. Select the **Non-transactional data source** check box.
 - p. Click **OK**.
 - q. Click **Save**.
 - r. Click **Custom properties** for the data source, select property **currentSchema**, and set the value to the schema used to create the Application Center tables (APPSCHM in this example).
5. Test the data source connection by selecting **Data Source** and clicking **Test Connection**.

Configuring Apache Tomcat for DB2 manually for Application Center:

If you want to manually set up and configure your DB2 database for Application Center with Apache Tomcat server, use the following procedure.

About this task

Before you continue, complete the DB2 database setup procedure.

Procedure

1. Add the DB2 JDBC driver JAR file.

You can retrieve this JAR file in one of the following ways:

- Download it from DB2 JDBC Driver Versions.
- Or fetch it from the directory db2_install_dir/java on the DB2 server) to \$TOMCAT_HOME/lib.

2. Prepare an XML statement that defines the data source, as shown in the following code example.

```
<Resource auth="Container"
  driverClassName="com.ibm.db2.jcc.DB2Driver"
  name="jdbc/AppCenterDS"
  username="worklight"
  password="password"
  type="javax.sql.DataSource"
  url="jdbc:db2://server:50000/APPCNTR:currentSchema=APPSCHM;"/>
```

The **worklight** parameter after **username=** is the name of the system user with "CONNECT" access to the **APPCNTR** database that you have previously created. The **password** parameter after **password=** is this user's password. If you have defined either a different user name, or a different password, or both, replace these entries accordingly.

DB2 enforces limits on the length of user names and passwords.

- For UNIX and Linux systems: 8 characters
- For Windows: 30 characters

3. Insert this statement in the `server.xml` file, as indicated in “Configuring Apache Tomcat for Application Center manually” on page 6-264.

Configuring the Apache Derby database manually for Application Center

You configure the Apache Derby database manually by creating the database and database tables, and then configuring the relevant application server to use this database setup.

Procedure

1. Create the database and the tables within them. This step is described in “Setting up your Apache Derby database manually for Application Center.”
2. Configure the application server to use this database setup. Go to one of the following topics:
 - “Configuring Liberty profile for Derby manually for Application Center”
 - “Configuring WebSphere Application Server for Derby manually for Application Center” on page 6-249
 - “Configuring Apache Tomcat for Derby manually for Application Center” on page 6-251

Setting up your Apache Derby database manually for Application Center:

You can set up your Apache Derby database for Application Center manually.

About this task

Set up your Apache Derby database for Application Center by creating the database schema.

Procedure

1. In the location where you want the database to be created, run `ij.bat` on Windows systems or `ij.sh` on UNIX and Linux systems.

Note: The `ij` program is part of Apache Derby. If you do not already have it installed, you can download it from [Apache Derby: Downloads](#).

For supported versions of Apache Derby, see “System requirements” on page 2-15.

The script displays `ij` version number.

2. At the command prompt, enter the following commands:

```
connect 'jdbc:derby:APPCNTR;user=APPCENTER;create=true';  
run '<product_install_dir>/ApplicationCenter/databases/create-appcenter-derby.sql';  
quit;
```

Configuring Liberty profile for Derby manually for Application Center:

If you want to manually set up and configure your Apache Derby database for Application Center with WebSphere Application Server Liberty profile, use the following procedure.

Before you begin

Complete the Apache Derby database setup procedure before continuing.

Procedure

Configure the data source in the \$LIBERTY_HOME/usr/servers/worklightServer/server.xml file (worklightServer may be replaced in this path by the name of your server) as follows:

```
<!-- Declare the jar files for Derby access through JDBC. -->
<library id="derbyLib">
  <fileset dir="C:/Drivers/derby" includes="derby.jar" />
</library>

<!-- Declare the IBM Application Center database. -->
<dataSource jndiName="jdbc/AppCenterDS" transactional="false" statementCacheSize="10">
  <jdbcDriver libraryRef="derbyLib"
    javax.sql.ConnectionPoolDataSource="org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource"
    <properties.derby.embedded databaseName="DERBY_DATABASES_DIR/APPCNTR" user="APPCENTER"
      shutdownDatabase="false" connectionAttributes="upgrade=true"/>
  <connectionManager connectionTimeout="180"
    maxPoolSize="10" minPoolSize="1"
    reapTime="180" maxIdleTime="1800"
    agedTimeout="7200" purgePolicy="EntirePool"/>
</dataSource>
```

Configuring WebSphere Application Server for Derby manually for Application Center:

You can set up and configure your Apache Derby database manually for Application Center with WebSphere Application Server.

About this task

Complete the Apache Derby database setup procedure before continuing.

Procedure

1. Determine a suitable directory for the JDBC driver JAR file in the WebSphere Application Server installation directory.
If this directory does not exist, create it.
 - For a standalone server, you can use a directory such as *was_install_dir/optionalLibraries/IBM/Worklight/derby*.
 - For deployment to a WebSphere Application Server ND cell, use *was_install_dir/profiles/profile-name/config/cells/cell-name/Worklight/derby*.
 - For deployment to a WebSphere Application Server ND cluster, use *was_install_dir/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/Worklight/derby*.
 - For deployment to a WebSphere Application Server ND node, use *was_install_dir/profiles/profile-name/config/cells/cell-name/nodes/node-name/Worklight/derby*.
 - For deployment to a WebSphere Application Server ND server, use *was_install_dir/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/Worklight/derby*.
2. Add the Derby JAR file from *product_install_dir/ApplicationCenter/tools/lib/derby.jar* to the directory determined in step 1.
3. Set up the JDBC provider.
 - a. In the WebSphere Application Server console, click **Resources > JDBC > JDBC Providers**.
 - b. Select the appropriate scope from the **Scope** combination box.

- c. Click **New**.
 - d. Set **Database Type** to **User-defined**.
 - e. Set **class Implementation name** to `org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource40`.
 - f. Set **Name** to **Worklight - Derby JDBC Provider**.
 - g. Set **Description** to **Derby JDBC provider for Worklight**.
 - h. Click **Next**.
 - i. Set the **Class path** to the JAR file in the directory determined in step 1, replacing `was_install_dir/profiles/profile-name` with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.
 - j. Click **Finish**.
4. Create the data source for the Worklight database.
 - a. In the WebSphere Application Server console, click **Resources > JDBC > Data sources**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Set **Data source Name** to **Application Center Database**.
 - e. Set **JNDI name** to `jdbc/AppCenterDS`.
 - f. Click **Next**.
 - g. Select the existing JDBC Provider that is named **Worklight - Derby JDBC Provider**.
 - h. Click **Next**.
 - i. Click **Next**.
 - j. Click **Finish**.
 - k. Click **Save**.
 - l. In the table, click the **Application Center Database** data source that you created.
 - m. Under **Additional Properties**, click **Custom properties**.
 - n. Click **databaseName**.
 - o. Set **Value** to the path to the APPCNTR database that is created in “Setting up your Apache Derby database manually for Application Center” on page 6-248.
 - p. Click **OK**.
 - q. Click **Save**.
 - r. At the top of the page, click **Application Center Database**.
 - s. Under **Additional Properties**, click **WebSphere Application Server data source properties**.
 - t. Select **Non-transactional datasource**.
 - u. Click **OK**.
 - v. Click **Save**.
 - w. In the table, select the **Application Center Database** data source that you created.
 - x. Optional: Only if you are not on the console of a WebSphere Application Server Deployment Manager, click **test connection**.

Configuring Apache Tomcat for Derby manually for Application Center:

You can set up and configure your Apache Derby database manually for Application Center with the Apache Tomcat application server.

About this task

Complete the Apache Derby database setup procedure before continuing.

Procedure

1. Add the Derby JAR file from *product_install_dir*/ApplicationCenter/tools/lib/derby.jar to the directory \$TOMCAT_HOME/lib.
2. Prepare an XML statement that defines the data source, as shown in the following code example.

```
<Resource auth="Container"
  driverClassName="org.apache.derby.jdbc.EmbeddedDriver"
  name="jdbc/AppCenterDS"
  username="APPCENTER"
  password=""
  type="javax.sql.DataSource"
  url="jdbc:derby:DERBY_DATABASES_DIR/APPCNTR"/>
```

3. Insert this statement in the *server.xml* file, as indicated in “Configuring Apache Tomcat for Application Center manually” on page 6-264.

Configuring the MySQL database manually for Application Center

You configure the MySQL database manually by creating the database, creating the database tables, and then configuring the relevant application server to use this database setup.

Procedure

1. Create the database. This step is described in “Creating the MySQL database for Application Center” on page 6-237.
2. Create the tables in the database. This step is described in “Setting up your MySQL database manually for Application Center.”
3. Perform the application server-specific setup as the following list shows.

Setting up your MySQL database manually for Application Center:

You can set up your MySQL database for Application Center manually.

About this task

Complete the following procedure to set up your MySQL database.

Procedure

1. Create the database schema.
 - a. Run a MySQL command line client with the option `-u root`.
 - b. Enter the following commands:

```
CREATE DATABASE APPCNTR CHARACTER SET utf8 COLLATE utf8_general_ci;
GRANT ALL PRIVILEGES ON APPCNTR.* TO 'worklight'@'Worklight-host' IDENTIFIED BY 'worklight';
GRANT ALL PRIVILEGES ON APPCNTR.* TO 'worklight'@'localhost' IDENTIFIED BY 'worklight';
FLUSH PRIVILEGES;
```

```
USE APPCNTR;
SOURCE product_install_dir/ApplicationCenter/databases/create-appcenter-mysql.sql;
```

Where **worklight** before the "at" sign (@) is the user name, **worklight** after **IDENTIFIED BY** is its password, and **Worklight-host** is the name of the host on which IBM MobileFirst Platform Foundation runs.

2. Add the following property to your MySQL option file:
max_allowed_packet=256M
For more information about option files, see the MySQL documentation at MySQL.
3. Add the following property to your MySQL option file: innodb_log_file_size = 250M
For more information about the **innodb_log_file_size** property, see the MySQL documentation, section innodb_log_file_size.

Configuring Liberty profile for MySQL manually for Application Center:

If you want to manually set up and configure your MySQL database for Application Center with WebSphere Application Server Liberty profile, use the following procedure.

Before you begin

Complete the MySQL database setup procedure before continuing.

Note: MySQL in combination with WebSphere Application Server Liberty profile or WebSphere Application Server full profile is not classified as a supported configuration. For more information, see WebSphere Application Server Support Statement. You can use IBM DB2 or another database supported by WebSphere Application Server to benefit from a configuration that is fully supported by IBM Support.

Procedure

1. Add the MySQL JDBC driver JAR file to \$LIBERTY_HOME/wlp/usr/shared/resources/mysql. If that directory does not exist, create it.
2. Configure the data source in the \$LIBERTY_HOME/usr/servers/worklightServer/server.xml file (worklightServer may be replaced in this path by the name of your server) as follows:

```
<!-- Declare the jar files for MySQL access through JDBC. -->
<library id="MySQLLib">
  <fileset dir="{shared.resource.dir}/mysql" includes="*.jar"/>
</library>
```

```
<!-- Declare the IBM Application Center database. -->
<dataSource jndiName="jdbc/AppCenterDS" transactional="false">
  <jdbcDriver libraryRef="MySQLLib"/>
  <properties databaseName="APPCNTR"
    serverName="mysqlserver" portNumber="3306"
    user="worklight" password="worklight"/>
</dataSource>
```

where **worklight** after **user=** is the user name, **worklight** after **password=** is this user's password, and **mysqlserver** is the host name of your MySQL server (for example, localhost, if it is on the same machine).

3. You can encrypt the database password with the securityUtility program in <liberty_install_dir>/bin.

Configuring WebSphere Application Server for MySQL manually for Application Center:

If you want to manually set up and configure your MySQL database for Application Center with WebSphere Application Server, use the following procedure.

About this task

Complete the MySQL database setup procedure before continuing.

Note: MySQL in combination with WebSphere Application Server Liberty profile or WebSphere Application Server full profile is not classified as a supported configuration. For more information, see WebSphere Application Server Support Statement. We suggest that you use IBM DB2 or another database supported by WebSphere Application Server to benefit from a configuration that is fully supported by IBM Support.

Procedure

1. Determine a suitable directory for the JDBC driver JAR file in the WebSphere Application Server installation directory.
 - For a standalone server, you can use a directory such as `WAS_INSTALL_DIR/optionalLibraries/IBM/Worklight/mysql`.
 - For deployment to a WebSphere Application Server ND cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/Worklight/mysql`.
 - For deployment to a WebSphere Application Server ND cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/Worklight/mysql`.
 - For deployment to a WebSphere Application Server ND node, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/Worklight/mysql`.
 - For deployment to a WebSphere Application Server ND server, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/Worklight/mysql`.

If this directory does not exist, create it.
2. Add the MySQL JDBC driver JAR file downloaded from Download Connector/J to the directory determined in step 1.
3. Set up the JDBC provider:
 - a. In the WebSphere Application Server console, click **Resources > JDBC > JDBC Providers**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Create a **JDBC provider** named **MySQL**.
 - e. Set **Database type** to **User defined**.
 - f. Set **Scope** to **Cell**.
 - g. Set **Implementation class** to **com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource**.
 - h. Set **Database classpath** to the JAR file in the directory determined in step 1, replacing `WAS_INSTALL_DIR/profiles/profile-name` with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.

- i. Save your changes.
4. Create a data source for the IBM Application Center database:
 - a. Click **Resources > JDBC > Data sources**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New** to create a data source.
 - d. Type any name (for example, Application Center Database).
 - e. Set **JNDI Name** to jdbc/AppCenterDS.
 - f. Use the existing **JDBC Provider MySQL**, defined in the previous step.
 - g. Set Scope to **New**.
 - h. On the **Configuration** tab, select **Non-transactional data source**.
 - i. Click **Next** a number of times, leaving all other settings as defaults.
 - j. Save your changes.
5. Set the custom properties of the new data source.
 - a. Select the new data source.
 - b. Click **Custom properties**.
 - c. Set the following properties:
 - portNumber = 3306
 - relaxAutoCommit=true
 - databaseName = APPCNTR
 - serverName = the host name of the MySQL server
 - user = the user name of the MySQL server
 - password = the password associated with the user name
6. Set the WebSphere Application Server custom properties of the new data source.
 - a. In **Resources > JDBC > Data sources**, select the new data source.
 - b. Click **WebSphere Application Server data source properties**.
 - c. Select **Non-transactional data source**.
 - d. Click **OK**.
 - e. Click **Save**.

Configuring Apache Tomcat for MySQL manually for Application Center:

If you want to manually set up and configure your MySQL database for Application Center with the Apache Tomcat server, use the following procedure.

About this task

Complete the MySQL database setup procedure before continuing.

Procedure

1. Add the MySQL Connector/J JAR file to the \$TOMCAT_HOME/lib directory.
2. Prepare an XML statement that defines the data source, as shown in the following code example. Insert this statement in the server.xml file, as indicated in "Configuring Apache Tomcat for Application Center manually" on page 6-264.

```
<Resource name="jdbc/AppCenterDS"
  auth="Container"
  type="javax.sql.DataSource"
  maxActive="100"
  maxIdle="30"
  maxWait="10000"
  username="worklight"
```

```
password="worklight"  
driverClassName="com.mysql.jdbc.Driver"  
url="jdbc:mysql://server:3306/APPCNTR"/>
```

Configuring the Oracle database manually for IBM MobileFirst Platform Application Center

You configure the Oracle database manually by creating the database, creating the database tables, and then configuring the relevant application server to use this database setup.

Procedure

1. Create the database. This step is described in “Creating the Oracle database for Application Center” on page 6-237.
2. Create the tables in the database. This step is described in “Setting up your Oracle database manually for Application Center.”
3. Perform the application server-specific setup as the following list shows.

Setting up your Oracle database manually for Application Center:

You can set up your Oracle database for Application Center manually.

About this task

Complete the following procedure to set up your Oracle database.

Procedure

1. Ensure that you have at least one Oracle database.
In many Oracle installations, the default database has the SID (name) ORCL. For best results, specify **Unicode (AL32UTF8)** as the character set of the database.
If the Oracle installation is on a UNIX or Linux computer, make sure that the database is started next time the Oracle installation is restarted. To this effect, make sure that the line in `/etc/oratab` that corresponds to the database ends with a `Y`, not with an `N`.
2. Create the user APPCENTER, either by using Oracle Database Control, or by using the Oracle SQLPlus command-line interpreter.

- To create the user for the Application Center database/schema, by using Oracle Database Control, proceed as follows:

- a. Connect as SYSDBA.
- b. Go to the Users page.
- c. Click **Server**, then **Users** in the Security section.
- d. Create a user, named APPCENTER with the following attributes:

```
Profile: DEFAULT  
Authentication: password  
Default tablespace: USERS  
Temporary tablespace: TEMP  
Status: Unlocked  
Add system privilege: CREATE SESSION  
Add system privilege: CREATE SEQUENCE  
Add system privilege: CREATE TABLE  
Add quota: Unlimited for tablespace USERS
```

- To create the user by using Oracle SQLPlus, enter the following commands:

```
CONNECT SYSTEM/<SYSTEM_password>@ORCL  
CREATE USER APPCENTER IDENTIFIED BY password DEFAULT TABLESPACE USERS QUOTA UNLIMITED ON USE  
GRANT CREATE SESSION, CREATE SEQUENCE, CREATE TABLE TO APPCENTER;  
DISCONNECT;
```

3. Create the tables for the Application Center database:
 - a. Using the Oracle SQLPlus command-line interpreter, create the tables for the Application Center database by running the create-appcenter-oracle.sql file:

```
CONNECT APPCENTER/APPCENTER_password@ORCL
@product_install_dir/ApplicationCenter/databases/create-appcenter-oracle.sql
DISCONNECT;
```
4. Download and configure the Oracle JDBC driver:
 - a. Download the JDBC driver from the Oracle website at Oracle: JDBC, SQLJ, Oracle JPublisher and Universal Connection Pool (UCP):
 - b. Ensure that the Oracle JDBC driver is in the system path. The driver file is ojdbc6.jar.

Configuring Liberty profile for Oracle manually for Application Center:

You can set up and configure your Oracle database manually for Application Center with WebSphere Application Server Liberty profile by adding the JAR file of the Oracle JDBC driver.

Before you begin

Before continuing, set up the Oracle database.

Procedure

1. Add the JAR file of the Oracle JDBC driver to `$LIBERTY_HOME/wlp/usr/shared/resources/oracle`.
If that directory does not exist, create it.
2. If you are using JNDI, configure the data sources in the `$LIBERTY_HOME/wlp/usr/servers/mobileFirstServer/server.xml` file as shown in the following JNDI code example:

Note: In this path, you can replace `mobileFirstServer` with the name of your server.

```
<!-- Declare the jar files for Oracle access through JDBC. -->
<library id="OracleLib">
  <fileset dir="{shared.resource.dir}/oracle" includes="*.jar"/>
</library>

<!-- Declare the IBM Application Center database. -->
<dataSource jndiName="jdbc/AppCenterDS" transactional="false">
  <jdbcDriver libraryRef="OracleLib"/>
  <properties.oracle driverType="thin"
    serverName="oserver" portNumber="1521"
    databaseName="ORCL"
    user="APPCENTER" password="APPCENTER_password"/>
</dataSource>
```

where

- **APPCENTER** after **user=** is the user name,
- **APPCENTER_password** after **password=** is this user's password, and
- **oserver** is the host name of your Oracle server (for example, localhost if it is on the same machine).

Note: For more information on how to connect the Liberty server to the Oracle database with a service name, or with a URL, see the WebSphere Application Server Liberty Core 8.5.5 documentation, section **properties.oracle**.

3. You can encrypt the database password with the securityUtility program in `<liberty_install_dir>/bin`.

What to do next

For more steps to configure Application Center, see “Deploying the Application Center WAR files and configuring the application server manually” on page 6-259.

Configuring WebSphere Application Server for Oracle manually for Application Center:

If you want to manually set up and configure your Oracle database for Application Center with WebSphere Application Server, use the following procedure.

About this task

Complete the Oracle database setup procedure before continuing.

Procedure

1. Determine a suitable directory for the JDBC driver JAR file in the WebSphere Application Server installation directory.
 - For a standalone server, you can use a directory such as `WAS_INSTALL_DIR/optionalLibraries/IBM/Worklight/oracle`.
 - For deployment to a WebSphere Application Server ND cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/Worklight/oracle`.
 - For deployment to a WebSphere Application Server ND cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/Worklight/oracle`.
 - For deployment to a WebSphere Application Server ND node, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/Worklight/oracle`.
 - For deployment to a WebSphere Application Server ND server, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/Worklight/oracle`.

If this directory does not exist, create it.

2. Add the Oracle `ojdbc6.jar` file downloaded from JDBC and Universal Connection Pool (UCP) to the directory determined in step 1.
3. Set up the JDBC provider:
 - a. In the WebSphere Application Server console, click **Resources > JDBC > JDBC Providers**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Complete the JDBC Provider fields as indicated in the following table:

Table 6-53. JDBC Provider field values

Field	Value
Database type	Oracle
Provider type	Oracle JDBC Driver
Implementation type	Connection pool data source
Name	Oracle JDBC Driver

- e. Click **Next**.
 - f. Set the class path to the JAR file in the directory determined in step 1, replacing `WAS_INSTALL_DIR/profiles/profile-name` with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`
 - g. Click **Next**.
The JDBC provider is created.
4. Create a data source for the Worklight database:
- a. Click **Resources > JDBC > Data sources**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Set **Data source name** to **Oracle JDBC Driver DataSource**.
 - e. Set **JNDI name** to `jdbc/AppCenterDS`.
 - f. Click **Next**.
 - g. Click **Select an existing JDBC provider** and select **Oracle JDBC driver** from the list.
 - h. Click **Next**.
 - i. Set the URL value to `jdbc:oracle:thin:@oserver:1521:ORCL`, where **oserver** is the host name of your Oracle server (for example, localhost, if it is on the same machine).
 - j. Click **Next** twice.
 - k. Click **Resources > JDBC > Data sources > Oracle JDBC Driver DataSource > Custom properties**.
 - l. Set **oracleLogPackageName** to `oracle.jdbc.driver`.
 - m. Set **user** = `APPCENTER`.
 - n. Set **password** = `APPCENTER_password`.
 - o. Click **OK** and save the changes.
 - p. In **Resources > JDBC > Data sources**, select the new data source.
 - q. Click **WebSphere Application Server data source properties**.
 - r. Select the **Non-transactional data source** check box.
 - s. Click **OK**.
 - t. Click **Save**.

Configuring Apache Tomcat for Oracle manually for Application Center:

If you want to manually set up and configure your Oracle database for Application Center with the Apache Tomcat server, use the following procedure.

About this task

Complete the Oracle database setup procedure before continuing.

Procedure

1. Add the Oracle JDBC driver JAR file to the directory `$TOMCAT_HOME/lib`.
2. Prepare an XML statement that defines the data source, as shown in the following code example. Insert this statement in the `server.xml` file, as indicated in “Configuring Apache Tomcat for Application Center manually” on page 6-264

```
<Resource name="jdbc/AppCenterDS"
          auth="Container"
          type="javax.sql.DataSource"
```

```

driverClassName="oracle.jdbc.driver.OracleDriver"
url="jdbc:oracle:thin:@oserver:1521:ORCL"
username="APPCENTER"
password="APPCENTER_password"/>

```

Where **APPCENTER** after **username=** is the name of the system user with "CONNECT" access to the **APPCNTR** database that you have previously created, and **APPCENTER_password** after **password=** is this user's password. If you have defined either a different user name, or a different password, or both, replace these values accordingly.

Deploying the Application Center WAR files and configuring the application server manually

The procedure to manually deploy the Application Center WAR files manually to an application server depends on the type of application server being configured.

These manual instructions assume that you are familiar with your application server.

Note: Using the MobileFirst Server installer to install Application Center is more reliable than installing manually, and should be used whenever possible.

If you prefer to use the manual process, follow these steps to configure your application server for Application Center. You must deploy the `appcenterconsole.war` and `applicationcenter.war` files to your Application Center. The files are located in `product_install_dir/ApplicationCenter/console`.

Configuring the Liberty profile for Application Center manually:

After you deploy WAR files, to configure WebSphere Application Server Liberty profile manually for Application Center, you must modify the `server.xml` file.

About this task

In addition to modifications for the databases that are described in "Manually installing Application Center" on page 6-243, you must make the following modifications to the `server.xml` file.

Procedure

1. Ensure that the `<featureManager>` element contains at least the following `<feature>` elements:
 - For WebSphere Application Server Liberty profile V8.5.0.x:

```

<feature>ssl-1.0</feature>
<feature>servlet-3.0</feature>
<feature>jdbc-4.0</feature>
<feature>appSecurity-1.0</feature>
<feature>jndi-1.0</feature>

```
 - For WebSphere Application Server Liberty profile V8.5.0 and later:

```

<feature>jdbc-4.0</feature>
<feature>appSecurity-2.0</feature>
<feature>servlet-3.0</feature>

```
2. Add the following declarations for Application Center:

```

<!-- The directory with binaries of the 'aapt' program, from the Android SDK's
platform-tools package. -->
<jndiEntry jndiName="android.aapt.dir" value="product_install_dir/ApplicationCenter/tools/android-sdk"/>
<!-- Declare the Application Center Console application. -->
<application id="appcenterconsole"
name="appcenterconsole"

```

```

        location="appcenterconsole.war"
        type="war">
<application-bnd>
  <security-role name="appcenteradmin">
    <group name="appcentergroup"/>
  </security-role>
</application-bnd>
<classloader delegation="parentLast">
  <commonLibrary>
    <fileset dir="{wlp.install.dir}/lib" includes="com.ibm.ws.crypto.passwordutil_*.jar"/>
  </commonLibrary>
</classloader>
</application>

<!-- Declare the IBM Application Center Services application. -->
<application id="applicationcenter"
  name="applicationcenter"
  location="applicationcenter.war"
  type="war">
<application-bnd>
  <security-role name="appcenteradmin">
    <group name="appcentergroup"/>
  </security-role>
</application-bnd>
<classloader delegation="parentLast">
  <commonLibrary>
    <fileset dir="{wlp.install.dir}/lib"
      includes="com.ibm.ws.crypto.passwordutil_*.jar"/>
  </commonLibrary>
</classloader>
</application>

<!-- Declare the user registry for the IBM Application Center. -->
<basicRegistry id="applicationcenter-registry"
  realm="ApplicationCenter">
  <!-- The users defined here are members of group "appcentergroup",
    thus have role "appcenteradmin", and can therefore perform
    administrative tasks through the Application Center Console. -->
  <user name="appcenteradmin" password="admin"/>
  <user name="demo" password="demo"/>
  <group name="appcentergroup">
    <member name="appcenteradmin"/>
    <member name="demo"/>
  </group>
</basicRegistry>

```

The groups and users that are defined in the `basicRegistry` element are example logins which you can use to test Application Center. Similarly, the groups that are defined in the `<security-role name="appcenteradmin">` for the Application Center console and the Application Center service are examples. For more information about how to modify these groups, see “Configuring the Java EE security roles on WebSphere Application Server Liberty profile” on page 6-272.

3. If the database is Oracle, add the **commonLibraryRef** attribute to the class loader of the Application Center service application.

```

...
<classloader delegation="parentLast" commonLibraryRef="OracleLib">
  <commonLibrary>
...

```

The name of the library reference (`OracleLib` in this example) must be the ID of the library that contains the JDBC JAR file. This ID is declared in the procedure that is documented in “Configuring Liberty profile for Oracle manually for Application Center” on page 6-256.

4. Copy the Application Center WAR files to your Liberty server.

- On UNIX and Linux systems:

```
mkdir -p $LIBERTY_HOME/wlp/usr/servers/<server_name>/apps
cp product_install_dir/ApplicationCenter/console/*.war
```

- On Windows systems:

```
mkdir LIBERTY_HOME\wlp\usr\servers\<server_name>\apps
copy /B product_install_dir\ApplicationCenter\console\appcenterconsole.war LIBERTY_HOME\
wlp\usr\servers\<server_name>\apps\appcenterconsole.war
copy /B product_install_dir\ApplicationCenter\console\applicationcenter.war LIBERTY_HOME\
wlp\usr\servers\<server_name>\apps\applicationcenter.war
```

5. Start the Liberty server.

What to do next

For more steps to configure Application Center, see “Configuring the Java EE security roles on WebSphere Application Server Liberty profile” on page 6-272.

Configuring WebSphere Application Server for Application Center manually:

After you deploy WAR files, to configure WebSphere Application Server for Application Center manually, you must configure variables, custom properties, and class loading policies.

Before you begin

Make sure that a WebSphere Application Server profile exists.

Procedure

1. Log on to the WebSphere Application Server administration console for your IBM MobileFirst Platform Server.
2. Enable application security.
 - a. Click **Security > Global Security**.
 - b. Ensure that **Enable administrative security** is selected. Application security can be enabled only if administrative security is enabled.
 - c. Ensure that **Enable application security** is selected.
 - d. Click **OK**.
 - e. Save the changes.

For more information, see Enabling security.

3. Create the Application Center JDBC data source and provider.
See the appropriate section in “Manually installing Application Center” on page 6-243.
4. Install the Application Center console WAR file.
 - a. Depending on your version of WebSphere Application Server, click one of the following options:
 - **Applications > New > New Enterprise Application**
 - **Applications > New Application > New Enterprise Application**
 - b. Go to the MobileFirst Server installation directory *mfserver_install_dir*/ApplicationCenter/console.
 - c. Select **appcenterconsole.war** and click **Next**.
 - d. On the How do you want to install the application? page, click **Detailed**, and then click **Next**.

- e. On the Application Security Warnings page, click **Continue**.
 - f. Click **Next** until you reach the "Map context roots for web modules" page.
 - g. In the **Context Root** field, type /appcenterconsole.
 - h. Click **Next** until you reach the "Map security roles to users or groups" page.
 - i. Select all roles, click **Map Special Subjects** and select **All Authenticated in Application's Realm**.
 - j. Click **Next** until you reach the Summary page.
 - k. Click **Finish** and save the configuration.
5. Configure the class loader policies and then start the application:
 - a. Click **Applications > Application types > WebSphere Enterprise Applications**.
 - b. From the list of applications, click **appcenterconsole_war**.
 - c. In the Detail Properties section, click the **Class loading and update detection** link.
 - d. In the Class loader order pane, click **Classes loaded with local class loader first (parent last)**.
 - e. Click **OK**.
 - f. In the Modules section, click **Manage Modules**.
 - g. From the list of modules, click **ApplicationCenterConsole**.
 - h. In the Class loader order pane, click **Classes loaded with local class loader first (parent last)**.
 - i. Click **OK** twice.
 - j. Click **Save**.
 - k. Select **appcenterconsole_war** and click **Start**.
 6. Install the WAR file for Application Center services.
 - a. Depending on your version of WebSphere Application Server, click one of the following options:
 - **Applications > New > New Enterprise Application**
 - **Applications > New Application > New Enterprise Application**
 - b. Go to the MobileFirst Server installation directory `mfserver_install_dir/ApplicationCenter/console`.
 - c. Select **applicationcenter.war** and click **Next**.
 - d. On the How do you want to install the application? page, click **Detailed**, and then click **Next**.
 - e. On the Application Security Warnings page, click **Continue**.
 - f. Click **Next** until you reach the "Map resource references to resources" page.
 - g. Click **Browser** and select the data source with the jdbc/AppCenterDS JNDI name.
 - h. Click **Apply**.
 - i. In the **Context Root** field, type /applicationcenter.
 - j. Click **Next** until you reach the "Map security roles to users or groups" page.
 - k. Select all roles, click **Map Special Subjects**, and select **All Authenticated in Application's Realm**.
 - l. Click **Next** until you reach the Summary page.
 - m. Click **Finish** and save the configuration.
 7. Repeat step 5.

- a. Select **applicationcenter.war** from the list of applications in substeps b and k.
 - b. Select **ApplicationCenterServices** in substep g.
8. Review the server class loader policy: Depending on your version of WebSphere Application Server, click **Servers > Server Types > Application Servers** or **Servers > Server Types > WebSphere application servers** and then select the server.
 - If the class loader policy is set to **Multiple**, do nothing.
 - If the class loader policy is set to **Single** and **Class loading mode** is set to **Classes loaded with local class loader first (parent last)**, do nothing.
 - If **Classloader policy** is set to **Single** and **Class loading mode** is set to **Classes loaded with parent class loader first**, set **Classloader policy** to **Multiple** and set the class loader policy of all applications other than MobileFirst applications to **Classes loaded with parent class loader first**.
 9. Save the configuration.
 10. Configure a JNDI environment entry to indicate the directory with binary files of the aapt program, from the Android SDK platform-tools package.
 - a. Determine a suitable directory for the aapt binary files in the WebSphere Application Server installation directory.
 - For a stand-alone server, you can use a directory such as `WAS_INSTALL_DIR/optionalLibraries/IBM/Worklight/android-sdk`.
 - For deployment to a WebSphere Application Server Network Deployment cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/Worklight/android-sdk`.
 - For deployment to a WebSphere Application Server Network Deployment cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/Worklight/android-sdk`.
 - For deployment to a WebSphere Application Server Network Deployment node, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/Worklight/android-sdk`.
 - For deployment to a WebSphere Application Server Network Deployment server, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/Worklight/android-sdk`.
 - b. Copy the `product_install_dir/ApplicationCenter/tools/android-sdk` directory to the directory that you determined in Substep a.
 - c. For WebSphere Application Server Network Deployment, click **System administration > Nodes**, select the nodes, and click **Full Synchronize**.
 - d. Configure the environment entry (JNDI property) `android.aapt.dir`, and set as its value the directory that you determined in Substep a. The `WAS_INSTALL_DIR/profiles/profile-name` profile is replaced with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.

Results

You can now access the Application Center at `http://<server>:<port>/appcenterconsole`, where *server* is the host name of your server and *port* is the port number (by default 9080).

What to do next

For more steps to configure the Application Center, see “Configuring the Java EE security roles on WebSphere Application Server full profile” on page 6-271.

Configuring Apache Tomcat for Application Center manually:

To configure Apache Tomcat for Application Center manually, you must copy JAR and WAR files to Tomcat, add database drivers, edit the `server.xml` file, and then start Tomcat.

Procedure

1. Add the database drivers to the Tomcat `lib` directory. See the instructions for the appropriate DBMS in “Manually installing Application Center” on page 6-243.
2. Edit `tomcat_install_dir/conf/server.xml`.
 - a. Uncomment the following element, which is initially commented out:
`<Valve className="org.apache.catalina.authenticator.SingleSignOn" />`
 - b. Declare the Application Center console and services applications and a user registry:

```
<!-- Declare the IBM Application Center Console application. -->
<Context path="/appcenterconsole" docBase="appcenterconsole">

  <!-- Define the AppCenter services endpoint in order for the AppCenter
  console to be able to invoke the REST service.
  You need to enable this property if the server is behind a reverse
  proxy or if the context root of the Application Center Services
  application is different from '/applicationcenter'. -->
  <!-- <Environment name="ibm.appcenter.services.endpoint"
  value="http://proxy-host:proxy-port/applicationcenter"
  type="java.lang.String" override="false"/>
  -->

</Context>

<!-- Declare the IBM Application Center Services application. -->
<Context path="/applicationcenter" docBase="applicationcenter">
  <!-- The directory with binaries of the 'aapt' program, from
  the Android SDK's platform-tools package. -->
  <Environment name="android.aapt.dir"
  value="product_install_dir/ApplicationCenter/tools/android-sdk"
  type="java.lang.String" override="false"/>
  <!-- The protocol of the application resources URI.
  This property is optional. It is only needed if the protocol
  of the external and internal URI are different. -->
  <!-- <Environment name="ibm.appcenter.proxy.protocol"
  value="http" type="java.lang.String" override="false"/>
  -->

  <!-- The host name of the application resources URI. -->
  <!-- <Environment name="ibm.appcenter.proxy.host"
  value="proxy-host"
  type="java.lang.String" override="false"/>
  -->

  <!-- The port of the application resources URI.
  This property is optional. -->
  <!-- <Environment name="ibm.appcenter.proxy.port"
  value="proxy-port"
  type="java.lang.Integer" override="false"/> -->

  <!-- Declare the IBM Application Center Services database. -->
```

```

        <!-- <Resource name="jdbc/AppCenterDS" type="javax.sql.DataSource" ... -->

    </Context>

    <!-- Declare the user registry for the IBM Application Center.
        The MemoryRealm recognizes the users defined in conf/tomcat-users.xml.
        For other choices, see Apache Tomcat's "Realm Configuration HOW-TO"
        http://tomcat.apache.org/tomcat-7.0-doc/realms-howto.html . -->
    <Realm className="org.apache.catalina.realm.MemoryRealm"/>

```

where you fill in the <Resource> element as described in one of the sections:

- “Configuring Apache Tomcat for DB2 manually for Application Center” on page 6-247
- “Configuring Apache Tomcat for Derby manually for Application Center” on page 6-251
- “Configuring Apache Tomcat for MySQL manually for Application Center” on page 6-254
- “Configuring Apache Tomcat for Oracle manually for Application Center” on page 6-258

3. Copy the Application Center WAR files to Tomcat.

- On UNIX and Linux systems: `cp product_install_dir/ApplicationCenter/console/*.war TOMCAT_HOME/webapps`
- On Windows systems:

```

copy /B product_install_dir\ApplicationCenter\console\appcenterconsole.war tomcat_install_dir\webapps
copy /B product_install_dir\ApplicationCenter\console\applicationcenter.war tomcat_install_dir\webapps

```

4. Start Tomcat.

What to do next

For more steps to configure the Application Center, see “Configuring the Java EE security roles on Apache Tomcat” on page 6-274.

Deploying the Application Center EAR file and configuring the application server manually

As an alternative to the MobileFirst Server installer procedure, you can use a manual procedure to deploy the Application Center EAR file and configure your WebSphere application server manually.

Before you begin

These manual instructions assume that you are familiar with your application server.

About this task

The procedure to deploy the Application Center EAR file manually to an application server depends on the type of application server. Manual deployment is supported only for WebSphere Application Server Liberty profile and WebSphere Application Server.

Tip: It is more reliable to install Application Center through the MobileFirst Server installer than manually. Therefore, whenever possible, use the MobileFirst Server installer. If, however, you prefer the manual procedure, deploy the `appcentercenter.ear` file, which you can find in the `product_install_dir/ApplicationCenter/console` directory.

Configuring the Liberty profile for Application Center manually:

After you deploy the Application Center EAR file, to configure WebSphere Application Server Liberty profile manually for Application Center, you must modify the `server.xml` file.

About this task

In addition to modifications for the databases that are described in Manually installing Application Center, you must make the following modifications to the `server.xml` file.

Procedure

1. Ensure that the `<featureManager>` element contains at least the following `<feature>` elements:

-

For WebSphere Application Server Liberty profile V8.5.0.x:

```
<feature>ssl-1.0</feature>
<feature>servlet-3.0</feature>
<feature>jdbc-4.0</feature>
<feature>appSecurity-1.0</feature>
<feature>jndi-1.0</feature>
```

- For WebSphere Application Server Liberty profile V8.5.5.0 and later:

```
<feature>jdbc-4.0</feature>
<feature>appSecurity-2.0</feature>
<feature>servlet-3.0</feature>
```

2. Add the following declarations for Application Center:

```
<!-- The directory with binaries of the 'aapt' program, from the Android SDK's platform-tools package -->
<jndiEntry jndiName="android.aapt.dir" value="product_install_dir/ApplicationCenter/tools/android"
```

```
<!-- Declare the IBM Application Center application. -->
```

```
<application id="applicationcenter"
  name="applicationcenter"
  location="applicationcenter.ear"
  type="ear">
  <application-bnd>
    <security-role name="appcenteradmin">
      <group name="appcentergroup"/>
    </security-role>
  </application-bnd>
  <classloader delegation="parentLast">
    <commonLibrary>
      <fileset dir="{wlp.install.dir}/lib"
        includes="com.ibm.ws.crypto.passwordutil_*.jar"/>
    </commonLibrary>
  </classloader>
</application>
```

```
<!-- Declare the user registry for the IBM Application Center. -->
```

```
<basicRegistry id="applicationcenter-registry"
  realm="ApplicationCenter">
  <!-- The users defined here are members of group "appcentergroup",
  thus have role "appcenteradmin", and can therefore perform
  administrative tasks through the Application Center Console. -->
  <user name="appcenteradmin" password="admin"/>
  <user name="demo" password="demo"/>
  <group name="appcentergroup">
    <member name="appcenteradmin"/>
    <member name="demo"/>
  </group>
</basicRegistry>
```

The groups and users that are defined in the `basicRegistry` element are example logins, which you can use to test Application Center. Similarly, the groups that are defined in the `<security-role name="appcenteradmin">` element are examples. For more information about how to modify these groups, see “Configuring the Java EE security roles on WebSphere Application Server Liberty profile” on page 6-272.

3. If the database is Oracle, add the `commonLibraryRef` attribute to the class loader of the Application Center service application.

```
...
<classloader delegation="parentLast" commonLibraryRef="OracleLib">
  <commonLibrary>
...

```

The name of the library reference (`OracleLib` in this example) must be the ID of the library that contains the JDBC JAR file. This ID is declared in the procedure that is documented in “Configuring Liberty profile for Oracle manually for Application Center” on page 6-256.

4. Copy the Application Center EAR files to your Liberty server.

- On UNIX and Linux systems:

```
mkdir -p $LIBERTY_HOME/wlp/usr/servers/server_name/apps
cp product_install_dir/ApplicationCenter/console/*.ear
```

- On Windows systems:

```
mkdir LIBERTY_HOME\wlp\usr\servers\<server_name>\apps\copy /B
product_install_dir\ApplicationCenter\console\applicationcenter.ear
LIBERTY_HOME\wlp\usr\servers\<server_name>\apps\applicationcenter.ear
```

5. Start the Liberty server.

What to do next

For more steps to configure Application Center, see “Configuring the Java EE security roles on WebSphere Application Server Liberty profile” on page 6-272.

Configuring WebSphere Application Server for Application Center manually:

After you deploy the Application Center EAR file, to configure WebSphere Application Server profile manually for Application Center, you must configure variables, custom properties, and class loader policies.

Before you begin

Make sure that a WebSphere Application Server profile exists.

Procedure

1. Log on to the WebSphere Application Server administration console for your IBM MobileFirst Platform Server.
2. Enable application security.
 - a. Click **Security > Global Security**.
 - b. Ensure that **Enable administrative security** is selected. Application security can be enabled only if administrative security is enabled.
 - c. Ensure that **Enable application security** is selected.
 - d. Click **OK**.
 - e. Save the changes.

For more information, see Enabling security.

3. Create the Application Center JDBC data source and provider.
See the appropriate section in “Manually installing Application Center” on page 6-243.
4. Install the Application Center EAR file.
 - a. Depending on your version of WebSphere Application Server, click one of the following options:
 - **Applications > New > New Enterprise Application**
 - **Applications > New Application > New Enterprise Application**
 - b. Go to the MobileFirst Server installation directory `mfserver_install_dir/ApplicationCenter/console`.
 - c. Select **applicationcenter.ear**, and then click **Next**.
 - d. On the How do you want to install the application? page, click **Detailed**, and then click **Next**.
 - e. Click **Next** until you reach the "Map resource references to resources" page.
 - f. Click **Browse** and select the data source with the jdbc/AppCenterDS JNDI name.
 - g. Click **Next** until you reach the "Map context roots for web modules" page.
 - h. In the **Context Root** fields, if they are not already set, type `/appcenterconsole` for the ApplicationCenterConsole module and type `/applicationcenter` for the ApplicationCenterServices module.
 - i. Click **Next** until you reach the "Map security roles to users or groups" page.
 - j. Select all roles, click **Map Special Subjects** and select **All Authenticated in Application's Realm**.
 - k. Click **Next** until you reach the Summary page.
 - l. Click **Finish** and save the configuration.
5. Configure the class loader policies and then start the application:
 - a. Click **Applications > Application types > WebSphere Enterprise Applications**.
 - b. From the list of applications, click **AppCenterEAR**.
 - c. In the Detail Properties section, click the **Class loading and update detection** link.
 - d. In the Class loader order pane, click **Classes loaded with local class loader first (parent last)**.
 - e. Click **OK**.
 - f. In the Modules section, click **Manage Modules**.
 - g. From the list of modules, click **ApplicationCenterConsole**.
 - h. In the Class loader order pane, click **Classes loaded with local class loader first (parent last)**.
 - i. Click **OK**.
 - j. From the list of modules, click **ApplicationCenterServices**.
 - k. In the Class loader order pane, click **Classes loaded with local class loader first (parent last)**.
 - l. Click **OK** twice.
 - m. Click **Save**.
 - n. Select **AppCenterEAR** and click **Start**.
6. Review the server class loader policy:

Depending on your version of WebSphere Application Server, click **Servers > Server Types > Application Servers** or **Servers > Server Types > WebSphere application servers** and then select the server.

- If the class loader policy is set to **Multiple**, do nothing.
 - If the class loader policy is set to **Single** and **Class loading mode** is set to **Classes loaded with local class loader first (parent last)**, do nothing.
 - If **Classloader policy** is set to **Single** and **Class loading mode** is set to **Classes loaded with parent class loader first**, set **Classloader policy** to **Multiple** and set the class loader policy of all applications other than MobileFirst applications to **Classes loaded with parent class loader first**.
7. Save the configuration.
 8. Configure a JNDI environment entry to indicate the directory with binary files of the aapt program, from the Android SDK platform-tools package.
 - a. Determine a suitable directory for the aapt binary files in the WebSphere Application Server installation directory.
 - For a stand-alone server, you can use a directory such as `WAS_INSTALL_DIR/optionalLibraries/IBM/Worklight/android-sdk`.
 - For deployment to a WebSphere Application Server Network Deployment cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/Worklight/android-sdk`.
 - For deployment to a WebSphere Application Server Network Deployment cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/Worklight/android-sdk`.
 - For deployment to a WebSphere Application Server Network Deployment node, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/Worklight/android-sdk`.
 - For deployment to a WebSphere Application Server Network Deployment server, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/Worklight/android-sdk`.
 - b. Copy the `product_install_dir/ApplicationCenter/tools/android-sdk` directory to the directory that you determined in Substep a.
 - c. For WebSphere Application Server Network Deployment, click **System administration > Nodes**, select the nodes, and click **Full Synchronize**.
 - d. Configure the environment entry (JNDI property) `android.aapt.dir` and set as its value the directory that you determined in Substep a. The `WAS_INSTALL_DIR/profiles/profile-name` profile is replaced with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.

Results

You can now access the Application Center at `http://<server>:<port>/appcenterconsole`, where *server* is the host name of your server and *port* is the port number (by default 9080).

What to do next

For more steps to configure the Application Center, see “Configuring the Java EE security roles on WebSphere Application Server full profile” on page 6-271.

Configuring Application Center after installation

After you install Application Center in the web application server that you designated, you have additional configuration to do.

Configuring user authentication for Application Center

You configure user authentication and choose an authentication method. The configuration procedure depends on the web application server that you use.

Application Center requires user authentication.

You must perform some configuration after the installer deploys Application Center web applications in the web application server.

Application Center has two Java Platform, Enterprise Edition (Java EE) security roles defined:

- The **appcenteruser** role that represents an ordinary user of Application Center who can install mobile applications from the catalog to a mobile device belonging to that user.
- The **appcenteradmin** role that represents a user who can perform administrative tasks through the Application Center console.

You must map the roles to the corresponding sets of users.

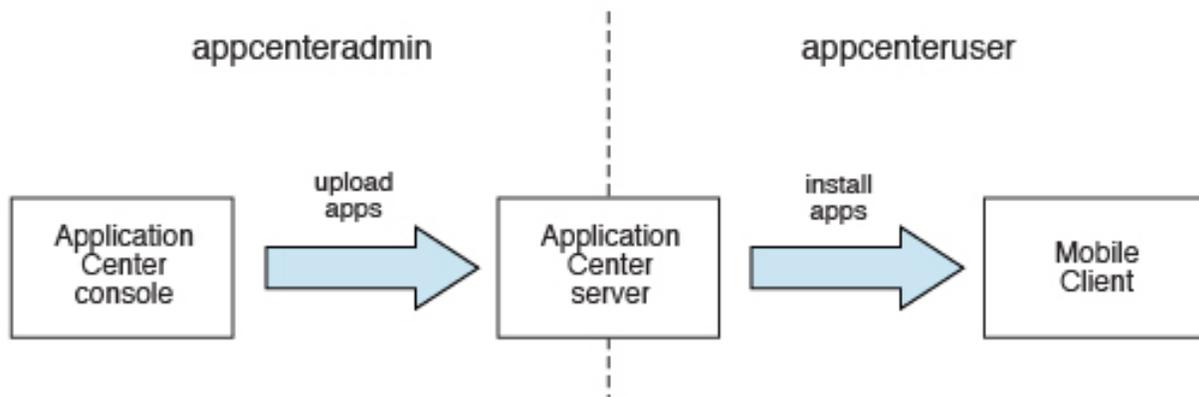

Figure 6-21. Java EE security roles of the Application Center and the components that they influence

If you choose to use an authentication method through a user repository such as LDAP, you can configure Application Center so that you can use users and groups with the user repository to define the Access Control List (ACL) of Application Center. This procedure is conditioned by the type and version of the web application server that you use. See “Managing users with LDAP” on page 6-274 for information about LDAP used with Application Center.

After you configure authentication of the users of Application Center, which includes configuring LDAP if you plan to use it, you can, if necessary, define the endpoint of the application resources. You must then build the Application Center mobile client. The mobile client is used to install applications on mobile devices. See “Preparations for using the mobile client” on page 13-71 for how to build the Application Center mobile client.

Related concepts:

“Managing users with LDAP” on page 6-274

Use the Lightweight Directory Access Protocol (LDAP) registry to manage users.

Related reference:

Preparations for using the mobile client

To use the mobile client to install apps on mobile devices, you must either generate the app by using the provided Eclipse and Visual Studio projects or use the version of the client provided for Android, iOS, Windows Phone, Windows 8, or BlackBerry directly.

Configuring the Java EE security roles on WebSphere Application Server full profile:

Configure security by mapping the Application Center Java EE roles to a set of users for both web applications.

Before you begin

Review the definition of roles at “Configuring user authentication for Application Center” on page 6-270.

Procedure

You define the basics of user configuration in the WebSphere Application Server console. Access to the console is usually by this address: <https://localhost:9043/ibm/console/>

1. Select **Security > Global Security**.
2. Select **Security Configuration Wizard** to configure users.
You can manage individual user accounts by selecting **Users and Groups > Manage Users**.
3. If you deployed WAR files, map the **appcenteruser** and **appcenteradmin** roles to a set of users as follows:
 - a. Select **Servers > Server Types > WebSphere application servers**.
 - b. Select the server.
 - c. In the **Configuration** tab, select **Applications > Enterprise applications**.

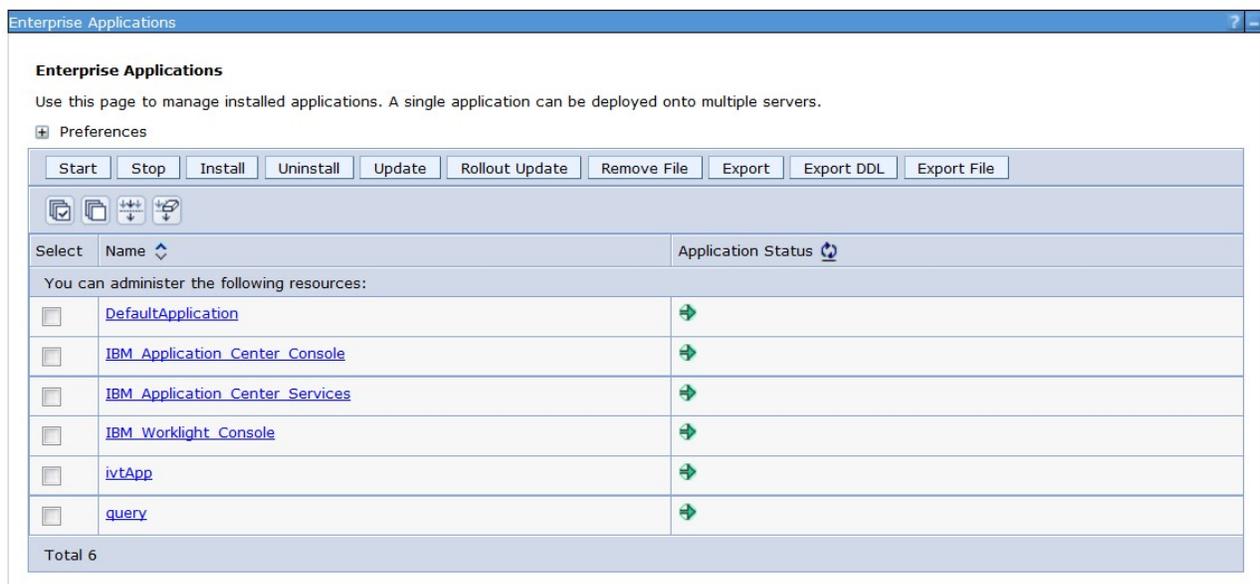

Figure 6-22. Mapping the Application Center roles

- d. Select **IBM_Application_Center_Services**.
- e. In the **Configuration** tab, select **Details > Security role to user/group mapping**.

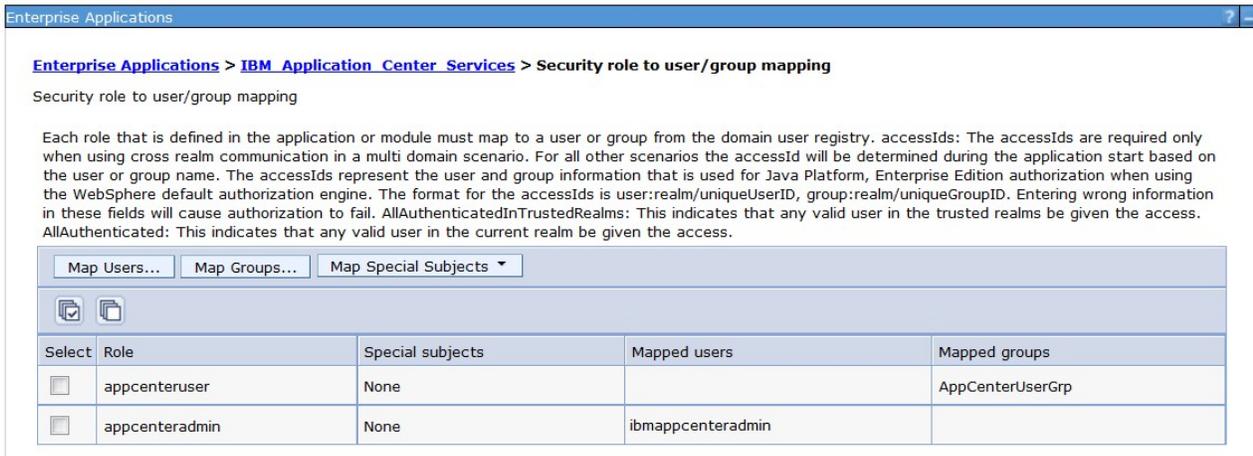

Figure 6-23. Mapping the **appcenteruser** and **appcenteradmin** roles: user groups

- f. Customize as necessary.
- g. Click **OK**.
- h. Repeat steps 3c on page 6-271 to 3g to map the roles for the console web application; in step 3d, select **IBM_Application_Center_Console**.
- i. Click **Save**.
4. If you deployed an EAR file, map the **appcenteruser** and **appcenteradmin** roles to a set of users as follows:
 - a. Select **Applications > Application Types > WebSphere application servers**.
 - b. Click **AppCenterEAR**.
 - c. In the Detail Properties section, click **Security role to user/group mapping**.
 - d. Customize as necessary.
 - e. Click **OK**.
 - f. Click **Save**.

Configuring the Java EE security roles on WebSphere Application Server Liberty profile:

Configure the Java EE security roles of the Application Center and the data source in the `server.xml` file.

Before you begin

Review the definition of roles at “Configuring user authentication for Application Center” on page 6-270.

In WebSphere Application Server Liberty profile, you configure the roles of `appcenteruser` and `appcenteradmin` in the `server.xml` configuration file of the server.

About this task

To configure the security roles, you must edit the `server.xml` file. In the `<application-bnd>` element of each `<application>` element, create two `<security-role>` elements. One `<security-role>` element is for the **appcenteruser** role and the other is for the **appcenteradmin** role. Map the roles to the appropriate user group name **appcenterusergroup** or **appcenteradmingroup**. These groups are defined through the `<basicRegistry>` element. You can customize this element or replace it entirely with an `<ldapRegistry>` element or a `<safRegistry>` element.

Then, to maintain good response times with a large number of installed applications, for example with 80 applications, configure a connection pool for the Application Center database.

Procedure

1. Edit the `server.xml` file. For example:

```
<security-role name="appcenteradmin">
  <group name="appcenteradmingroup"/>
</security-role>
<security-role name="appcenteruser">
  <group name="appcenterusergroup"/>
</security-role>
```

You must include this example in the following location :

- If you deployed WAR files, in the `<application-bnd>` element of each `<application>` element: the `appcenterconsole` and `applicationcenter` applications.
- If you deployed an EAR file, in the `<application-bnd>` element of the `applicationcenter` application.

Replace the `<security-role>` elements that have been created during installation for test purposes.

```
<basicRegistry id="appcenter">
  <user name="admin" password="admin"/>
  <user name="guest" password="guest"/>
  <user name="demo" password="demo"/>
  <group name="appcenterusergroup">
    <member name="guest"/>
    <member name="demo"/>
  </group>
  <group name="appcenteradmingroup">
    <member name="admin" id="admin"/>
  </group>
</basicRegistry>
```

This example shows a definition of users and groups in the `basicRegistry` of WebSphere Application Server Liberty. For more information about configuring a user registry for WebSphere Application Server Liberty profile, see [Configuring a user registry for the Liberty profile](#).

2. Edit the `server.xml` file to define the **AppCenterPool** size.

```
<connectionManager id="AppCenterPool" minPoolSize="10" maxPoolSize="40"/>
```

3. In the `<dataSource>` element, define a reference to the connection manager:

```
<dataSource id="APPCNTR" jndiName="jdbc/AppCenterDS" connectionManagerRef="AppCenterPool"
...
</dataSource>
```

Configuring the Java EE security roles on Apache Tomcat:

You must configure the Java EE security roles for the Application Center on the Apache Tomcat web application server.

Before you begin

Review the definition of roles at “Configuring user authentication for Application Center” on page 6-270.

Procedure

1. In the Apache Tomcat web application server, you configure the roles of **appcenteruser** and **appcenteradmin** in the `conf/tomcat-users.xml` file. The installation creates the following users:

```
<user username="appcenteradmin" password="admin" roles="appcenteradmin"/>
<user username="demo" password="demo" roles="appcenteradmin"/>
<user username="guest" password="guest" roles="appcenteradmin"/>
```

2. You can define the set of users as described in the Apache Tomcat documentation, Realm Configuration HOW-TO.

Managing users with LDAP

Use the Lightweight Directory Access Protocol (LDAP) registry to manage users.

LDAP is a way to centralize the user management for multiple web applications in an LDAP Server that maintains a user registry. It can be used instead of specifying one by one the users for the security roles **appcenteradmin** and **appcenteruser**.

If you plan to use an LDAP registry with the Application Center, you must configure your WebSphere Application Server or your Apache Tomcat server to use an LDAP registry to authenticate users.

In addition to authentication of users, configuring the Application Center for LDAP also enables you to use LDAP to define the users and groups who can install mobile applications through the Application Center. The means of defining these users and groups is the Access Control List (ACL).

Since IBM Worklight V6.0, use the JNDI environment entries for defining LDAP configuration properties.

Expert users could configure the application servers to use LDAP authentication by using the methods that were documented in releases before IBM Worklight V6.0.

LDAP with WebSphere Application Server V7:

Use LDAP to authenticate users and define the users and groups who can install mobile applications with the Application Center; you can use the JNDI environment or the VMM API to define the LDAP mapping

You use LDAP to define the roles **appcenteradmin** and **appcenteruser**. Then, you have two ways of defining LDAP mapping for WebSphere Application Server V7:

- By using the JNDI environment with a stand-alone LDAP configuration
- By using federated repositories with the Virtual Member Manager (VMM) API

Configuring LDAP authentication for WebSphere Application Server V7:

Define the users who can access the Application Center console and the users who can log in to the client by configuring LDAP as a stand-alone LDAP server or as a federated repository.

About this task

This procedure shows you how to use LDAP to define the roles **appcenteradmin** and **appcenteruser** in WebSphere Application Server V7.

Procedure

1. Log in to the WebSphere Application Server console.
2. In **Security > Global Security**, verify that administrative security and application security are enabled.
3. Select **Federated repositories** or **Standalone LDAP registry**.
4. Click **Configure**. For federated repositories, follow step 5. For stand-alone LDAP registry, follow step 6
5. **Option for federated repositories:** add the new repository and configure the necessary additional properties.
 - a. To add a repository, click **Add Base entry to Realm**.
 - b. Specify the value of **Distinguished name of a base entry that uniquely identifies entries in the realm** and click **Add Repository**.
 - c. Select **LDAP Repository**.
 - d. Give this repository a name and enter the values that are required to connect to your LDAP server.
 - e. Under **Additional Properties**, click **LDAP entity types**.
 - f. Configure the **Group**, **OrgContainer**, and **PersonAccount** properties. These configuration details depend on your LDAP server.
6. **Option for stand-alone LDAP registry:** Configure access control (ACL) management. You can use JNDI properties for this configuration, but you cannot use VMM.
 - a. Enter the values of **General Properties**. These values depend on your LDAP server.
 - b. Under **Additional Properties**, click **Advanced Lightweight Directory Access Protocol (LDAP)** and configure the user and group filters and maps. These configuration details depend on your LDAP server.
7. Save the configuration, log out, and restart the server.
8. If you deployed WAR files, in the WebSphere Application Server console, map the security roles to users and groups.
 - a. In the **Configuration** tab, select **Applications > WebSphere Enterprise applications**.
 - b. Select **IBM_Application_Center_Services**.
 - c. In the **Configuration** tab, select **Details > Security role to user/group mapping**.
 - d. For **appcenteradmin** and **appcenteruser** roles, select **Map groups**.

You can then select users and groups inside the WebSphere user repository, including LDAP users and groups. The selected users can access the Application Center as **appcenteradmin** or **appcenteruser**. You can also map the roles to **Special Subjects** "All authenticated in application realm" to

- give access to the Application Center to everyone in the WebSphere user repository, including everyone registered in the LDAP registry
9. Repeat step 8 on page 6-275 for **IBM_Application_Center_Console**.
Make sure that in step 8.b you select **IBM_Application_Center_Console** instead of **IBM_Application_Center_Services**.
 10. If you deployed an EAR file, in the WebSphere Application Server console, map the security roles to users and groups.
 - a. Click **Applications > Application Types > WebSphere enterprise applications**.
 - b. From the list of applications, click **AppCenterEAR**.
 - c. In the Detail Properties section, click **Security role to user/group mapping**.
 - d. For appcenteradmin and appcenteruser roles, select **Map groups** or **Map users** to select users or groups inside the WebSphere user repository, including LDAP users and groups.
The selected users can access the Application Center as **appcenteradmin** or **appcenteruser**. You can also map the roles to **Special Subjects** "All authenticated in application realm" to give access to the Application Center to everyone in the WebSphere user repository, including everyone registered in the LDAP registry.
 11. Click **Save** to save your changes.

Configuring LDAP ACL management with JNDI for WebSphere Application Server V7:

Use LDAP to define the users and groups who can install mobile applications with the Application Center by using the JNDI environment.

About this task

Since IBM Worklight V6.0, two configuration approaches are available: the JNDI API or the Virtual Member Manager (VMM) API. This procedure shows you how to use the JNDI API to configure LDAP based on the federated repository configuration or with the stand-alone LDAP registry.

Note: Only the simple type of LDAP authentication is supported.

Procedure

1. Log in to the WebSphere Application Server console.
2. Select **Applications > Application Types > WebSphere enterprise applications**.
3. Click **IBM_Application_Center_Services** if you deployed WAR files or **APPCenterEAR** if you deployed an EAR file.
4. In the **Web Module Properties** section, select **Environment entries for Web modules**.
 - a. For the **ibm.appcenter.ldap.vmm.active** entry, assign the false value.
 - b. For the **ibm.appcenter.ldap.active** entry, assign the true value.
5. Continue to configure the remaining entries:
 - **ibm.appcenter.ldap.connectionURL**: LDAP connection URL.
 - **ibm.appcenter.ldap.user.base**: search base for users.
 - **ibm.appcenter.ldap.user.loginName**: LDAP login attribute.
 - **ibm.appcenter.ldap.user.displayName**: LDAP attribute for the user name to be displayed, for example, a person's full name.
 - **ibm.appcenter.ldap.group.base**: search base for groups.

- **ibm.appcenter.ldap.group.name:** LDAP attribute for the group name.
- **ibm.appcenter.ldap.group.uniquemember:** LDAP attribute that identifies the members of a group.
- **ibm.appcenter.ldap.user.groupmembership:** LDAP attribute that identifies the groups that a user belongs to.
- **ibm.appcenter.ldap.group.nesting:** management of nested groups. If nested groups are not managed, set the value to `false`.
- **ibm.appcenter.ldap.cache.expiration.seconds:** delay in seconds before the LDAP cache expires. If no value is entered, the default value is 86400, which is equal to 24 hours.

Changes to users and groups on the LDAP server become visible to the Application Center after a delay, which is specified by **ibm.appcenter.ldap.cache.expiration.seconds**. The Application Center maintains a cache of LDAP data and the changes become visible only after the cache expires. By default, the delay is 24 hours. If you do not want to wait for this delay to expire after changes to users or groups, you can call this command to clear the cache of LDAP data:

```
acdeploytool.sh -clearLdapCache -s serverurl -c context -u user -p password
```

See Using the stand-alone tool to clear the LDAP cache for details.

- Enter the value of each property.
 - Click **OK** and save the configuration.
- Option:** *If the LDAP external SASL authentication mechanism is required to bind to the LDAP server, configure the **ibm.appcenter.ldap.security.sasl** property, which defines the value of the security authentication mechanism. The value depends on the LDAP server; usually, it is set to EXTERNAL.*
 - Option:** *If security binding is required, follow this step.* Configure the following entries:
 - **ibm.appcenter.ldap.security.binddn:** the distinguished name of the user who is permitted to search the LDAP directory.
 - **ibm.appcenter.ldap.security.bindpwd:** the password of the user who is permitted to search the LDAP directory. The password can be encoded with the WebSphere PropFilePasswordEncoder utility. Run the utility before you configure the **ibm.appcenter.ldap.security.bindpwd** custom property.
 - Enter the value of each optional property and click **OK**. Set the value of the **ibm.appcenter.ldap.security.bindpwd** property to the encoded password generated by the WebSphere PropFilePasswordEncoder utility.
 - Save the configuration.
 - Option:** *If LDAP referrals must be handled, follow this step.* Configure **ibm.appcenter.ldap.referral**: support of referrals by the JNDI API. • If no value is given, the JNDI API does not handle LDAP referrals. Possible values:
 - **ignore:** ignores the referrals that are found in the LDAP server.
 - **follow:** automatically follows any referrals that are found in the LDAP server.
 - **throw:** causes an exception to occur for each referral that is found in the LDAP server.
 - Enter the value of the property and click **OK**.
 - Save the configuration.
 - Option:** *If users and groups are defined in the same subtree (the properties **ibm.appcenter.ldap.user.base** and **ibm.appcenter.ldap.group.base** have the same value), follow this step.* Configure the following entries:

- **ibm.appcenter.ldap.user.filter**: LDAP user search filter for the attribute of user login name. Use %v as the placeholder for the login name attribute.
 - **ibm.appcenter.ldap.group.filter**: LDAP group search filter. Use %v as the placeholder for the group attribute.
 - **ibm.appcenter.ldap.user.displayName.filter**: LDAP user search filter for the attribute of user display name. Use %v as the placeholder for the user display name attribute.
- Enter the value of each optional property and click **OK**.
 - Save the configuration.

Results

The following figure shows the values to assign to each property.

See “List of JNDI properties for the Application Center” on page 6-307 for a complete list of properties.

ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.active	String	ACL management with LDAP (set to true to enable, set to false to disable)	<input type="text" value="true"/>
ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.vmm.active	String	Use of the VMM API (Set to true to enable, set to false to disable)	<input type="text" value="false"/>
ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.federated.active	String	Use of a federated registry in Liberty Profile (Set to true to enable, set to false to disable)	<input type="text" value="false"/>
ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.referral	String	Management type of the LDAP referrals	<input type="text" value="follow"/>
ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.connectionURL	String	LDAP connection URL	<input type="text" value="bluepages.ibm.com:389"/>
ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.cache.expiration.seconds	String	Expiration of cached LDAP entries, in seconds. The default value is 86400 (i.e., 24h).	<input type="text"/>
ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.user.base	String	Search base of users	<input type="text" value="ou=bluepages,o=ibm.com"/>
ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.user.loginName	String	LDAP login attribute	<input type="text" value="mail"/>
ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.user.displayName	String	LDAP attribute for the user name to be displayed	<input type="text" value="cn"/>
ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.user.groupmembership	String	LDAP attribute that identifies the groups to which a user belongs	<input type="text" value="ibm-allGroups"/>
ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.user.filter	String	LDAP user search filter for the login name (placeholder = %v)	<input type="text"/>
ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.user.displayName.filter	String	LDAP user search filter for the display name (placeholder = %v)	<input type="text"/>
ApplicationCenterServices	ApplicationCenterServices-6.0.5.x-SNAPSHOT_war,WEB-INF/web.xml	ibm.appcenter.ldap.group.base	String	Search base of groups	<input type="text" value="ou=memberlist,o=ibm.com"/>

Figure 6-24. Environment entries and their values (LDAP and WebSphere Application Server V7)

Configuring LDAP ACL management with VMM for WebSphere Application Server V7:

Use LDAP to define the users and groups who can install mobile applications with the Application Center with the Virtual Member Manager (VMM) API.

About this task

Since IBM Worklight V6.0, two configuration approaches are available: the JNDI API or the VMM API. This procedure shows you how to use the VMM API to configure LDAP based on the federated repository configuration.

You must configure LDAP based on the federated repository configuration.

Note: The stand-alone LDAP registry is not supported.

Several different repositories, LDAP and non-LDAP, can be configured in the federated repository.

Procedure

1. Configure the attribute mapping. For users, the Application Center refers to these VMM attributes:

- **uid:** represents the user login name.
- **sn:** represents the full name of the user.

For groups, the Application Center refers only to the VMM attribute **cn**.

If VMM attributes are not identical to LDAP attributes, you must map the VMM attributes to the corresponding LDAP attributes.

Note: In WebSphere Application Server V7, you cannot configure this mapping with the WebSphere Application Server console.

- a. Find in the file `WAS_HOME/profiles/profileName/config/cells/cellName/wim/config/wimconfig.xml` the section that contains the LDAP repository configuration with `id="your LDAP id"`:

```
<config:repositories xsi:type="config:LdapRepositoryType" adapterClassName="com.ibm.ws.wim.  
id="your LDAP id"....
```

Where *your LDAP id* is the user ID that is configured for you in the LDAP repository.

- b. In this section, after the element **<config:attributeConfiguration>**, add these entries:

```
<config:attributes name="your LDAP attribute for the user full name" propertyName="sn">  
  <config:entityTypes>PersonAccount</config:entityTypes>  
</config:attributes>  
<config:attributes name="your LDAP attribute for the user login name " property  
  <config:entityTypes>PersonAccount</config:entityTypes>  
</config:attributes>
```

- c. Save the file and restart the server.

2. Configure the Application Center for ACL management with LDAP. In WebSphere Application Server V7, only a WebSphere administrator user can run VMM access. VMM roles are supported only by WebSphere Application Server V8.

You must define these properties:

- `ibm.appcenter.ldap.active = true.`
- `ibm.appcenter.ldap.vmm.active = true.`
- `ibm.appcenter.ldap.vmm.adminuser = WebSphere administrator user.`
- `ibm.appcenter.ldap.vmm.adminpwd = WebSphere administrator password.`
The password can be encoded or not.
- `ibm.appcenter.ldap.cache.expiration.seconds = :` the delay in seconds before the LDAP cache expires. If no value is entered, the default value is 86400, which is equal to 24 hours.

Note: See “List of JNDI properties for the Application Center” on page 6-307 for a complete list of properties.

Changes to users and groups on the LDAP server become visible to the Application Center after a delay, which is specified by **ibm.appcenter.ldap.cache.expiration.seconds**. The Application Center maintains a cache of LDAP data and the changes become visible only after the cache expires. By default, the delay is 24 hours. If you do not want to wait for this delay to expire after changes to users or groups, you can call this command to clear the cache of LDAP data:

```
acdeploytool.sh -clearLdapCache -s serverurl -c context -u user -p password
```

For more information, see Using the stand-alone tool to clear the LDAP cache.

- a. Log in to the WebSphere Application Server console.
 - b. Select **Applications > Application Types > WebSphere enterprise applications**.
 - c. In the Web Module Properties section, select **IBM_Application_Center_Services** if you deployed WAR files or **APPCenterEAR** if you deployed an EAR file, and then select **Environment entries for Web modules**.
 - d. Set the values for the properties.
 - e. Click **OK** and save the configuration.
The application is automatically restarted.
3. Optional: Encode the password with the **PropFilePasswordEncoder** utility.
- a. Create a `pwd.txt` file that contains the entry `adminpwd=your clear password`, where *your clear password* is the unencoded administrator password.
 - b. Run this command:

```
{WAS_HOME}/profiles/profile_name/bin/PropFilePasswordEncoder "file_path/pwd.txt" adminpwd
```
 - c. Open the `pwd.txt` file and copy the encoded password into the value of the **ibm.appcenter.ldap.vmm.adminpwd** property.

LDAP with WebSphere Application Server V8.x:

LDAP authentication is achieved based on the federated repository configuration. ACL management configuration of the Application Center uses the Virtual Member Manager API.

You must configure LDAP based on the federated repository configuration. The stand-alone LDAP registry is not supported.

Several different repositories, LDAP and non-LDAP, can be configured in the federated repository.

For information about configuring federated repositories, see the WebSphere Application Server V8.0 user documentation or the WebSphere Application Server V8.5 user documentation, depending on your version.

Configuration of the Application Center for ACL management with LDAP

Some configuration details of ACL management are specific to the Application Center, because it uses the Virtual Member Manager (VMM) API.

The Application Center refers to these VMM attributes for users:

uid represents the user login name.
sn represents the full name of the user.

For groups, the Application Center refers only to the VMM attribute **cn**.

If VMM attributes are not identical in LDAP, you must map the VMM attributes to the corresponding LDAP attributes.

Configuring LDAP authentication for WebSphere Application Server V8.x:

Use LDAP to define users who can access the Application Center console and users who can log in to the client.

About this task

You can configure LDAP based on the federated repository configuration only. This procedure shows you how to use LDAP to define the roles **appcenteradmin** and **appcenteruser** in WebSphere Application Server V8.x.

Procedure

1. Log in to the WebSphere Application Server console.
2. Select **Security > Global security** and verify that administrative security and application security are enabled.
3. In the “User account repository” section, select **Federated repositories**.
4. Click **Configure**.
5. Add a repository and configure it.
 - a. Click **Add Base entry to Realm**.
 - b. Specify the value of **Distinguished name of a base entry that uniquely identifies entries in the realm** and click **Add Repository**.
 - c. Select **LDAP Repository**.
 - d. Give this repository a name and enter the values that are required to connect to your LDAP server.
 - e. Under **Additional Properties**, click **LDAP entity types**.
 - f. Configure the **Group**, **OrgContainer**, and **PersonAccount** properties. These configuration details depend on your LDAP server.
6. Save the configuration, log out, and restart the server.
7. If you deployed WAR files, in the WebSphere Application Server console, map the security roles to users and groups.
 - a. In the **Configuration** tab, select **Applications > WebSphere Enterprise applications**.
 - b. Select **IBM_Application_Center_Services**.
 - c. In the **Configuration** tab, select **Details > Security role to user/group mapping**.
 - d. For **appcenteradmin** and **appcenteruser** roles, select **Map groups**. This selection enables you to select users and groups inside the WebSphere user repository, including LDAP users and groups. The selected users can access the Application Center as **appcenteradmin** or **appcenteruser**. You can also map the roles to **Special Subjects** “All authenticated in application realm” to give everyone in the WebSphere user repository, including everyone registered in the LDAP registry, access to the Application Center.

8. Repeat step 7 on page 6-281 for **IBM_Application_Center_Console**.
Make sure that you select **IBM_Application_Center_Console** in step 7.b instead of **IBM_Application_Center_Services**.
9. If you deployed an EAR file, in the WebSphere Application Server console, map the security roles to users and groups.
 - a. Click **Applications > Application Types > WebSphere enterprise applications**.
 - b. From the list of applications, click **AppCenterEAR**.
 - c. In the Detail Properties section, click **Security role to user/group mapping**.
 - d. For appcenteradmin and appcenteruser roles, select **Map groups** or **Map users** to select users or groups inside the WebSphere user repository, including LDAP users and groups.
The selected users can access the Application Center as **appcenteradmin** or **appcenteruser**. You can also map the roles to **Special Subjects** "All authenticated in application realm" to give access to the Application Center to everyone in the WebSphere user repository, including everyone registered in the LDAP registry.
10. Click **Save** to save your changes.

What to do next

You must enable ACL management with LDAP. See "Configuring LDAP ACL management (WebSphere Application Server V8.x)."

Configuring LDAP ACL management (WebSphere Application Server V8.x):

Use LDAP to define the users and groups who can install mobile applications with the Application Center with the Virtual Member Manager (VMM) API.

About this task

To configure ACL with LDAP, you should define three properties: **uid**, **sn**, and **cn**. These properties enable the login name and the full name of users and the name of user groups to be identified in the Application Center.

Then you should enable ACL management with VMM. You can configure LDAP based on the federated repository configuration only.

Procedure

1. Log in to the WebSphere Application Server console.
2. Select **Security > Global security**.
3. In the "User account repository" section, select **Configure**.
4. Select your LDAP repository entry.
5. Under **Additional Properties**, select **LDAP attributes** (WebSphere Application Server V8.0) or **Federated repositories property names to LDAP attributes mapping** (WebSphere Application Server V8.5).
6. Select **Add > Supported**.
7. Enter these property values:
 - a. For **Name** enter your LDAP login attribute.
 - b. For **Property name** enter **uid**.
 - c. For **Entity types** enter the LDAP entity type.

- d. Click **OK**.

The screenshot shows the configuration console with the following fields filled in:
Name: mail
Property name: uid
Entity types: PersonAccount
Buttons: Apply, OK, Reset, Cancel

Figure 6-25. Associating LDAP login with uid property (WebSphere Application Server V8.0)

8. Select **Add > Supported**.
 - a. For **Name** enter your LDAP attribute for full user name.
 - b. For **Property name** enter **sn**.
 - c. For **Entity types** enter the LDAP entity type.
 - d. Click **OK**.

The screenshot shows the configuration console with the following fields filled in:
Name: sn
Property name: sn
Entity types: PersonAccount
Buttons: Apply, OK, Reset, Cancel

Figure 6-26. Associating LDAP full user name with sn property (WebSphere Application Server V8.0)

9. Select **Add > Supported** to configure a group name:
 - a. For **Name** enter the LDAP attribute for your group name.
 - b. For **Property name** enter **cn**.
 - c. For **Entity types** enter the LDAP entity type.
 - d. Click **OK**.
10. Enable ACL management with LDAP:
 - a. Select **Servers > Server Types > WebSphere application servers**.
 - b. Select the appropriate application server.

In a clustered environment you must configure all the servers in the cluster in the same way.
 - c. In the **Configuration** tab, under “Server Infrastructure”, click the **Java and Process Management** tab and select **Process definition**.
 - d. In the **Configuration** tab, under “Additional Properties”, select **Java Virtual Machine**.
 - e. In the **Configuration** tab, under “Additional Properties”, select **Custom properties**.
 - f. Enter the required property-value pairs in the form. To enter each pair, click **New**, enter the property and its value, and click **OK**.

Property-value pairs:

 - `ibm.appcenter.ldap.vmm.active = true`
 - `ibm.appcenter.ldap.active = true`
 - `ibm.appcenter.ldap.cache.expiration.seconds = delay_in_seconds`

Enter the delay in seconds before the LDAP cache expires. If you do not enter a value, the default value is 86400, which is equal to 24 hours.

Changes to users and groups on the LDAP server become visible to the Application Center after a delay, which is specified by **ibm.appcenter.ldap.cache.expiration.seconds**. The Application Center maintains a cache of LDAP data and the changes only become visible after the cache expires. By default, the delay is 24 hours. If you do not want to wait for this delay to expire after changes to users or groups, you can call this command to clear the cache of LDAP data:

```
acdeploytool.sh -clearLdapCache -s serverurl -c context -u user -p password
```

See Using the stand-alone tool to clear the LDAP cache for details.

Results

The following figure shows an example of custom properties with the correct settings.

Figure 6-27. ACL management for Application Center with LDAP on WebSphere Application Server V8

What to do next

Save the configuration and restart the server.

To use the VMM API, you must assign the “IdMgrReader” role to the users who run the VMM code, or to the group owners of these users. You must assign this role to all users and groups who have the roles of “appcenteruser” or “appcenteradmin”.

In the `<was_home>\bin` directory, where `<was_home>` is the home directory of your WebSphere Application Server, run the **wsadmin** command.

After connecting with the WebSphere Application Server administrative user, run the following command:

```
$AdminTask mapIdMgrGroupToRole {-roleName IdMgrReader -groupId your_LDAP_group_id}
```

Run the same command for all the groups mapped to the roles of “appcenteruser” and “appcenteradmin”.

For individual users who are not members of groups, run the following command:

```
$AdminTask mapIdMgrUserToRole {-roleName IdMgrReader -userId your_LDAP_user_id}
```

You can assign the special subject “All Authenticated in Application's Realm” as roles for **appcenteruser** and **appcenteradmin**. If you choose to assign this special subject, **IdMgrReader** must be configured in the following way:

```
$AdminTask mapIdMgrGroupToRole {-roleName IdMgrReader -groupId ALLAUTHENTICATED}
```

Enter **exit** to end **wsadmin**.

LDAP with Liberty profile:

Use LDAP to authenticate users and to define the users and groups who can install mobile applications with the Application Center by using the JNDI environment.

Using LDAP with Liberty profile requires you to configure LDAP authentication and LDAP ACL management.

Configuring LDAP authentication for the Liberty profile:

You configure LDAP authentication by defining one or more LDAP registries in the `server.xml` file and you map LDAP users and groups to Application Center roles.

About this task

You can configure LDAP authentication of users and groups in the `server.xml` file by defining an LDAP registry or, since WebSphere Application Server Liberty profile V8.5.5, a federated registry that uses several LDAP registries. Then, you map users and groups to Application Center roles. The mapping configuration is the same for LDAP authentication and basic authentication.

Procedure

1. To open the `server.xml` descriptor file, enter `{server.config.dir}/server.xml`
2. Insert one or several LDAP registry definitions after the `<httpEndpoint>` element. Example for the LDAP registry:

```
<ldapRegistry baseDN="o=ibm.com" host="employees.com" id="Employees"
             ldapType="IBM Tivoli Directory Server" port="389" realm="AppCenterLdap"
             recursiveSearch="true">
  <idsFilters
    groupFilter="(& (cn=%v) (|(objectclass=groupOfNames) (objectclass=groupOfUniqueNames)))"
    userFilter="(& (emailAddress=%v) (objectclass=ibmPerson))"
    groupMemberIdMap="ibm-allGroups:member;ibm-allGroups:uniqueMember"
    userIdMap="*:emailAddress"/>
</ldapRegistry>
```

For information about the parameters that are used in this example, see the WebSphere Application Server V8.5 user documentation.

3. Insert a security role definition after each Application Center application definition.

- If you deployed WAR files: **applicationcenter** and **appcenterconsole**
-

If you deployed an EAR file: **applicationcenter**

Group names unique within LDAP

This sample code shows how to use the group names **ldapGroupForAppcenteruser** and **ldapGroupForAppcenteradmin** when they exist and are unique within LDAP.

```
<application-bnd>
  <security-role name="appcenteruser" id="appcenteruser">
    <group name="ldapGroupForAppcenteruser" />
  </security-role>
  <security-role name="appcenteradmin" id="appcenteradmin">
    <group name="ldapGroupForAppcenteradmin" />
  </security-role>
</application-bnd>
```

Group names not unique within LDAP

This sample code shows how to code the mapping when the group

names are not unique within LDAP. The groups must be specified with the **access-id** attribute. The **access-id** attribute must refer to the realm name that is used to specify the LDAP realm. In this sample code, the realm name is **AppCenterLdap**. The remainder of the **access-id** attribute specifies one of the LDAP groups named **ldapGroup** in a way that makes it unique.

```
<application-bnd>
  <security-role name="appcenteruser" id="appcenteruser">
    <group name="ldapGroup"
      id="ldapGroup"
      access-id="group:AppCenterLdap/CN=ldapGroup,OU=myorg,
        DC=mydomain,DC=AD,DC=myco,DC=com"/>
    </security-role>
    ...
  </application-bnd>
```

If applicable, use similar code to map the **appcenteradmin** role.

Configuring LDAP ACL management (Liberty profile):

Use LDAP to define the users and groups who can install mobile applications through the Application Center. The means of defining these users and groups is the Access Control List (ACL).

Purpose

To enable ACL management with LDAP. You enable ACL management after you configure LDAP and map users and groups to Application Center roles. Only the simple type of LDAP authentication is supported.

Properties

To be able to define JNDI entries, make sure that the following feature is defined in the `server.xml` file:

```
<feature>jndi-1.0</feature>
```

Add an entry for each property in the `<server>` section of the `server.xml` file. This entry should have the following syntax:

```
<jndiEntry jndiName="JNDI_property_name" value="property_value"/>
```

Where:

The `JNDI_property_name` argument is the name of the property that you are adding.

The `property_value` argument is the value of the property that you are adding.

Table 6-54. JNDI properties for configuring ACL management with LDAP in the server.xml file

Property	Description
ibm.appcenter.ldap.active	Set it to true to enable LDAP or to false to disable LDAP.
ibm.appcenter.ldap.federated.active	Since WebSphere Application Server Liberty profile V8.5.5: set it to true to enable use of the federated registry; set to false to disable use of the federated registry, which is the default setting.

Table 6-54. JNDI properties for configuring ACL management with LDAP in the `server.xml` file (continued)

Property	Description
<code>ibm.appcenter.ldap.connectionURL</code>	LDAP connection URL.
<code>ibm.appcenter.ldap.user.base</code>	Search base of users.
<code>ibm.appcenter.ldap.user.loginName</code>	LDAP login attribute.
<code>ibm.appcenter.ldap.user.displayName</code>	LDAP attribute for the user name to be displayed, for example, a person's full name.
<code>ibm.appcenter.ldap.group.base</code>	Search base of groups.
<code>ibm.appcenter.ldap.group.name</code>	LDAP attribute for the group name.
<code>ibm.appcenter.ldap.group.uniqueMember</code>	LDAP attribute that identifies the members of a group.
<code>ibm.appcenter.ldap.user.groupMembers</code>	LDAP attribute that identifies the groups to which a user belongs.
<code>ibm.appcenter.ldap.group.nesting</code>	Management of nested groups: if nested groups are not managed, set the value to <code>false</code> .
<code>ibm.appcenter.ldap.user.filter</code>	<p>LDAP user search filter for the attribute of user login name. Use <code>%v</code> as the placeholder for the login name attribute.</p> <p>This property is required only when LDAP users and groups are defined in the same subtree; that is, when the properties <code>ibm.appcenter.ldap.user.base</code> and <code>ibm.appcenter.ldap.group.base</code> have the same value.</p>
<code>ibm.appcenter.ldap.displayName.filter</code>	<p>LDAP user search filter for the attribute of user display name. Use <code>%v</code> as the placeholder for the display name attribute.</p> <p>This property is required only when LDAP users and groups are defined in the same subtree; that is, when the properties <code>ibm.appcenter.ldap.user.base</code> and <code>ibm.appcenter.ldap.group.base</code> have the same value.</p>
<code>ibm.appcenter.ldap.group.filter</code>	<p>LDAP group search filter. Use <code>%v</code> as the placeholder for the group attribute.</p> <p>This property is required only when LDAP users and groups are defined in the same subtree; that is, when the properties <code>ibm.appcenter.ldap.user.base</code> and <code>ibm.appcenter.ldap.group.base</code> have the same value.</p>
<code>ibm.appcenter.ldap.security.sasl</code>	The value of the security authentication mechanism when the LDAP external SASL authentication mechanism is required to bind to the LDAP server. The value depends on the LDAP server; usually, it is set to <code>EXTERNAL</code> .
<code>ibm.appcenter.ldap.security.binddn</code>	This property identifies the distinguished name of the user who is allowed to search the LDAP directory. Use this property only if security binding is required.

Table 6-54. JNDI properties for configuring ACL management with LDAP in the server.xml file (continued)

Property	Description
ibm.appcenter.ldap.security.bindpwd	<p>This property identifies the password of the user who is allowed to search the LDAP directory. Use this property only if security binding is required. The password can be encoded with the "Liberty profile securityUtility" tool. Run the tool and then set the value of this property to the encoded password that is generated by the tool. The supported encoding types are xor and aes (only with the default key).</p> <p>Edit the Liberty profile server.xml file to check whether the <i>classloader</i> is enabled to load the JAR file that decodes the password.</p>
ibm.appcenter.ldap.cache.expiration.seconds	<p>seconds seconds before the LDAP cache expires. If no value is entered, the default value is 86400, which is equal to 24 hours.</p> <p>Changes to users and groups on the LDAP server become visible to the Application Center after a delay, which is specified by ibm.appcenter.ldap.cache.expiration.seconds. The Application Center maintains a cache of LDAP data and the changes become visible only after the cache expires. By default, the delay is 24 hours. If you do not want to wait for this delay to expire after changes to users or groups, you can call this command to clear the cache of LDAP data:</p> <pre>acdeploytool.sh -clearLdapCache -s serverurl -c context -u user</pre> <p>See Using the stand-alone tool to clear the LDAP cache for details.</p>
ibm.appcenter.ldap.referral	<p>This property indicates whether referrals are supported by the JNDI API. If no value is passed, the JNDI API handles no LDAP referrals. Valid values:</p> <ul style="list-style-type: none"> ignore: ignores referrals found in the LDAP server. follow: automatically follows any referrals found in the LDAP server. throw: causes an exception to occur for each referral found in the LDAP server.

See "List of JNDI properties for the Application Center" on page 6-307 for a complete list of LDAP properties that you can set.

Example of setting properties for ACL management with LDAP

This example shows the settings of the properties in the server.xml file required for ACL management with LDAP.

```
<jndiEntry jndiName="ibm.appcenter.ldap.active" value="true"/>
<jndiEntry jndiName="ibm.appcenter.ldap.connectionURL" value="ldap://employees.com:636"/>
<jndiEntry jndiName="ibm.appcenter.ldap.user.loginName" value="uid"/>
<jndiEntry jndiName="ibm.appcenter.ldap.user.base" value="dc=ibm,dc=com"/>
```

```

<jndiEntry jndiName="ibm.appcenter.ldap.group.base" value="dc=ibm,dc=com"/>
<jndiEntry jndiName="ibm.appcenter.ldap.user.displayName" value="sn"/>
<jndiEntry jndiName="ibm.appcenter.ldap.group.name" value="cn"/>
<jndiEntry jndiName="ibm.appcenter.ldap.group.uniquemember" value="uniqueMember"/>
<jndiEntry jndiName="ibm.appcenter.ldap.user.groupmembership" value="ibm-allGroups"/>
<jndiEntry jndiName="ibm.appcenter.ldap.cache.expiration.seconds" value="43200"/>
<jndiEntry jndiName="ibm.appcenter.ldap.security.sasl" value="EXTERNAL"/>
<jndiEntry jndiName="ibm.appcenter.ldap.referral" value="follow"/>
<jndiEntry jndiName="ibm.appcenter.ldap.user.filter" value="(&uid=%v)(objectclass=inetOrgPer
<jndiEntry jndiName="ibm.appcenter.ldap.user.displayName.filter" value="(&cn=%v)(objectclass
<jndiEntry jndiName="ibm.appcenter.ldap.group.filter" value="(&cn=%v)(objectclass=groupOfM

```

LDAP with Apache Tomcat:

Configure the Apache Tomcat server for LDAP authentication and configure security (Java™ Platform, Enterprise Edition) in the `web.xml` file of the Application Center.

To configure ACL management of the Application Center; configure LDAP for user authentication, map the Java Platform, Enterprise Edition (Java EE) roles of the Application Center to the LDAP roles, and configure the Application Center properties for LDAP authentication. Only the simple type of LDAP authentication is supported.

Configuration of LDAP authentication (Apache Tomcat):

Define the users who can access the Application Center console and the users who can log in with the mobile client by mapping Java Platform, Enterprise Edition roles to LDAP roles.

Purpose

To configure ACL management of the Application Center, follow this process:

1. Configure LDAP for user authentication.
2. Map the Java Platform, Enterprise Edition (Java EE) roles of the Application Center to the LDAP roles.
3. Configure the Application Center properties for LDAP authentication.

Restriction: Only the simple type of LDAP authentication is supported.

You configure the Apache Tomcat server for LDAP authentication and configure security (Java™ Platform, Enterprise Edition) in the `web.xml` file of the Application Center Services web application (`applicationcenter.war`) and of the Application Center Console web application (`appcenterconsole.war`).

LDAP user authentication

You must configure a `JNDIRealm` in the `server.xml` file in the `<Host>` element. For more information about configuring a realm, see the Realm Component on the Apache Tomcat website.

Example of configuration on Apache Tomcat to authenticate against an LDAP server

This example shows how to configure user authentication on an Apache Tomcat server by comparing with the authorization of these users on a server enabled for LDAP authentication.

```

<Host appBase="webapps" autoDeploy="true" name="localhost" unpackWARs="true">
  ...
<Realm className="org.apache.catalina.realm.JNDIRealm"
  connectionURL="ldap://bluepages.ibm.com:389"
  userSubtree="true"
  userBase="ou=bluepages,o=ibm.com"
  userSearch="(emailAddress={0})"
  roleBase="ou=ibmgroups,o=ibm.com"
  roleName="cn"
  roleSubtree="true"
  roleSearch="(uniqueMember={0})"
  allRolesMode="authOnly"
  commonRole="appcenter"/>
  ...
</Host>

```

The value of **connectionURL** is the LDAP URL of your LDAP server.

The **userSubtree**, **userBase**, and **userSearch** attributes define how to use the name that is given to the Application Center in login form (in the browser message box) to match an LDAP user entry.

In the example, the definition of **userSearch** specifies that the user name is used to match the email address of an LDAP user entry.

The basis or scope of the search is defined by the value of the **userBase** attribute. In LDAP, an information tree is defined; the user base indicates a node in that tree.

Set the value of **userSubtree** to true; if it is set to false, the search runs only on the direct child nodes of the user base. It is important that the search penetrates the subtree and does not stop at the first level.

For authentication, you define only the **userSubtree**, **userBase**, and **userSearch** attributes. The Application Center also uses Java EE security roles. Therefore, you must map LDAP attributes to some Java EE roles. These attributes are used for mapping LDAP attributes to security roles:

- **roleBase**
- **roleName**
- **roleSubtree**
- **roleSearch**

In this example, the value of the **roleSearch** attribute matches all LDAP entries with a **uniqueMember** attribute whose value is the Distinguished Name (DN) of the authenticated user.

- The **roleBase** attribute specifies a node in the LDAP tree below which the roles are defined.
- The **roleSubtree** attribute indicates whether the LDAP search should search the entire subtree, whose root is defined by the value of **roleBase**, or only the direct child nodes.
- The **roleName** attribute defines the name of the LDAP attribute.
- The **allRolesMode** attribute specifies that you can use the asterisk (*) character as the value of **role-name** in the web.xml file. This attribute is optional.
- The **commonRole** attribute adds a role that is shared by all authenticated users. This attribute is optional.

Mapping the Java EE roles of the Application Center to LDAP roles

After you define the LDAP request for the Java EE roles, you must change the `web.xml` file of the Application Center Services web application (`applicationcenter.war`) and of the Application Center Console web application (`appcenterconsole.war`) to map the Java EE roles of `appcenteradmin` and `appcenteruser` to the LDAP roles.

These examples, where LDAP users have LDAP roles, called `MyLdapAdmin` and `MyLdapUser`, show where and how to change the `web.xml` file. Replace the names `MyLdapAdmin` and `MyLdapUser` with the roles that are defined in your LDAP. Modify the following files:

- `tomcat_install_dir/webapps/appcenterconsole/WEB-INF/web.xml`
- `tomcat_install_dir/webapps/applicationcenter/WEB-INF/web.xml`

The `security-role-ref` element in the `JAX_RS` servlet

```
<servlet>
  <servlet-name>...</servlet-name>
  <servlet-class>...</servlet-class>
  <init-param>
    ...
  </init-param>
  <load-on-startup>1</load-on-startup>
  <security-role-ref>
    <role-name>appcenteradmin</role-name>
    <role-link>MyLdapAdmin</role-link>
  </security-role-ref>
  <security-role-ref>
    <role-name>appcenteruser</role-name>
    <role-link>MyLdapUser</role-link>
  </security-role-ref>
</servlet>
```

The `security-role` element

```
<security-role>
  <role-name>MyLdapAdmin</role-name>
</security-role>
<security-role>
  <role-name>MyLdapUser</role-name>
</security-role>
```

The `auth-constraint` element

After you edit the `security-role-ref` and the `security-role` elements, you can use the roles that are defined in the `auth-constraint` elements to protect the web resources. Edit these roles for the `appcenteradminConstraint` element in both the `web.xml` file of both `appcenterconsole` and `applicationcenter`, and for the `appcenteruserConstraint` element in the `appcenterconsole` `web.xml` file.

```
<security-constraint>
  <display-name>appcenteradminConstraint</display-name>
  <web-resource-collection>
    ...
  </web-resource-collection>
  <auth-constraint>
    <role-name>MyLdapAdmin</role-name>
  </auth-constraint>
  <user-data-constraint>
    ...
  </user-data-constraint>
</security-constraint>
```

```

and
<security-constraint>
  <display-name>appcenteruserConstraint</display-name>
  <web-resource-collection>
    ...
  </web-resource-collection>
  <auth-constraint>
    <role-name>MyLdapUser</role-name>
  </auth-constraint>
  <user-data-constraint>
    ...
  </user-data-constraint>
</security-constraint>

```

Configuring LDAP ACL management (Apache Tomcat):

Use LDAP to define the users and groups who can install mobile applications with the Application Center by defining the Application Center LDAP properties through JNDI.

Purpose

To configure LDAP ACL management of the Application Center, add an entry for each property in the <context> section of the IBM Application Center Services application in the server.xml file. This entry must have the following syntax:

```
<Environment name="JNDI_property_name" value="property_value" type="java.lang.String" override="false">
```

Where:

- The JNDI_property_name parameter is the name of the property that you are adding.
- The property_value parameter is the value of the property that you are adding.

Table 6-55. Properties for configuring ACL management for LDAP in the server.xml file on Apache Tomcat

Property	Description
ibm.appcenter.ldap.active	Set to true to enable LDAP; set to false to disable LDAP.
ibm.appcenter.ldap.connectionURL	LDAP connection URL.
ibm.appcenter.ldap.user.base	Search base of users.
ibm.appcenter.ldap.user.loginName	LDAP login attribute.
ibm.appcenter.ldap.user.displayName	LDAP attribute for the user name to be displayed, for example, a person's full name.
ibm.appcenter.ldap.group.base	Search base of groups.
ibm.appcenter.ldap.group.name	LDAP attribute for the group name.
ibm.appcenter.ldap.group.uniqueMemberID	LDAP attribute that identifies the members of a group.
ibm.appcenter.ldap.user.groupmemberships	LDAP attribute that identifies the groups to which a user belongs.
ibm.appcenter.ldap.group.nesting	Management of nested groups: if nested groups are not managed, set the value to false.

Table 6-55. Properties for configuring ACL management for LDAP in the `server.xml` file on Apache Tomcat (continued)

Property	Description
ibm.appcenter.ldap.user.filter	<p>LDAP user search filter for the attribute of user login name. Use %v as the placeholder for the login name attribute.</p> <p>This property is only required when LDAP users and groups are defined in the same subtree; that is, when the properties ibm.appcenter.ldap.user.base and ibm.appcenter.ldap.group.base have the same value.</p>
ibm.appcenter.ldap.displayName.filter	<p>LDAP user search filter for the attribute of user display name. Use %v as the placeholder for the display name attribute.</p> <p>This property is only required when LDAP users and groups are defined in the same subtree; that is, when the properties ibm.appcenter.ldap.user.base and ibm.appcenter.ldap.group.base have the same value.</p>
ibm.appcenter.ldap.group.filter	<p>LDAP group search filter. Use %v as the placeholder for the group attribute.</p> <p>This property is only required when LDAP users and groups are defined in the same subtree; that is, when the properties ibm.appcenter.ldap.user.base and ibm.appcenter.ldap.group.base have the same value.</p>
ibm.appcenter.ldap.security.sasl	<p>The value of the security authentication mechanism when the LDAP external SASL authentication mechanism is required to bind to the LDAP server. The value depends on the LDAP server; usually, it is set to "EXTERNAL".</p>
ibm.appcenter.ldap.security.binddn	<p>Property that identifies the distinguished name of the user permitted to search the LDAP directory. Use this property only if security binding is required.</p>
ibm.appcenter.ldap.security.bindpwd	<p>Property that identifies the password of the user permitted to search the LDAP directory. Use this property only if security binding is required.</p>

Table 6-55. Properties for configuring ACL management for LDAP in the server.xml file on Apache Tomcat (continued)

Property	Description
ibm.appcenter.ldap.cache.expiration.seconds	<p>seconds before the LDAP cache expires. If no value is entered, the default value is 86400, which is equal to 24 hours.</p> <p>Changes to users and groups on the LDAP server become visible to the Application Center after a delay, which is specified by ibm.appcenter.ldap.cache.expiration.seconds. The Application Center maintains a cache of LDAP data and the changes only become visible after the cache expires. By default, the delay is 24 hours. If you do not want to wait for this delay to expire after changes to users or groups, you can call this command to clear the cache of LDAP data:</p> <pre>acdeploytool.sh -clearLdapCache -s serverurl -c context -u user -p password</pre> <p>See Using the stand-alone tool to clear the LDAP cache for details.</p>
ibm.appcenter.ldap.referral	<p>Property that indicates whether referrals are supported by the JNDI API. If no value is given, the JNDI API will not handle LDAP referrals. Possible values are:</p> <ul style="list-style-type: none"> • ignore: ignores referrals found in the LDAP server. • follow: automatically follows any referrals found in the LDAP server. • throw: causes an exception to occur for each referral found in the LDAP server.

See “List of JNDI properties for the Application Center” on page 6-307 for a complete list of LDAP properties that you can set.

Example

The example shows LDAP properties that are defined in the server.xml file.

```
<Environment name="ibm.appcenter.ldap.active" value="true" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.connectionURL" value="ldaps://employees.com:636" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.user.base" value="dc=ibm,dc=com" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.user.loginName" value="uid" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.user.displayName" value="cn" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.user.groupmembership" value="ibm-allGroups" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.group.base" value="dc=ibm,dc=com" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.group.name" value="cn" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.group.uniquemember" value="uniquemember" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.cache.expiration.seconds" value="43200" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.security.sasl" value="EXTERNAL" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.security.referral" value="follow" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.user.filter" value="(&uid=%v)(objectclass=inetOrgPerson)" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.user.displayName.filter" value="(&cn=%v)(objectclass=inetOrgPerson)" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.ldap.group.filter" value="(&cn=%v)(objectclass=groupOfNames)" type="java.lang.String" override="false"/>
```

Configuring properties of DB2 JDBC driver in WebSphere Application Server

Add some JDBC custom properties to avoid DB2 exceptions from a WebSphere Application Server that uses the IBM DB2 database.

About this task

When you use WebSphere Application Server with an IBM DB2 database, this exception could occur:

```
Invalid operation: result set is closed. ERRORCODE=-4470, SQLSTATE=null
```

To avoid such exceptions, you must add custom properties in WebSphere Application Server at the Application Center data source level.

Procedure

1. Log in to the WebSphere Application Server administration console.
2. Select **Resources > JDBC > Data sources > Application Center DataSource name > Custom properties** and click **New**.
3. In the **Name** field, enter **allowNextOnExhaustedResultSet**.
4. In the **Value** field, type 1.
5. Change the type to `java.lang.Integer`.
6. Click **OK**.
7. Click **New**.
8. In the **Name** field, enter **resultSetHoldability**.
9. In the **Value** field, type 1.
10. Change the type to `java.lang.Integer`.
11. Click **OK** and save your changes.

Managing the DB2 transaction log size

When you upload an application that is at least 40 MB with IBM MobileFirst Platform Application Center console, you might receive a transaction log full error.

About this task

The following system output is an example of the transaction log full error code.

```
DB2 SQL Error: SQLCODE=-964, SQLSTATE=57011
```

The content of each application is stored in the Application Center database.

The active log files are defined in number by the **LOGPRIMARY** and **LOGSECOND** database configuration parameters, and in size by the **LOGFILSIZ** database configuration parameter. A single transaction cannot use more log space than **LOGFILSZ * (LOGPRIMARY + LOGSECOND) * 4096 KB**.

The **DB2 GET DATABASE CONFIGURATION** command includes information about the log file size, and the number of primary and secondary log files.

Depending on the largest size of the MobileFirst application that is deployed, you might need to increase the DB2 log space.

Procedure

Using the **DB2 update db cfg** command, increase the **LOGSECOND** parameter. Space is not allocated when the database is activated. Instead, the space is allocated only as needed.

Defining the endpoint of the application resources

When you add a mobile application from the Application Center console, the server-side component creates Uniform Resource Identifiers (URI) for the application resources (package and icons). The mobile client uses these URI to manage the applications on your device.

Purpose

To manage the applications on your device, the Application Center console must be able to locate the Application Center REST services and to generate the required number of URI that enable the mobile client to find the Application Center REST services.

By default, the URI protocol, host name, and port are the same as those defined in the web application server used to access the Application Center console; the context root of the Application Center REST services is `applicationcenter`. When the context root of the Application Center REST services is changed or when the internal URI of the web application server is different from the external URI that can be used by the mobile client, the externally accessible endpoint (protocol, host name, and port) of the application resources must be defined by configuring the web application server. (Reasons for separating internal and external URI could be, for example, a firewall or a secured reverse proxy that uses HTTP redirection.)

The following figure shows a configuration with a secured reverse proxy that hides the internal address (192.168...). The mobile client must use the external address (**appcntr.net**).

Figure 6-28. Configuration with secured reverse proxy

Table 6-56. The endpoint properties

Property name	Purpose	Example
ibm.appcenter.services.endpoint	This property enables the Application Center console to locate the Application Center REST services. The value of this property must be specified as the external address and context root of the applicationcenter.war web application. You can use the asterisk (*) character as wildcard to specify that the Application Center REST services use the same value as the Application Center console. For example: <code>*://*/*/appcenter</code> means use the same protocol, host, and port as the Application Center console, but use appcenter as context root. This property must be specified for the Application Center console application.	<code>https://appcntr.net:443/applicationcenter</code>
ibm.appcenter.proxy.protocol	This property specifies the protocol required for external applications to connect to the Application Center.	https
ibm.appcenter.proxy.host	This property specifies the host name required for external applications to connect to the Application Center.	appcntr.net
ibm.appcenter.proxy.port	This property specifies the port required for external applications to connect to the Application Center.	443

See “List of JNDI properties for the Application Center” on page 6-307 for a complete list of endpoint properties that you can set.

Configuring the endpoint of application resources (full profile):

For the WebSphere Application Server full profile, configure the endpoint of the application resources in the environment entries of the Application Center services and the Application Center console applications. The procedure differs depending on whether you deployed WAR files or an EAR file.

If you deployed WAR files:

About this task

Follow this procedure when you must change the URI protocol, host name, and port used by the mobile client to manage the applications on your device. Since IBM Worklight V6.0, you use JNDI environment entries.

For a complete list of JNDI properties, see “List of JNDI properties for the Application Center” on page 6-307.

Procedure

1. Log in to the WebSphere Application Server console.
2. Select **Applications > Application Types > WebSphere enterprise applications**.
3. Click **IBM Application Center Services**.
4. In the Web Module Properties section, select **Environment entries for Web modules**.
5. Assign the appropriate values for the following environment entries:
 - a. For **ibm.appcenter.proxy.host**, assign the host name.
 - b. For **ibm.appcenter.proxy.port**, assign the port number.
 - c. For **ibm.appcenter.proxy.protocol**, assign the external protocol.
 - d. Click **OK** and save the configuration.
6. Select **Applications > Application Types > WebSphere enterprise applications**.
7. Click **IBM Application Center Console**.
8. In the Web Module Properties section, select **Environment entries for Web modules**.
9. For **ibm.appcenter.services.endpoint**, assign the full URI of the Application Center REST services (the URI of the `applicationcenter.war` file).
 - In a scenario with a firewall or a secured reverse proxy, this URI must be the external URI and not the internal URI inside the local LAN.
 - You can use the asterisk (*) character as wildcard to specify that the Application Center REST services use the same value as the Application Center console.

For example: `*://*/*/appcenter` means use the same protocol, host, and port as the Application Center console, but use `appcenter` as the context root.
10. Click **OK** and save the configuration.

If you deployed an EAR file:

Procedure

1. Log in to the WebSphere Application Server console.
2. Select **Applications > Application Types > WebSphere enterprise applications**.
3. Click **AppCenterEAR**.
4. In the Web Module Properties section, select **Environment entries for Web modules**.
5. Assign the appropriate values for the following environment entries:
 - a. For **ibm.appcenter.proxy.host**, assign the host name.
 - b. For **ibm.appcenter.proxy.port**, assign the port number.
 - c. For **ibm.appcenter.proxy.protocol**, assign the external protocol.
6. For **ibm.appcenter.services.endpoint**, assign the full URI of the Application Center REST services (the URI of the `applicationcenter.war` file).
 - In a scenario with a firewall or a secured reverse proxy, this URI must be the external URI and not the internal URI inside the local LAN.
 - You can use the asterisk (*) character as wildcard to specify that the Application Center REST services use the same value as the Application Center console.

For example: `*://*:*/appcenter` means use the same protocol, host, and port as the Application Center console, but use `appcenter` as the context root.

7. Click **OK** and save the configuration.

Configuring the endpoint of the application resources (Liberty profile):

For the Liberty profile, configure the endpoint of the application resources through the JNDI environment.

Purpose

Since IBM Worklight V6.0, follow this procedure when you must change the URI protocol, host name, and port used by the Application Center client to manage the applications on your device.

Properties

Edit the `server.xml` file. To be able to define JNDI entries, the **<feature>** element must be defined correctly in the `server.xml` file:

```
<feature>jndi-1.0</feature>
```

Add an entry for each property in the `<server>` section of the `server.xml` file. This entry should have the following syntax:

```
<jndiEntry jndiName="JNDI_property_name" value="property_value"/>
```

Where:

`JNDI_property_name` is the name of the property that you are adding.

`property_value` is the value of the property that you are adding.

Table 6-57. Properties in the server.xml file for configuring the endpoint of the application resources

Property	Description
ibm.appcenter.services.endpoint	The URI of the Application Center REST services. In a scenario with a firewall or a secured reverse proxy, this URI must be the external URI and not the internal URI inside the local LAN.
ibm.appcenter.proxy.protocol	The protocol of the application resources URI. This property is optional. It is only needed if the protocol of the external and of the internal URI are different.
ibm.appcenter.proxy.host	The host name of the application resources URI.
ibm.appcenter.proxy.port	The port of the application resources URI. This property is optional. It is only needed if the protocol of the external and of the internal URI are different.

For a complete list of LAPD properties that you can set, see “List of JNDI properties for the Application Center” on page 6-307.

Example of setting properties for configuring the endpoint

This example shows the settings of the properties in the `server.xml` file required for configuring the endpoint of the application resources.

```
<jndiEntry jndiName="ibm.appcenter.services.endpoint" value=" https://appcntr.net:443/applicationcenter" />
<jndiEntry jndiName="ibm.appcenter.proxy.protocol" value="https" />
<jndiEntry jndiName="ibm.appcenter.proxy.host" value="appcntr.net" />
<jndiEntry jndiName="ibm.appcenter.proxy.port" value=" 443"/>
```

You can use the asterisk (*) character as wildcard to specify that the Application Center REST services use the same value as the Application Center console. For example: `*://*:*/*/appcenter` means use the same protocol, host, and port as the Application Center console, but use `appcenter` as context root.

Configuring the endpoint of the application resources (Apache Tomcat):

For the Apache Tomcat server, configure the endpoint of the application resources in the `server.xml` file.

Purpose

Since IBM Worklight V6.0, follow this procedure when you must change the URI protocol, host name, and port used by the Application Center client to manage the applications on your device.

Properties

Edit the `server.xml` file in the `conf` directory of your Apache Tomcat installation.

Add an entry for each property in the `<context>` section of the corresponding application. This entry should have the following syntax:

```
<Environment name="JNDI_property_name" value="property_value" type="property_type" override="false"/>
```

Where:

`JNDI_property_name` is the name of the property you are adding.

`property_value` is the value of the property you are adding.

`property_type` is the type of the property you are adding.

Table 6-58. Properties in the `server.xml` file for configuring the endpoint of the application resources

Property	Type	Description
ibm.appcenter.services.endpoint	<code>java.lang.String</code>	The URI of the Application Center REST services (<code>applicationcenter.war</code>). In a scenario with a firewall or a secured reverse proxy, this URI must be the external URI and not the internal URI inside the local LAN.
ibm.appcenter.proxy.protocol	<code>java.lang.String</code>	The protocol of the application resources URI. This property is optional. It is only needed if the protocol of the external and of the internal URI are different.
ibm.appcenter.proxy.host	<code>java.lang.String</code>	The host name of the application resources URI.

Table 6-58. Properties in the server.xml file for configuring the endpoint of the application resources (continued)

Property	Type	Description
ibm.appcenter.proxy.port	java.lang.Integer	The port of the application resources URI. This property is optional. It is only needed if the protocol of the external and of the internal URI are different.

For a complete list of JNDI properties that you can set, see “List of JNDI properties for the Application Center” on page 6-307.

Example of setting server.xml properties for configuring the endpoint

This example shows the settings of the properties in the server.xml file required for configuring the endpoint of the application resources.

In the <context> section of the Application Center console application:

```
<Environment name="ibm.appcenter.services.endpoint" value="https://appcntr.net:443/applicationcenter" type="java.lang.String" override="false"/>
```

You can use the asterisk (*) character as wildcard to specify that the Application Center REST services use the same value as the Application Center console. For example: */*/*/appcenter means use the same protocol, host, and port as the Application Center console, but use appcenter as context root.

In the <context> section of the Application Center services application:

```
<Environment name="ibm.appcenter.services.endpoint" value="https://appcntr.net:443/applicationcenter" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.proxy.protocol" value="https" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.proxy.host" value="appcntr.net" type="java.lang.String" override="false"/>
<Environment name="ibm.appcenter.proxy.port" value="443" type="java.lang.Integer" override="false"/>
```

Configuring Secure Sockets Layer (SSL)

Learn about configuring SSL for the Application Center on supported application servers and the limitations of certificate verification on mobile operating systems.

You can configure the Application Center with SSL or without SSL, **unless** you intend to install applications on iOS devices. For iOS applications, you must configure the Application Center server with SSL and enable the TLS v1.2 protocol.

SSL transmits data over the network in a secured channel. You must purchase an official SSL certificate from an SSL certificate authority. The SSL certificate must be compatible with Android, iOS, and BlackBerry OS 6 and 7. Self-signed certificates do not work with the Application Center.

When the client accesses the server through SSL, the client verifies the server through the SSL certificate. If the server address matches the address filed in the SSL certificate, the client accepts the connection. For the verification to be successful, the client must know the root certificate of the certificate authority. Many root certificates are preinstalled on Android, iOS, and BlackBerry devices. The exact list of preinstalled root certificates varies between versions of mobile operating systems.

You should consult the SSL certificate authority for information about the mobile operating system versions that support its certificates.

If the SSL certificate verification fails, a normal web browser requests confirmation to contact an untrusted site. The same behavior occurs when you use a self-signed certificate that was not purchased from a certificate authority. When mobile applications are installed, this control is not performed by a normal web browser, but by operating system calls.

Some versions of Android, iOS, and Windows Phone operating systems do not support this confirmation dialog in system calls. This limitation is a reason to avoid self-signed certificates or SSL certificates that are not suited to mobile operating systems. On Android, iOS, and Windows Phone operating systems, you can install a self-signed CA certificate on the device to enable the device to handle system calls with respect to this self-signed certificate. This practice is not appropriate for Application Center in a production environment, but it may be suitable during the testing period. For details, see “Configuring SSL by using untrusted certificates” on page 6-193 and “Managing and installing self-signed CA certificates in an Application Center test environment” on page 6-304.

The following topics describe how to enable SSL on the application servers. If your server is behind a reverse proxy that decrypts the SSL-encoded packets before passing them the application server, you must configure this reverse proxy. For IBM HTTP Server, see the IHS documentation.

Configuring SSL for WebSphere Application Server full profile:

Request a Secure Sockets Layer (SSL) certificate and process the received documents to import them into the keystore.

About this task

This procedure indicates how to request an SSL certificate and import it and the chain certificate into your keystore.

Procedure

1. Create a request to a certificate authority; in the WebSphere administrative console, select **Security > SSL certificate and key management > Key stores and certificates > keystore > Personal certificate requests > New**.

Where *keystore* identifies your keystore.

The request is sent to the certificate authority.

2. When you receive the SSL certificate, import it and the corresponding chain certificate into your keystore by following the instructions provided by the certificate authority. In the WebSphere administrative console, you can find the corresponding option in **Security > SSL certificate and key management > Manage endpoint security configurations > node SSL settings > Key stores and certificates > keystore > Personal certificates > certificate > Receive a certificate from a certificate authority**.

Where:

- *node SSL settings* shows the SSL settings of the nodes in your configuration.
- *keystore* identifies your keystore.
- *certificate* identifies the certificate that you received.

3. Create an SSL configuration. See the instructions in the user documentation that corresponds to the version of the WebSphere Application Server full profile that supports your applications.

You can find configuration details in the WebSphere administrative console at **Security > SSL certificate and key management > Manage endpoint security configurations > SSL Configurations**.

To enable TLS v1.2, which is required for iOS9, the collection of all SSL configurations is listed.

4. For each SSL configuration in the list, modify the SSL protocol to use SSL_TLSv2.
 - a. Select an SSL Configuration and then, under **Additional Properties**, click **Quality of protection (QoP) settings**.
 - b. In **Quality of protection (QoP) settings**, from **Protocol**, select **SSL_TLSv2**.
 - c. Select **Apply** and then **Save**.
 - d. Make sure that the JRE supports the TLS v1.2 protocol. Use a JRE described in IBM Security Bulletin Vulnerability in SSLv3 affects IBM WebSphere Application Server (CVE-2014-3566) or later.

Configuring SSL for Liberty profile:

Create a keystore, import the Secure Socket Layer (SSL) certificate, and edit the `server.xml` file to configure SSL on Liberty profile.

About this task

Follow the steps in this procedure to configure SSL on Liberty profile.

Procedure

1. Create a keystore for your web server; use the `securityUtility` with the `createSSLCertificate` option. See Enabling SSL communication for the Liberty profile for more information.
2. Import the SSL certificate and the corresponding chain certificate into your keystore by following the instructions provided by the certificate authority.
3. Enable the `ssl-1.0` Liberty feature in the `server.xml` file.

```
<featureManager>
  <feature>ssl-1.0</feature>
</featureManager>
```
4. Add the keystore service object entry to the `server.xml` file. The `keyStore` element is called `defaultKeyStore` and contains the keystore password. For example:

```
<keyStore id="defaultKeyStore" location="/path/to/myKeyStore.p12"
  password="myPassword" type="PKCS12"/>
```
5. Make sure that the value of the `httpEndpoint` element in the `server.xml` file defines the `httpsPort` attribute. For example:

```
<httpEndpoint id="defaultHttpEndpoint" host="*" httpPort="9080" httpsPort="9443" >
```
6. Enable TLS v1.2, which is required for iOS9.
 - a. If you use an IBM Java SDK, add the following line to the `server.xml` file:

```
<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore" sslProtocol="SSL_TLSv2"/>
```
 - b. To all existing `<ssl>` elements, add `sslProtocol="SSL_TLSv2"`. You must use a JRE that supports the TLS v1.2 protocol. Use a JRE described in IBM

Security Bulletin Vulnerability in SSLv3 affects IBM WebSphere Application Server (CVE-2014-3566) or later, or Oracle JRE 1.7.0_75 or later, or Oracle JRE 1.8.0_31 or later.

- Restart the web server. Now you can access the web server by `https://myserver:9443/...`

Configuring SSL for Apache Tomcat:

Create a keystore, import the Secure Socket Layer (SSL) certificate, and edit the `conf/server.xml` file to define a connector for SSL on Apache Tomcat.

About this task

Follow the steps in this procedure to configure SSL on Apache Tomcat. See SSL Configuration HOW-TO for more details and examples of configuring SSL for Apache Tomcat.

Procedure

- Create a keystore for your web server. You can use the Java **keytool** command to create a keystore.

```
keytool -genkey -alias tomcat -keyalg RSA -keystore /path/to/keystore.jks
```

- Import the SSL certificate and the corresponding chain certificate into your keystore by following the instructions provided by the certificate authority.
- Edit the `conf/server.xml` file to define a connector to use SSL. This connector must point to your keystore.

```
<Connector port="8443" protocol="HTTP/1.1" SSLEnabled="true"
  maxThreads="150" scheme="https" secure="true"
  clientAuth="false" sslProtocol="TLS"
  keystoreFile="/path/to/keystore.jks"
  keystorePass="mypassword" />
```

- To enable TLS v1.2, which is required for iOS9, add the following attribute to the `<Connector>` element:

```
sslEnabledProtocols="TLSv1.2,TLSv1.1,TLSv1,SSLv2Hello"
```

The result should be similar to this example:

```
<Connector port="8443" protocol="HTTP/1.1" SSLEnabled="true"
  maxThreads="150" scheme="https" secure="true"
  clientAuth="false" sslProtocol="TLS"
  keystoreFile="/path/to/keystore.jks"
  sslEnabledProtocols="TLSv1.2,TLSv1.1,TLSv1,SSLv2Hello"
  keystorePass="mypassword" />
```

You must use a JRE that supports TLS v1.2.

- Oracle JRE 1.7.0_75 or later
 - Oracle JRE 1.8.0_31 or later
- Restart the web server. Now you can access the web server by `https://myserver:8443/...`

Managing and installing self-signed CA certificates in an Application Center test environment:

Use self-signed certificate authority (CA) certificates in test environments to install applications with Application Center on a mobile device from a secured server.

Uploading or deleting a certificate:

Before you begin

When you install the Application Center mobile client from OTA (the bootstrap page), the device user must upload and install the self-signed CA file before the Application Center mobile client is installed.

About this task

When you use Application Center for a test installation, the administrator might not have a real Secure Sockets Layer (SSL) certificate available. You might want to use a self-signed CA certificate. Such certificates work if they get installed on the device as root certificate. For the basic concepts of CA certificates and further details about such certificates, see “Configuring SSL by using untrusted certificates” on page 6-193.

As an administrator, you can easily distribute self-signed CA certificates to devices.

The following procedure focuses mostly on the iOS and Android environments. Support for X.509 certificates comes from the individual mobile platforms, not from IBM MobileFirst Platform Foundation. For more information about specific requirements for X.509 certificates, see the documentation of each mobile platform.

Procedure

Managing self-signed certificates: in your role of administrator of Application Center, you can access the list of registered self-signed CA certificates to upload or delete certificates.

1. To display Application Center settings, click the gear icon .
2. To display the list of registered certificates, select **Self Signed Certificates**.
3. Upload or delete a certificate.
 - To upload a self-signed CA certificate, in the Application Center console, click **Upload a certificate** and select a certificate file.

Note: The certificate file must be in PEM file format. Typical file name suffixes for this type of file are .pem, .key, .cer, .cert. The certificate must be a self-signed one, that is, the values of the **Issuer** and **Subject** fields must be the same. And the certificate must be a CA certificate, that is, it must have the X509 extension named BasicConstraint set to CA:TRUE.

- To delete a certificate, click the trash can icon on the right of the certificate file name in the list.

Installing a self-signed CA certificate on a device:

About this task

Registered self-signed CA certificates are available through the bootstrap page at `http://hostname:portnumber/appcenterconsole/installers.html`

Where:

- *hostname* is the name of the server that hosts the Application Center console.
- *portnumber* is the corresponding port number.

Procedure

1. Click the **SSL Certificates** tab.

2. To display the details of a certificate, select the appropriate registered certificate.
3. To download and install the certificate on the device, click **Install**.

Troubleshooting SSL:

Learn how to troubleshoot SSL configurations.

The topics in this section describe how to resolve various situations that might occur in different SSL configurations.

Incompatibility between SSL certificate and mobile devices:

Resolve the situation when an SSL certificate is not compatible with mobile devices.

Symptoms

You cannot connect to the web server, either through the browser when you open the `installers.html` page, or through the mobile client; you cannot download any application from the Application Center web server.

Causes

Different mobile devices recognize different trusted root certificates.

Resolving the problem

User response: Contact the certificate authority for information about compatibility of the certificate with mobile devices.

SSL certificate is incompatible with browser, but compatible with mobile operating system:

Resolve the situation where you cannot install applications from the Application Center website, but can see the website.

Symptoms

You cannot connect to the web server, either through the browser when you open the `installers.html` page, or through the mobile client; you cannot download any application from the Application Center web server. This situation can occur in particular with iOS and Microsoft Windows Phone operating systems.

Causes

The installation procedure is done by the iOS or Windows Phone operating system; the trusted root certificates of the operating system might not be the same as the trusted root certificates of the browser.

Resolving the problem

User response: Contact the certificate authority for information about compatibility of the certificate with mobile devices.

Apache Tomcat: cannot connect to Android devices after correction of LogJam/WeakDH vulnerability:

Resolve the situation when you cannot connect to Android devices and the application server is Apache Tomcat.

Symptoms

You cannot connect to the web server, either through the browser when you open the `installers.html` page, or through the mobile client; you cannot download any application from the Application Center web server.

Causes

This situation occurs if Apache Tomcat runs with Oracle Java 8. The official WeakDH vulnerability fix (<https://weakdh.org>) is incompatible with some Android 5.x devices.

Resolving the problem

User response: Edit the `server.xml` file to modify the `<Connector>` element and enable the following ciphers:

```
<Connector ... SSLEnabled="true" scheme="https" secure="true" ciphers="TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA,
TLS_ECDHE_RSA_WITH_RC4_128_SHA,TLS_RSA_WITH_AES_128_CBC_SHA256,TLS_RSA_WITH_AES_128_CBC_SHA,
TLS_RSA_WITH_AES_256_CBC_SHA256,TLS_RSA_WITH_AES_256_CBC_SHA,SSL_RSA_WITH_RC4_128_SHA,
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256,
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384,TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,
TLS_DHE_DSS_WITH_AES_128_GCM_SHA256,TLS_ECDHE_RSA_WITH_AES_128_SHA256,TLS_ECDHE_ECDSA_WITH_AES_128_SHA256,
TLS_ECDHE_RSA_WITH_AES_128_SHA,TLS_ECDHE_ECDSA_WITH_AES_128_SHA,TLS_ECDHE_RSA_WITH_AES_256_SHA384,
TLS_ECDHE_ECDSA_WITH_AES_256_SHA384,TLS_ECDHE_RSA_WITH_AES_256_SHA,TLS_ECDHE_ECDSA_WITH_AES_256_SHA,
TLS_DHE_RSA_WITH_AES_128_SHA256,TLS_DHE_RSA_WITH_AES_128_SHA,TLS_DHE_DSS_WITH_AES_128_SHA256,
TLS_DHE_RSA_WITH_AES_256_SHA256,TLS_DHE_DSS_WITH_AES_256_SHA,TLS_DHE_RSA_WITH_AES_256_SHA" />
```

List of JNDI properties for the Application Center

You can configure JNDI properties for the Application Center.

Table 6-59. List of the JNDI properties for the Application Center.

Property	Description
<code>appcenter.database.type</code>	The database type, which is only required when the database is not specified in <code>appcenter.jndi.name</code> .
<code>appcenter.jndi.name</code>	The JNDI name of the database. This parameter is the normal mechanism to specify the database. The default value is <code>java:comp/env/jdbc/AppCenterDS</code> .
<code>appcenter.openjpa.ConnectionDriverName</code>	The fully qualified class name of the database connection driver class. This property is only needed when the database is not specified in <code>appcenter.jndi.name</code> .
<code>appcenter.openjpa.ConnectionPassword</code>	The password for the database connection. This property is only needed when the database is not specified in <code>appcenter.jndi.name</code> .
<code>appcenter.openjpa.ConnectionURL</code>	The URL specific to the database connection driver class. This property is only needed when the database is not specified in <code>appcenter.jndi.name</code> .
<code>appcenter.openjpa.ConnectionUserName</code>	The user name or the database connection. This property is only needed when the database is not specified in <code>appcenter.jndi.name</code> .
<code>ibm.appcenter.apns.p12.certificateSystemDevelopmentCertificate</code>	System Development Certificate that enables Application Center to send push notifications about updates of iOS applications is a development certificate. Set to true to enable or false to disable. See “Configuring the Application Center server for connection to Apple Push Notification Services” on page 13-83.

Table 6-59. List of the JNDI properties for the Application Center (continued).

Property	Description
ibm.appcenter.apns.p12.certificate.location	Location to the file of the development certificate that enables Application Center to send push notifications about updates of iOS applications. For example, /Users/someUser/someDirectory/apache-tomcat/conf/AppCenter_apns_dev_cert.p12. See “Configuring the Application Center server for connection to Apple Push Notification Services” on page 13-83.
ibm.appcenter.apns.p12.certificate.password	Password of the certificate that enables Application Center to send push notifications about updates of iOS applications. See “Configuring the Application Center server for connection to Apple Push Notification Services” on page 13-83.
ibm.appcenter.forceUpgradeDBTo60	The database design was changed starting from IBM Worklight version 6.0. The database is automatically updated when the Application Center web application starts. If you want to repeat this update, you can set this parameter to true and start the web application again. Later you can set this parameter to false.
ibm.appcenter.gcm.signature.googleApiKey	Google API key that enables the Application Center to send push notifications about updates for Android applications. For example, AIxaScCHg0VSGdgf0ZKtzDJ44-oi0muUasMZvAs. See “Configuring the Application Center server for connection to Google Cloud Messaging” on page 13-82.
ibm.appcenter.ios.plist.onetimeurl	Specifies whether URLs stored in iOS plist manifests use the one-time URL mechanism without credentials. If you set this property to true, the security level is medium since the one-time URLs are generated with a cryptographic mechanism so that nobody can guess the URL. However, they do not require the user to log in when you use these URLs. Setting this property to false is maximally secure, since the user is then required to log in for each URL. However, requesting the user to log in multiple times when you install an iOS application can degrade the user experience. See “Installing the client on an iOS mobile device” on page 13-124.
ibm.appcenter.ldap.active	Specifies whether Application Center is configured for LDAP. Set to true to enable LDAP; set to false to disable LDAP. See “Managing users with LDAP” on page 6-274.

Table 6-59. List of the JNDI properties for the Application Center (continued).

Property	Description
ibm.appcenter.ldap.cache.expiration	<p>The Application Center maintains a cache of LDAP data and the changes become visible only after the cache expires. Specify the amount of time in seconds an entry in the LDAP cache is valid. Set this property to a value larger than 3600 (1 hour) to reduce the amount of LDAP requests. If no value is entered, the default value is 86400, which is equal to 24 hours.</p> <p>If you need to manually clear the cache of LDAP data, enter this command:</p> <pre>acdeploytool.sh -clearLdapCache -s serverurl -c context -u user</pre> <p>See Using the stand-alone tool to clear the LDAP cache for details.</p>
ibm.appcenter.ldap.connectionURL	The URL to access the LDAP server when no VMM is used. See “Configuring LDAP ACL management (Liberty profile)” on page 6-286 and “Configuring LDAP ACL management (Apache Tomcat)” on page 6-292.
ibm.appcenter.ldap.federated.active	Specifies whether Application Center is configured for LDAP with federated repositories. Since WebSphere Application Server Liberty Profile V8.5.5, set this property to true to enable use of the federated registry. Set this property to false to disable use of the federated registry, which is the default setting. See “Managing users with LDAP” on page 6-274.
ibm.appcenter.ldap.group.base	The search base to find groups when you use LDAP without VMM. See “Configuring LDAP ACL management (Liberty profile)” on page 6-286 and “Configuring LDAP ACL management (Apache Tomcat)” on page 6-292.
ibm.appcenter.ldap.group.filter	<p>LDAP group search filter. Use %v as the placeholder for the group attribute.</p> <p>This property is only required when LDAP users and groups are defined in the same subtree; that is, when the properties ibm.appcenter.ldap.user.base and ibm.appcenter.ldap.group.base have the same value.</p>
ibm.appcenter.ldap.group.name	The group name attribute when you use LDAP without VMM. See “Configuring LDAP ACL management (Liberty profile)” on page 6-286 and “Configuring LDAP ACL management (Apache Tomcat)” on page 6-292.
ibm.appcenter.ldap.group.nesting	Specifies whether the LDAP contains nested groups (that is, groups in groups) when you use LDAP without VMM. Setting this property to false speeds up the LDAP access since the groups are then not searched recursively. See “Configuring LDAP ACL management (Liberty profile)” on page 6-286 and “Configuring LDAP ACL management (Apache Tomcat)” on page 6-292.

Table 6-59. List of the JNDI properties for the Application Center (continued).

Property	Description
ibm.appcenter.ldap.group.uniquemembership	Specifies the members of a group when you use LDAP without VMM. This property is the inverse of ibm.appcenter.ldap.user.groupmembership . See “Configuring LDAP ACL management (Liberty profile)” on page 6-286 and “Configuring LDAP ACL management (Apache Tomcat)” on page 6-292.
ibm.appcenter.ldap.referral	Specifies whether referrals are supported by the JNDI API. If no value is given, the JNDI API does not handle LDAP referrals. Here are the possible values: <ul style="list-style-type: none"> ignore: ignores referrals that are found in the LDAP server. follow: automatically follows any referrals that are found in the LDAP server. throw: causes an exception to occur for each referral found in the LDAP server.
ibm.appcenter.ldap.security.binddn	The distinguished name of the user that is allowed to search the LDAP directory. Use this property only if security binding is required. The password can be encoded with the “Liberty Profile securityUtility” tool. Run the tool and then set the value of this property to the encoded password generated by the tool. The supported encoding types are xor and aes (only with the default key). Edit the Liberty Profile server.xml file to check whether the <i>classloader</i> is enabled to load the JAR file that decodes the password. See “Configuring LDAP ACL management (Apache Tomcat)” on page 6-292.
ibm.appcenter.ldap.security.bindpwd	The password of the user that is permitted to search the LDAP directory. Use this property only if security binding is required. See “Configuring LDAP ACL management (Apache Tomcat)” on page 6-292.
ibm.appcenter.ldap.security.sasl	Specifies the security authentication mechanism when the LDAP external SASL authentication mechanism is required to bind to the LDAP server. The value depends on the LDAP server and it is typically set to EXTERNAL. If set, security authentication is used when you connect to LDAP without VMM. See “Configuring LDAP ACL management (Liberty profile)” on page 6-286 and “Configuring LDAP ACL management (Apache Tomcat)” on page 6-292.
ibm.appcenter.ldap.user.base	The search base to find users when you use LDAP without VMM. See “Configuring LDAP ACL management (Liberty profile)” on page 6-286 and “Configuring LDAP ACL management (Apache Tomcat)” on page 6-292.
ibm.appcenter.ldap.user.displayName	The display name attribute, such as the user's real name, when you use LDAP without VMM. See “Configuring LDAP ACL management (Liberty profile)” on page 6-286 and “Configuring LDAP ACL management (Apache Tomcat)” on page 6-292.

Table 6-59. List of the JNDI properties for the Application Center (continued).

Property	Description
ibm.appcenter.ldap.displayName.filter	LDAP user search filter for the attribute of ibm.appcenter.ldap.user.displayName . Use %v as the placeholder for the display name attribute. This property is only required when LDAP users and groups are defined in the same subtree; that is, when the properties ibm.appcenter.ldap.user.base and ibm.appcenter.ldap.group.base have the same value.
ibm.appcenter.ldap.user.filter	LDAP user search filter for the attribute of ibm.appcenter.ldap.user.loginName . Use %v as the placeholder for the login name attribute. This property is only required when LDAP users and groups are defined in the same subtree; that is, when the properties ibm.appcenter.ldap.user.base and ibm.appcenter.ldap.group.base have the same value.
ibm.appcenter.ldap.user.groupmembership	Specifies the groups of a member when you use LDAP without VMM. This property is the inverse of ibm.appcenter.ldap.group.uniqueMember . This property is optional, but if it is specified, the LDAP access is faster. See “Configuring LDAP ACL management (Liberty profile)” on page 6-286 and “Configuring LDAP ACL management (Apache Tomcat)” on page 6-292.
ibm.appcenter.ldap.user.loginName	The login name attribute when you use LDAP without VMM. See “Configuring LDAP ACL management (Liberty profile)” on page 6-286 and “Configuring LDAP ACL management (Apache Tomcat)” on page 6-292.
ibm.appcenter.ldap.vmm.active	Specifies whether LDAP is done through VMM. Set to true to enable or false to disable. See “Configuring LDAP ACL management (WebSphere Application Server V8.x)” on page 6-282 and “Configuring LDAP ACL management with VMM for WebSphere Application Server V7” on page 6-278.
ibm.appcenter.ldap.vmm.adminpwd	The password when LDAP is done through VMM. See “Configuring LDAP ACL management (WebSphere Application Server V8.x)” on page 6-282 and “Configuring LDAP ACL management with VMM for WebSphere Application Server V7” on page 6-278.
ibm.appcenter.ldap.vmm.adminuser	The user when LDAP is done through VMM. See “Configuring LDAP ACL management (WebSphere Application Server V8.x)” on page 6-282 and “Configuring LDAP ACL management with VMM for WebSphere Application Server V7” on page 6-278.
ibm.appcenter.logging.formatjson	This property has only an effect when ibm.appcenter.logging.tosystemerror is set to true. If enabled, it formats JSON responses in logging messages that are directed to System.Error. Setting this property is helpful when you debug the server.

Table 6-59. List of the JNDI properties for the Application Center (continued).

Property	Description
ibm.appcenter.logging.tosystemerror	Specifies whether all logging messages are also directed to System.Error. Setting this property is helpful when you debug the server.
ibm.appcenter.openjpa.Log	This property is passed to OpenJPA and enables JPA logging. For details, see the Apache OpenJPA User's Guide.
ibm.appcenter.proxy.host	If the Application Center server is behind a firewall or reverse proxy, this property specifies the address of the host. Setting this property allows a user outside the firewall to reach the Application Center server. Typically, this property is the address of the proxy. See "Defining the endpoint of the application resources" on page 6-296.
ibm.appcenter.proxy.port	If the Application Center server is behind a firewall or reverse proxy, this property specifies the address of the host. Setting this property allows a user outside the firewall to reach the Application Center server. Typically, this property is the port of the proxy, for example 443. It is only needed if the protocol of the external and of the internal URI are different. See "Defining the endpoint of the application resources" on page 6-296.
ibm.appcenter.proxy.protocol	If the Application Center server is behind a firewall or reverse proxy, this property specifies the protocol (http or https). Setting this property allows a user outside the firewall to reach the Application Center server. Typically, this property is set to the protocol of the proxy. For example, appcntr.net . This property is only needed if the protocol of the external and of the internal URI are different. See "Defining the endpoint of the application resources" on page 6-296.
ibm.appcenter.proxy.scheme	This property is just an alternative name for ibm.appcenter.proxy.protocol .
ibm.appcenter.push.schedule.period	Specifies the time schedule when you send push notifications of application updates. When applications are frequently changed on the server, set this property to send batches of notifications. For example, send all notifications that happened within the past hour, instead of sending each individual notification.
ibm.appcenter.push.schedule.periodUnit	Specifies the unit for the time schedule when you send push notifications of application updates.
ibm.appcenter.services.endpoint	Enables the Application Center console to locate the Application Center REST services. Specify the external address and context root of the applicationcenter.war web application. In a scenario with a firewall or a secured reverse proxy, this URI must be the external URI and not the internal URI inside the local LAN. For example, https://appcntr.net:443/applicationcenter . See "Defining the endpoint of the application resources" on page 6-296.

Table 6-59. List of the JNDI properties for the Application Center (continued).

Property	Description
<code>ibm.appcenter.services.iconCacheMaxAge</code>	Specifies the amount of time in seconds cached icons remain valid for the Application Center console and the Client. Application icons rarely change, therefore they are cached. Specify values larger than 600 (10 min) to reduce the amount of data transfer for the icons.
<code>ibm.worklight.jndi.configuration</code>	Optional. If the JNDI configuration is injected into the WAR files or provided as a shared library, the value of this property is the name of the JNDI configuration. This value can also be specified as a system property. See “Predefining MobileFirst Server configuration for several deployment environments” on page 6-315.
<code>ibm.worklight.jndi.file</code>	Optional. If the JNDI configuration is stored as an external file, the value of this property is the path of a file that describes the JNDI configuration. This value can also be specified as a system property. See “Predefining MobileFirst Server configuration for several deployment environments” on page 6-315.

Configuring WebSphere Application Server to support applications in public app stores

Configure WebSphere Application Server full profile and Liberty profile before access to public app stores through application links, because of the use of SSL connections.

The constraint imposed by the use of SSL connections requires the root certificates of public app stores to exist in the WebSphere truststore before you can use application links to access these public stores. The configuration requirement applies to both WebSphere Application Server full profile and Liberty profile.

The root certificate of Google play must be imported into the WebSphere truststore before you can use application links to Google play.

The root certificate of Apple iTunes must be imported into the WebSphere truststore before you can use application links to iTunes.

To use application links to Google play, see “Configuring WebSphere Application Server to support applications in Google play.”

To use application links to Apple iTunes, see “Configuring WebSphere Application Server to support applications in Apple iTunes” on page 6-314.

Configuring WebSphere Application Server to support applications in Google play:

Configure WebSphere Application Server to enable links in the Application Center console to access applications in Google play.

About this task

Follow this procedure to import the root certificate of Google play into the WebSphere truststore. You must import this certificate before the Application Center can support links to applications stored in Google Play.

Procedure

1. Log in to the WebSphere Application Server console and navigate to **Security > SSL certificate and key management > Key stores and certificates > NodeDefaultTrustStore > Signer certificates**.
2. Click **Retrieve from port**.
3. In the **Host** field, enter `play.google.com`.
4. In the **Port** field, enter 443.
5. In the **Alias** field, enter `play.google.com`.
6. Click **Retrieve signer information**.
7. Click **OK** and save the configuration.

Configuring WebSphere Application Server to support applications in Apple iTunes:

Configure WebSphere Application Server to enable links in the Application Center console to access applications in Apple iTunes.

About this task

Follow this procedure to import the root certificate of Apple iTunes into the WebSphere truststore. You must import this certificate before the Application Center can support links to applications stored in iTunes.

Procedure

1. Log in to the WebSphere Application Server console and navigate to **Security > SSL certificate and key management > Key stores and certificates > NodeDefaultTrustStore > Signer certificates**.
2. Click **Retrieve from port**.
3. In the **Host** field, enter `itunes.apple.com`.
4. In the **Port** field, enter 443.
5. In the **Alias** field, enter `itunes.apple.com`.
6. Click **Retrieve signer information**.
7. Click **OK** and save the configuration.

Configuring Liberty profile when IBM JDK is used:

Configure Liberty profile to use default JSSE socket factories instead of SSL socket factories of WebSphere Application Server when IBM JDK is used.

Purpose

The purpose is to configure the IBM JDK SSL factories to be compatible with Liberty profile. This configuration is required only when IBM JDK is used. The configuration does not apply for use of Oracle JDK. By default, IBM JDK uses the SSL socket factories of WebSphere Application Server. These factories are not supported by Liberty profile.

Exception when WebSphere Application Server SSL socket factories are used

If you use the IBM JDK of WebSphere Application Server, this exception could occur because this JDK uses SSL socket factories that are not supported by the Liberty profile. In this case, follow the requirements documented in [Troubleshooting tips](#).

```
java.net.SocketException: java.lang.ClassNotFoundException: Cannot find the specified class com.ibm
    at javax.net.ssl.DefaultSSLSocketFactory.a(SSLSocketFactory.java:11)
    at javax.net.ssl.DefaultSSLSocketFactory.createSocket(SSLSocketFactory.java:6)
    at com.ibm.net.ssl.www2.protocol.https.c.afterConnect(c.java:161)
    at com.ibm.net.ssl.www2.protocol.https.d.connect(d.java:36)
    at sun.net.www.protocol.http.HttpURLConnection.getInputStream(HttpURLConnection.java:1184)
    at java.net.HttpURLConnection.getResponseCode(HttpURLConnection.java:390)
    at com.ibm.net.ssl.www2.protocol.https.b.getResponseCode(b.java:75)

```

Predefining MobileFirst Server configuration for several deployment environments

You can configure JNDI properties in a property file for easy transfer between one web application server and another; for example, to transfer from test to production environments.

As part of the installation of administration components of IBM MobileFirst Platform Foundation, various JNDI properties must be set. These components include MobileFirst Operations Console, MobileFirst Administration Service, and Application Center. Normally, JNDI properties are specified in the configuration of the web application server and are outside the web archive (WAR) file that represents the server component.

Instead, you can specify the JNDI properties in a property file. Having JNDI properties in a property file makes it easier to transfer the entire configuration from one web application server to another. For example, you can configure a test web server and, once the configuration is stable, you can transfer the configuration to the production web server by copying the property file to the production server.

This property file can be made available to the server components in various ways:

- The property file can be placed on the file system.
This solution is particularly useful for a stand-alone test server when you are experimenting with JNDI properties to determine the final configuration. You can easily change the file on the file system with a text editor. Then you have only to restart the web server to enable the changed configuration.
- The property file can be injected into web archive (WAR) files.
This solution is useful when you want to transfer the configuration together with the web archive file to another web server. You only have to handle the web archive file, and no other files. The configuration is, in this case, fused into the web archive file.
- The property file can be installed as a shared library for all server components.
This solution is useful when you intend to exchange the web archive files often, but want to keep the same configuration all the time.

Creating the property file

Define JNDI properties in a property file by using a text editor. Determine where to set JNDI properties according to a selective priority.

The property file follows the standard Java property file syntax and can be edited with any text editor. It has the file extension `.properties`. You can include all properties of all web archive (WAR) files in the same property file.

Here is an example of the content of a property file.

```
publicWorkLightHostname=myworklighthost.net
publicWorkLightPort=9080
publicWorkLightProtocol=https
push.gcm.proxy.enabled=false
push.gcm.proxy.host=myproxyhost.net
push.gcm.proxy.port=-1
push.gcm.proxy.protocol=https
ibm.worklight.admin.environmentid=id123
```

JNDI properties

You can refer to the details of JNDI properties in the relevant parts of the user documentation:

Application Center

“List of JNDI properties for the Application Center” on page 6-307

MobileFirst Application Services

“List of JNDI properties for MobileFirst Server administration” on page 6-111

MobileFirst runtime

“Configuration of MobileFirst applications on the server” on page 12-50

You do not have to specify all the possible JNDI properties in the property file. You can specify some in the property file and others as JNDI properties that are explicitly set in the web application server. The following list indicates the priority by which properties are enacted.

1. If a JNDI property is explicitly set in the web application server, this property value is taken. Refer to the documentation of your web application server for how to set JNDI properties.
2. If that is not the case, but the JNDI property is set in the property file injected into the web archive file or in the property file provided as a shared library, the property value is taken from this property file.
3. If that is not the case, but the JNDI property is set in the property file provided on the file system, the property value is taken from this property file.
4. If that is not the case, the default value of the JNDI property is taken.

Using a property file in the file system

You can place the property file directly into the file system of the web application server.

The property file can be stored directly in the file system. This approach is particularly useful for a stand-alone test server when you are experimenting with JNDI properties to determine the final configuration. You can easily change the file on the file system with a text editor. Then you have only to restart the web server to enable the changed configuration.

You must define the property **ibm.worklight.jndi.file** to point to the location of the property file. This property can be defined as a Java Virtual Machine system property or explicitly as a JNDI property. This property cannot be defined in the property file.

WebSphere Application Server full profile

Determine a suitable directory for the JNDI property file in the WebSphere Application Server installation directory.

- For a stand-alone server, you can use a directory such as:
`$WAS_INSTALL_DIR/profiles/profile-name/config/mywlconfig.properties`
- For deployment to a WebSphere Application Server ND cell, use for example:
`$WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/mywlconfig.properties`
- For deployment to a WebSphere Application Server ND cluster, use for example:
`$WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/mywlconfig.properties`
- For deployment to a WebSphere Application Server ND node, use for example:
`$WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/mywlconfig.properties`
- For deployment to a WebSphere Application Server ND server, use for example:
`$WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/mywlconfig.properties`

Next, add the setting of the **ibm.worklight.jndi.file** property to the Java Virtual Machine custom properties in the WebSphere Application Server administration console. For details of how to add this setting, see “Setting the file pointer property (WebSphere Application Server full profile)” on page 6-318.

WebSphere Application Server Liberty profile

You must place the property file inside the server directory of the Liberty server; for example, place it in `$LIBERTY_HOME/usr/servers/worklightServer/mywlconfig.properties`.

Edit the `$LIBERTY_HOME/usr/servers/worklightServer/bootstrap.properties` file and add the property **ibm.worklight.jndi.file** to point to the property file; for example, `ibm.worklight.jndi.file=mywlconfig.properties`.

Alternatively, instead of editing `bootstrap.properties`, create or edit the file `$LIBERTY_HOME/usr/servers/worklightServer/jvm.options` and add, for example:
`-Dibm.worklight.jndi.file=mywlconfig.properties`

You can use the normal web archive (WAR) files of the web applications. They can be installed as described elsewhere in “Installing and configuring” on page 6-1.

Restart the web application server. Whenever the property file changes, the web application server must be restarted.

Apache Tomcat

You must place the property file inside the `conf` directory of the Apache Tomcat server; for example, place it in `$TOMCAT_HOME/conf/mywlconfig.properties`.

Edit the `$TOMCAT_HOME/conf/catalina.properties` file and add the property **ibm.worklight.jndi.file** to point to the property file; for example, **ibm.worklight.jndi.file=../conf/mywlconfig.properties**.

Alternatively, on UNIX systems, instead of editing `catalina.properties`, create or edit the `$TOMCAT_HOME/bin/setenv.sh` file and add, for example:

```
CATALINA_OPTS="$CATALINA_OPTS  
-Dibm.worklight.jndi.file=../conf/mywlconfig.properties"
```

or on microsoft Windows systems, create or edit the `$TOMCAT_HOME/bin/setenv.bat` file and add , for example:

```
set CATALINA_OPTS=%CATALINA_OPTS%  
-Dibm.worklight.jndi.file=../conf/mywlconfig.properties
```

You can use the normal web archive (WAR) files of the web applications. They can be installed as described elsewhere in “Installing and configuring” on page 6-1.

Restart the web application server. Whenever the property file changes, the web application server must be restarted.

Setting the file pointer property (WebSphere Application Server full profile)

Define the **ibm.worklight.jndi.file** property through the administration console of the WebSphere Application Server full profile.

Before you begin

Determine the location in the file system of the JNDI property file. See “WebSphere Application Server full profile” on page 6-317.

About this task

When you opt to configure JNDI properties by using a property file located directly in the file system, you must set a property to point to the property file. This property is outside the property file and is set through the administration console.

You must log in to the WebSphere Application Server administration console and add the setting of the **ibm.worklight.jndi.file** property to the Java Virtual Machine custom properties.

Procedure

1. Select **Servers > Server types > WebSphere Application Servers**.
2. Select the name of your server.
3. Expand “Java and process management” and select “Process Definition”.
4. Select “Java Virtual Machine”.
5. Select “Custom Properties” and click **New**.
6. Specify the name as **ibm.worklight.jndi.file**.
7. Specify the value as the path to the property file. The directory `$WAS_INSTALL_DIR/profiles/profile-name` can be specified as `${USER_INSTALL_ROOT}`; for example, that can be one of the following values:
 - `${USER_INSTALL_ROOT}/config/mywlconfig.properties`
 - `${USER_INSTALL_ROOT}/config/cells/cell-name/mywlconfig.properties`

- `${USER_INSTALL_ROOT}/config/cells/cell-name/clusters/cluster-name/mywlconfig.properties`
 - `${USER_INSTALL_ROOT}/config/cells/cell-name/nodes/node-name/mywlconfig.properties`
 - `${USER_INSTALL_ROOT}/config/cells/cell-name/nodes/node-name/servers/server-name/mywlconfig.properties`
8. Click **Apply**.
 9. Click **Save**.

What to do next

You can use the normal web archive (WAR) files of the web applications. They can be installed as described elsewhere in “Installing and configuring” on page 6-1.

To enable the property file, restart all MobileFirst Server components. These components are displayed in the WebSphere Application Server administration console under WebSphere enterprise applications.

Using property files injected into a web archive file

You can inject several configuration files into the WAR file of a MobileFirst Server component.

The property file can be injected into the web archive (WAR) files for MobileFirst Operations Console, MobileFirst Administration Service, MobileFirst runtime, or Application Center. This approach is useful when you want to transfer the configuration together with the web archive file to another web application server. In this case, you only have to handle the web archive file, and no other files. The configuration is, in this case, fused into the web archive file.

You can inject several different configurations into the same web archive file and then select in the web application server which configuration should be used. For example, you could have a test configuration and a production configuration injected at the same time. To do so, create multiple property files with different settings, one named `testconf.properties` and the other named `prodconf.properties`.

Some JNDI properties must have the same value in all MobileFirst Server components. Therefore, you should inject the same property files into all web archive files. The following JNDI properties must be the same for MobileFirst Operations Console, MobileFirst Administration Services, and MobileFirst runtime:

- `ibm.worklight.admin.environmentid`
- `ibm.worklight.topology.clustermode`
- `ibm.worklight.topology.platform`
- `ibm.worklight.admin.jmx.connector`
- `ibm.worklight.admin.jmx.dmgr.host`
- `ibm.worklight.admin.jmx.dmgr.port`
- `ibm.worklight.admin.jmx.host`
- `ibm.worklight.admin.jmx.port`
- `ibm.worklight.admin.jmx.user`
- `ibm.worklight.admin.jmx.pword`
- `ibm.worklight.admin.rmi.registryPort`

- `ibm.worklight.admin.rmi.serverPort`

Injecting property files into a WAR file by using the Command Line tool

The `wljndiinject` command line tool is used to inject a set of property files into a web archive file. To add the property files `testconf.properties` and `prodconf.properties` to a war file, use the following command:

```
wljndiinject --sourceWarFile source.war testconf.properties prodconf.properties
```

The resulting web archive file can be found in the folder `jndi-injected`. It contains the property files inside the web archive file.

Options of the tool:

--help Shows the help.

--sourceWarFile *file*

The web archive file that is used to add the property files.

--destFile *file*

The destination file name. If not specified, the destination file is placed in the `jndi-injected` directory.

--sharedJar

Used to create a shared library; For details, see “Creating a shared library of JNDI properties” on page 6-323.

Injecting property files into a WAR file by using an Ant task

You can use the `com.worklight.ant.jndi.JNDIInjectionTask` Ant task to inject a set of property files into a web archive file.

Here is a sample ant script that shows the use of the ant task:

```
<?xml version="1.0" encoding="UTF-8"?>
<project name="WlJndiInjectTask" basedir="." default="jndiinject.Sample">
  <property name="install.dir" value="/path.to.worklight.installation" />
  <path id="classpath.run">
    <fileset dir="${install.dir}/WorklightServer/">
      <include name="worklight-ant-deployer.jar" />
    </fileset>
  </path>
  <target name="jndiinject.init">
    <taskdef name="jndiinject"
      classname="com.worklight.ant.jndi.JNDIInjectionTask">
      <classpath refid="classpath.run" />
    </taskdef>
  </target>
  <target name="jndiinject.Sample"
    description="Injects properties into the Worklight war file"
    depends="jndiinject.init">
    <!-- This is just an example:
      Mandatory parameters are sourceWarFile and the fileset.
      All other parameters are optional and could be omitted.
      The source war files are expected in the wars directory.
      The property files are expected in the properties directory.
    -->
    <jndiinject
      sourceWarFile="wars/worklightproject.war"
      destWarFile="worklightproject-injected.war" >
      <fileset dir="." casesensitive="yes">
        <include name="properties/*.properties"/>
      </fileset>
    </jndiinject>
  </target>
</project>
```

```

        </fileset>
    </jndiinject>
</jndiinject>
    sourceWarFile="wars/worklightadmin.war"
    destWarFile="worklightadmin-injected.war" >
        <fileset dir="." casesensitive="yes">
            <include name="properties/*.properties"/>
        </fileset>
    </jndiinject>
</jndiinject>
    sourceWarFile="wars/worklightconsole.war"
    destWarFile="worklightconsole-injected.war" >
        <fileset dir="." casesensitive="yes">
            <include name="properties/*.properties"/>
        </fileset>
    </jndiinject>
</target>
</project>

```

Installing the property-injected WAR files in the web application server

After injection of the property files into the web archive files, the web archive files contain the property files and can be installed like any normal web archive file in the web application server.

For the MobileFirst Administration Services, MobileFirst Operations Console, and the MobileFirst runtime, you can use the ant task to install the web archive files, or you can update the web archive files manually.

For details of how to install web archive files for MobileFirst components, see:

- “Using Ant tasks to install MobileFirst Server administration” on page 6-73
- “Deploying a project WAR file and configuring the application server with Ant tasks” on page 12-16
- “Deploying the Application Center WAR files and configuring the application server manually” on page 6-259

When the web archive file is deployed, you must define the **ibm.worklight.jndi.configuration** property to point to the name of the required configuration.

Selecting the configuration in a property-injected WAR file

The default configuration is called `default.properties`. If the configuration of JNDI properties has a different name, you must define the **ibm.worklight.jndi.configuration** property. The value of this property must be the configuration name without the extension `.properties`. This property can be specified as a Java Virtual Machine system property or explicitly as a JNDI property. This property cannot be defined in the configuration property file.

Selecting the configuration: WebSphere Application Server full profile

You must log in to the WebSphere Application Server administration console and add the setting of the **ibm.worklight.jndi.configuration** property to the Java Virtual Machine custom properties.

To add this property setting:

1. Select **Servers > Server types > WebSphere Application Servers**.
2. Select the name of your server.
3. Expand “Java and process management” and select “Process Definition”
4. Select “Java Virtual Machine”.
5. Select “Custom Properties” and click **New**.
6. Specify the name as **ibm.worklight.jndi.configuration**.
7. Specify the value as the name of the configuration.
8. Click **Apply**.
9. Click **Save**.

When the property is set, to enable the configuration, restart the appropriate MobileFirst Server components. These components are displayed in the WebSphere Application Server administration console under WebSphere enterprise applications.

Selecting the configuration: WebSphere Application Server Liberty profile

You must edit the `$LIBERTY_HOME/usr/servers/worklightServer/bootstrap.properties` file and set the **ibm.worklight.jndi.configuration** property to point to the name of the configuration.

For example:

```
ibm.worklight.jndi.configuration=testconf
```

Alternatively, instead of editing the `bootstrap.properties` file, create or edit the `$LIBERTY_HOME/usr/servers/worklightServer/jvm.options` file. For example, add:
`-Dibm.worklight.jndi.configuration=testconf`

To enable the configuration, restart the web application server.

Selecting the configuration: Apache Tomcat

You must edit the `$TOMCAT_HOME/conf/catalina.properties` file and set the **ibm.worklight.jndi.configuration** property to point to the name of the configuration.

For example:

```
ibm.worklight.jndi.configuration=testconf
```

Alternatively, instead of editing the `catalina.properties` file, depending on the operating system, create or edit one of the following files:

- On UNIX systems: `$TOMCAT_HOME/bin/setenv.sh`

For example, add:

```
CATALINA_OPTS="$CATALINA_OPTS -Dibm.worklight.jndi.configuration=testconf"
```

- On Microsoft Windows systems: `$TOMCAT_HOME/bin/setenv.bat`

For example, add:

```
set CATALINA_OPTS=%CATALINA_OPTS% -Dibm.worklight.jndi.configuration=testconf
```

To enable the configuration, restart the web application server.

Using a shared library of JNDI properties

You can create a shared library to hold different configurations for any MobileFirst Server component.

If you do not want to inject properties into web archive files, the property file can be installed as a shared library for all MobileFirst Server components. This approach is useful when you intend to exchange the web archive files often, but want to keep the same configuration all the time. The original web archive files remain unchanged, but you need to install an additional shared library.

You can add several different configurations to the same shared library and then select in the web application server which configuration to use. For example, you could have a test configuration and a production configuration injected at the same time. To do so, create property files with different settings, one named `testconf.properties` and the other `prodconf.properties`.

Creating a shared library of JNDI properties

The `wljndiinject` command line tool is used to create a shared library for a set of property files. To create a shared library named `jndiprops.jar` with the property files `testconf.properties` and `prodconf.properties`, use the following command:

```
wljndiinject --sharedJar --destFile jndiprops.jar testconf.properties prodconf.properties
```

Options of the tool:

--help Shows the help.

--sourceWarFile *file*

This option is not required for creating a shared library. This option is used when a property file is injected into a web archive file to identify the web archive file.

--destFile *file*

The destination file name of the shared library.

--sharedJar

Used to create a shared library instead of injecting a property file into a web archive file.

Installing a shared library of JNDI configurations

Assume that all web applications are already installed. The shared library is added to the web applications.

WebSphere Application Server full profile

Determine a suitable directory for the shared library `jndiprops.jar` in the WebSphere Application Server installation directory and place the `jndiprops.jar` file there.

- For a stand-alone server, you can use a directory such as:
`$WAS_INSTALL_DIR/optionalLibraries/IBM/Worklight`
- For deployment to a WebSphere Application Server ND cell, use for example:
`$WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/Worklight`
- For deployment to a WebSphere Application Server ND cluster, use:

`$WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/
clusters/cluster-name/Worklight`

- For deployment to a WebSphere Application Server ND node, use:
`$WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/
nodes/node-name/Worklight`
- For deployment to a WebSphere Application Server ND server, use:
`$WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/
nodes/node-name/servers/server-name/Worklight`

For details about adding the shared library, see “Adding the shared library (WebSphere Application Server full profile)” on page 6-326.

WebSphere Application Server Liberty profile

Place the `jndiprops.jar` file in a suitable directory; for example, `$LIBERTY_HOME/usr/shared/resources/lib/jndiprops.jar`.

Edit the `$LIBERTY_HOME/usr/servers/worklightServer/server.xml` file. For each `<application>` element, add or update the `<classloader>` element.

```
<application ...>  
  ...  
  <classloader delegation="parentLast"></p>  
  ...  
  <privateLibrary>  
    <fileset dir="{shared.resource.dir}/lib"  
      includes="jndiprops.jar"/>  
  </privateLibrary>  
</classloader>  
</application>
```

Restart the web application server after these changes.

Apache Tomcat

Place the shared library, `jndiprops.jar` file, in a suitable directory; for example, `$TOMCAT_HOME/Worklight/jndiprops.jar`.

Edit the `$TOMCAT_HOME/conf/server.xml` file. For each `<Context>` element, add or update the `<Loader>` element.

```
<Context docBase="worklightconsole" path="/worklightconsole">  
  <Loader className="org.apache.catalina.loader.VirtualWebappLoader"  
    virtualClasspath="{catalina.base}/Worklight/jndiprops.jar"  
    searchVirtualFirst="true"/>  
  ...  
</Context>
```

For the MobileFirst project, which uses additional shared libraries, the example code is:

```
<Context docBase="worklightconsole" path="/worklight">  
  <Loader className="org.apache.catalina.loader.VirtualWebappLoader"  
    virtualClasspath="{catalina.base}/Worklight/worklight/worklight-jee-library.jar;${ca  
    searchVirtualFirst="true"/>  
  ...  
</Context>
```

Restart the web application server after these changes.

Selecting the configuration in a shared library of JNDI configurations

The default configuration is called `default.properties`. If the configuration of JNDI properties has a different name, you must define the

ibm.worklight.jndi.configuration property. The value of this property must be the configuration name without the extension `.properties`. This property can be specified as a Java Virtual Machine system property or explicitly as a JNDI property. This property cannot be defined in the configuration property file.

WebSphere Application Server full profile

You must log in to the WebSphere Application Server administration console and add the setting of the **ibm.worklight.jndi.configuration** property to the Java Virtual Machine custom properties.

To add this property setting:

1. Select **Servers > Server types > WebSphere Application Servers**.
2. Select the name of your server.
3. Expand "Java and process management" and select "Process Definition"
4. Select "Java Virtual Machine".
5. Select "Custom Properties" and click **New**.
6. Specify the name as **ibm.worklight.jndi.configuration**.
7. Specify the value as the name of the configuration.
8. Click **Apply**.
9. Click **Save**.

When the property is set, to enable the configuration, restart the appropriate MobileFirst Server components. These components are displayed in the WebSphere Application Server administration console under WebSphere enterprise applications.

WebSphere Application Server Liberty profile

You must edit the `$LIBERTY_HOME/usr/servers/worklightServer/bootstrap.properties` file and set the **ibm.worklight.jndi.configuration** property to point to the name of the configuration.

For example:

```
ibm.worklight.jndi.configuration=testconf
```

Alternatively, instead of editing the `bootstrap.properties` file, create or edit the `$LIBERTY_HOME/usr/servers/worklightServer/jvm.options` file. For example, add:

```
-Dibm.worklight.jndi.configuration=testconf
```

To enable the configuration, restart the web application server.

Apache Tomcat

You must edit the `$TOMCAT_HOME/conf/catalina.properties` file and set the **ibm.worklight.jndi.configuration** property to point to the name of the configuration. For example:

```
ibm.worklight.jndi.configuration=testconf
```

Alternatively, instead of editing the `catalina.properties` file, depending on the operating system, create or edit one of the following files:

- On UNIX systems: `$TOMCAT_HOME/bin/setenv.sh`

For example, add:

```
CATALINA_OPTS="$CATALINA_OPTS -Dibm.worklight.jndi.configuration=testconf"
```

- On Microsoft Windows systems: `$TOMCAT_HOME/bin/setenv.bat`

For example, add:

```
set CATALINA_OPTS=%CATALINA_OPTS% -Dibm.worklight.jndi.configuration=testconf
```

To enable the configuration, restart the web application server.

Adding the shared library (WebSphere Application Server full profile)

Define the shared library and specify which web applications use it.

Before you begin

Install the shared library `jndiprops.jar` in a suitable directory in the WebSphere Application Server installation directory.

About this task

You can install the property file as a shared library for all MobileFirst Server components. To do so, you must log in to the WebSphere Application Server administration console to add the shared library.

Procedure

1. Select **Environment > Shared Libraries**.
2. Select your scope in the fields **Node=** and **Server=**.
3. Click **New**.
4. Enter a name, for example, "MobileFirst JNDI Properties".
5. Enter a description, for example, "IBM MobileFirst JNDI property package".
6. Enter the classpath of the `jndiprops.jar` file. The `$WAS_INSTALL_DIR/profiles/profile-name` directory can be specified as `${USER_INSTALL_ROOT}`.
7. Select the option "Use an isolated class loader for this shared library".
8. Click **Apply**.
9. Click **Save**.
10. Specify which web applications should use the shared library.
 - a. In the administration console, select **Applications > Application Types > WebSphere enterprise applications**. You should stop all applications that you are going to change, because the operations run faster when the applications are stopped.
 - b. Select an application, for example, IBM MobileFirst Administration Service.
 - c. Select **Shared library references**.
 - d. In "Application", select IBM MobileFirst Administration Service.
 - e. Click **Reference shared libraries**.
 - f. Move the MobileFirst JNDI Properties library from Available to Selected.
 - g. Click **OK**.
 - h. Click **Save**.

Repeat this procedure for the other required web applications from among MobileFirst Operations Console, MobileFirst project, Application Center Service, Application Center Console.

What to do next

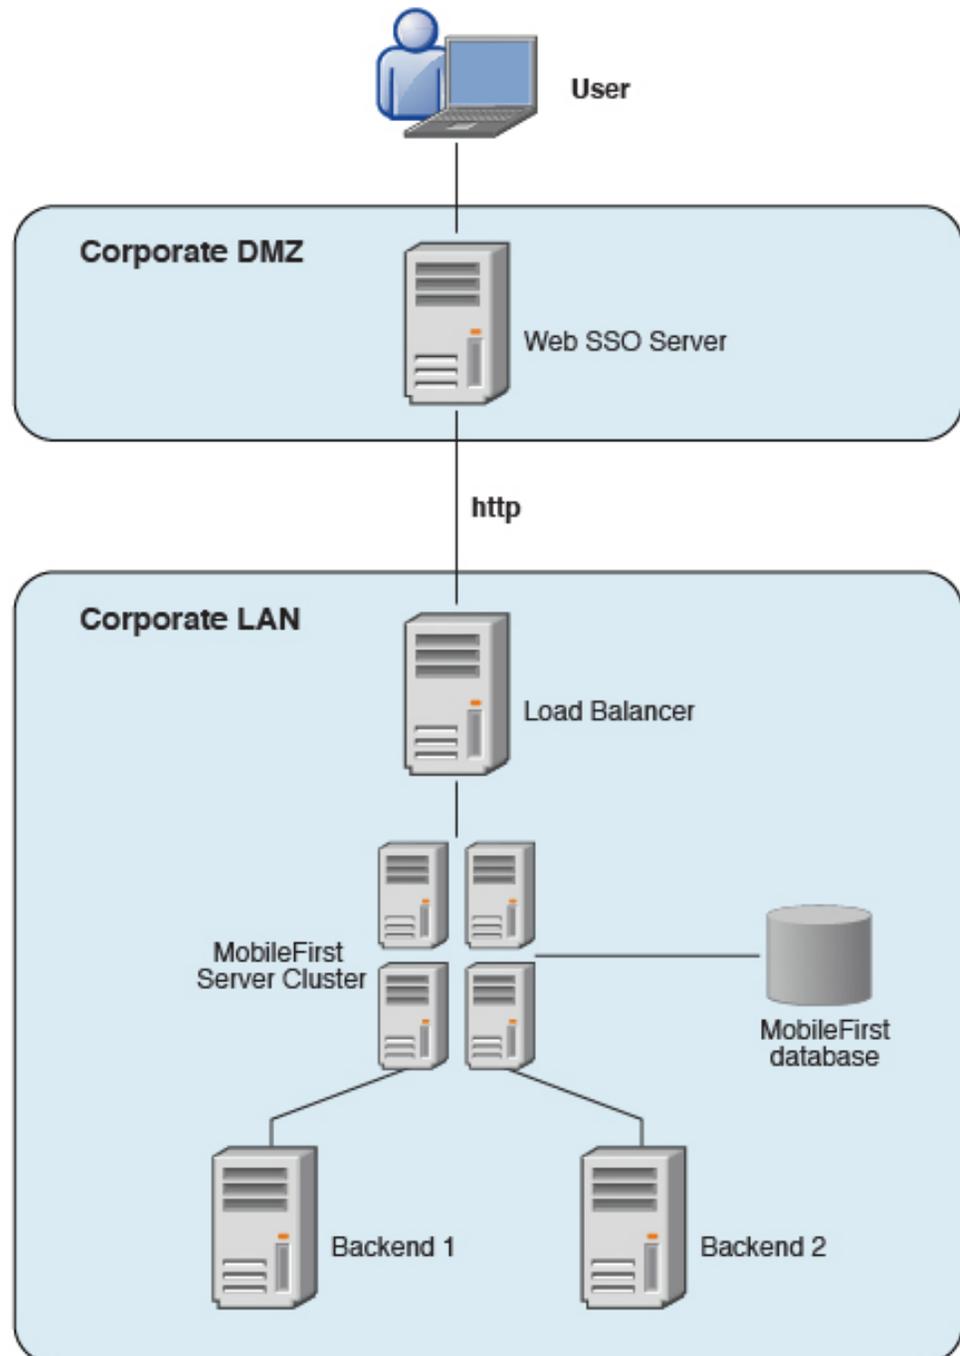

Go to **Applications > Application Types > WebSphere enterprise applications** and restart all the web applications.

Typical topologies of a MobileFirst instance in an extranet infrastructure

A MobileFirst instance uses a particular topology that is typical for organizations with an established extranet infrastructure.

The following figure depicts this topology.

Figure 6-29. Typical topology of a MobileFirst instance

Such a topology is based on the following principles:

- MobileFirst Server is installed in the organization local area network (LAN), connecting to various enterprise back-end systems.
- MobileFirst Server can be clustered for high availability and scalability.
- MobileFirst Server uses a database for storing push notification information, statistics for reporting and analytics, and the metadata that the server needs at run time. All instances of MobileFirst Server share a single instance of the database.
- MobileFirst Server is installed behind a web Single Sign-On (SSO) authentication infrastructure, which acts as a reverse proxy and provides the Security Socket Layer (SSL).

MobileFirst Server can be installed in different network configurations, which might include several DMZ layers (firewall configurations for securing local area networks), reverse proxies, Network Address Translation (NAT) devices, firewalls, high availability components such as load balancers, IP sprayers, clustering, and alike. Some of these components are explained. However, this document assumes a simpler configuration in which MobileFirst Server is installed in the DMZ.

- “Integration and authentication with a reverse proxy” on page 15-3
- “Integration with IBM WebSphere DataPower” on page 15-13

Setting up IBM MobileFirst Platform Foundation in WebSphere Application Server cluster environment

You can set up a MobileFirst cluster environment with IBM WebSphere Application Server Network Deployment V8.5 and IBM HTTP Server.

About this task

This procedure explains how to set up IBM MobileFirst Platform Foundation in the topology shown in Figure 1:

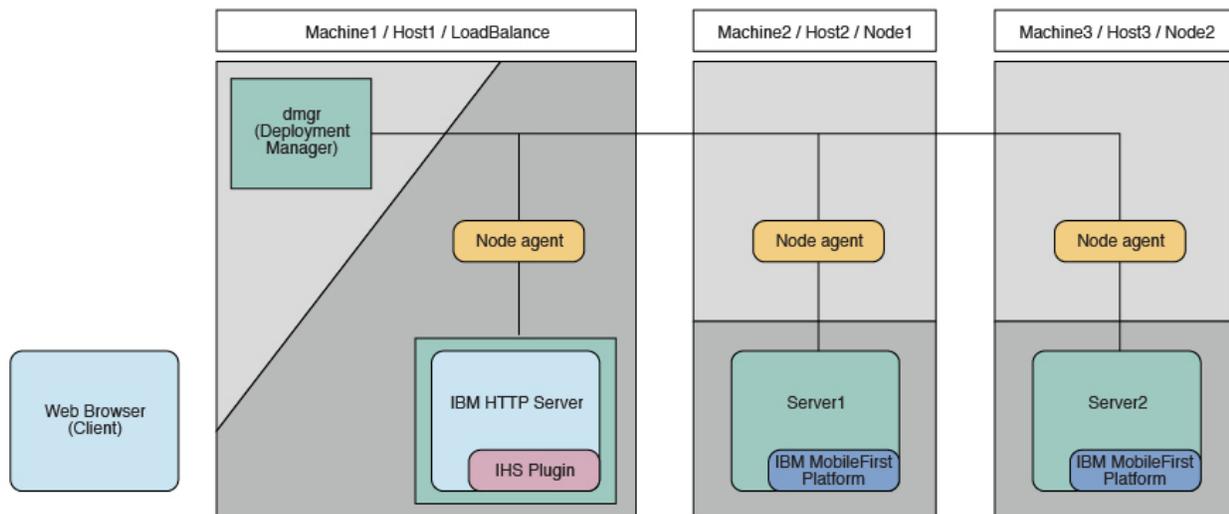

Figure 6-30. MobileFirst cluster topology with IBM WebSphere Application Server Network Deployment

If you install IBM HTTP Server, the administration components require certain JNDI properties to be configured. For more information, see “Using a reverse proxy with server farm and WebSphere Application Server Network Deployment topologies” on page 6-29 and “Defining the endpoint of the MobileFirst Administration services” on page 6-102.

The instructions are based on the hardware and software that are listed in the following Table 6-60 and Table 6-61 tables.

Table 6-60. Hardware

Host name	Operating system	Description
Host1	RHEL 6.2	WebSphere Application Server Deployment Manager and IBM HTTP Server.
Host2	RHEL 6.2	WebSphere Application Server cluster node / server 1
Host3	RHEL 6.2	WebSphere Application Server cluster node / server 2
Host4	RHEL 6.2	DB2 server

Table 6-61. Software

Name	Description
IBM Installation Manager 1.8	Install IBM WebSphere Application Server Network Deployment, IBM HTTP Server, IBM Web Server Plug-ins for WebSphere Application Server, and IBM MobileFirst Platform Foundation.
IBM WebSphere Application Server 8.5	WebSphere Application Server. You need to get the installation repository before you start.
IBM HTTP Server 8.5	IBM HTTP Server. You need to get the installation repository before you start. It is also included in the WebSphere Application Server installation repository.
Web Server Plug-ins 8.5	IBM HTTP Server Plugin. You need to get the installation repository before you start. It is also included in the WebSphere Application Server installation repository.
IBM MobileFirst Platform Foundation V7.1.0	IBM MobileFirst Platform Foundation runtime. You need to get access to the installation repository before you start.
IBM DB2 V9.7 or later	DB2 Database. Your DB2 server must be available before you start the IBM MobileFirst Platform Foundation installation.
Ant 1.8.3	Configure IBM MobileFirst Platform Foundation with Liberty Profile Server.

Procedure

1. Install WebSphere Application Server Network Deployment, IBM HTTP Server, and Web Server Plugins.

- a. On the Host1 machine, log on with the “root” user ID and run IBM Installation Manager to install WebSphere Application Server Network Deployment, IBM HTTP server and Web Server Plugins. This documentation assumes that the applications are installed in the following places:

WebSphere Application Server Network Deployment home
/opt/WAS85

IBM HTTP Server home
/opt/IBM/HTTPServer

Web Server Plugins home
/opt/IBM/HTTPServer/Plugins

- b. Repeat step 1a on Host2 and Host3, but install only WebSphere Application Server Network Deployment.
2. Create a deployment manager and nodes.

- a. To avoid network errors, add the host name and IP mapping to the /etc/hosts file.

On Windows:

Add the IP-to-host mapping to C:\Windows\System32\drivers\etc\hosts.

On Linux:

Add the IP-to-host mapping to /etc/hosts.

For example:

```
9.186.9.75 Host1
9.186.9.73 Host2
9.186.9.76 Host3
```

- b. Create a deployment manager and IBM HTTP Server node on Host1. You can change the profile name and profile path to suit your environment.

- 1) Create the deployment manager profile. The following command creates a profile named “dmgr:”

On Windows:

```
./manageprofiles.bat -create -profileName dmgr
-profilePath ../profiles/dmgr -templatePath
../profileTemplates/management -enableAdminSecurity true
-adminUserName wasadmin -adminPassword wasadmin
-serverType DEPLOYMENT_MANAGER
```

On Linux:

```
./manageprofiles.sh -create -profileName dmgr
-profilePath ../profiles/dmgr506 -templatePath
../profileTemplates/management -enableAdminSecurity true
-adminUserName wasadmin -adminPassword wasadmin
-serverType DEPLOYMENT_MANAGER
```

- 2) Create an IBM HTTP Server node profile. The following command creates a profile named “ihs”:

On Windows:

```
./manageprofiles.bat -create -profileName ihs
-profilePath ../profiles/ihs -templatePath
../profileTemplates/managed
```

On Linux:

```
./manageprofiles.sh -create -profileName ihs -profilePath  
../profiles/ihs506 -templatePath ../profileTemplates/  
managed
```

- 3) Start the deployment manager:

On Windows:

```
./startManager.bat
```

On Linux:

```
./startManager.sh
```

- 4) Add an IBM HTTP Server node to the deployment manager. The following command adds the node defined by the “ihs” profile to the deployment manager running on Host1, and assigns port 8879:

On Windows:

```
./addNode.bat Host1 8879 -profileName ihs
```

On Linux:

```
./addNode.sh Host1 8879 -profileName ihs
```

- 5) From the WebSphere Application Server administrative console, click **System administration > Nodes** and check that the node is added to the deployment manager.

Select	Name	Host Name	Version	Discovery Protocol	Status
	topoIhsCellManager01	topoIhs	ND 8.5.5.0	TCP	↔
<input type="checkbox"/>	topoIhsNode01	topoIhs	ND 8.5.5.0	TCP	↔

Note: Node names might be different from the profile names you specify because WebSphere Application Server automatically generates a display name for a new node.

- c. Create MobileFirst node1 on Host2.

- 1) Create a profile for the node. The following command creates a profile named node1:

On Windows:

```
./manageprofiles.bat -create -profileName node1  
-profilePath ../profiles/node1 -templatePath  
../profileTemplates/managed
```

On Linux:

```
./manageprofiles.sh -create -profileName node1  
-profilePath ../profiles/node1 -templatePath  
../profileTemplates/managed
```

- 2) Add the node to the deployment manager. The following command adds the node defined by the node1 profile to the deployment manager running on Host1, and assigns port 8879:

On Windows:

```
./addNode.bat Host1 8879 -profileName node1
```

On Linux:

```
./addNode.sh Host1 8879 -profileName node1
```

- d. Repeat step 2c to create MobileFirst node2 on Host3.

- e. From the WebSphere Application Server administrative console, click **System administration > Nodes** and check that the nodes you added to the deployment manager are listed.

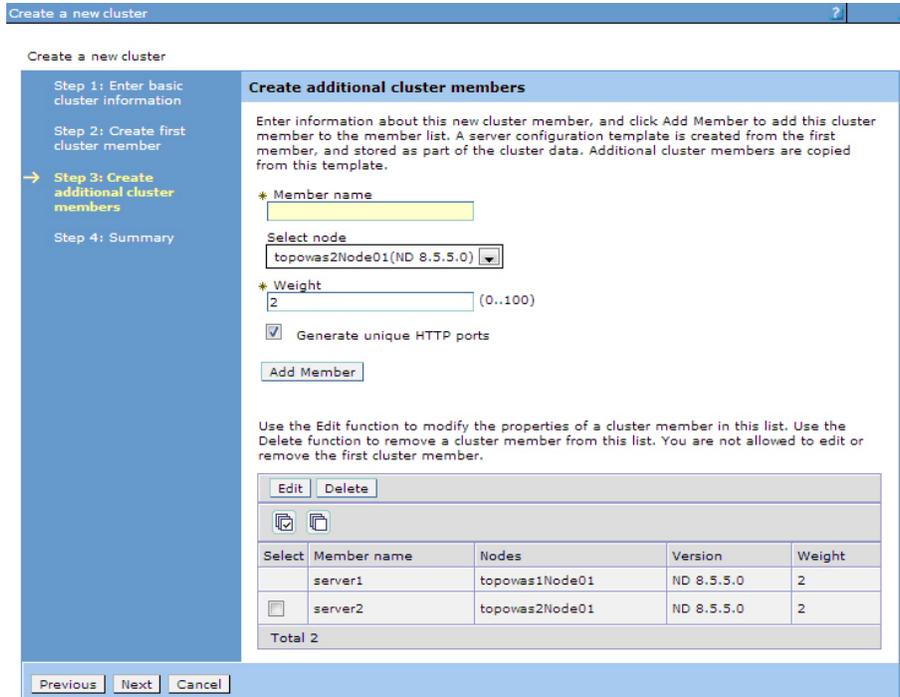

Select	Name	Host Name	Version	Discovery Protocol	Status
You can administer the following resources:					
<input type="checkbox"/>	topoihsCellManager01	topoihs	ND 8.5.5.0	TCP	↔
<input type="checkbox"/>	topoihsNode01	topoihs	ND 8.5.5.0	TCP	↔
<input type="checkbox"/>	topowas1Node01	topowas1	ND 8.5.5.0	TCP	↔
<input type="checkbox"/>	topowas2Node01	topowas2	ND 8.5.5.0	TCP	↔

Note: Node names might be different from the profile names you specify because WebSphere Application Server automatically generates a display name for a new node.

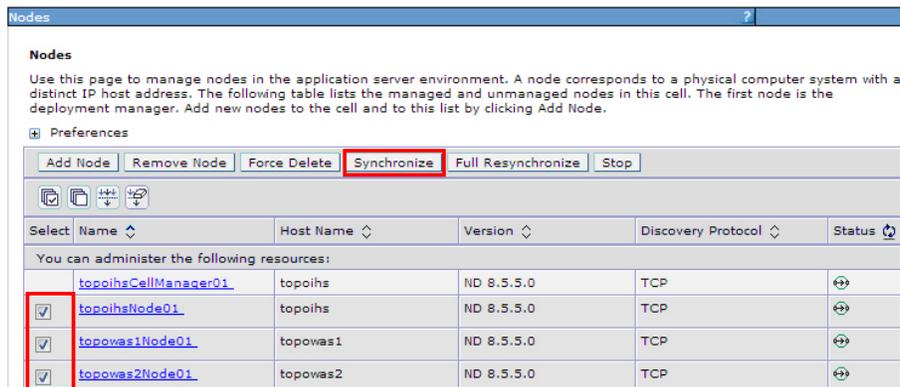

3. Create a cluster and add MobileFirst nodes as members.
 - a. From the WebSphere Application Server administrative console, click **Servers > Clusters > WebSphere application server clusters**, and then click **New** to create a new cluster.

The screenshot shows the WebSphere Application Server administrative console. On the left, a navigation tree is visible with 'WebSphere application server clusters' selected and highlighted with a red box. The main content area displays the 'WebSphere application server clusters' page, which includes a 'New...' button also highlighted with a red box, along with other buttons like 'Delete', 'Start', 'Stop', 'Ripplestart', and 'ImmediateStop'. Below the buttons is a table with columns for 'Select', 'Name', and 'Status', currently showing 'None' and 'Total 0'.

- b. For each MobileFirst node, add a member to the cluster: in the fields provided, enter the required information, and then click **Add Member**.

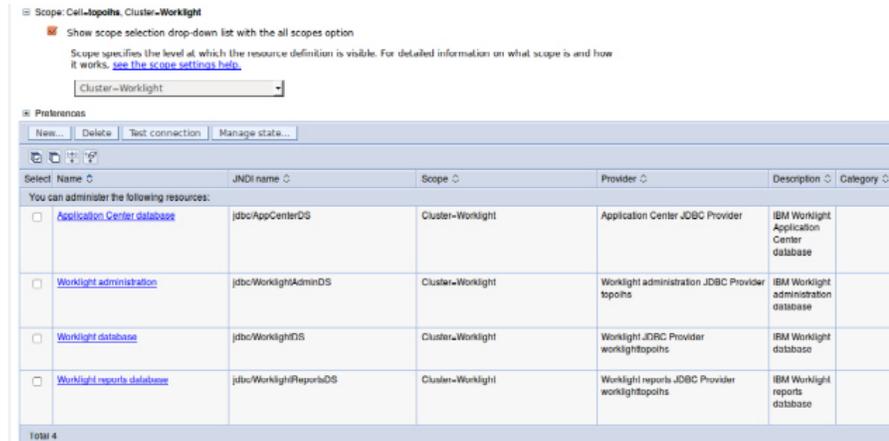

- c. From the WebSphere Application Server administrative console, click **Servers > Server Types > WebSphere application servers** to check that the cluster member servers are listed.
- d. If the status column indicates that nodes are not synchronized, click **System Administration > Nodes**, and then click **Synchronize** to synchronize your nodes to the deployment manager.

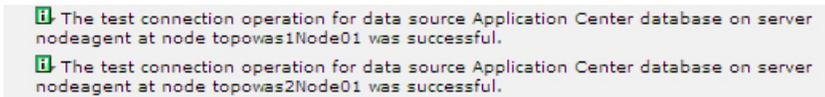

4. Install MobileFirst Server on Host1. Ensure that the WebSphere Application Server Network Deployment cluster is created without errors before you begin the installation. For installation instructions, see “Installing MobileFirst Server” on page 6-14.
5. Configure the databases. For instructions, see “Creating and configuring the databases with Ant tasks” on page 12-15.
6. In MobileFirst Studio, create a MobileFirst project and build a MobileFirst project WAR file. See “Artifacts produced during development cycle” on page 8-230.
7. Configure IBM MobileFirst Platform Foundation with the WebSphere Application Server Network Deployment cluster. For instructions, see “Deploying a project WAR file and configuring the application server with

Ant tasks” on page 12-16. Modify the Ant template to match your WebSphere Application Server cluster and database server.

8. Verify the installation.
 - a. Restart the WebSphere Application Server cluster.
 - b. From the WebSphere Application Server administrative console, click **Resources > JDBC > Data sources**, and check that the data sources jdbc/WorklightAdminDS, jdbc/WorklightDS and jdbc/WorklightReportsDS exist. If Application Center is installed, check that the data source jdbc/AppCenterDS exists.

- c. Select the data sources and click **Test connection** to verify the DB2 database connection. Confirmations similar to the ones in the following messages indicate a successful connection.

- d. Go to **Applications > Application Types > WebSphere enterprise applications** and check that the MobileFirst Operations Console application is running.
 - e. Now that you have deployed IBM MobileFirst Platform Foundation on the two node servers, you can access the MobileFirst Operations Console on each host by browsing to the associated URLs:
 - http://Host2:9080/worklightconsole
 - http://Host3:9080/worklightconsole

Check that both MobileFirst Operations Console are running.

9. Configure the IBM HTTP Server.
 - a. From the WebSphere Application Server administrative console, go to **Servers > Server Types > Web servers**, and then click **New** to create a new IBM HTTP server.

- b. Select the "ihs" node you previously created on Host1, then from the **Type** list, select **IBM HTTP Server**, and then click **Next**.

Use this page to create a new web server.

Step 1: Select a node for the Web server and select the Web server type

Step 2: Select a Web server template

Step 3: Enter the properties for the new Web server

Step 4: Confirm new Web server

Select a node for the Web server and select the Web server type

Select a node that corresponds to the Web server you want to add.

Select node
topo1hsNode01

* Server name
ihs

* Type
IBM HTTP Server

Next Cancel

- c. Enter the IBM HTTP Server home and Web Server Plugins home you previously selected on Host1, and then click **Next** and save your configuration.

Use this page to create a new web server.

Step 1: Select a node for the Web server and select the Web server type

Step 2: Select a Web server template

Step 3: Enter the properties for the new Web server

Step 4: Confirm new Web server

Enter the properties for the new Web server

Enter the Web server properties.

* Port
80

* Web server installation location
/opt/HTTPServer

* Plug-in installation location
/opt/Plugins

Application mapping to the Web server
All

Previous Next Cancel

- d. In the administrative console, on the Web servers page, click **Generate Plug-in** to generate the plug-in configuration file.

Web servers

Use this page to view a list of the installed web servers.

Preferences

Generate Plug-in Propagate Plug-in New... Delete Templates... Start Stop Terminate

Select	Name	Web server Type	Node	Host Name	Version	Status
<input checked="" type="checkbox"/>	ihs	IBM HTTP Server	topo1hsNode01	topo1hs	ND 8.5.5.0	✖

Total 1

A confirmation message is displayed.

Web servers

Messages

PLGC00521: Plug-in configuration file generation is complete for the Web server. topo1hsCell01.topo1hsNode01.ihs.

Web servers

Use this page to view a list of the installed web servers.

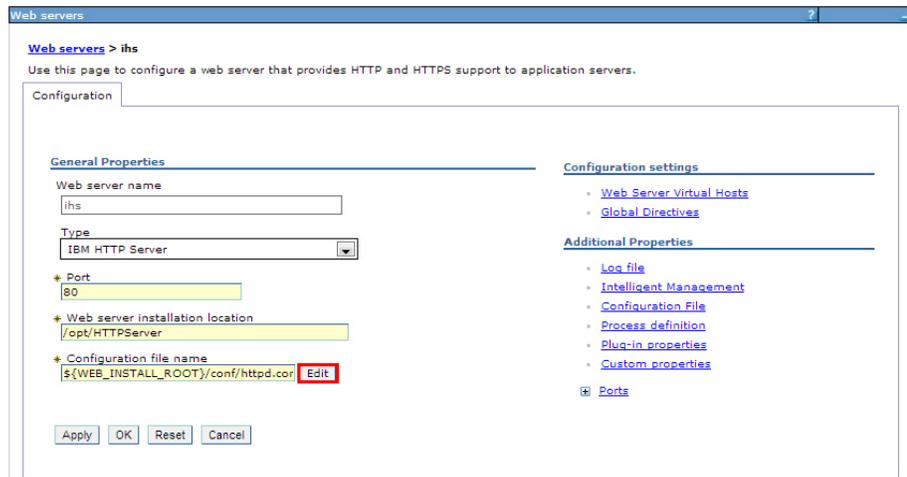

Preferences

Generate Plug-in Propagate Plug-in New... Delete Templates... Start Stop Terminate

<input type="checkbox"/>	ihs	IBM HTTP Server	topo1hsNode01	topo1hs	ND 8.5.5.0	✖

Total 1

- e. Make a note of the plugin-cfg.xml location displayed in the confirmation message.
- f. In the administrative console, on the Web servers page, click **ihs**, and then in the **Configuration file name** field, click **Edit**.

- g. In the editor, add a `was_ap22_module` and a `WebSpherePluginConfig` configuration to your `http.conf` file by adding the following text:

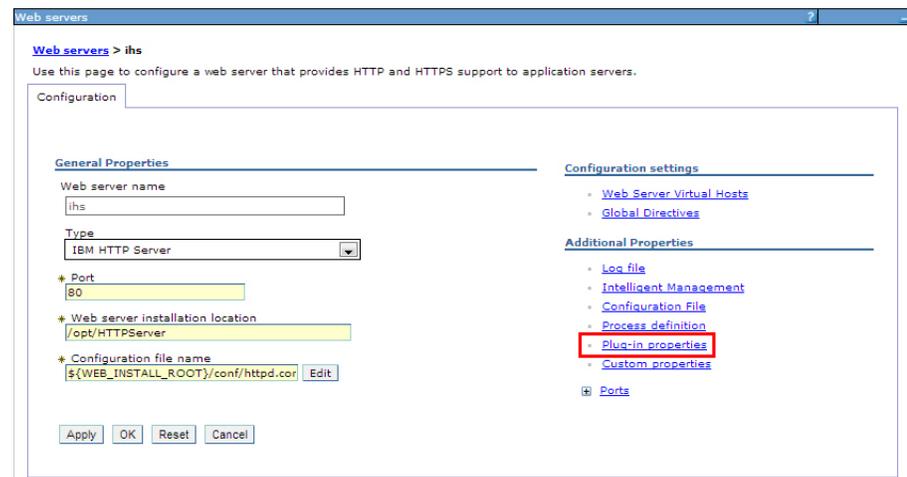

On Windows:

```
LoadModule was_ap22_module {IHS_Plugin_HOME}/bin/{64bits}/mod_was_ap22_http.dll
WebSpherePluginConfig {path to}/plugin-cfg.xml
```

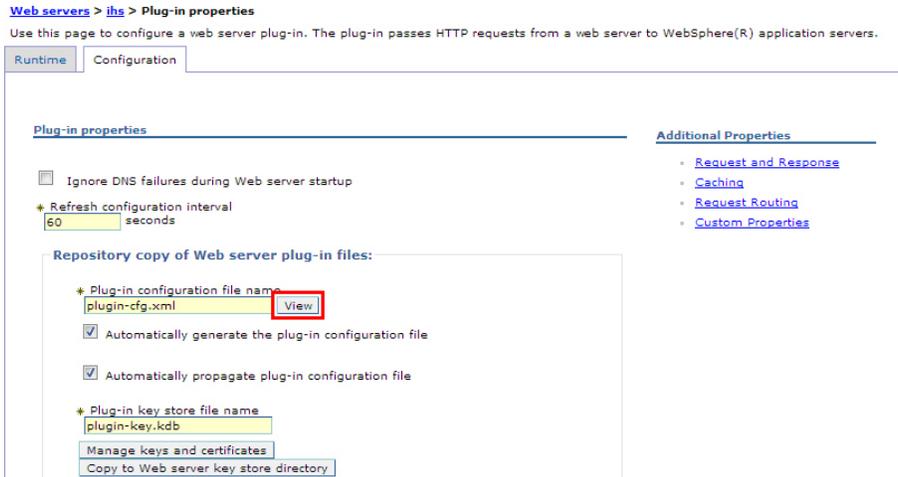

On Linux:

```
LoadModule was_ap22_module {IHS_Plugin_HOME}/bin/{64bits}/mod_was_ap22_http.so
WebSpherePluginConfig {path to}/plugin-cfg.xml
```

- h. In the administrative console, on the Web servers page for the "ihs" server, click **Plug-in properties**.

- i. In the **Plug-in Configuration file name** field, click **View**.

- j. Search for the cluster node and MobileFirst URI in the plugin-cfg.xml file.
For example:

```
<ServerCluster CloneSeparatorChange="false"
  GetDWLMTTable="false"
  IgnoreAffinityRequests="true"
  LoadBalance="Round Robin"
  Name="Worklight"
  PostBufferSize="0"
  PostSizeLimit="-1"
  RemoveSpecialHeaders="true"
  RetryInterval="60"
  ServerIOTimeoutRetry="-1">
<Server CloneID="17oi9lu2o"
  ConnectTimeout="5"
  ExtendedHandshake="false"
  LoadBalanceWeight="2"
  MaxConnections="-1"
  Name="topowas1Node01_server1"
  ServerIOTimeout="900"
  WaitForContinue="false">
  <Transport Hostname="topowas1" Port="9080" Protocol="http"/>
  <Transport Hostname="topowas1" Port="9443" Protocol="https">
    <Property Name="keyring" Value="/opt/Plugins/config/ihs/plugin-key.kdb"/>
    <Property Name="stashfile" Value="/opt/Plugins/config/ihs/plugin-key.sth"/>
  </Transport>
</Server>
<Server CloneID="17oi9m7kg"
  ConnectTimeout="5"
  ExtendedHandshake="false"
  LoadBalanceWeight="2"
  MaxConnections="-1"
  Name="topowas2Node01_server2"
  ServerIOTimeout="900"
  WaitForContinue="false">
  <Transport Hostname="topowas2" Port="9080" Protocol="http"/>
  <Transport Hostname="topowas2" Port="9443" Protocol="https">
    <Property Name="keyring" Value="/opt/Plugins/config/ihs/plugin-key.kdb"/>
    <Property Name="stashfile" Value="/opt/Plugins/config/ihs/plugin-key.sth"/>
  </Transport>
</Server>

<PrimaryServers>
  <Server Name="topowas1Node01_server1"/>
  <Server Name="topowas2Node01_server2"/>
</PrimaryServers>
</ServerCluster>
```

```

<UriGroup Name="default_host_Worklight_URIs">
  <Uri AffinityCookie="JSESSIONID"
    AffinityURLIdentifier="jsessionid"
    Name="/appcenterconsole/*"/>
  <Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/worklight/*"/>
  <Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/applicationcenter/*"/>
</UriGroup>

```

If your configuration file does not include cluster servers and URIs, delete the "ihs" server and create it again.

- k. Optional: On the Plug-in properties page for the "ihs" server, click **Request Routing** if you want to set a load-balancing policy.

Additional Properties

- [Request and Response](#)
- [Caching](#)
- **[Request Routing](#)**
- [Custom Properties](#)

- l. Optional: On the Plug-in properties page for the "ihs" server, click **Caching** if you want to configure caching.

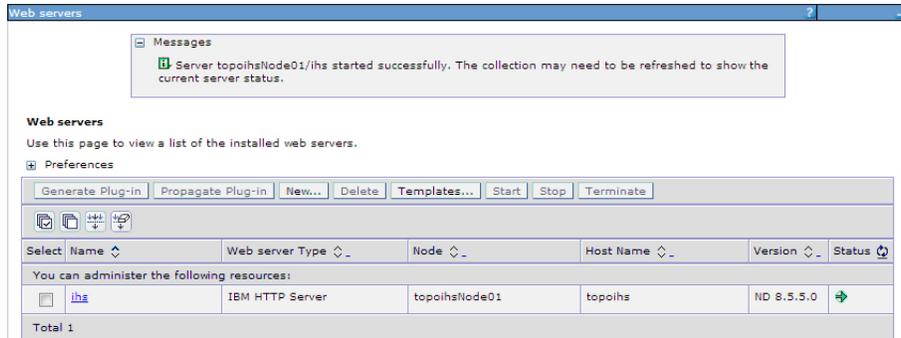

Caching

Enable Edge Side Include (ESI) processing to cache the responses
 Enable invalidation monitor to receive notifications

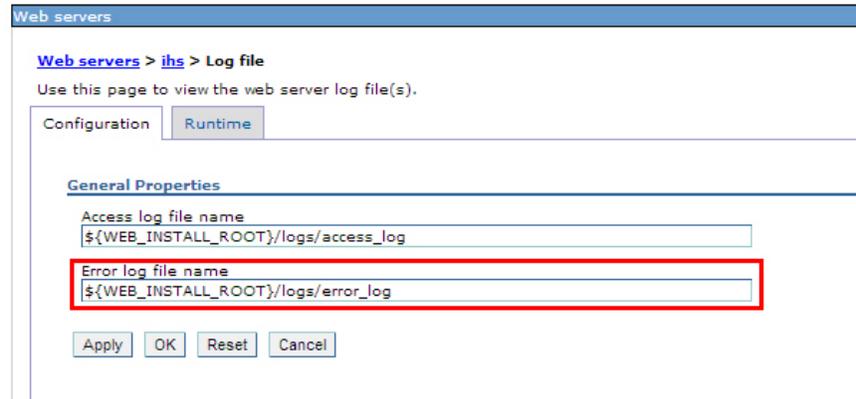

Maximum cache size
 1024 KB

Apply OK Reset Cancel

10. Start the IBM HTTP server and verify that the server is running.
 - a. In the WebSphere Application Server administrative console, go to **Servers > Server Types > Web servers**.
 - b. Select the IBM HTTP server you created (in this example, named "ihs"), and then click **Start**.

- c. If the server fails to start, check the log file. To find the location of the log file:
- 1) In the administrative console, on the Web servers page for the "ihs" server, click **Log file**.
 - 2) On the log file page, click the **Configuration** tab.
 - 3) The location of the log file is displayed in the **Error log file name** field.

- d. To verify that the IBM HTTP server is running, enter the URL for the MobileFirst Operations Console in a web browser. For example:
 http://Host1:80/worklightconsole.

Results

IBM MobileFirst Platform Foundation is now installed on an IBM WebSphere Application Server Network Deployment cluster, and is ready for use.

Setting up HTTP Server in a WebSphere Application Server Liberty profile farm

You can set up an IBM HTTP Server in a MobileFirst cluster environment with the Liberty profile.

Before you begin

Install a server farm for Liberty. See "Installing a server farm" on page 6-138. If a server farm is not configured, the MobileFirst Server installation does not work properly. As a consequence, the changes that are made by using the MobileFirst Operations Console or the Administration Service are not replicated to all the servers of the farm. The result is inconsistent behavior for client devices that connect to the MobileFirst Server.

About this task

You can set up IBM MobileFirst Platform Foundation in the topology similar to the one shown in Figure 6-31.

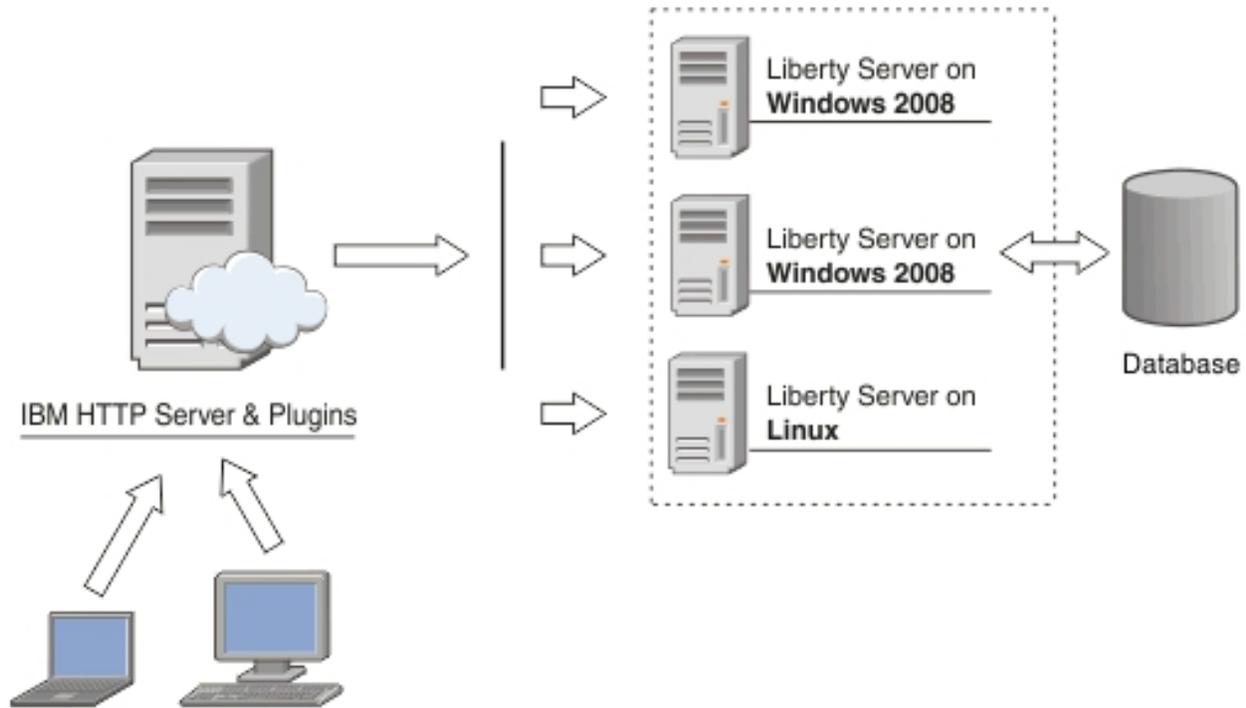

Figure 6-31. MobileFirst cluster topology with the Liberty profile

If you install IBM HTTP Server, you set up some JNDI properties to configure the administration components. For more information, see “Using a reverse proxy with server farm and WebSphere Application Server Network Deployment topologies” on page 6-29 and “Defining the endpoint of the MobileFirst Administration services” on page 6-102.

This procedure uses the following hardware and software elements.

Table 6-62. Hardware

Host name	Operating system	Description
Host1	RHEL 6.2	IBM HTTP server with Web Server plug-in, acting as load balancer.
Host2	RHEL 6.2	Liberty farm server 1
Host3	RHEL 6.2	Liberty farm server 2
Host4	RHEL 6.2	DB2 server

Table 6-63. Software

Name	Description
IBM Installation Manager	Install IBM HTTP Server , IBM Liberty profile, and IBM MobileFirst Platform Foundation.

Table 6-63. Software (continued)

Name	Description
IBM HTTP Server	You need to get access to the installation repository before you start the procedure. IBM HTTP Server is also included in the WebSphere Application Server installation repository.
Web Server Plug-ins	You need to get access to the installation repository before you start the procedure. IBM HTTP Server Plug-in is also included in the WebSphere Application Server installation repository.
IBM Liberty profile	You need to get access to the installation repository before you start the procedure. IBM Liberty profile is also included in the WebSphere Application Server installation repository.
IBM MobileFirst Platform Foundation	You need to get access to the installation repository before you start the procedure.
IBM DB2	Your DB2 server must be available before you start the IBM MobileFirst Platform Foundation installation.

Procedure

1. Install IBM HTTP Server and Web Server Plug-ins.
 - a. On the Host1 server, log on as the root user ID and run IBM Installation Manager to install the IBM HTTP server and Web Server Plug-ins. This documentation assumes that the applications are installed in the following places:
 - IBM HTTP Server home**
/opt/HTTPServer
 - Web Server Plug-ins home**
/opt/Plugins
2. Start the Liberty profile servers to test whether you can access the MobileFirst Operations Console on Host2 and Host3 by browsing to the associated URLs:
 - http://Host2:9080/worklight/console
 - http://Host3:9080/worklight/console

Check that both MobileFirst Operations Console are running.
3. Run the following command on Host1 to start the IBM HTTP server.

```
/opt/HTTPServer/bin/apachectl start
```

If you encounter problems when IBM HTTP server is starting, see “Troubleshooting IBM HTTP Server startup” on page 6-346.
4. Ensure that the IBM HTTP Server can be accessed at the following URL in a web browser:

```
http://<hostname>:<port>
```
5. For each Liberty server, generate a web server plug-in configuration file named `plugin-cfg.xml`.

The web server plug-in is used to forward HTTP requests from the web server to the application server.

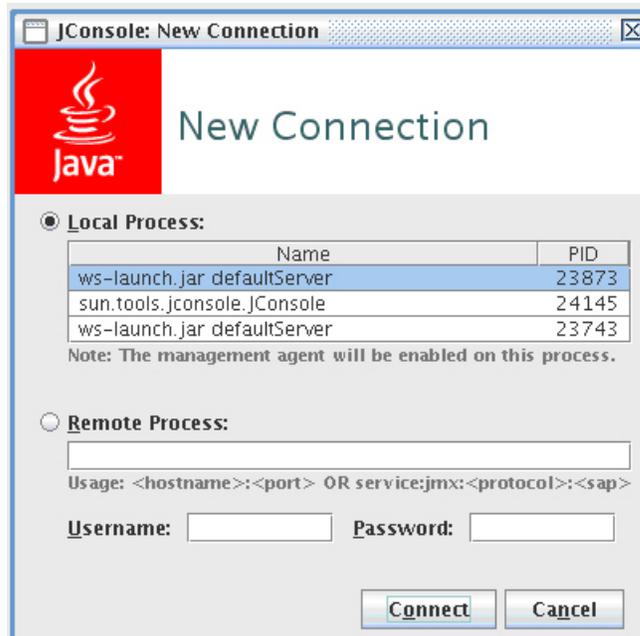

- a. Start the server that hosts your applications and ensure that the localConnector-1.0 feature and other required features are included in the server configuration. Use the pluginConfiguration element in the server configuration file to specify the **webserverPort** and **webserverSecurePort** attributes for requests that are forwarded from the web server. By default, the value of **webserverPort** is 80 and the value of **webserverSecurePort** is 443. Assign the value * to the host attribute to ensure that applications on the Liberty server can be accessed from a remote browser. Here is an example of a server.xml server configuration file:

```
<server description="new server">
  <featureManager>
    <feature>localConnector-1.0</feature>
    <feature>jsp-2.2</feature>
  </featureManager>
  <httpEndpoint id="defaultHttpEndpoint" host="*" httpPort="9080">
    <tcpOptions soReuseAddr="true" />
  </httpEndpoint>
  <pluginConfiguration webserverPort="80" webserverSecurePort="443"/>
</server>
```

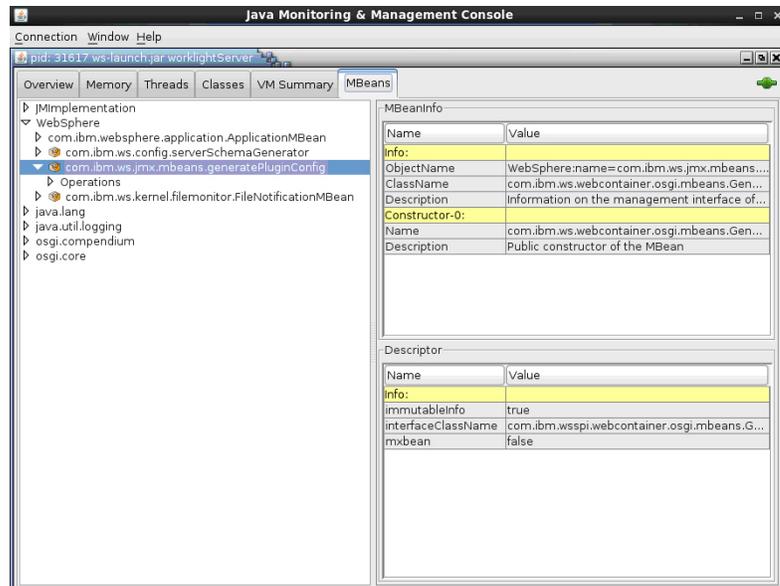

- b. Use one of the following methods to generate the plugin-cfg.xml file for the Liberty server that is running your application.

jConsole

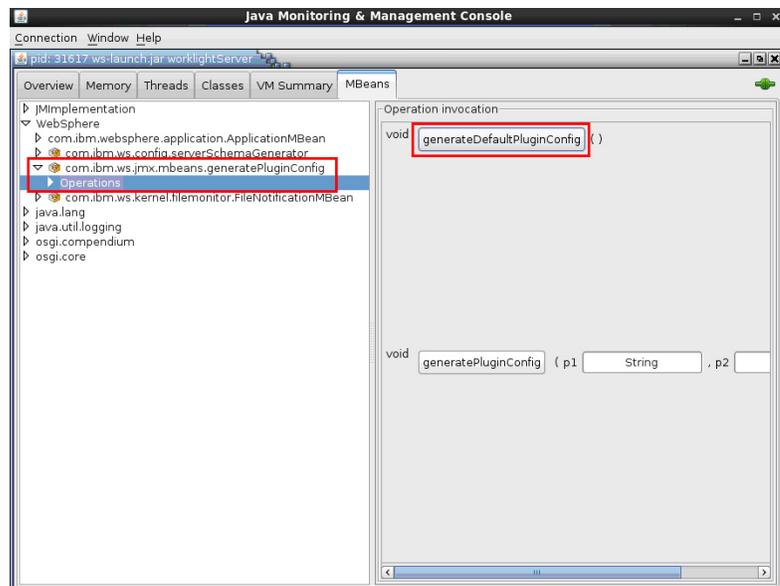

- 1) Using the same JDK as the server, run the jConsole Java utility from a command prompt. For example, run the following command:
C:\java\bin\jconsole
- 2) In the jConsole window, click **Local Process**, click the server process in the list of local processes, and then click **Connect**.

- 3) In the Java Monitoring & Management Console, click the **MBeans** tab.

- 4) Select and invoke the defaultPluginConfig generation MBean operation to generate the plugin-cfg.xml file.

You can find the generated file in the \wlp\usr\servers\

```
<?xml version="1.0" encoding="UTF-8"?>
<Config ASDisableNagle="false"
  AcceptAllContent="false"
  AppServerPortPreference="HostHeader"
  ChunkedResponse="false"
  FIPSEnable="false"
  IISDisableNagle="false"
  IISPluginPriority="High"
  IgnoreDNSFailures="false"
  RefreshInterval="60"
  ResponseChunkSize="64"
  SSLConsolidate="false"
  SSLPKCSDriver="REPLACE"
  SSLPKCSPassword="REPLACE"
  TrustedProxyEnable="false">
```

```

VHostMatchingCompat="false">
<Log LogLevel="Error" Name="String\logs\String\http_plugin.log"/>
<Property Name="ESIEnable" Value="true"/>
<Property Name="ESIMaxCacheSize" Value="1024"/>
<Property Name="ESIInvalidationMonitor" Value="false"/>
<Property Name="ESIEnableToPassCookies" Value="false"/>
<Property Name="PluginInstallRoot" Value="String"/>
<VirtualHostGroup Name="default_host">
  <VirtualHost Name="*:443"/>
  <VirtualHost Name="*:80"/>
  <VirtualHost Name="*:9080"/>
</VirtualHostGroup>
<ServerCluster CloneSeparatorChange="false"
  GetDWLMTable="false"
  IgnoreAffinityRequests="true"
  LoadBalance="Round Robin"
  Name="String_default_node_Cluster"
  PostBufferSize="64"
  PostSizeLimit="-1"
  RemoveSpecialHeaders="true"
  RetryInterval="60">
  <Server CloneID="s56"
    ConnectTimeout="0"
    ExtendedHandshake="false"
    MaxConnections="-1"
    Name="default_node_String0"
    ServerIOTimeout="900"
    WaitForContinue="false">
    <Transport Hostname="wasvm56" Port="9080" Protocol="http"/>
  </Server>
  <PrimaryServers>
    <Server Name="default_node_String0"/>
  </PrimaryServers>
</ServerCluster>
<UriGroup Name="default_host_String_default_node_Cluster_URIs">
  <Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/tr
</UriGroup>
<Route ServerCluster="String_default_node_Cluster"
  UriGroup="default_host_String_default_node_Cluster_URIs"
  VirtualHostGroup="default_host"/>
</Config>

```

Eclipse

- 1) Make sure that your Liberty server is started.
 - 2) In Eclipse, in the servers panel, right-click the Liberty server, and then click **Utilities > Generate Plugin Config**.
- c. Copy the plugin-cfg.xml file to the machine that hosts the IBM HTTP Server web server, and then restart the web server to activate the settings in the file. Typically, you must enable the plug-in within the httpd.conf file of the web server by using the LoadModule phrase, and you must specify the location of the plugin-cfg.xml file using the WebSpherePluginConfig phrase.

On Windows

```
LoadModule was_ap22_module "path\to\mod_was_ap22_http.dll"
WebSpherePluginConfig "path\to\plugin-cfg.xml"
```

On other distributed systems

```
LoadModule was_ap22_module "path\to\mod_was_ap22_http.so"
WebSpherePluginConfig "path\to\plugin-cfg.xml"
```

6. Use one of the following methods to merge the plugin-cfg.xml files for all the Liberty servers in the cluster.
 - Manually merge the files by using a text editor.

- Use the job manager to submit a **Generate merged plugin configuration for Liberty servers** job.

For more information about the job manager, see [Generating a merged plug-in configuration for Liberty profile servers using the job manager](#).

7. Verify that workloads are distributed to multiple Liberty servers via the IBM HTTP Server and Web Server Plug-ins.
 - a. Ensure that session affinity is enabled.

To do so, check that a **CloneID** attribute is included for each server in the `plugin-cfg.xml` file of the IBM HTTP Server and Web Server Plug-ins. Although you can generate **CloneID** values automatically, in production environments, you must specify particular strings in the Liberty Profile `server.xml` file. See [Configuring session persistence for the Liberty profile](#).

If you do not specify particular strings, the value of the **CloneID** might change under some circumstances and session affinity would stop working. Automatically generated **CloneID** attributes should not be used in a production environment. In the WebSphere Application Server Liberty profile, the **CloneID** attribute is generated when you start a server for the first time; it is regenerated if you start the server with the `--clean` option.

In a production use case, manually assigning a clone ID ensures that the **CloneID** attribute is stable and that request affinity is correctly maintained. The **CloneID** attribute must be unique for each server and can be 8 to 9 alphanumeric characters in length.

The following example shows **CloneID** attributes for three servers:

```
<ServerCluster CloneSeparatorChange="false"
  GetDWLMTable="false"
  IgnoreAffinityRequests="true"
  LoadBalance="Round Robin"
  Name="String_default_node_Cluster1"
  PostBufferSize="64"
  PostSizeLimit="-1"
  RemoveSpecialHeaders="true"
  RetryInterval="60">
  <Server CloneID="s59"
    ConnectTimeout="0"
    ExtendedHandshake="false"
    MaxConnections="-1"
    Name="default_node_String1"
    ServerIOTimeout="900"
    WaitForContinue="false">
    <Transport Hostname="wasvm59.example.com" Port="9080" Protocol="http"/>
  </Server>
  <Server CloneID="s56"
    ConnectTimeout="0"
    ExtendedHandshake="false"
    MaxConnections="-1"
    Name="default_node_String2"
    ServerIOTimeout="900"
    WaitForContinue="false">
    <Transport Hostname="wasvm56.example.com" Port="9080" Protocol="http"/>
  </Server>
  <Server CloneID="vm28"
    ConnectTimeout="0"
    ExtendedHandshake="false"
    MaxConnections="-1"
    Name="default_node_String3"
    ServerIOTimeout="900"
    WaitForContinue="false">
    <Transport Hostname="wasvm28.example.com" Port="9080" Protocol="http"/>
  </Server>
</PrimaryServers>
```

```

        <Server Name="default_node_String1"/>
        <Server Name="default_node_String2"/>
        <Server Name="default_node_String3"/>
    </PrimaryServers>
</ServerCluster>

```

- b. Ensure that each Liberty server is started.
- c. Verify that the round-robin load balancing process is successfully routing application requests to each of the back-end Liberty servers.

Troubleshooting IBM HTTP Server startup

Problems to start the IBM HTTP Server during deployment of a IBM MobileFirst Platform Server on a WebSphere Application Server Liberty profile farm might be caused by an exception in the runtime library.

About this task

When you set up IBM MobileFirst Platform Foundation on a WebSphere Application Server Liberty profile farm, you are instructed to start the IBM HTTP Server by running the following command:

```
/opt/HTTPServer/bin/httpd -d /opt/HTTPServer -k start -f /opt/HTTPServer/conf/httpd.conf
```

If the attempt fails with the following message, the problem might be caused by an attempt to start IBM HTTP Server outside a WebSphere Application Server environment in which certain libraries cannot be found.

```
/opt/HTTPServer/bin/httpd: error while loading shared libraries: libexpat.so.0: cannot open shared object file: No such file or directory
```

If a similar message is displayed, you can make the required libraries available as follows.

Procedure

1. Check the IBM HTTP Server libraries:

```
ldd /opt/HTTPServer/bin/httpd
```

The output shows that `libexpat.so.0` cannot be found:

```

linux-vdso.so.1 => (0x00007fff8c9d3000)
libc.so.6 => /lib64/libc.so.6 (0x00000039fb000000)
libaprutil-1.so.0 => /usr/lib64/libaprutil-1.so.0 (0x00007fc371a7d000)
librt.so.1 => /lib64/librt.so.1 (0x000000039fac000000)
libcrypt.so.1 => /lib64/libcrypt.so.1 (0x00000003a07c000000)
libpthread.so.0 => /lib64/libpthread.so.0 (0x000000039fa8000000)
libdl.so.2 => /lib64/libdl.so.2 (0x000000039fa0000000)
libexpat.so.0 => not found
libapr-1.so.0 => /usr/lib64/libapr-1.so.0 (0x00007fc37184f000)
libc.so.6 => /lib64/libc.so.6 (0x000000039fa4000000)
libuuid.so.1 => /lib64/libuuid.so.1 (0x00000003a04c000000)
libexpat.so.1 => /lib64/libexpat.so.1 (0x000000039ff4000000)
libdb-4.7.so => /lib64/libdb-4.7.so (0x000000039fd8000000)
/lib64/ld-linux-x86-64.so.2 (0x000000039f9c000000)
libfreeb13.so => /lib64/libfreeb13.so (0x00000003a080000000)

```

2. Find the library on the file system.

```
ls -l `locate libexpat.so.0`
```

```

[root@topowas1 opt]# ls -l `locate libexpat.so.0`
lrwxrwxrwx. 1 root root    17 Apr 20 04:20 /opt/HTTPServer/lib/libexpat.so.0 -> libexpat.so.0.1.0
-rwxr-xr-x. 1 root root 158148 Feb 20 13:54 /opt/HTTPServer/lib/libexpat.so.0.1.0

```

3. Check `/etc/ld.so.conf`.

```
cat /etc/ld.so.conf
```

The output shows that it includes all conf files under /etc/ld.so.conf.d/.
include ld.so.conf.d/*.conf

4. Add the IBM HTTP Server library to the configuration.
 - a. `cd /etc/ld.so.conf.d/`
 - b. Add the http library to the system configuration. The location of the IBM HTTP Server lib is shown in Step 1.
`echo /opt/HTTPServer/lib > httpd-lib.conf`
 - c. Remove the ldd cache.
`rm /etc/ld.so.cache`
 - d. Reload the ldd configuration.
`/sbin/ldconfig`
5. Check the IBM HTTP Server libraries again:
`ldd /opt/HTTPServer/bin/httpd`

The output shows that `libexpat.so.0` is available:

```
linux-vdso.so.1 => (0x00007ffffd594a000)
libm.so.6 => /lib64/libm.so.6 (0x00000039fb000000)
libaprutil-1.so.0 => /opt/HTTPServer/lib/libaprutil-1.so.0 (0x00007f20474bf000)
librt.so.1 => /lib64/librt.so.1 (0x00000039fac00000)
libcrypt.so.1 => /lib64/libcrypt.so.1 (0x0000003a07c00000)
libpthread.so.0 => /lib64/libpthread.so.0 (0x00000039fa800000)
libdl.so.2 => /lib64/libdl.so.2 (0x00000039fa000000)
libexpat.so.0 => /opt/HTTPServer/lib/libexpat.so.0 (0x00007f204739c000)
libapr-1.so.0 => /opt/HTTPServer/lib/libapr-1.so.0 (0x00007f2047271000)
libc.so.6 => /lib64/libc.so.6 (0x00000039fa400000)
/lib64/ld-linux-x86-64.so.2 (0x00000039f9c00000)
libfreeb13.so => /lib64/libfreeb13.so (0x0000003a08000000)
```

6. Start the IBM HTTP Server.

Integrating IBM WebSphere DataPower with a cluster of instances of MobileFirst Server

You can use IBM WebSphere DataPower as a gateway for all incoming connections for IBM MobileFirst Platform Foundation and Application Center, and IBM HTTP Server (IHS) for load-balancing MobileFirst Server that are deployed on an IBM WebSphere Application Server 8.5 cluster or a Liberty profile server farm.

Before you begin

Ensure that the following environments are available:

- MobileFirst Server is deployed on an IBM WebSphere Application Server ND cluster or on a Liberty profile server farm and is configured to use DB2 or any compatible database. For more information, see “Typical topologies of a MobileFirst instance in an extranet infrastructure” on page 6-327.
- IBM MobileFirst Platform Foundation Application Center is set up on an IBM WebSphere Application Server ND cluster. For more information, see “Installing and configuring the Application Center” on page 6-235.
- IBM WebSphere DataPower XI52.
- IBM HTTP Server.
- Any LDAP server with SSL enabled.

About this task

This procedure explains how to set up IBM MobileFirst Platform Foundation in the topology similar to the one shown in Figure 6-32.

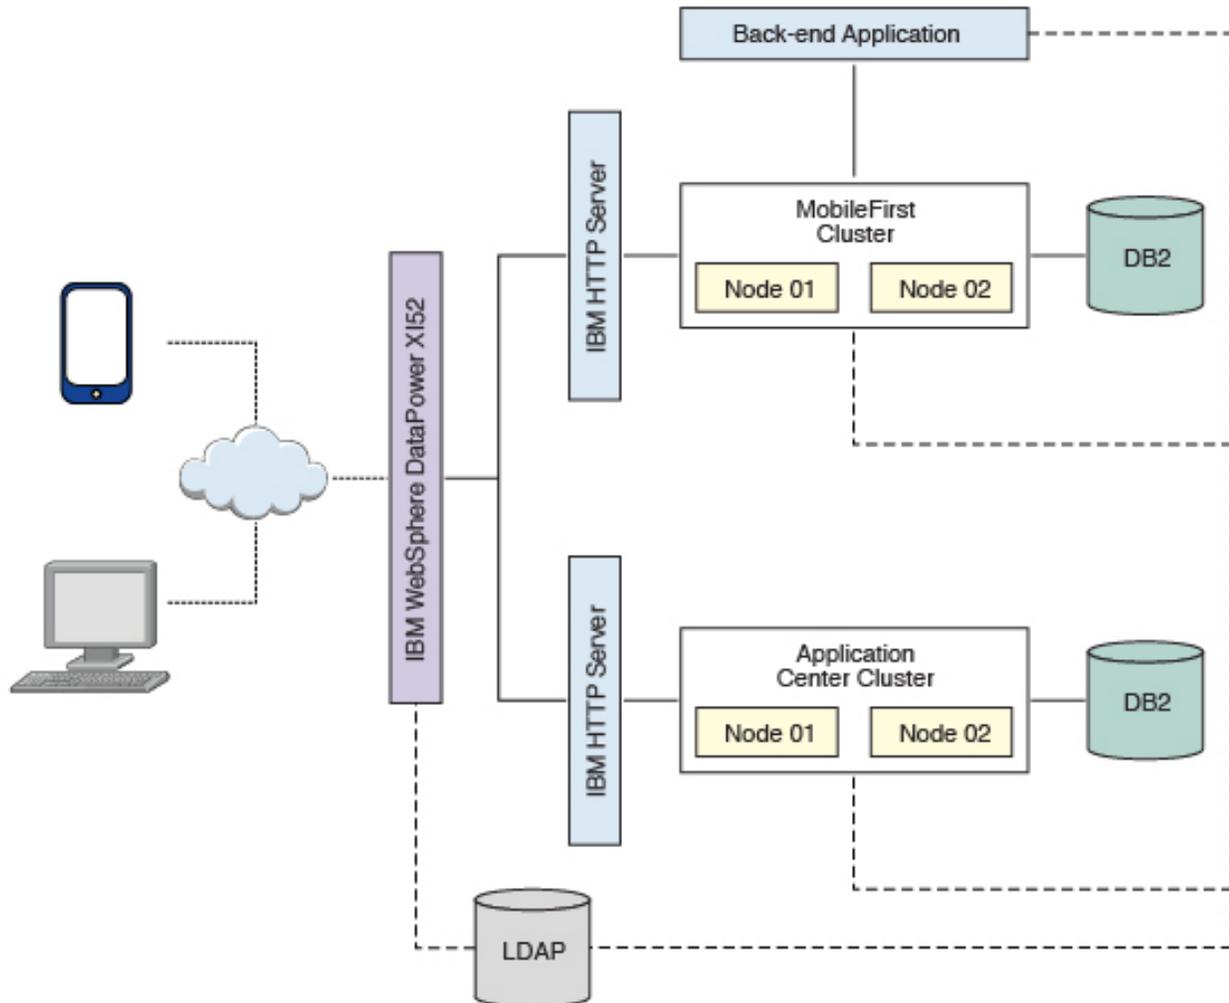

Figure 6-32. IBM MobileFirst Platform Foundation integration with an IBM WebSphere Application Server 8.5 Cluster or a Liberty profile Server Farm

DataPower XI52 acts as the gateway for all IBM MobileFirst Platform Foundation and Application Center requests. DataPower validates all incoming user credentials against an LDAP registry. If the validation is successful, DataPower generates an LTPA token, which is present as part of a session cookie. This cookie is only valid for one session and is used for all further requests during that session. The cookies themselves contain information about the user that has been authenticated, the realm for which the user was authenticated (such as an LDAP server) and a timestamp. A request with a valid LTPA cookie can access a server that is a member of the same authentication domain as the first server. The request is automatically authenticated, thereby enabling single-sign-on (SSO).

All requests that reach the MobileFirst cluster or the backend application validate only the LTPA token. If the LTPA token is valid, the request is authenticated according to the rules that are set. The LTPA token guarantees that as long as the

token is valid, all requests have SSO capability into all backend servers, including IBM MobileFirst Platform Foundation and Application Center.

The following sequence of events takes place when a mobile application makes a request (see Figure 6-33):

1. The mobile application makes a request to the DataPower gateway.
2. DataPower checks for an LTPA token in the incoming request.
3. If a valid LTPA token is present, the request is sent to the IBM MobileFirst Platform Foundation cluster.
 - If an LTPA token is not present or if the token is not valid, DataPower throws an authentication challenge. The mobile application handles the challenge and then prompts for user credentials.
4. The MobileFirst cluster validates the LTPA token and sends the request to the backend application server along with the LTPA token.
5. The backend application server validates the LTPA token and sends the response back to IBM MobileFirst Platform Foundation.
6. IBM MobileFirst Platform Foundation forwards the request to DataPower, and DataPower forwards it to the requesting mobile application.

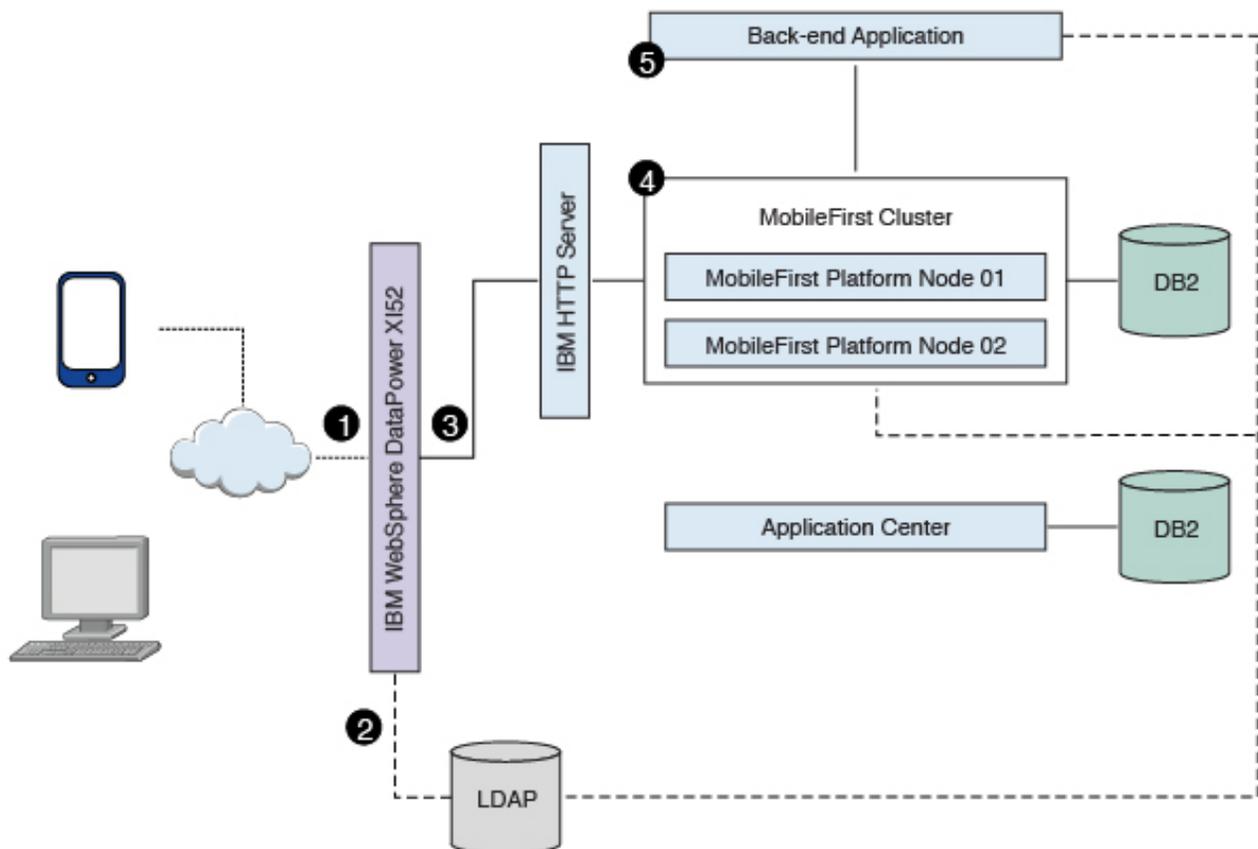

Figure 6-33. Mobile application request-response flow

The Application Center request-response flow takes a similar route to the mobile application flow, except that requests are routed to the Application Center server instead of to the MobileFirst cluster (see Figure 6-34 on page 6-350).

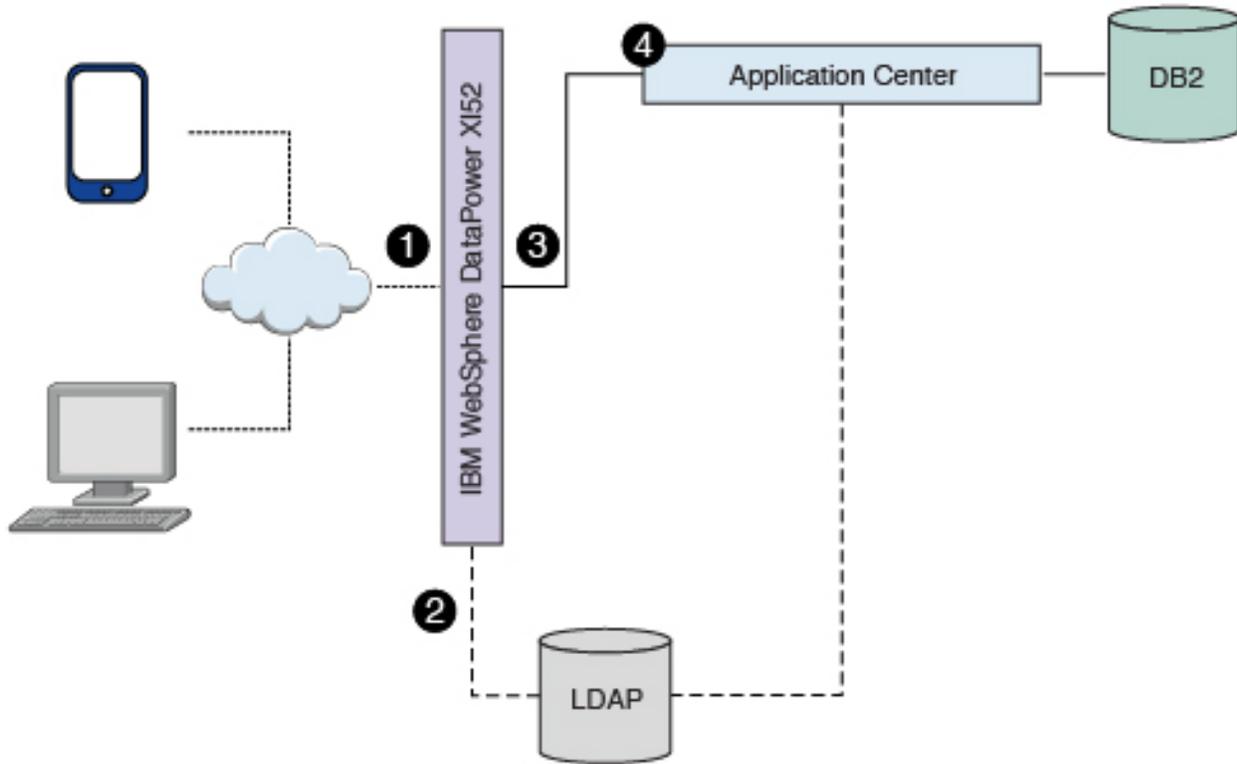

Figure 6-34. Application Center request-response flow

Procedure

1. Configure server security.
 - On a WebSphere Application Server cluster:
 - a. Login to the WebSphere Application Server integrated solutions console.
 - b. Enable and configure application security.
 - 1) Navigate to **Security > Global security**, and then click **Security Configuration Wizard**.
 - 2) In the "Specify extent of protection" pane, select **Enable application security**.
 - 3) In the "Select user repository" pane, click **Federated repositories** to integrate with the LDAP server. Several different repositories, both LDAP and non-LDAP, can be configured in the federated repository. Enter the LDAP server details. Refer to the WebSphere Application Server documentation for detailed instructions.
 - 4) Complete the configuration steps and save your changes.
 - 5) On the "Global security" page, confirm that the following settings apply:
 - The **Enable administrative security** is selected.
 - The user account repository is set to LDAP.
 - c. Enable WebSphere Application Server LTPA SSO between the MobileFirst Server cluster and backend servers. To support SSO across multiple WebSphere Application Server domains or cells, you must share the LTPA keys and the password among the domains. You need to export the LTPA

keys from one of the domains and import them into all other domains in which you want to enable SSO. For detailed instructions, see *Configuring LTPA and working with keys*.

- d. Stop and restart the WebSphere Application Server cluster for the application security changes to take effect.
- On a Liberty profile server farm:
 - a. Integrate the LDAP server with Liberty profile, For detailed instructions, see *Configuring LDAP user registries with the Liberty profile*. You must configure LDAP user registries on each member of the liberty server farm. The following file is a sample LDAP configuration for Liberty server:

```
<!-- LDAP configuration Start -->
<ldapRegistry id="IBMDirectoryServerLDAP" realm="WASLTPARealm"
  host="9.186.9.169" port="389" ignoreCase="true"
  baseDN="dc=worklight,dc=com"
  bindDN="cn=admin,dc=worklight,dc=com"
  bindPassword="password"
  ldapType="IBM Tivoli Directory Server">
<idsFilters userFilter="(&(uid=%v)(objectclass=posixAccount))"
  groupFilter="(&(cn=%v)(objectclass=posixGroup))"
  userIdMap="*:uid"
  groupIdMap="*:cn"
  groupMemberIdMap="ibm-allGroups:member;ibm-allGroups:uniqueMember;groupOfName"
</ldapRegistry>
```

- b. Configure SSO for the Liberty server farm. To enable SSO on Liberty, you must configure an LTPA key file for each Liberty server in the Liberty farm. See *Configuring LTPA on the Liberty profile*. The following file is a sample LTPA configuration for Liberty server:

```
<ltpa keysFileName="${server.config.dir}/resources/security/ltpa.keystore" keysPassword=
```

2. Configure MobileFirst Server.

You can secure IBM MobileFirst Platform Foundation in a typical WebSphere Application Server runtime environment in two ways:

Option 1

Securing WebSphere Application Server using application security and securing the IBM MobileFirst Platform Foundation WAR file.

Option 2

Securing WebSphere Application Server using application security but not securing the IBM MobileFirst Platform Foundation WAR file.

Option 1 provides greater authentication security. The application server, such as the IBM WebSphere Application Server Liberty profile (Liberty) protects all resources and forces users to log in before any other authentication mechanism. The behavior occurs regardless of the expected authentication order for a security test. See “Supported configurations for LTPA” on page 12-96 for more information.

Once the user has been successfully authenticated, an LTPA token is returned. This LTPA token needs to be present as part of all future requests from the mobile application, including adapter invocations. On the MobileFirst Server side, the call to the backend application should be modified to carry this LTPA token.

For the purpose of explaining how this is done, assume that authentication configuration has a security test that uses a realm called WASLTPARealm, which is of type WebSphere LTPA. Assume also that there is an HTTP adapter defined on the server. Assume that the adapter is called SecureAdapter, and that it contains a procedure called getAccountInfo.

The following code snippet shows how to pass the LTPA token when invoking an adapter procedure from the mobile application.

```
function getAccountInfo(){
  var ltpaToken
  if(WL.Client.isUserAuthenticated('WASLTPARealm')){
    var attrs = WL.Client.getUserInfo('WASLTPARealm', 'attributes');
    if(attrs){
      ltpaToken = attrs.LtpaToken;
      console.log('Set ltpaToken again: '+ltpaToken);
    }
  }

  var token = {'LtpaToken2' : ltpaToken};
  var invocationData = {
    adapter: "SecureAdapter",
    procedure: "getAccountInfo",
    parameters: [token]
  };

  WL.Client.invokeProcedure(invocationData, {
    onSuccess: <on success callback>,
    onFailure: <on failure callback>
  });
}
```

On the server side, the adapter procedure needs to get the token, which is passed as a parameter. This parameter holds the LTPA token information that is used by the adapter to contact the backend service.

```
function getAccountInfo(token) {
  WL.Logger.info(token);

  var input = {
    method : 'get',
    returnedContentType : 'xml',
    cookies: token,
    path : '<path to the backend service>'
  };

  return WL.Server.invokeHttp(input);
}
```

Since V6.2.0, MobileFirst Server is composed of one or more runtime environments, an administration console and administration services, an enterprise application store, and an operational analytics feature. MobileFirst Server components run as web applications on an application server. For more information about MobileFirst Server components, see “Introduction to the MobileFirst Server components” on page 6-17.

The roles associated with the MobileFirst Operations Console and Administration Services components are different from the role defined in the WASLTPAModule login module (see “WASLTPAModule login module” on page 8-620). The MobileFirst Operations Console and Administration services roles should be mapped to the IT administrator users who are responsible for running administration tasks on the mobile application such as application deployment, management, version enforcement, and management of push notifications.

The roles defined in the WASLTPAModule login module are part of the MobileFirst runtime environments. These roles should be mapped to the users or user groups that have been cleared to access the MobileFirst applications. MobileFirst Operations Console and Administration Services must be set up and configured before you proceed to deploy the MobileFirst runtime services

See the following instructions depending on your application server, to map the administration user roles for MobileFirst Operations Console and Administration Services:

- “Configuring WebSphere Application Server full profile for MobileFirst Server administration” on page 6-108
- “Configuring WebSphere Application Server Liberty profile for MobileFirst Server administration” on page 6-109

Once the runtime deployment is completed, you need to map the users against the roles defined in the WASLTPAModule login module or web.xml. In the WebSphere Application Server console, open the application configuration tab of the deployed MobileFirst Server and click **Security role to user/group mapping** to map the LDAP user to the MobileFirst roles.

- [View Deployment Descriptor](#)
- [Last participant support extension](#)

Figure 6-35. Mapping the LDAP user to WebSphere Application Server

Select your role name and click **Map users** to map the LDAP user to this application.

For IBM Worklight V6.0 and earlier, you must edit the web.xml file and add the user roles. For V6.1.0 and later, the roles can be added as part of the WASLTPAModule login module. See “WASLTPAModule login module” on page 8-620.

3. Configure Application Center.

- a. Complete the following configuration tasks depending on the server being used:
 - “Configuring the Java EE security roles on WebSphere Application Server full profile” on page 6-271
 - “Configuring the Java EE security roles on WebSphere Application Server Liberty profile” on page 6-272

- b. Manage users with LDAP.

Application Center uses two security roles: appcenteradmin and appcenteruser. The LDAP users need to be mapped against the security roles.

Depending on the server that you are using, refer to the "Configuring LDAP authentication" section under one of the following documentation links:

- "LDAP with WebSphere Application Server V7" on page 6-274
- "LDAP with WebSphere Application Server V8.x" on page 6-280
- "LDAP with Liberty profile" on page 6-285

c. Define the endpoint of the application resources.

In this configuration, Application Center is behind DataPower, which is acting as a secure reverse proxy. To manage the applications on your device, the Application Center console must be able to locate the Application Center REST services and generate the required number of URI that enable the mobile client to find the Application Center REST services.

By default, the URI protocol, host name, and port are the same as those defined in the web application server used to access the Application Center console; the context root of the Application Center REST services is `applicationcenter`. When the context root of the Application Center REST services is changed or when the internal URI of the web application server is different from the external URI that can be used by the mobile client, the externally accessible endpoint (protocol, host name, and port) of the application resources must be defined by configuring the web application server. (Reasons for separating internal and external URI could be, for example, a firewall or a secured reverse proxy that uses HTTP redirection.)

The following Application Center JNDI properties must reference the DataPower gateway's details:

- **`ibm.appcenter.services.endpoint`**
- **`ibm.appcenter.proxy.protocol`**
- **`ibm.appcenter.proxy.host`**
- **`ibm.appcenter.proxy.port`**

Depending on the server type, set the Application Center JNDI properties by completing one of the following procedures:

- "Configuring the endpoint of application resources (full profile)" on page 6-297
- "Configuring the endpoint of the application resources (Liberty profile)" on page 6-299

4. Configure DataPower. DataPower XI52 acts as the gateway for all IBM MobileFirst Platform Foundation and Application Center requests. DataPower validates all incoming user credentials against an LDAP registry. The following sections show how to configure DataPower.

a. Create a new multi-protocol gateway. Complete the following steps:

- 1) From the DataPower XI52 control panel, click the **Multi-Protocol Gateway** icon to open the Multi-Protocol Gateway main page.

Control Panel

Services

Figure 6-36. Accessing the Multi-Protocol Gateway main page

- 2) Click **Add** to add a new gateway.
- 3) Provide a name for the gateway and set **Type** to dynamic-backend.
- 4) Make sure that **Request Type** and **Response Type** are set to Non-XML.
- 5) On the Advanced tab page, select **Follow Redirects** and **Process Backend Errors**.
- 6) On the Stylesheet Params tab page, add the parameters listed in Table 6-64:

Table 6-64. Stylesheet parameters

Parameter name	Value
{http://www.datapower.com/param/config}applicationcenterBackend	http://<appcenterHostName>:<port>
{http://www.datapower.com/param/config}worklightBackend	http://<worklightIHSHostName>:<port>

- 7) On the General tab page, add an HTTPS (SSL) Front Side Handler with reverse SSL Proxy profile. Ensure that the following methods and versions are selected:
 - HTTP 1.0
 - HTTP 1.1
 - POST method
 - GET method
 - PUT method
 - HEAD method
 - OPTIONS
 - DELETE method
 - URL with Query Strings
 - URL with Fragment Identifiers
- 8) Click the plus sign (+) to add a new multi-protocol gateway policy.
- 9) Provide a name for the policy, click **Apply Policy**, and then click **Close Window**. The policy is added to the gateway.
- 10) Apply your configuration.

b. Edit the multi-protocol gateway policy. Add the following rules to provide form-based authentication, generate an LTPA token and verify the LTPA token. All the rules are described in the following tables. You must list them in the same order.

- 1) worklight-ssl-policy_skipFavicon: see Table 6-65
- 2) worklight-ssl-policy_verifyLTPA: see Table 6-66
- 3) worklight-ssl-policy_allowSSLLoginPage: see Table 6-67
- 4) worklight-ssl-policy_worklightSSLLogin: see Table 6-68 on page 6-357

Result	Not applicable.

Results

The different pieces of the topology are now configured and provide a seamless SSO experience for mobile applications as well as for Application Center.

Related information

Integrating with IBM WebSphere DataPower

Use IBM WebSphere DataPower as a reverse proxy and security gateway for handling inbound mobile traffic, or as a proxy and gateway for handling outbound traffic to a notification mediator.

Integration and authentication with a reverse proxy

You can use a reverse proxy to enable enterprise connectivity within a MobileFirst environment and to provide authentication to IBM MobileFirst Platform Foundation.

MobileFirst Security and LTPA

A lightweight third-party authentication (LTPA) token is a type of security token that is used by IBM WebSphere Application Server and other IBM products. LTPA can be used to send the credentials of an authenticated user to back-end services. It can also be used as a single sign-on (SSO) token between the user and multiple servers.

Sample dynamic routing stylesheet

You can use this sample stylesheet to handle the dynamic routing of requests between IBM MobileFirst Platform Foundation and IBM MobileFirst Platform Application Center. You refer to the stylesheet when you create rules to define a form-based authentication policy that generates and verifies LTPA tokens.

You provide a custom dynamic routing stylesheet when you define rule `worklight-ssl-policy_verifyLTPA` (see “Integrating IBM WebSphere DataPower with a cluster of instances of MobileFirst Server” on page 6-347, Table 6-66 on page 6-356), and when you define rule `worklight-ssl-policy_worklightSSLLogin` (see “Integrating IBM WebSphere DataPower with a cluster of instances of MobileFirst Server” on page 6-347, Table 6-68 on page 6-357).

Endpoints of the MobileFirst Server production server

You can create whitelists and blacklists for the endpoints of the IBM MobileFirst Platform Server.

Note: Information regarding URLs that are exposed by IBM MobileFirst Platform Foundation is provided as a guideline. Organizations must ensure the URLs are tested in an enterprise infrastructure, based on what has been enabled for white and black lists.

Table 6-69. MobileFirst applications

API URL, under <i><application root context>/</i>	Description	Suggested for whitelist?	For more information
apps/services/api/*	Used by client applications for operations such as init, Direct Update requests, invocation of adapter procedures, and more.	Yes	"HTTP Interface of the production server" on page 6-364
apps/services/random/*	Used for generating a random number. Used by JSON store implementation and encrypted cache on the client side.	Yes, if you plan to use offline storage such as JSON store.	"JSONStore overview" on page 8-416
apps/services/reach	Used for the reach API, this servlet returns status 200 with OK, letting you verify that the MobileFirst Server is up and running.	Yes	
apps/services/www/*	Used by mobile web or desktop application to access its resources.	Yes	Web application resource requests
apps/services/download/*	Deprecated	No	

Table 6-69. MobileFirst applications (continued)

API URL, under <i><application root context>/</i>	Description	Suggested for whitelist?	For more information
apps/services/preview/*	Used to preview the application.	No. Used for development and administration purposes.	Preview application resource requests

Table 6-70. Direct update

API URL, under <i><application root context>/</i>	Description	Suggested for whitelist?	For more information
directUpdate/*	Used for serving the direct update .zip file.	Yes, if you plan to use Direct Update.	“Direct Update as a security realm” on page 8-382

Table 6-71. Node synchronization

API URL, under <i><application root context>/</i>	Description	Suggested for whitelist?	For more information
node/integration/*	Used to receive notifications from IBM MobileFirst Platform Foundation adapters that are based on Node.js. Not in use and can be blocked.	No	

Table 6-72. Vitality

API URL, under <i><application root context>/</i>	Description	Suggested for whitelist?	For more information
ws/rest/vitality	Used to check server availability. Returns a list of applications and adapters. For server administrators.	No	“Vitality queries for checking server health” on page 14-2

Table 6-73. Invoke back end procedure

API URL, under <application root context>/	Description	Suggested for whitelist?	For more information
invoke	Used to invoke an adapter procedure.	Yes, if application uses adapter authentication features, or if you want to access the adapter directly and not from the application. Note: If this API passes the firewall, everyone is able to invoke any adapter procedure and it is protected only by the adapter security test and not by the application security test.	"Accessing adapters from the /invoke endpoint" on page 8-336
subscribeSMS	Push subscription service API. Used by applications.	Yes, if application uses push subscription API.	"Web-based SMS subscription" on page 8-518
receiveSMS	SMS subscription service API. Used by applications.	Yes, if application uses SMS subscription API.	"Using two-way SMS communication" on page 8-522

Table 6-74. Client side logging

API URL, under <application root context>/	Description	Suggested for whitelist?	For more information
apps/services/loguploader/*	Used by client applications to upload their accumulated debug and analytics logs.	Yes	"Client-side log capture" on page 8-673
apps/services/configprofile/*	Used by client applications to GET their log configuration, which the admin set via the Log Configuration tab in the IBM MobileFirst Platform Operations Console.	Yes	"Client-side log capture" on page 8-673

Table 6-75. Dev

API URL, under <i><application root context>/</i>	Description	Suggested for whitelist?	For more information
dev/*	Development service API such as /invoke, /appdata, /preview, and others. Used in development environments only.	No, only for the development environment and not for QA, preproduction, or production.	

Table 6-76. Unstructured Supplementary Service Data (USSD)

API URL, under <i><application root context>/</i>	Description	Suggested for whitelist?	For more information
ussd/*	Used for communication with the USSD gateway.	Yes	"USSD Support" on page 8-316

Table 6-77. OAuth Server

API URL, under <i><application root context>/</i>	Description	Suggested for whitelist?	For more information
authorization/v1/clients/instance	Used by clients applications to register with the OAuth Server	No	"OAuth-based security model" on page 8-527 "Challenge handling in a gateway topology" on page 8-558
authorization/v1/authorization	Used by client applications to perform authorization	Yes, if you are using OAuth	"OAuth-based security model" on page 8-527
authorization/v1/token	Used by client applications to obtain access tokens	Yes, if you are using OAuth	"OAuth-based security model" on page 8-527
authorization/v1/publickey	Used by external resource filters to obtain the public key of the MobileFirst Server	Yes, if you are using OAuth	"OAuth-based security model" on page 8-527
authorization/v1/token/validation	Used for performing online token validation	Yes, if you are using OAuth	"OAuth-based security model" on page 8-527
authorization/v1/clients/preview	Used for registering applications in preview mode	No, only for development	"OAuth-based security model" on page 8-527
authorization/v1/testtoken	Used for obtaining access tokens during development	No, only for development	"OAuth-based security model" on page 8-527

HTTP Interface of the production server

You can use the HTTP interface of the production server to make application API requests or web application resource requests. Use the following request structures, headers, and elements.

Application API requests

Use the following request structure to perform an application API request:

```
{Protocol}://{Worklight Server}/apps/services/api/{Application ID}/{Application Environment}/{Action}
```

Table 6-78. Application API request headers

Header Name	Data Type	Description	Valid values
x-wl-app-version	String	Version of the application	
WL-Instance-ID	String	Protection mechanism for XSS attacks.	

Table 6-79. Application API request elements

Header Name	Data Type	Description	Valid values
Protocol	String		HTTP
Worklight Server	String	Host name or IP address (and possibly port) identifying the MobileFirst Server	
Application ID	String	Unique Identifier of the application within the MobileFirst Server. Every application deployed on the MobileFirst Server must have a unique identifier	Up to 256 alphanumeric and underscore characters
Application Environment	String	Name of the environment that the application is running on	air, android, Androidnative, blackberry, desktopbrowser, iOSnative, ipad, iphone, JavaMEnative, mobilewebapp, windows8, windowsphone
Action	String	Requested action	Details in following table

Table 6-80. Actions

Action	HTTP Request	Parameters
init	POST	x, isAjaxRequest – see the following table showing common parameters.
heartbeat	POST	x, isAjaxRequest – see the following table showing common parameters.
logactivity	POST	x, isAjaxRequest – see the following table showing common parameters. activity – string.
query	POST	x, isAjaxRequest – see the following table showing common parameters. filterList – JSON block parameterList – JSON block sorterList – JSON block Note: When the action is query , the request URL has the following structure: <code>.../query/{Adapter Name}/{Procedure Name}</code> where Adapter Name and Procedure Name are strings.
logout	POST	x, isAjaxRequest - see the following table showing common parameters.
login	POST	x, isAjaxRequest – see the following table showing common parameters. realm – string.
updates	POST	x, isAjaxRequest – see the following table showing common parameters. skin – current skin name (string) checksum – the checksum of the current skin (string) skinLoaderChecksum – the checksum of the skin selection code (string)
getup	POST	x, isAjaxRequest - see the following table showing common parameters.

Table 6-80. Actions (continued)

Action	HTTP Request	Parameters
deleteup	POST	x, isAjaxRequest – see the following table showing common parameters. userprefkey – the user preference to delete.
getuserinfo	POST	x, isAjaxRequest – see the following table showing common parameters.
getgadgetprefs	POST	x, isAjaxRequest - see the following table showing common parameters.
notifications	POST	x, isAjaxRequest – see the following table showing common parameters. subscribe – JSON string containing subscribe options unsubscribe – when specified, designates an unsubscribe action updateToken – the update notification token (string) adapter – the name of the notification adapter (string) eventSource – the name of the notification event source (string) alias – notification subscription alias (string) tag – the name of the tag (string)
fbcallback	GET or POST	x, isAjaxRequest – see the following table showing common parameters. popup – string
composite	POST	x, isAjaxRequest - see the following table showing common parameters. requests – a JSON string containing information about other actions to invoke. This action is used to combine several actions in a single HTTP request.
appversionaccess	GET	x, isAjaxRequest – see the following table showing common parameters.

Table 6-80. Actions (continued)

Action	HTTP Request	Parameters
setup	POST	x, isAjaxRequest - see the following table showing common parameters. userprefs contains JSON pairs of preference key and value
authentication	POST	x, isAjaxRequest - see the following table showing common parameters. action values are popup, test, or test_img
authenticate	POST	x, isAjaxRequest - see the following table showing common parameters. This is an empty handler used to allow the client to respond to authentication challenges with a challengeResponse that cannot fit in a single header or when all headers combined are bigger than the limit for header size.

Table 6-81. Common parameters

Parameter	Values	Comments
isAjaxRequest	true	Included with every GET and POST request only from Adobe™ AIR application.
-	None	Included with every POST request only from Webkit-based browsers and application frameworks: Safari, Chrome, and Adobe AIR.

Web application resource requests

Use the following request structure to submit a web application resource request:

{Protocol}://{Worklight Server}/apps/services/www/{Application ID}/{Application Environment}/{AppID}

Request elements

See *Application API Request Elements* for details about the following request elements: **Protocol**, **Worklight Server**, **Application ID**, and **Application Environment**.

Table 6-82. Request elements

Element	Data Type	Description	Valid Values
Application Resource Path	String	HTML, image, JavaScript, CSS, and any other application resource	Example values: img/bg.png, myWidget.html, js/myWidget.js

Preview application resource requests

Use the following request structure to preview application resource requests:

{Protocol}://{Worklight Server}/apps/services/preview/{Application ID}/{Application Environment}/{Ap

Request elements

See *Application API Request Elements* for details about the following request elements: **Protocol**, **Worklight Server**, **ApplicationID**, and **Application Environment**.

Table 6-83. Request elements

Element	Data Type	Description	Valid Values
Application Resource Path	String	HTML, image, JavaScript, CSS, and any other application resource	Example values: img/bg.png, myWidget.html, js/myWidget.js

Troubleshooting MobileFirst Server

You can troubleshoot to locate the server and databases on Windows 8, Windows 7, and Windows XP, or to find the cause of installation or database creation failure.

Troubleshooting to find the cause of installation failure

You can troubleshoot to find the cause of installation failure.

About this task

If installation failed but the cause is not obvious, you can troubleshoot by completing the following procedure:

Procedure

See the failed-install.log file in the installation directory or, if this file does not exist, the install.log file in the installation directory. On Windows systems, if the default installation location was chosen, the directory is C:\Program Files\IBM\Worklight\. This file contains details about the installation process.

What to do next

If you still cannot determine the cause of the installation failure, you can use the manual installation instructions to investigate the problem more thoroughly. See “Deploying a project WAR file and configuring the application server manually” on page 12-37.

Troubleshooting failure to create the DB2 database

An incompatible database connection mode might result in failure to create the DB2 database.

About this task

If the following message is displayed when you attempt to create a DB2 database, proceed as follows:

```
"Creating database <WL_DB> (this may take 5 minutes) ... failed: Cannot connect to database <WL_DB> after it was created: com.ibm.db2.jcc.am.SqlException: DB2 SQL Error: SQLCODE=-1035, SQLSTATE=57019, SQLERRMC=null, DRIVER=<driver_version>"
```

Procedure

1. Wait a few minutes for the current DB2 database connections to close, and then click **Back**, and then **Next** to check whether the issue is solved.
2. If the problem persists, contact your database administrator to solve the database connection issue that is documented on the SQL1035N web page.

Troubleshooting a MobileFirst Server upgrade with Derby as the database

If IBM MobileFirst Platform Application Center is installed and uses Apache Derby as a database, stop the application server that runs the application before you run IBM Installation Manager to upgrade a IBM MobileFirst Platform Server installation.

About this task

During an upgrade of MobileFirst Server, if Application Center is installed, the installer migrates the database that is used by Application Center. When Apache Derby is the database, this operation can fail if the application server that runs Application Center is not stopped.

The symptom of this problem is that the upgrade fails and the log file contains the error message Another instance of Derby may have already booted the database.

Procedure

Before you run IBM Installation Manager to upgrade an installation of MobileFirst Server and Application Center, stop the application server that runs the Application Center application.

WebSphere Application Server Liberty profile: troubleshooting Administration Services

In IBM MobileFirst Platform Foundation on Liberty profile, learn how to troubleshoot version incompatibility, JMX configuration, communication, and server farm topology.

If the MobileFirst runtime is not initialized correctly when you log in to MobileFirst Operations Console, the runtime is not displayed. You could receive the following error message:

The runtime environment has not initialized successfully; check server logs.

When you start the Administration Services and MobileFirst runtimes, one or more exceptions are reported in the server logs of WebSphere Application Server Liberty profile, because of a configuration issue.

Check the server log file of WebSphere Application Server Liberty profile, by default, messages.log. In the case of a server farm topology, you must check the log file of each member of the farm.

Versions of Administration Services and runtimes

Check that the version of the Administration Services and the MobileFirst runtime are exactly the same.

Procedure

1. To check the versions of all the components, use the wladm **show versions** command. For more information about this command, see “Commands for troubleshooting” on page 13-60.

If the values of **wladmVersion** and **productVersion** of each project WAR file are not all the same, you must upgrade the component with the earlier version to the same version as the component with the later version.

2. Upgrade the earlier version. To upgrade the Administration Services or the runtimes, see “Upgrading the MobileFirst runtime environment for MobileFirst Server V7.1.0 manually, or with Ant tasks” on page 7-55.

Troubleshooting the JMX configuration

You can encounter several exceptions in the Liberty profile server logs that are related to the JMX configuration.

Table 6-84. Errors in JMX configuration for WebSphere Application Server Liberty profile.

Message title	Error	Cause	Resolution
Invalid administrator user	Failed to obtain JMX connection to access an MBean. There might be a JMX configuration error: CWKX0215E: There was a problem with the user name or password provided. The server responded with code 401 and message 'Unauthorized'	The value of the ibm.worklight.admin.jmx.user JNDI property is not an administrative Liberty profile user.	Edit the server.xml file and make sure that the user referenced in ibm.worklight.admin.jmx.user is defined in the <administrator-role> element.
SSL socket factory not found	Failed to obtain JMX connection to access an MBean. There might be a JMX configuration error: java.lang.ClassNotFoundException: Cannot find the specified class com.ibm.websphere.ssl.protocol.SSLSocketFactory	The IBM JDK cannot be used with the SSL socket factories of WebSphere Application Server Liberty profile.	For information about resolving this issue, see “Configuring Liberty profile when IBM JDK is used” on page 6-314.

Table 6-84. Errors in JMX configuration for WebSphere Application Server Liberty profile (continued).

Message title	Error	Cause	Resolution
No JMX connector configured	Failed to obtain JMX connection to access an MBean. There might be a JMX configuration error: No JMX connector is configured	The host name or the port number that is required for the JMX connection is not configured.	Edit the server.xml file and make sure that both the <code>ibm.worklight.admin.jmx.port</code> and the <code>ibm.worklight.admin.jmx.host</code> JNDI properties are defined.
Read timed out	Failed to obtain JMX connection to access an MBean. There might be a JMX configuration error: Read timed out	The JMX connection times out before the operation completes. By default, the JMX connection times out after one minute.	Edit the Liberty profile <code>jvm.options</code> file and add the following property: <code>-Dcom.ibm.ws.jmx.connector.client.</code> The default value is 60000. Use a greater value. The following example uses three minutes. <code>-Dcom.ibm.ws.jmx.connector.client.</code>
Invalid certification path	Failed to obtain JMX connection to access an MBean. There might be a JMX configuration error: <code>com.ibm.jsse2.util.h:</code> PKIX path building failed: <code>java.security.cert.CertPathBuilderException:</code> unable to find valid certification path to requested target	The SSL configuration of the Liberty profile server is not correct.	For instructions about how to resolve this issue, see Configuring secure JMX connection to the Liberty profile .
Connection exception	<code>java.net.ConnectException:</code> Connection refused: connect	The JMX connection fails.	Edit the server.xml file. Make sure that both the <code>ibm.worklight.admin.jmx.port</code> and the <code>ibm.worklight.admin.jmx.host</code> JNDI properties reference the local host, and that the https port number is defined in the <code><httpEndpoint></code> element.

Troubleshooting communication between the runtime and the Administration Services

Determine the causes of communication failure that lead to an exception reported in the server log.

At startup, each MobileFirst runtime must communicate with the Administration Services in JMX and HTTP or HTTPS for the purpose of synchronization. If communication fails, the runtime cannot initialize and the following exception is reported in the server log:

```
java.lang.RuntimeException: Timeout while waiting for the management
service to start up.120 secs.
```

This communication failure can be due to one of several causes. You can determine the cause from the messages in the server log that are reported before the exception.

Administration Services Mbean not found

If the log contains one of the following exceptions, the runtime has not been able to locate the Administration Services Mbean by name. Therefore, the Administration Services Mbean is not registered or is registered under a different name.

```
Caused by: javax.management.InstanceNotFoundException: CWWKX0217E: No MBean
is currently registered with the given ObjectName <Administration Services
Mbean name>
```

or an exception beginning:

```
javax.management.InstanceNotFoundException:
WebSphere:type=WorklightAdmin[_<environmentid>]
```

The registration of the Administration Services is logged in this way:

```
FWLSE2008I: MBean registration succeeded for:
com.worklight.common.server.jmx.api:type=WorklightAdmin[_<environmentid>],qualifier=
```

You can find the root cause by comparing this MBean name with the one referenced in the CWWKX0217E error and then checking in the Liberty Profile `server.xml` file the value of the JNDI properties **ibm.worklight.admin.environmentid** or, for a server farm topology, **ibm.worklight.admin.serverid**. These properties must have the same values for the Administration Services and the runtime. See “Stand-alone server topology” on page 6-19 and “Server farm topology” on page 6-22.

Administration Services endpoint not found

If the log contains the following exception, the endpoint of the Administration Services could not be determined.

```
Could not determine the own endpoint from the application server's
configuration.
```

By default, the Administration Services detects its own endpoint. If for some reason it cannot, or you want all HTTP requests to go through a web server, you must configure the endpoint properties in accordance with the information given in “Configuring the endpoint (Liberty profile)” on page 6-104.

Administration Services endpoint not accessible

If the log contains many information messages like Accessing the ping service `<ping endpoint>`, and does not contain an information message like The ping service `<ping endpoint>` is available, the Administration Services endpoint identified in the first kind of information message cannot be accessed.

Check that this endpoint is correct and whether it can be accessed from the server of WebSphere Application Server Liberty profile.

- If this endpoint references a web server and a firewall is used on this server, you must check that the firewall authorizes access from the server of WebSphere Application Server Liberty profile.
- If the protocol used for invoking the web server is SSL, you must check that SSL is correctly configured between the server of WebSphere Application Server Liberty profile and the web server.

See *Configuring a web server plug-in for the Liberty profile*.

Troubleshooting server farm topology

Learn how to troubleshoot when you get exceptions in a server farm.

When you have a server farm topology, exceptions are raised when the Administration Services MBean is registered and the farm configuration is not correct. For more information, see “*Troubleshooting server farm configuration issues*” on page 6-382.

WebSphere Application Server full profile: troubleshooting Administration Services in a stand-alone topology

Learn how to troubleshoot version incompatibility, JMX configuration, communication, and server farm topology in IBM MobileFirst Platform Foundation on WebSphere Application Server full profile, stand-alone server.

If the MobileFirst runtime is not initialized correctly when you log in to MobileFirst Operations Console, the runtime is not displayed. You could receive the following error message:

```
The runtime environment has not initialized successfully; check server logs.
```

When you start the Administration Services and MobileFirst runtimes, one or more exceptions are reported in the server logs of WebSphere Application Server, because of a configuration issue.

Check the WebSphere Application Server server log file, by default, `SystemOut.log`. (In the case of a server farm topology, you must check the log file of each member of the farm.)

Versions of Administration Services and runtimes

Check that the version of the Administration Services and the MobileFirst runtime are exactly the same.

Procedure

1. To check the versions of all the components, use the `wladm show versions` command. For more information about this command, see “*Commands for troubleshooting*” on page 13-60.

If the values of **wladmVersion** and **productVersion** of each project WAR file are not all the same, you must upgrade the component with the earlier version to the same version as the component with the later version.

- Upgrade the earlier version. To upgrade the Administration Services or the runtimes, see “Upgrading the MobileFirst runtime environment for MobileFirst Server V7.1.0 manually, or with Ant tasks” on page 7-55.

Troubleshooting the JMX configuration

When the MobileFirst runtime starts, it must communicate by using JMX with the Administration Services instance that manages this runtime and that is deployed in the same JVM.

Table 6-85. Errors in JMX configuration for WebSphere Application Server full profile.

Message title	Error	Cause	Resolution
Invalid JMX Connector	invalid JMX Connector <type>	The value of the ibm.worklight.admin.jmx.connector JNDI property is invalid; it must be SOAP or RMI.	See “Stand-alone JMX connectivity” on page 6-19 for information about how to resolve this problem.
SOAP connection timeout	SOAPException: faultCode=SOAP-ENV:Client; msg=Read timed out; targetException=java.net.SocketTimeoutException: Read timed out	The JMX connection timed out before the operation completed. By default, the SOAP connection times out three minutes after the operation starts.	Increase the value of the com.ibm.SOAP.requestTimeout property in the WebSphere soap.client.props file. See SOAP connector properties.

Troubleshooting communication between the runtime and the Administration Services

Determine the causes of communication failure that lead to an exception reported in the server log.

At startup, each MobileFirst runtime must communicate with the Administration Services in JMX and HTTP or HTTPS for the purpose of synchronization. If communication fails, the runtime cannot initialize and the following exception is reported in the server log:

```
java.lang.RuntimeException: Timeout while waiting for the management service to start up.120 secs.
```

This communication failure can be due to one of several causes. You can determine the cause from the messages in the server log that are reported before the exception.

Administration Services Mbean not found

If the log contains one of the following exceptions, the runtime has not been able to locate the Administration Services Mbean by name. Therefore, the Administration Services Mbean is not registered or is registered under a different name.

Caused by: javax.management.InstanceNotFoundException: CWWKX0217E: No MBean is currently registered with the given ObjectName <Administration Services Mbean name>

or an exception beginning:

```
javax.management.InstanceNotFoundException:  
WebSphere:type=WorklightAdmin[_<environmentid>]
```

The registration of the Administration Services is logged in this way:

```
FWLSE2008I: MBean registration succeeded for:  
com.worklight.common.server.jmx.api:type=WorklightAdmin[_<environmentid>],qualifier=
```

You can find the root cause by comparing this MBean name with the one referenced in the CWWKX0217E error and then checking in the WebSphere Application Server administration console the value of the JNDI property **ibm.worklight.admin.environmentid** (and for a server farm topology, **ibm.worklight.admin.serverid**). These properties must have the same values for the Administration Services and the runtime. See “Stand-alone server topology” on page 6-19 and “Server farm topology” on page 6-22.

Administration Services endpoint not found

If the log contains the following exception, the endpoint of the Administration Services could not be determined.

```
Could not determine the own endpoint from the application server's  
configuration.
```

By default, the Administration Services detects its own endpoint by using the WebSphere Application Server virtual host definition mapped to the Administration Services application.

You must first check that the virtual host configuration, by default, set as `default_host`, contains at least one virtual host alias with the HTTP or HTTPS port number of the WebSphere Application Server server. If no entry is defined, you must create one as described in Configuring virtual hosts.

If for some reason detection fails, or you want all HTTP requests to go through a web server, you must configure the endpoint properties in accordance with the information given in “Configuring the endpoint (WebSphere Application Server full profile)” on page 6-104.

Administration Services endpoint not accessible

If the log contains many information messages like Accessing the ping service <ping endpoint>, and does not contain an information message like The ping service <ping endpoint> is available, the Administration Services endpoint identified in the first kind of information message cannot be accessed.

Check that this endpoint is correct and whether it can be accessed from the server of WebSphere Application Server.

- If this endpoint references a web server and a firewall is used on this server, you must check that the firewall authorizes access from the server of WebSphere Application Server.

- If the protocol used for invoking the web server is SSL, you must check that SSL is correctly configured between the server of WebSphere Application Server and the web server. See *Configuring the web server plug-in for Secure Sockets Layer*.

Troubleshooting server farm topology

Learn how to troubleshoot when you get exceptions in a server farm.

When you have a server farm topology, exceptions are raised when the Administration Services MBean is registered and the farm configuration is not correct. For more information, see “*Troubleshooting server farm configuration issues*” on page 6-382.

WebSphere Application Server Network Deployment: troubleshooting Administration Services

Learn how to troubleshoot version incompatibility, JMX configuration, and communication in IBM MobileFirst Platform Foundation on WebSphere Application Server Network Deployment.

If the MobileFirst runtime is not initialized correctly when you log in to MobileFirst Operations Console, the runtime is not displayed. You could receive the following error message:

The runtime environment has not initialized successfully; check server logs.

When you start the Administration Services and MobileFirst runtimes, one or more exceptions are reported in the server logs of WebSphere Application Server Network Deployment, because of a configuration issue.

Check the WebSphere Application Server Network Deployment server log file, by default, `SystemOut.log`. In the case of a clustered topology, you must check the log file of each cluster member. In an asymmetric deployment, the Administration Services are not deployed in the same JVM as the runtimes; you must check all the logs where these components are deployed.

Versions of Administration Services and runtimes

Check that the version of the Administration Services and the MobileFirst runtime are exactly the same.

Procedure

1. To check the versions of all the components, use the `wladm show versions` command. For more information about this command, see “*Commands for troubleshooting*” on page 13-60.

If the values of `wladmVersion` and `productVersion` of each project WAR file are not all the same, you must upgrade the component with the earlier version to the same version as the component with the later version.

2. Upgrade the earlier version. To upgrade the Administration Services or the runtimes, see “*Upgrading the MobileFirst runtime environment for MobileFirst Server V7.1.0 manually, or with Ant tasks*” on page 7-55.

Troubleshooting the JMX configuration

When the MobileFirst runtime starts, it must communicate by using JMX with the Administration Services instance that manages this runtime.

Table 6-86. Errors in JMX configuration for WebSphere Application Server Network Deployment

Message title	Error	Cause	Resolution
Invalid JMX Connector	invalid JMX Connector <type>	The value of the ibm.worklight.admin.jmx.connector JNDI property is invalid; it must be SOAP or RMI.	See “WebSphere Application Server Network Deployment topologies” on page 6-26 for information about how to resolve this problem.
SOAP connection failed	com.ibm.websphere.management.exception.ConnectionException: ADMC0016E: The system cannot create a SOAP connector to connect to host <host> at port <port>	The value of the ibm.worklight.admin.jmx.connector or the ibm.worklight.admin.jmx.connector JNDI property is invalid.	See “WebSphere Application Server Network Deployment topologies” on page 6-26 for information about how to resolve this problem.
SOAP connection timeout	SOAPException: faultCode=SOAP-ENV:Client; msg=Read timed out; targetException=java.net.SocketTimeoutException: Read timed out	The JMX connection timed out before the operation completed. By default, the SOAP connector times out three minutes after the operation starts.	Increase the value of the com.ibm.SOAP.requestTimeout property in the WebSphere <code>soap.client.props</code> file. See SOAP connector properties.

Troubleshooting communication between the runtime and the Administration Services

Determine the causes of communication failure that lead to an exception reported in the server log.

At startup, each MobileFirst runtime must communicate with the Administration Services in JMX and HTTP or HTTPS for the purpose of synchronization. If communication fails, the runtime cannot initialize and the following exception is reported in the server log:

```
java.lang.RuntimeException: Timeout while waiting for the management service to start up.120 secs.
```

This communication failure can be due to one of several causes. You can determine the cause from the messages in the server log that are reported before the exception.

Administration Services Mbean not found

If the log contains one of the following exceptions, the runtime has not been able to locate the Administration Services Mbean by name. Therefore, the Administration Services Mbean is not registered or is registered under a different name.

```
Caused by: javax.management.InstanceNotFoundException: CWWX0217E: No MBean is currently registered with the given ObjectName <Administration Services Mbean name>
```

or an exception beginning:

```
javax.management.InstanceNotFoundException:  
WebSphere:type=WorklightAdmin[_<environmentid>]
```

The registration of the Administration Services is logged in this way:

```
FWLSE2008I: MBean registration succeeded for:  
com.worklight.common.server.jmx.api:type=WorklightAdmin[_<environmentid>],qualifier=
```

You can find the root cause by comparing this MBean name with the one referenced in the CWWKX0217E error and then checking in the WebSphere Application Server administration console the value of the JNDI property **ibm.worklight.admin.environmentid**. These properties must have the same values for the Administration Services and the runtime. See “WebSphere Application Server Network Deployment topologies” on page 6-26.

Administration Services endpoint not found

If the log contains the following exception, the endpoint of the Administration Services could not be determined.

```
Could not determine the own endpoint from the application server's  
configuration.
```

By default, the Administration Services detects its own endpoint by using the WebSphere Application Server virtual host definition mapped to the Administration Services application.

You must first check that the virtual host configuration, by default, set as default_host, contains at least one virtual host alias with the HTTP or HTTPS port number of the WebSphere Application Server server. In the case of a clustered topology, you must check the virtual host configuration for every cluster member. If no entry is defined, you must create one as described in Configuring virtual hosts.

If for some reason detection fails and you do not want all HTTP requests to go through a web server, you must configure the endpoint properties at the JVM level. In the case of a clustered environment, you must configure the endpoint properties for the JVM of every cluster member.

1. Log in to the WebSphere Application Server administration console.
2. Select **Servers > Server Types > WebShere application servers > server_name.**
3. Under **Server Infrastructure**, select **Java and process management > Process definition > Java virtual machine > Custom properties.**
4. Add the following properties:

Property name	Value
ibm.worklight.admin.proxy.protocol	http
ibm.worklight.admin.proxy.host	hostname of the server
ibm.worklight.admin.proxy.port	http port number of the server

5. Save the configuration and restart the server.

In the case of a clustered environment, you must perform these steps for all the cluster members where the Administration Services application is deployed.

If you want all the HTTP requests to go through a web server, you must configure the endpoint properties in accordance with the information given in “Configuring the endpoint (WebSphere Application Server full profile)” on page 6-104.

Administration Services endpoint not accessible

If the log contains many information messages like Accessing the ping service *<ping endpoint>*, and does not contain an information message like The ping service *<ping endpoint>* is available, the Administration Services endpoint identified in the first kind of information message cannot be accessed.

Check that this endpoint is correct and whether it can be accessed from the server in WebSphere Application Server Network Deployment.

- If this endpoint references a web server and a firewall is used on this server, you must check that the firewall authorizes access from the server in WebSphere Application Server Network Deployment.
- If the protocol used for invoking the web server is SSL, you must check that SSL is correctly configured between the server in WebSphere Application Server Network Deployment and the web server. See Configuring the web server plug-in for Secure Sockets Layer.

Apache Tomcat: troubleshooting Administration Services

In IBM MobileFirst Platform Foundation on Apache Tomcat, learn how to troubleshoot version incompatibility, JMX configuration, communication, and server farm topology.

If the MobileFirst runtime is not initialized correctly when you log in to MobileFirst Operations Console, the runtime is not displayed. You could receive the following error message:

```
The runtime environment has not initialized successfully; check server logs.
```

When you start the Administration Services and MobileFirst runtimes, one or more exceptions are reported in the Apache Tomcat server logs, because of a configuration issue.

Check the Apache Tomcat server log file, by default, *catalina.log*. In the case of a server farm topology, you must check the log file of each member of the farm.

Versions of Administration Services and runtimes

Check that the version of the Administration Services and the MobileFirst runtime are exactly the same.

Procedure

1. To check the versions of all the components, use the `wladm show versions` command. For more information about this command, see “Commands for troubleshooting” on page 13-60.

If the values of `wladmVersion` and `productVersion` of each project WAR file are not all the same, you must upgrade the component with the earlier version to the same version as the component with the later version.

- Upgrade the earlier version. To upgrade the Administration Services or the runtimes, see “Upgrading the MobileFirst runtime environment for MobileFirst Server V7.1.0 manually, or with Ant tasks” on page 7-55.

Troubleshooting the JMX configuration

You can encounter several exceptions in the Apache Tomcat server logs that are related to the JMX configuration.

When the MobileFirst runtime starts, it uses JMX to communicate with the Administration Services deployed in the same JVM. Exceptions are reported in the `catalina.log` and the `output.log` files.

Table 6-87. Errors in JMX configuration on Apache Tomcat

Message title	Error	Cause	Resolution
RMI server hostname not configured	The JVM is not properly configured to support JMX over RMI. The JVM property <code>java.rmi.server.hostname</code> must be defined	The value of the <code>java.rmi.server.hostname</code> System property is not set.	For information about resolving this issue, see “Configuring Apache Tomcat” on page 6-65
RMI port number not configured	The JVM is not properly configured to support JMX over RMI. If the Tomcat instance is not running behind a firewall, the JVM property <code>com.sun.management.jmxremote.port</code> must be defined	The value of the <code>com.sun.management.jmxremote.port</code> System property is not set.	For information about resolving this issue, see “Configuring Apache Tomcat” on page 6-65.
Unknown host exception	<code>java.rmi.UnknownHostException: Unknown host <hostname></code>	The hostname referenced by the <code>java.rmi.server.hostname</code> System property is not accessible.	The value of the <code>java.rmi.server.hostname</code> System property must be the hostname of the Apache Tomcat server.
Port in use	<code>java.rmi.server.ExportException: Port already in use (emitted in the outputfile.log)</code>	The process is already using the port referenced by the <code>com.sun.management.jmxremote.port</code> System property.	Set the value of the <code>com.sun.management.jmxremote.port</code> System property to a port number that is not in use.
Connection exception	<code>java.io.IOException: Failed to retrieve RMI Server stub</code> <code>java.net.ConnectException: Connection refused: connect</code>	The value of the <code>ibm.worklight.admin.rab.registry.port</code> JNDI property refers to an invalid port.	For information about resolving this issue, see “Configuring Apache Tomcat” on page 6-65.

Table 6-87. Errors in JMX configuration on Apache Tomcat (continued)

Message title	Error	Cause	Resolution
Socket timeout	java.net.SocketTimeoutException: Read timed out	The JMX connection times out before the operation completes. By default, the RMI connection never times out.	The <code>sun.rmi.transport.tcp.responseTimeout</code> JVM property must be set to 0, which means that no timeout is set, or its value must be increased.
SSL handshake Exception	javax.net.ssl.SSLHandshakeException: sun.security.validator.ValidatorException: PKIX path building failed	The exception is not correct. Possibly, the Apache Tomcat certificate is not present in the trust store referenced by the <code>javax.net.ssl.trustStore</code> System property	For information about resolving this issue, see “Configuring Apache Tomcat” on page 6-65.

Troubleshooting communication between the runtime and the Administration Services

Determine the causes of communication failure that lead to an exception reported in the server log.

At startup, each MobileFirst runtime must communicate with the Administration Services in JMX and HTTP or HTTPS for the purpose of synchronization. If communication fails, the runtime cannot initialize and the following exception is reported in the server log:

```
java.lang.RuntimeException: Timeout while waiting for the management
service to start up.120 secs.
```

This communication failure can be due to one of several causes. You can determine the cause from the messages in the server log that are reported before the exception.

Administration Services Mbean not found

If the log contains one of the following exceptions, the runtime has not been able to locate the Administration Services Mbean by name. Therefore, the Administration Services Mbean is not registered or is registered under a different name.

```
Caused by: javax.management.InstanceNotFoundException: CWWKX0217E: No MBean
is currently registered with the given ObjectName <Administration Services
Mbean name>
```

or an exception beginning:

```
com.worklight.common.server.jmx.api:type=WorklightAdmin[_<environmentid>]
```

The registration of the Administration Services is logged in this way:

FWLSE2008I: MBean registration succeeded for:
com.worklight.common.server.jmx.api:type=WorklightAdmin[_<environmentid>],qualifier=

You can find the root cause by comparing this MBean name with the one referenced in the CWWKX0217E error and then checking in the Apache Tomcat `server.xml` file the value of the JNDI properties

ibm.worklight.admin.environmentid or, for a server farm topology, **ibm.worklight.admin.serverid**. These properties must have the same values for the Administration Services and the runtime. See “Stand-alone server topology” on page 6-19 and “Server farm topology” on page 6-22.

Administration Services endpoint not found

If the log contains the following exception, the endpoint of the Administration Services could not be determined.

```
Could not determine the own endpoint from the application server's configuration.
```

By default, the Administration Services detects its own endpoint. If for some reason it cannot, or you want all HTTP requests to go through a web server, you must configure the endpoint properties in accordance with the information given in “Configuring the endpoint (Apache Tomcat)” on page 6-105.

Administration Services endpoint not accessible

If the log contains many information messages like Accessing the ping service <ping endpoint>, and does not contain an information message like The ping service <ping endpoint> is available, the Administration Services endpoint identified in the first kind of information message cannot be accessed.

Check that this endpoint is correct and whether it can be accessed from the Apache Tomcat server.

- If this endpoint references a web server and a firewall is used on this server, you must check that the firewall authorizes access from the Apache Tomcat server.
- If the protocol used for invoking the web server is SSL, you must check that SSL is correctly configured between the Apache Tomcat server and the web server.

Troubleshooting server farm topology

Learn how to troubleshoot when you get exceptions in a server farm.

When you have a server farm topology, exceptions are raised when the Administration Services MBean is registered and the farm configuration is not correct. For more information, see “Troubleshooting server farm configuration issues.”

Troubleshooting server farm configuration issues

When you start the Administration Services and the MobileFirst runtime environments, several exception types can be emitted in the application server logs if the configuration of the server farm is incorrect.

Server ID is not set

MBeanRegistrationException "server id JNDI property is not set".

This is because in the application server configuration, the JNDI property `ibm.worklight.admin.serverid` is not set.

You must configure the property `ibm.worklight.admin.serverid` in the application server. Restart the application server. For more information, see “JNDI environment entries for MobileFirst projects in production” on page 12-68.

Administration Services MBean is already registered

The Administration Services MBean *<MBean name>* is already registered on another node of the farm, which means that the JNDI property `ibm.worklight.admin.serverid` has the same value on other nodes.

This situation occurs because the Administration Services MBean is already registered under the same name on another server of the farm. The value of the JNDI property `ibm.worklight.admin.serverid` is the same as one defined in another server of the farm.

You must configure the property `ibm.worklight.admin.serverid` in the application server. This property must be unique among the servers of the farm. Restart the application server.

Use of a Derby database

MBeanRegistrationException "Derby databases are not supported in a farm of servers".

You must use a DB2, Oracle, or MySQL database for the runtime and Administration Services databases, because Derby is not supported in server farm topology.

Troubleshooting failure to authenticate to Application Center and applications that use the basic registry element

Authentication fails when attempting to log in to the Application Center and other applications that run on WebSphere Application Server Liberty profile and use the `basicRegistry` element.

About this task

When IBM MobileFirst Platform Foundation is installed with Application Center on WebSphere Application Server Liberty profile, it adds a `basicRegistry` element in the `server.xml` file of the Liberty server instance, with demo users, even if a `basicRegistry` element already exists. Authentication into the Application Center and other applications that use users from the basic registry no longer works. For example, after an attempt to log in to the Application Center, the following error message is displayed:

```
Error 404: java.io.FileNotFoundException: SRVE0190E: File not found: /j_security_check
```

The liberty server log file contains the following error message:

```
[ERROR] CWWKS3006E: A configuration exception has occurred. There are multiple available UserRegis
```

When IBM MobileFirst Platform Foundation is uninstalled, the basic registry that was created during the installation by the IBM MobileFirst Platform Server installer is removed from the `server.xml` file, even if other users have been added to that basic registry. If other applications than Application Center use the basic registry, authentication on these applications is no longer possible. This issue might include

installations of the IBM MobileFirst Platform Operations Console and Administration Services.

Procedure

1. Move the content of the basic registry that was created by IBM Installation Manager in the initial basic registry element. For an installation that is not for test purposes only, do not copy the users demo and appcenteradmin, and remove them from the appcentergroup. Remove the following code from the server.xml file:

```
<!-- Declare the user registry for the Application Center. -->
<basicRegistry id="applicationcenter-registry" realm="ApplicationCenter">
  <!-- The users defined here are members of group "appcentergroup", thus have role "appcenteradm
  <user name="appcenteradmin" password="admin"/>
  <user name="demo" password="demo"/>
  <group name="appcentergroup">
    <member name="appcenteradmin"/>
    <member name="demo"/>
  </group>
</basicRegistry>
```

2. When you uninstall IBM MobileFirst Platform Foundation, the uninstaller of MobileFirst Server creates a backup of the server.xml file under the name server.xml.saved2. Open the server.xml.saved2 file, and copy the basicRegistry element back in the server.xml file. Remove the users and groups that were only needed by the Application Center.

Upgrading to IBM MobileFirst Platform Foundation V7.1.0

This section contains the procedures for upgrading from IBM Worklight V5.0.6 or later to V7.1.0 and migrating the applications you created in earlier versions of the product to work with IBM MobileFirst Platform Foundation V7.1.0.

About this task

Upgrading from one version of the product to another involves upgrading the software, upgrading your database, if needed, and sometimes upgrading your apps. Most of this upgrade is automatically done for you when you use the installer. However, the upgrade might also involve some manual operations, such as setting various properties, using special command facilities, and running supplied Ant tasks. The complete upgrade procedures are detailed in the following topics.

Those topics cover how to upgrade to V7.1.0 of MobileFirst Studio and MobileFirst Server, and how to migrate your applications for V7.1.0.

Version compatibility

Compatibility among different versions of the IBM MobileFirst Platform Foundation client and server depends on several factors.

The following table describes different situations and the compatibility rules that apply to each.

To understand the compatibility rules, it can be useful to understand the IBM product release conventions. Each full number of a release is composed of the following parts, where each part is replaced by a digit from 0 to 9:

version.release.modification.fixpack

Note: Version numbers cited in the table examples are for illustrative purposes only, and might not correspond to actual releases.

Table 7-1. Version compatibility rules

Description	Compatibility rule	Examples
The server and client have the same version and release. (Modification and fix pack release numbers can be different.)	Server and client with the same version and release are fully compatible.	7.1.0.0 server is compatible with 7.1.0.0 client.
The server is newer than the client.	Compatible.	7.1.0.0 server is compatible with 7.0.0.0 client
The server is older than the client.	Not compatible.	7.0.0.0 server is not compatible with 7.1.0.0 client

Table 7-1. Version compatibility rules (continued)

Description	Compatibility rule	Examples
<p>The server artifacts were created with older version of MobileFirst Studio or MobileFirst Platform Command Line Interface than the version of the server.</p>	<p>For complete details of which server, .war file, and artifacts work together, see Table 2. However, the following guidelines apply:</p> <p>For versions earlier than 6.1.0, only the same versions of server, .war file, and application (.wlapp file) and adapters can work together.</p> <p>If the initial server version is Worklight Server 6.1 or 6.2, the .war file that was created with the same version of Worklight Studio or Command Line Interface for IBM Worklight Developers can be migrated to a later server version, but the newer server can accommodate only artifacts (.wlapp and adapter files) that were built from the initial version.</p> <p>If the initial server version is Worklight Server 6.2.0.1 or later, including MobileFirst Server 6.3 or later, the .war file that was created with the same initial version of Studio or the Command Line Interface can be migrated to the later server version. The migrated .war file can accommodate artifacts that were created with any of the following versions of Studio or the Command Line Interface:</p> <ul style="list-style-type: none"> • Initial version • Later server version that the .war file is migrated to • Any version earlier than the initial version <p>The artifacts behave as though they are running on the older version of the server.</p> <p>For information about migrating the .war file, see “Migrating a project WAR file for use with a new MobileFirst Server” on page 12-38.</p>	<p>Example 1:</p> <p>Artifacts built with MobileFirst Studio 7.0.0.0 can run on server 7.1.0.0. However, the artifacts will behave as though they are running on server version 7.0.0.0.</p> <p>Example 2:</p> <p>Initially, a version 6.2.0.1 .war file can run the artifacts from 6.2.01 and earlier versions on a 6.2.0.1 server. If this .war file is migrated to 7.1, then the migrated .war file can run 7.1 artifacts. However, this .war file cannot run MobileFirst Server 7.0.0.0 artifacts.</p>
<p>Server artifacts created with a later version of MobileFirst Studio or the MobileFirst Platform Command Line Interface than the version of the server.</p>	<p>Not compatible.</p>	<p>Artifacts built with MobileFirst Studio 7.1.0.0 cannot run on server 7.0.0.0.</p>

Table 7-1. Version compatibility rules (continued)

Description	Compatibility rule	Examples
Direct Update feature	If the version of MobileFirst Studio or the MobileFirst Platform Command Line Interface that was used to build an update package differs from the version of MobileFirst Studio or the MobileFirst Platform Command Line Interface that was used to build the original application package then the update will not be applied.	Original application was built with MobileFirst Studio 7.0.0.0; update was built with MobileFirst Studio 7.1.0.0. Update will not occur.

The following table shows which .war file and artifact versions can work with each server version. Application behavior remains as with the original version of the application. Version numbers Before 6.3 apply to Worklight products. Version numbers of 6.3 and later apply to MobileFirst products.

Table 7-2. Server, project and artifact compatibility

Server version	Can work with the following project versions (.war file created with this version of Studio or Command Line Interface)	Can work with the following artifact versions (application and adapter files created with this version of Studio or command line)
7.1.0	7.1.0	5.0.6, 6.0.0, 6.1.0, 6.2.0, 6.3.0, 7.0.0, 7.1.0
7.1.0	7.0.0 migrated to 7.1.0	.0.6, 6.0.0, 6.1.0, 6.2.0, 6.3.0, 7.0.0
7.1.0	6.3.0 migrated to 7.1.0	5.0.6, 6.0.0, 6.1.0, 6.2.0, 6.3.0
7.1.0	6.2.0 migrated to 7.1.0	6.2.0
7.1.0	6.1.0 migrated to 7.1.0	6.1.0
7.1.0	6.0.0 migrated to 7.1.0	6.0.0
7.1.0	5.0.6 migrated to 7.1.0	5.0.6
7.0.0	7.0.0	5.0.6, 6.0.0, 6.1.0, 6.2.0, 6.3.0, 7.0.0
7.0.0	6.3.0 migrated to 7.0.0	5.0.6, 6.0.0, 6.1.0, 6.2.0, 6.3.0
7.0.0	6.2.0 migrated to 7.0.0	6.2.0
7.0.0	6.1.0 migrated to 7.0.0	6.1.0
7.0.0	6.0.0 migrated to 7.0.0	6.0.0
7.0.0	5.0.6 migrated to 7.0.0	5.0.6
6.3.0	6.3.0	5.0.6, 6.0.0, 6.1.0, 6.2.0, 6.3.0
6.3.0	6.2.0 migrated to 6.3.0	6.2.0
6.3.0	6.1.0 migrated to 6.3.0	6.1.0
6.3.0	6.0.0 migrated to 6.3.0	6.0.0
6.3.0	5.0.6 migrated to 6.3.0	5.0.6
6.2.0.1	6.2.0.1	5.0.6, 6.0.0, 6.1.0, 6.2.0, 6.2.0.1
6.2.0.1	6.2.0 migrated to 6.2.0.1	6.2.0
6.2.0.1	6.1.0 migrated to 6.2.0.1	6.1.0
6.2.0	6.2.0	6.2.0
6.2.0	6.1.0 migrated to 6.2.0	6.1.0
6.2.0	6.0.0 migrated to 6.2.0	6.0.0
6.2.0	5.0.6 migrated to 6.2.0	5.0.6

Table 7-2. Server, project and artifact compatibility (continued)

Server version	Can work with the following project versions (.war file created with this version of Studio or Command Line Interface)	Can work with the following artifact versions (application and adapter files created with this version of Studio or command line)
6.1.0	6.1.0	6.1.0
6.1.0	6.0.0 migrated to 6.1.0	6.1.0
6.1.0	5.0.6 migrated to 6.1.0	6.0.0
6.0.0	6.0.0	6.0.0
5.0.6	5.0.6	5.0.6

Separation of lifecycle between MobileFirst Server and MobileFirst Studio

There is a separation of the MobileFirst Studio and the MobileFirst Server upgrade lifecycles, which provides benefits to both developers and IT staff.

Starting with V6.1.0, IBM MobileFirst Platform Foundation allows a separation between the MobileFirst Server and MobileFirst Studio lifecycles. This separation means that you can deploy project WAR files, apps, and adapters that are developed with any supported version of MobileFirst development tools to a more recent instance of MobileFirst Server. For more information, see “Version compatibility” on page 7-1.

- For project WAR files that were built with versions earlier than V6.2.0.x, the apps and adapters that you deploy must be built with the same version of Worklight Studio as the version that you used to build the project WAR file. For example, if you develop a project with Worklight Studio V5.0.6 and deploy it to Worklight Server V6.2.0, the WAR file is deployed as a V5.0.6 project. You can deploy to this project only applications and adapters that are developed with Worklight Studio V5.0.6.
- For project WAR files that were built with versions V6.2.0.x and later, apps and adapters that were built with any version V5.0.6.x and later (but not later than the project WAR version itself) can be deployed.

Some limitations of this lifecycle separation are as follows:

- Only application environments that are supported by MobileFirst Server V7.1.0 can be migrated. Older application environments that are not supported by MobileFirst Server V7.1.0 (for example, iGoogle, Windows Phone 7.5, or Facebook) will no longer be available after the server upgrade.
- To deploy a project WAR file, you must use the tools that are provided with the target MobileFirst Server version you are deploying to. That is, to deploy with an Ant task to MobileFirst Server, you must use the `worklight-ant-deployer.jar` file that is located in the `WorklightServer` directory of the MobileFirst Server installation directory.

Terminology

In the topics that deal with migration and updating, the following definitions of several important terms are used:

- *Upgrade* – Moving from one version of software to the next. For example, you upgrade an installation of Worklight Server V6.1.0 to MobileFirst Server V7.1.0.

- *Migrate* – Updating, either automatically or manually, a piece of software so that it is able to use the next level of the software. For example, you migrate database schema of a MobileFirst project to use the next version level of MobileFirst Server. Or you migrate a MobileFirst application to use the next version level of MobileFirst Studio.
- *Deploy* – Installing an application on a server. For example, you *deploy* a MobileFirst application to a production instance of MobileFirst Server running on an application server.

Upgrade paths

The topics under this section apply to the following types of upgrade and migration paths:

- *Major version change* – For example, upgrading from V5.0.6.x to V7.1.0.
- *Minor version change* – For example, upgrading from to V7.0.0 to V7.1.0.
- *Fix pack upgrades* – For example, upgrading from V7.1.0 to V7.1.0.x.
- *Interim fix* – For example, upgrading from V7.1.0 to an interim fix identified by a build number.

Related concepts:

“Version compatibility” on page 7-1

Compatibility among different versions of the IBM MobileFirst Platform Foundation client and server depends on several factors.

Upgrading to MobileFirst Studio V7.1.0

How to upgrade your current version of MobileFirst Studio to the latest version.

- To upgrade to MobileFirst Studio V7.1.0 from previous versions of MobileFirst Studio Consumer Edition or MobileFirst Studio Enterprise Edition, you must perform an Eclipse P2 update operation.
- You cannot directly upgrade to MobileFirst Studio V7.1.0 from a previous version of MobileFirst Studio Developer edition. You must first uninstall your current instance of MobileFirst Studio, and install MobileFirst Studio V7.1.0. After MobileFirst Studio V7.1.0 is installed, you can then point to your earlier workspace and work with your existing projects.

Upgrading MobileFirst Studio in the Consumer or Enterprise Editions to MobileFirst Studio V7.1.0

How to upgrade MobileFirst Studio in IBM MobileFirst Platform Foundation to MobileFirst Studio V7.1.0.

About this task

The upgrade to MobileFirst Studio V7.1.0 is performed as an Eclipse P2 update operation. After MobileFirst Studio V7.1.0 is installed, you can then point to your earlier workspace and work with your existing projects.

Procedure

1. Start your Eclipse IDE workbench and verify your version of Eclipse
 - You must use a version of Eclipse that is supported in MobileFirst Studio V7.1.0, see “System requirements” on page 2-15.
 - If you have an older version of Eclipse, update it before continuing this procedure.

2. Click **Help > Install new software**.
3. In the Add Repository window, click **Archive**.
4. Browse to the update site directory on the installation disk or to your downloaded installation files.
5. Select the update site .zip file and then click **OK**.
6. On the Available Software page, select **IBM MobileFirst Platform Studio Development Tools**, and click **Next**. If you want to see the components to be installed, expand **IBM MobileFirst Platform Studio Development Tools**, and select the components you want:
 - Always select **IBM MobileFirst Platform Studio**.
 - Select **IBM Dojo Mobile Tools** if you anticipate using that JavaScript library.
 - Select **IBM jQuery Mobile Tools** if you anticipate using that JavaScript library.
7. On the Install Details page, review the features of MobileFirst Studio to be installed.

You may see one or more messages in the lower part of the page similar to Your original request has been modified. "IBM Dojo Mobile Tools" is already installed, so an update will be performed instead. This is expected, and indicates that an update is being performed.
8. Click **Next**.
9. On the Review Licenses page, review the license text. If you agree to the terms, select **I accept the terms of the license agreement** and then click **Finish**. The installation process starts.
10. Follow the prompts to complete the installation.

Results

MobileFirst Studio is now updated.

Note:

If the update appears to hang, it might be because you are using a bad mirror site. Add this line to your `eclipse.ini` file to solve the problem:

```
-Declipse.p2.mirrors=false
```

What to do next

The topic “Migrating projects to MobileFirst Studio V7.1.0” on page 7-15 contains information about how to migrate and work with your existing projects.

Upgrading MobileFirst Studio in the Developer Edition to MobileFirst Studio V7.1.0

How to upgrade from an earlier version of IBM MobileFirst Platform Foundation Developer Edition, to MobileFirst Studio V7.1.0.

About this task

You cannot directly upgrade to MobileFirst Studio V7.1.0 from an earlier version of IBM MobileFirst Platform Foundation Developer Edition. Instead, you must uninstall IBM MobileFirst Platform Foundation Developer Edition, and install MobileFirst Studio V7.1.0.

Note: The Eclipse menu **Help** > **Check for Updates** does not find a new version of IBM MobileFirst Platform Foundation. You must explicitly search for IBM MobileFirst Platform Foundation in Eclipse Marketplace.

Procedure

1. Start your Eclipse IDE workbench and verify your version of Eclipse:
 - You must use a version of Eclipse that is supported in MobileFirst Studio V7.1.0, see “System requirements” on page 2-15.
 - If you have an older version of Eclipse, update it before you continue with this procedure.
2. Uninstall your current MobileFirst Studio Developer Edition. For more information, see “Uninstalling MobileFirst Studio” on page 6-7.
3. Install MobileFirst Studio V7.1.0 by clicking **Get the Developer Edition** on the Developer Center for IBM MobileFirst Platform website, and by following the indicated steps.

What to do next

You can now point to your earlier workspace, and work with your existing projects. The topic “Migrating projects to MobileFirst Studio V7.1.0” on page 7-15 contains information about how to migrate and work with your existing projects.

Migrating projects to IBM MobileFirst Platform Foundation V7.1.0

How to migrate your existing projects to IBM MobileFirst Platform Foundation V7.1.0

Migrating projects to V7.1.0 using MobileFirst Platform Command Line Interface

If you are using IBM MobileFirst Platform Command Line Interface to develop an IBM MobileFirst Platform Foundation project that is from any release before V7.1.0, your project is automatically migrated to V7.1.0

When you run the **mfp add** command or the **mfp build** command, or when the MobileFirst Server starts, your MobileFirst project is migrated to V7.1.0.

Migrating MobileFirst Native API projects

After you migrate your existing MobileFirst native API project, you must replace SDK and configuration files with later versions. Follow the instructions at the links below, depending on your target environment:

- For iOS Native API projects, see “Upgrading existing native iOS applications” on page 7-10.
- For Android Native API projects, follow the instructions in “Copying SDK and configuration files from the MobileFirst project” on page 8-204 or “Adding the IBM MobileFirst Platform Foundation SDK to a new or existing application with Android Studio” on page 8-206.
- For JavaME Native API projects, follow the instructions in “Copying files of Native API applications for Java Platform, Micro Edition (Java ME)” on page 8-214.
- For Windows Phone Silverlight 8, see “Copying files of Native API applications for Windows Phone Silverlight 8” on page 8-218

- For Windows 8 Universal and Windows Phone 8 Universal, see “Copying files of native API applications for Windows 8 Universal and Windows Phone 8 Universal” on page 8-222

Migrating Windows 8 hybrid applications

Windows Phone 8 Universal environment is introduced in IBM MobileFirst Platform Foundation V7.1.0. When you import an existing Windows 8 hybrid application that is created with V7.0 or earlier into V7.1.0, it results with a Windows 8 Universal hybrid app. A Windows Phone 8 Universal environment is created at the same time. You can find a `<windowsphoneuniversal>` element in the application descriptor. A new Windows Phone 8 Universal folder with extra deployable files is added. If you deploy the application to MobileFirst Server, you can see both Windows 8 Universal and Windows Phone 8 Universal environments from the console.

iOS: MobileFirst Foundation iOS framework

In existing hybrid applications, the static library `WorklightSDK/libWorklightStaticLibProject.a` will be replaced with a MobileFirst Foundation iOS framework when you migrate the applications to IBM MobileFirst Platform Foundation version 7.1.0. The name of the framework is `IBMMobileFirstPlatformFoundationHybrid`.

iOS: ARC-enablement for upgraded iOS projects

The MobileFirst upgrade process does not enable ARC (Automatic Reference Counting) by default in existing iOS projects. Although ARC is enabled for the MobileFirst library, you must manually enable ARC for the upgraded project by following the steps that are described in the Apple Documentation.

iOS: changes in Xcode linker options

Before IBM Worklight Foundation V6.2.0, the iPhone and iPad environments specified the `-all_load` option in the **Other Linker Flags** of the **Build Settings** to load all symbols from all libraries into the app. Starting with IBM Worklight Foundation V6.2.0, this `-all_load` flag is replaced with `-force_load <library>` flags for each library from which all symbols are loaded.

Generally, the linker loads the symbols that are used within an app. However, in some cases, such as when Objective-C categories are used, the linker does not load all the necessary symbols, which results in unresolved symbol errors from the linker.

New V7.1.0 iOS environments and the iOS environments that are migrated from previous versions of IBM MobileFirst Platform Foundation have the `-force_load` flag specified for the following libraries:

- `libCordova.a`
- `libTLFLib.a` (added by the Tealeaf® SDK optional feature)
- `libfipshttp.a` (added by the FIPS 140-2 optional feature)

You might need to add a `-force_load` flag for third-party libraries that you include in your project.

If you use `xcodebuild` to build your projects, you must specify an extra flag or property to indicate the location of the libraries for which you use `-force_load`. You can use either the `-scheme` flag (if the project was previously opened in Xcode) or the `SYMROOT` property (whether the project was previously opened in Xcode or not). In the following examples, the values used for `-configuration` and `-sdk` are only indicated for illustration purposes. The values that you specify might be different.

1. If Xcode was not previously run on the generated `.xcodeproj` project, then specify `SYMROOT` (it can be any directory):

```
xcodebuild -project <PathToProject>/TestProjectTestAppIphone.xcodeproj -configuration Release
```

2. If Xcode was previously run on the generated `.xcodeproj` project, then you can specify the scheme:

```
xcodebuild -project <PathToProject>/TestProjectTestAppIphone.xcodeproj -scheme TestProjectTest
```

iOS: Targeting new iOS architectures for your existing apps

- For hybrid applications: To target `armv7`, `armv7s` and `arm64`, or only one architecture, you must manually change the architecture selection in the **Architectures** menu of the Xcode **Build Settings**:

1. In **Valid Architectures**, select `armv7` or `armv7s` or `arm64`, or all the three architectures.
2. In **Architectures**, depending on the slice that you want to create, select one, or several architectures that you chose in step 1.

To compile or to create a slice, you must include the slice name in both **Valid Architectures** and **Architectures** (so for `armv7s`, you must add `armv7s` to both menus). **Valid Architectures** specifies declaratively which slice can be created. In **Architectures**, select only the slice that you want to create.

- For native applications: After you replace the IBM Worklight V6.1.0 files with the V6.2.0 files in your Xcode project, you can change the selections in the Xcode **Valid Architectures** and **Architectures** menus to include any combination of `armv7`, `armv7s`, and `arm64`. You can then compile your project for the selected architectures.

iOS: Manually upgrading existing pre-V6.2 MobileFirst iOS hybrid applications

IBM MobileFirst Platform Foundation V7.1.0 supports existing applications that were created in earlier releases. However, if the application was developed with IBM MobileFirst Platform Foundation V 6.1 or earlier, and was not yet upgraded to V6.2 or later you must manually update the application code to simplify the usage of native code at the start of your application.

To manually migrate such an application, follow these steps:

1. Set the main app delegate, `MyAppDelegate` (in `appName.h`), to extend `WLAppDelegate` instead of `WLCordovaAppDelegate`.
2. Implement the protocol `WLInitWebFrameworkDelegate` (for example, set `MyAppDelegate` to implement it), and implement its method `wlInitWebFrameworkDidCompleteWithResult`.

Note: The method `didFinishWLNativeInit` is deprecated and cannot be called. If you had custom code in this method, move it to `wlInitWebFrameworkDidCompleteWithResult`.

For example, in `appName.h`, change

```
@interface MyAppDelegate : WLCordovaAppDelegate{
```

to

```
@interface MyAppDelegate : WAppDelegate <WInitWebFrameworkDelegate> {}
```

and implement the method of the protocol:

```
-(void)wInitWebFrameworkDidCompleteWithResult:(WLWebFrameworkInitResult *)result{
```

Note: CDVMainViewController and WLCordovaAppDelegate are deprecated and are no longer necessary (if some custom applicative code interacts with these classes, it continues to work as is).

3. Call `[[WL sharedInstance] initializeWebFrameworkWithDelegate:someDelegate]` whenever it applies, according to the logic of the application (it is recommended to call it as early as possible in the application lifecycle).
4. When the MobileFirst initialization process is complete, the framework notifies the delegate by calling the `wInitWebFrameworkDidCompleteWithResult` method with a `WLWebFrameworkInitResult` object. Check the initialization result by using the `statusCode` method of `WLWebFrameworkInitResult`. The success and failure scenarios are handled according to the logic of the app.
5. If the initialization finishes successfully, you can load the Cordova WebView to run the MobileFirst JavaScript framework:
 - a. Call `[[WL sharedInstance] mainHtmlFilePath]` to get the path of the main HTML file of the app.
 - b. Create the Cordova ViewController `CDVViewController`, and set its `startPage` to the HTML path.
 - c. Display the Cordova WebView.
6. Replace all links to the static library `WorklightSDK/libWorklightStaticLibProject.a` to the MobileFirst foundation iOS framework `IBMMobileFirstPlatformFoundationHybrid`. For example, all of the following import statements can be removed:

```
#import "WL.h"  
#import "WLResourceRequest.h"  
#import "WAppDelegate.h"  
#import "WLGeoUtils.h"  
#import "WLDevice.h"
```

and replaced with the following single statement:

```
#import <IBMMobileFirstPlatformFoundationHybrid/IBMMobileFirstPlatformFoundationHybrid.h>
```

Upgrading existing native iOS applications

To work with an existing native iOS project that was created with IBM MobileFirst Platform Foundation V7.0.0 or earlier to V7.1.0 (or more recent interim fixes), you must modify the project by manually modifying your project in Xcode, or by using CocoaPods.

The latest interim fixes introduced a number of changes for adapting to the latest version of iOS (iOS 9) and Xcode 7.1 and 7.1.1. CocoaPods also recently released a new version that changes the way the pods are installed.

In order to correctly configure Xcode 7.1 and 7.1.1 to work with the latest interim fixes, you need to understand what settings Xcode uses and why some settings can be problematic.

The latest interim fixes deliver the necessary libraries in the form of frameworks. Frameworks can contain a number of resources. Frameworks contain library as well as header files. One advantage of this method of delivering the SDK is that multiple resources are organized together, reducing the amount of linking required within the Xcode project.

It is important to clean up all unnecessary libraries, header files, and their links within Xcode before installing the latest interim fix. Xcode 9 continues to work with libraries and header files, so some non-IBM MobileFirst Platform Foundation library or header files may need to remain.

Upgrading existing native iOS applications to IBM MobileFirst Platform Foundation version V7.1.0 manually

You can upgrade your existing native iOS application manually, in Xcode, so that you can work with it in IBM MobileFirst Platform Foundation V7.1.0.

Before you begin

- You must have an existing native iOS project that was created with IBM MobileFirst Platform Foundation 7.0.0 or earlier.
- You must have already created a new, V7.1.0 or later MobileFirst native API project with MobileFirst Studio or the MobileFirst Platform Command Line Interface so that you can copy certain required files to your Xcode project. For more information, see “Creating MobileFirst projects with MobileFirst Studio” on page 8-6 or the “**create**” on page 16-15 command.

Procedure

1. Manually delete the WorklightAPI folder under the main Xcode project folder.
2. Replace the Worklight.plist file in your Xcode project folder with the Worklight.plist file from your new 7.1 MobileFirst Studio project.
3. In the Xcode **Build Phases** tab, **Link Binary With Libraries** section, remove all references, including the libWorklightStaticLibProjectNative.a reference.
4. Add the IBM MobileFirst Platform Foundation 7.1 SDK.
 - a. Find the WorklightAPI folder in your new IBM MobileFirst Platform Foundation 7.1 or MobileFirst Studio project folder and manually copy it to your main Xcode project folder.
 - b. Add the reference to your project: Choose **Add Files** from the **File** menu and navigate to the Worklight folder in your Xcode project folder.
5. In the **Search Paths** section of the **Build Settings** tab:
 - a. Check that the **Header Search Paths** values have been removed.
 - b. Verify that the **Framework Search Paths** value is `$(PROJECT_DIR)/WorklightAPI/Frameworks`.
 - c. The **Library Search Paths** values can also be removed.
6. If you are using Swift, make sure the `$SRCROOT/WorklightAPI/include/WLSwiftBridgingHeader.h` has been removed from **Swift compiler** section in the **Build Settings** tab (**Objective-C Bridging Header**). This header is included in the newly added IBM MobileFirst Platform Foundation 7.1 frameworks in the **Build Phases** tab, **Link Binary With Libraries** section.
7. Link the required frameworks, and possibly libraries, and headers in the **Build Phases** tab, **Link Binary With Libraries** section:
 - a. Make sure the IBM MobileFirst Platform Foundation frameworks have been linked:
 - `IBMMobileFirstPlatformFoundation.framework`

Important: If you are using the latest interim fix link the following frameworks:

- openssl.framework
- If you want to enable the JSONStore feature (which is optional in the latest interim fix) link these additional files:
 - IBMMobileFirstPlatformFoundationJSONStore
 - SQLCipher.framework

If the values are set correctly in the **Framework Search Paths** (see above), the above values should appear in the **Link Binary With Libraries**.

- b. Add additional required iOS frameworks, dylib files, and libraries (some libraries will already be linked):
 - MobileCoreServices.framework
 - CoreData.framework
 - CoreLocation.framework
 - Security.framework
 - SystemConfiguration.framework
 - libstdc++.dylib
 - libz.dylib
 - libc++.dylib

Note: From Xcode 7, the *.tbd replace the *.dylib files.

8. In the **Linking** section of the **Build Settings** tab make sure the **Other Linker Flags** value is set to -ObjC.
9. In your code import the new MobileFirst framework
 - If you are using Objective C:

```
#import <IBMMobileFirstPlatformFoundation/IBMMobileFirstPlatformFoundation.h>
```
 - If you are using Swift:

```
import IBMMobileFirstPlatformFoundation
```
10. If you are using IBM MobileFirst Platform Foundation and are using the JSONStore feature, replace all of the existing JSONStore imports of headers with a single entry of the following new umbrella header:
For Objective C

```
#import <IBMMobileFirstPlatformFoundationJSONStore/IBMMobileFirstPlatformFoundationJSONStore.h>
```

For Swift

```
import IBMMobileFirstPlatformFoundationJSONStore
```
11. Beginning with Xcode 7 TLS must be enforced, see “Enforcing TLS-secure connections in iOS apps” on page 8-198.
12. From Xcode 7 bitcode is set as a build default and must be disabled. For more information see “Disabling bitcode in Xcode builds” on page 8-199.

Results

Your application is now upgraded so that it will work with the IBM MobileFirst Platform Foundation, V7.1.0 iOS SDK.

Upgrading existing native iOS applications to IBM MobileFirst Platform Foundation V7.1.0 with CocoaPods

You can upgrade your existing native iOS application IBM MobileFirst Platform Foundation to work with V7.1.0 by making some changes in Xcode project, adding the IBM MobileFirst Platform Foundation iOS SDK with CocoaPods and adjusting your code.

Before you begin

- You must have CocoaPods installed in your development environment. For more information, see the "Getting Started" guide for CocoaPods installation.

About this task

Procedure

1. Make sure that your app is still registered on the server according to the `worklight.plist` client property file in your Xcode project. For example, as part of your upgrade, if you are using a new MobileFirst Studio or MobileFirst Platform Command Line Interface project, make sure you are using the version of the `worklight.plist` that corresponds to the server registration.
2. Open your project in Xcode.
3. If MobileFirst SDK was previously installed manually (not with CocoaPods), delete the `WorklightAPI` folder (move it to Trash).
4. Modify the **Build Settings** setup:
 - a. If it exists, remove `$(SRCROOT)/WorklightAPI/include` from the **Header Search Path**.
 - b. If it exists, remove `$(PROJECTDIR)/WorklightAPI/frameworks` from the **Frameworks Search Path**.
5. If you are using Swift, make sure the `$(SRCROOT)/WorklightAPI/include/WLSwiftBridgingHeader.h` has been removed from **Swift compiler** section from the **Build Settings** tab (**Objective-C Bridging Header**). The header will be installed as part of the new frameworks.
6. In the **Build Phases** tab, remove any existing MobileFirst links. These are the libraries that may have been previously installed for MobileFirst.
 - `libWorklightStaticLibProjectNative.a`
 - `SystemConfiguration.framework`
 - `MobileCoreServices.framework`
 - `CoreData.framework`
 - `CoreLocation.framework`
 - `Security.framework`
 - `sqlcipher.framework`
 - `libc++_shared.dylib`
 - `libz.dylib`
7. Close Xcode.
8. Get the IBM MobileFirst Platform Foundation iOS SDK from CocoaPods. To get the SDK, complete the following steps:
 - a. Open **Terminal** at the location of your new Xcode project.
 - b. Run the `pod init` command to create a podfile file.
 - c. Open the Podfile file that is in the root of the project with a text editor.
 - d. Comment out or remove the existing content.

- e. Add the following lines, including the iOS version, and save the changes:

```
use_frameworks!  
platform :ios, 9.0  
pod 'IBMMobileFirstPlatformFoundation'
```

Note: The pod examples assume you are upgrading to the latest version of the MobileFirst. If you are not using the latest version of MobileFirst, you need to indicate the version. For example, for importing the latest pod for 7.1.0 IBMMobileFirstPlatformFoundation the line would look like this:

```
pod 'IBMMobileFirstPlatformFoundation', '~> 7.1.0'
```

- f. Specify additional pods in the file, for additional functionality required by your app. For example, if your app uses Cloudant for data storage, the podfile might look like:

```
source 'https://github.com/CocoaPods/Specs.git'  
use_frameworks!  
platform :ios, 9.0  
pod 'IBMMobileFirstPlatformFoundation'  
pod 'CloudantToolkitLocal'
```

If you are using the latest interim fix for IBM MobileFirst Platform Foundation and your app uses JSONStore, the podfile might look like:

```
source 'https://github.com/CocoaPods/Specs.git'  
use_frameworks!  
platform :ios, 9.0  
pod 'IBMMobileFirstPlatformFoundation'  
pod 'IBMMobileFirstPlatformFoundationJSONStore'
```

Note: If the podfile in this example specified only the CloudantToolkitLocal or IBMMobileFirstPlatformFoundationJSONStore pods and not the IBMMobileFirstPlatformFoundation pod, the results would be the same due to the built-in dependencies.

- g. Verify that the Xcode project is closed.
- h. Run the **pod install** command. (If IBM MobileFirst Platform Foundation, V7.1.0 was installed previously with CocoaPods run the **pod update** command). This command installs the MobileFirst SDK IBMMobileFirstPlatformFoundation.framework and any other frameworks that are specified in the podfile and their dependencies. It then generates the pods project, and integrates the client project with the MobileFirst SDK.
9. Open your *ProjectName.xcworkspace* file in Xcode by typing `open ProjectName.xcworkspace` from a command line. This file is in the same folder as the *ProjectName.xcodeproj* file.
10. In the **Build Settings** tab, under **Other Linker Flags**, add `$(inherited)` value to the `-ObjC` flag. For example:

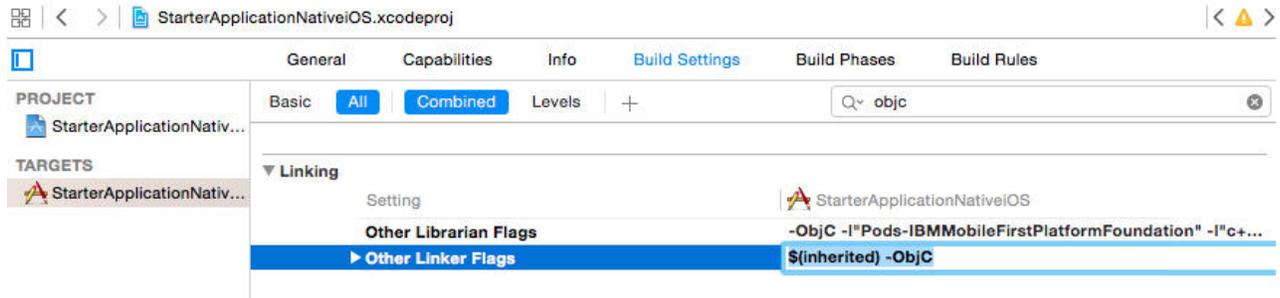

Figure 7-1. Adding `$(inherited)` to ObjC flag in Xcode Build Settings

11. In the **Search Paths** section of the **Build Settings** tab, make sure the **Header Search Paths** value has been cleared.
12. In your code, replace all of the existing MobileFirst imports of headers with frameworks.:
For Objective C:

```
#import <IBMMobileFirstPlatformFoundation/IBMMobileFirstPlatformFoundation.h>
```

For Swift:

```
import IBMMobileFirstPlatformFoundation
```
13. If you are using IBM MobileFirst Platform Foundation and are using the JSONStore feature, replace all of the existing JSONStore imports of headers with a single entry of the framework import:
For Objective C

```
#import <IBMMobileFirstPlatformFoundationJSONStore/IBMMobileFirstPlatformFoundationJSONStore.h>
```

For Swift

```
import IBMMobileFirstPlatformFoundationJSONStore
```
14. From Xcode 7 TLS needs to be enforced, see “Enforcing TLS-secure connections in iOS apps” on page 8-198.
15. From Xcode 7 bitcode is set as a build default and must be disabled. For more information see “Disabling bitcode in Xcode builds” on page 8-199.

Results

Your application is now upgraded so that it will work with the IBM MobileFirst Platform Foundation, V7.1.0 iOS SDK.

Migrating projects to MobileFirst Studio V7.1.0

How to migrate your existing projects to MobileFirst Studio V7.1.0.

Migrating older MobileFirst projects to MobileFirst Studio V7.1.0

Open your existing projects as you would normally. This action triggers a migration process that updates them to work with V7.1.0.

When the migration process finishes, redeploy your applications and adapters.

To migrate projects that were created in versions of Worklight Studio older than V5.0.5, you must first migrate these projects to an intermediate level such as V5.0.5, V5.0.6, or V6.0. For example, if you have a V5.0.0.3 project:

1. Migrate the V5.0.0.3 project to Worklight Studio V5.0.5.x, using the procedures that are listed in Migrating to a later version of IBM MobileFirst Platform Foundation of the IBM Worklight V5.0.5 user documentation.
2. Open the project (now migrated to V5.0.5) in MobileFirst Studio V7.1.0 to complete the migration process.

Note: Access to authenticity-protected resources is denied when you upgrade existing applications to V7.1.0. When you upgrade MobileFirst Studio, rebuild the project WAR and .w1app, and deploy those files to the server, the existing clients that use authenticity stop working. To resolve the problem, complete the following steps:

1. Upgrade the project by using the new MobileFirst Studio, as described in the previous steps.
2. Increment the versions of the upgraded applications.
3. Deploy the new WAR file that was built with the new MobileFirst Studio.
4. Deploy the new applications to the server alongside the applications that were built with the old version of IBM MobileFirst Platform Foundation.
5. Normally, both applications work as expected. If you want to use the new ones only, block the old ones and refer to the new ones for upgrade.

If for any reason you need to access the pre-migrated versions of your MobileFirst projects, a compressed file backup is made of those files. The location of this file is displayed in the second step of the migration procedure.

If any of your existing target environments are removed in the newest version of MobileFirst Studio, a message notifies you, and those folders are marked as plain source folders in your file hierarchy.

If any applications in your existing projects use the obsolete database login module for user authentication, modify them to use adapter-based authentication with the SQL adapter instead.

Managing the splash screen in iOS hybrid applications created before V6.2.0 that are migrated to V7.1.0

In iOS hybrid applications created before V6.2.0 that are migrated to V7.1.0, the splash screen is still managed internally by a compatibility layer in the same way it was managed in previous versions. Before V6.2.0, the showing and hiding of the splash screen was managed internally in native code by the MobileFirst Hybrid SDK. To be able to use the new splash API, migrate your application as described in “Migrating projects to IBM MobileFirst Platform Foundation V7.1.0” on page 7-7 “iOS: Manually upgrading existing pre-V6.2 MobileFirst iOS hybrid applications” on page 7-9.

Working with Android projects

In IBM MobileFirst Platform Foundation V7.1.0, developers are encouraged to use the latest Android SDK API level that is supported by the MobileFirst Studio – Android 5.1.1 (API Level 22). Using the latest Android SDK allows the Android system to disable compatibility behaviors that slow the mobile application and to use the latest capabilities and features it includes.

When a new Android project is created, an attribute named `android:targetSdkVersion` is added in the `androidManifest.xml` file under the

<uses-sdk> element, with a default value of 22. This value specifies that the API Level of the application targets is Android 5.1.1.

The default Android SDK API level is not changed for existing projects that are opened in MobileFirst Studio V7.1.0.

With project that were created with versions older than V6.1, the Cordova libraries are updated during the installation of MobileFirst Studio. Therefore, for Android applications, if you have any user/custom plug-in that refers to the `org.apache.cordova.api` package, you must replace `org.apache.cordova.api` with `org.apache.cordova`

Change from Tealeaf V8 to Tealeaf V9

- Starting with IBM Worklight Foundation V6.2.0, Tealeaf Client SDK V9 is delivered under the optional feature **Tealeaf Client SDK**. In previous versions of IBM Worklight, the name of this optional feature was Analytics.
- WL.Analytics JavaScript API no longer delegates to Tealeaf TLT JavaScript API. WL.Analytics JavaScript API now delegates to MobileFirst internal SDK and achieves the same results as the previous behavior.
- For IBM Worklight V6.1 projects in which the Analytics optional feature is already enabled and that you upgrade to MobileFirst Studio V7.1.0: the Tealeaf artifacts are replaced, including `uicandroid.jar` and `TLFConfigurableItems.properties` on Android, all Tealeaf `.h`, `.plist` and `libTLFLib.a` files on iOS, and `tealeaf.min.js`.

The three Tealeaf import statements are commented out in the `main.m` file of iPhone and iPad environments. This is necessary to avoid compile errors that are related to unresolved import statements, as the Tealeaf header files were removed from the Worklight SDK. The header files are available as part of the Tealeaf Client SDK optional feature. Applications that use the Tealeaf Client SDK optional feature must add the appropriate header file imports based on the Tealeaf version that is used.

- Applications are not automatically instrumented with Tealeaf Client SDK API calls. Make sure to instrument the application appropriately to capture the required events for Tealeaf CX server replay and analysis.

Impact of migrating to a new version of MobileFirst Studio for applications already in production

Since V6.2.0, there is a separation between the MobileFirst Server runtime environment and the MobileFirst apps or adapters.

This separation generally means the following:

- When you deploy a runtime environment that was built by using MobileFirst Studio V6.2.0 into MobileFirst Server V6.2.0.1 or later, you can deploy applications and adapters of any version, from V5.0.6.
- If you do not increase the application version when you rebuild it in the new MobileFirst Studio, important features such as app authenticity fails for the old clients and they are not able to connect to the MobileFirst Server.

For Direct Update and app authenticity to work, both the client application and the server-side artifacts (wlap) must be generated from the same version of MobileFirst Studio.

In certain cases, if you migrate your MobileFirst project to a new version of MobileFirst Studio, you must increment the version number of the application even if you do not change the code of the application. If you deploy a new, upgraded runtime environment that was built with the new MobileFirst Studio, it is possible to deploy both versions of applications. You can deploy the app built with an older version of MobileFirst Studio and the upgraded app that was built with a new version of MobileFirst Studio, with a different application version. You can serve the older, existing client application along with new ones, or block the old ones and refer to download of the new ones.

For more information about version compatibility among different MobileFirst components, see “Version compatibility” on page 7-1.

There are three such cases:

Applications were created with a version of Worklight Studio older than V5.0.0.3

Device users can continue to work without requiring a download of a new version of the application if the device user uses apps with the following criteria.

- The apps were built with IBM Worklight V5.0.0.3 or later.
- The apps server-side artifacts are successfully deployed to the latest version of IBM MobileFirst Platform Foundation and tested on a test server.

Device users can continue to work without being required to download a new version of the application if the following criteria is met.

- The apps were built with IBM Worklight V5.0.0.3 or later.
- The apps server-side artifacts were regenerated by using the new version of Worklight Studio.
- The apps are successfully deployed to the latest version of IBM MobileFirst Platform Foundation and tested on a test server.

However, the Direct Update and app authenticity are not available for these applications.

Applications that use the Direct Update feature

The Direct Update feature (“Direct updates of app versions to mobile devices” on page 8-379) to automatically update application versions stops working after some migration paths. MobileFirst Studio displays a warning when such situations are detected when you migrate apps created in older versions.

To notify your users that a new version of the application is available, you can use the start display notification feature that is documented at “Displaying a notification message on application startup” on page 13-5. If the application update is mandatory, another alternative is to deny access to the old application version by using the feature that is documented at “Remotely disabling application connectivity” on page 13-3.

To upload a new version of your application to an application store such as the Apple Store or Google Play, you may have to resubmit the app for approval by the store.

Applications that use application authenticity

App authenticity does not work properly for clients that are built with an older version of MobileFirst Studio when the app that is deployed on the

server was built with a later version of MobileFirst Studio, and both have the same application version. Requests from those clients to access resources that are authenticity-protected are always denied.

Upgrading projects to work in session-independent mode

Upgrading projects that were session-dependent in previous versions so that they work with IBM MobileFirst Platform Foundation V7.1.0 in session-independent mode.

About this task

Session-independent mode was introduced as the *default* mode for MobileFirst Server, starting with V7.1.0. For more information about session-independent mode, see “Session-independent mode” on page 8-324.

Note: Clients that were created using a version of IBM MobileFirst Platform Foundation earlier than V7.1.0 do not work with a MobileFirst Server that is operating in the new session-independent mode. So, to serve users who are using the session-independent mode, as well as existing users who are using session-dependent mode, you must deploy the new V7.1.0 WAR with its V7.1.0 artifacts, but **WITHOUT** removing the old WAR.

Tip: If you choose to move all your users to session-independent mode, for instance, to enable IT to scale down servers dynamically, you may consider remotely disabling the old apps in the old WAR.

Procedure

1. Import your old project into MobileFirst Studio V7.1.0. Alternatively, if you are using MobileFirst Platform Command Line Interface, make sure you have V7.1.0 installed, then run the `mfp push` command.
2. Inspect the settings for the session dependency properties in the `worklight.properties` file of your project.

Ensure that the following parameters appear and are configured as shown:

- `mfp.session.independent=true`.
- `mfp.attrStore.type=database`. Other options are: `extremescale` and `datacache` (if you are using Bluemix). Make sure that `mfp.attrStore.type` is not set to `HttpSession`, which does not work in session-independent mode.

For more information, see “Configuring session dependency” on page 12-54.

3. Inspect the expiration settings of the built-in realms in the `worklight.properties` file.

Ensure that the following parameters appear. Either set a positive expiration value for each, or use the following default values:

```
wl.realm.expiration.directUpdate=3600
wl.realm.expiration.remoteDisable=300
wl.realm.expiration.deviceAutoProvisioning=3600
wl.realm.expiration.deviceNoProvisioning=3600
wl.realm.expiration.antiXSRF=3600
wl.realm.expiration.authenticity=3600
wl.realm.expiration.anonymousUser=3600
```

4. Inspect the `loginModule` elements in the `authenticationConfig.xml` file of your project. Change the `expirationInSeconds` attribute value from `-1` to your

desired realm expiration, or completely remove this attribute to use a default expiration of 3600 seconds. For more information, see “Configuring login modules” on page 8-617.

5. Ensure that the apps in your project conform to the requirements in the section “Developing apps to work in IBM MobileFirst Platform Foundation V7.1.0” under Session-independent mode.

Migrating IBM SmartCloud Analytics Embedded to IBM MobileFirst Platform Operational Analytics

If you used IBM SmartCloud Analytics Embedded in previous versions of IBM MobileFirst Platform Foundation, you must now migrate to IBM MobileFirst Platform Operational Analytics.

About this task

In IBM MobileFirst Platform Foundation V7.1.0, IBM MobileFirst Platform Operational Analytics replaces IBM SmartCloud Analytics Embedded. Complete the following steps to migrate to IBM MobileFirst Platform Operational Analytics. For more information about IBM MobileFirst Platform Operational Analytics, see “Operational analytics” on page 14-9.

Procedure

1. Install the analytics WAR file on your application server, but do not start the server. For detailed information about installing the analytics WAR file, see “Installing the IBM MobileFirst Platform Operational Analytics” on page 6-216.
2. Locate the data folder on your IBM SmartCloud Analytics Embedded server. If the installation path for IBM SmartCloud Analytics Embedded was not modified, this folder is located in `/opt/IBM/analytics/data`.
3. Copy the data folder to the same machine as the machine where the analytics WAR file is hosted.

Note: The data folder then becomes the location where all analytics data is stored, so make sure to place this folder in an appropriate location.

4. Modify the `datapath` JNDI variable on your application server to point to the data folder that was copied from the IBM SmartCloud Analytics Embedded server folder in step 3. For example:

```
<jndiEntry jndiName="analytics/datapath" value="/home/system/data"/>
```

Important: Make sure the JNDI property points to a copied version of the data folder. This is to ensure that your data is still backed up in case of data corruption due to a migration failure.

5. Identify the cluster name that was specified when IBM SmartCloud Analytics Embedded was installed. This name will be the name of the folder at the root of the data folder.
6. Modify the `clustername` JNDI variable on your application server to match the cluster name that was installed by IBM SmartCloud Analytics Embedded. For example:

```
<jndiEntry jndiName="analytics/clustername" value="WLCLUSTER"/>
```

7. Start the Analytics WAR server and review the console. The migration process begins automatically. The data is available to view after the migration process is completed.

Migration to the V7.1.0 Analytics Console

Starting with V7.1.0, the MobileFirst Analytics Console was improved, which requires migration of your analytics data.

Why you must migrate

In V7.1.0, the internals of the Analytics Console were improved, which required changing the format in which the data is stored. To continue to interact with the analytics data that was already collected, the data must be migrated into the new data format.

Viewing the Analytics Console for the first time after you upgrade

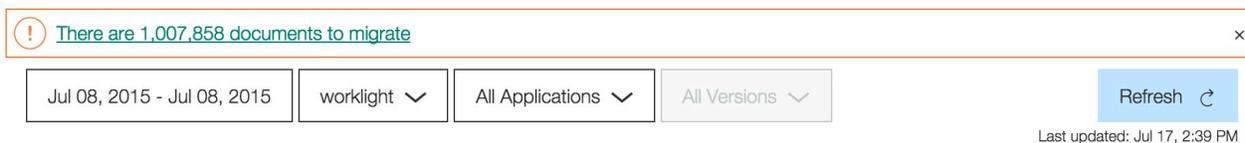

When you first view the Analytics Console after you upgrade to V7.1.0, no statistics are rendered in the console. Your data is not lost, but it must be migrated to the new data format.

How to migrate

An alert is displayed in the console that reminds you that there are documents to migrate. The alert includes a link to the Migration tab of the Administration page.

The following image shows a sample alert:

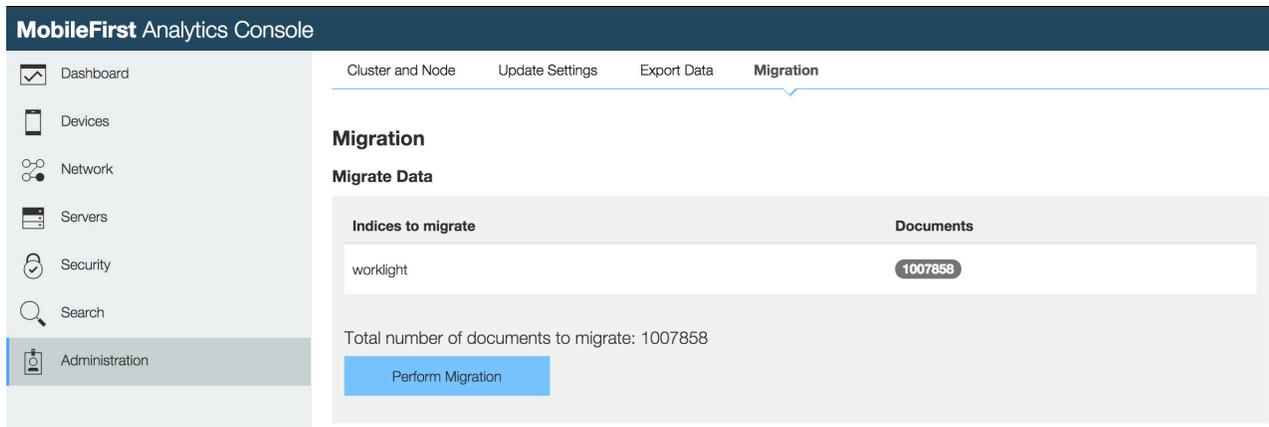

Overview

Migration tab

On the Migration tab of the Administration page, you can see how many documents must be migrated, and which indexes they are stored on. There is only one action: **Perform Migration**.

The following image shows the Migration tab of the Administration page:

Note: This process might take a long time, depending on the amount of data you have, and it cannot be stopped during migration.

The migration takes approximately 3 minutes to migrate 1 million documents on a single node with 32G of RAM, with 16G allocated to the JVM, with a 4 core processor. Documents that are not migrated are not queried, and therefore are not rendered in the console.

Troubleshooting

If the migration fails while in progress, retry the migration. Retrying the migration does not remigrate documents that were already migrated, and your data integrity is maintained.

Upgrading to MobileFirst Server V7.1.0 in a production environment

Upgrading MobileFirst Server in a production environment is a more exacting process than in your development environment because you must back up your data and prepare for the upgrade carefully to minimize production downtime. This section provides a series of steps to upgrade your production server or servers efficiently and in the shortest time possible.

When you upgrade from Worklight Server V5.0.6.x or later to V7.1.0 in a production environment, the process can be more complicated than upgrading to a new version in your development environment. The upgrade procedure can also take longer if you have existing MobileFirst applications that run in a production MobileFirst Server environment. For step-by-step instructions on how to upgrade your production MobileFirst Server to V7.1.0, see the following topics.

Note: The documentation in the topics that follow assumes the following facts:

- Your database type is IBM DB2, MySQL, or Oracle (not Apache Derby).
- Your application server type is WebSphere Application Server full profile, WebSphere Application Server Liberty profile, or Apache Tomcat.

Important: The topics are in a specific order, and must be completed in the order shown.

The upgrade procedure can take some time, several hours in fact, and so these activities must be scheduled to create the least disruption and downtime to production servers and the applications that run on them.

The topics provide essential information about backing up any existing databases or application server data, migrating your existing MobileFirst projects and applications to the new version, and performing other preparation tasks that must be completed before you install the new version of MobileFirst Server. These preparatory steps are followed by postinstallation, verification, and configuration tasks that must be completed before you restart the new MobileFirst Server and finish migrating your MobileFirst applications.

Read through the entire set of topics before you begin the actual upgrade process to become familiar with the tasks ahead of you, what must be done, and in what order.

Start with “Overview of the upgrade to MobileFirst Server V7.1.0 process,” and then read through the steps under each of the major topics that follow.

Alternatively, you can refer to one of the following topics that provide the complete steps-by-steps instructions to guide you through the entire upgrading process of your MobileFirst Server to V7.1.0:

- Applying a fix pack for MobileFirst Server V7.1.0
- Upgrading MobileFirst Server from V7.0.0 to V7.1.0
- Upgrading MobileFirst Server from V6.3.0 to V7.1.0
- Upgrading MobileFirst Server from V6.2.0 to V7.1.0
- Upgrading MobileFirst Server from V6.1.0 to V7.1.0
- Upgrading MobileFirst Server from V6.0.0 to V7.1.0
- Upgrading MobileFirst Server from V5.0.6 to V7.1.0

Overview of the upgrade to MobileFirst Server V7.1.0 process

An overview of the MobileFirst Server V7.1.0 upgrade process, including what is updated and what is not.

A typical instance of MobileFirst Server includes the following elements:

- A database management system (DBMS) that runs databases for the Application Center and for MobileFirst Server. This DBMS hosts and run the following databases:
 - The Application Center database (if Application Center is installed on that server).
 - The administration database.
 - One or more runtime databases. Each runtime environment requires one runtime database, and an optional reports database.
- Note:** The reports database is deprecated since IBM MobileFirst Platform Foundation V7.1.0. Use MobileFirst Operational Analytics instead. For more information, see “Installing the IBM MobileFirst Platform Operational Analytics” on page 6-216.
- One or more application servers. These application servers host and run the following web applications:
 - The Application Center application (if Application Center is installed on that server).
 - The MobileFirst Operations Console application. One MobileFirst Operations Console can be used to administer several MobileFirst runtime environments. It is defined by a WAR file, which is `worklightconsole.war`.

- The Administration Services application. This application provides the necessary services for the MobileFirst Operations Console and hosts all the services (REST services) and administration tasks. The Administration Services application is defined by a WAR file, which is `worklightadmin.war`, and is connected to the administration database.
- One or more MobileFirst runtime environments. Each MobileFirst runtime environment:
 - Is defined by a WAR file that is created with MobileFirst Studio, or MobileFirst Platform Command Line Interface.
 - Is connected to two databases, one for runtime and one for reports.
 - Can run on one or more physical servers, for both workload and service availability considerations.
- An installation of the MobileFirst Server programs, usually on the same computer as the application server or deployment manager.

An IBM MobileFirst Platform Foundation installation might contain other elements, such as the MobileFirst Data Proxy, or the IBM MobileFirst Platform Operational Analytics. The upgrade procedures for these components are described in different sections.

The topics in this section focus on the task of upgrading and configuring the following entities:

- The MobileFirst Server programs.
- The databases, including the creation of the administration database.
- The MobileFirst project runtime applications and Application Center applications that are deployed in the application server.

Note: The upgrade of the MobileFirst project runtime applications includes the installation and setup of the MobileFirst Operations Console and administration services applications.

- To upgrade the MobileFirst Data Proxy, see “Upgrading, or applying a fix pack to the MobileFirst Data Proxy” on page 7-92.
- To upgrade the MobileFirst Operational Analytics, see “Applying a fix pack to IBM MobileFirst Platform Operational Analytics” on page 7-94.

The actual steps that you must complete for the upgrade can change, depending on the particular *upgrade path* that you are pursuing. Your upgrade path is determined by your upgrading mode:

- From a previous version of Worklight Server or MobileFirst Server to MobileFirst Server V7.1.0 (for example, from V6.0.0.x to V7.1.0 or from V6.1.0.x to V7.1.0).
- From MobileFirst Server V7.1.0 to a fix pack release or an interim fix (for example, from V7.1.0 to V7.1.0.x).

The spreadsheet at the following link lists the individual steps for each of these upgrade paths, and helps you to determine:

- Whether the step is required or not required, depending on your MobileFirst upgrade path.
- Whether your Application Center, and MobileFirst Server (old version), are uninstalled, stopped, or upgraded (and running) during this step as the result of actions in the current step or previous steps.

The spreadsheet can be downloaded here: [MobileFirst Server Upgrade Steps spreadsheet](#)

To provide further assistance, at the beginning of each topic a shorter version of this spreadsheet is provided for that step. Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-3. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes/No
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes/No
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes/No
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes/No
MobileFirst Server V6.3.0 to MobileFirst Server V7.1.0	Yes/No
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes/No
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes/No

Table 7-4. System status after this step.

Module	Status
Application Center	Running/Stopped/Uninstalled/Upgraded
MobileFirst Server	Running/Stopped/Uninstalled/Upgraded

Preparation for upgrades to MobileFirst Server

Before you begin the actual upgrade to MobileFirst Server V7.1.0, you must complete several preparation tasks.

Upgrading to a new version of MobileFirst Server in a development environment is quick and easy because in most cases no critical data must be preserved in IBM MobileFirst Platform Foundation databases. In a production environment, however, more time and effort are required for the upgrade, to minimize production downtime and inconvenience to users of existing applications.

Complete the following preparation tasks before you begin upgrading to a new MobileFirst Server version. You can start any time before the upgrade, but you must complete these tasks before you move to the next major step, “Starting the MobileFirst Server V7.1.0 upgrade process” on page 7-42.

Gathering information for MobileFirst Server V7.1.0 upgrades

To avoid having to stop the upgrade process to look up required information, gather it in advance and have it handy.

About this task

One of the purposes of these instructions is to minimize the time for upgrades to MobileFirst Server. You do not want to start the procedure and then discover that you are missing some piece of information that is required by the installer.

To avoid this situation, prepare a list of information that you are likely to be asked for and keep it handy during the upgrade process.

In addition, it is often necessary to pre-plan certain aspects of the upgrade and clear them with your application server administrator and your database administrator. For example, you must know the correct user name. You must also either have sufficient permissions to create or update databases, or have your database administrator do it for you.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-5. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-6. System status after this step.

Module	Status
Application Center	All instances are kept running.
MobileFirst Server	All instances are kept running.

Procedure

Go through the following checklist.

- Verify that your operating system, application server, and Database Management System (DBMS) meet the system requirements for MobileFirst Server V7.1.0 at Detailed System Requirements for IBM MobileFirst Platform Foundation and IBM Mobile Foundation.
- Make a list of the host names and IP addresses of all servers that must be upgraded.
- Make a similar list of all database names and locations.

- Ensure that the correct JDBC drivers for the target databases are available on your computer. IBM Installation Manager needs access to these drivers to upgrade the Application Center database. Ant scripts also need access to these drivers to create the administration database and upgrade the MobileFirst runtime databases.
- Gather the credentials to the MobileFirst Server administration, the MobileFirst runtime environments, the MobileFirst reports, and Application Center databases. If you do not know the correct schemas, user names, and passwords, ask your database administrator for assistance.

Note: The administration database does not exist for IBM Worklight V6.1.0 or earlier.

- During the upgrade procedure, you must stop and restart the application server, and verify its configuration. Therefore, you must be familiar enough with your application server to complete these tasks, or have a system administrator do them.
- If the URL to the Application Center or the MobileFirst Server applications or their console changes, identify all the systems that you must update. If you upgrade from V6.1.0 to V7.1.0, the URLs to the Application Center and the MobileFirst runtime environment do not change, but a new URL is introduced for the MobileFirst Operations Console.
- The reports database is deprecated since IBM MobileFirst Platform Foundation V7.1.0. If you still use the reports database, you might consider using MobileFirst Operational Analytics instead. For more information, see “Operational analytics” on page 14-9.

For installation instructions, see “Installing the IBM MobileFirst Platform Operational Analytics” on page 6-216, and “Setting up a production cluster” on page 14-90.

Planning installation of the MobileFirst Administration Services and MobileFirst Operations Console

You must plan the steps that you perform later to upgrade the Administration Services and the MobileFirst Operations Console. These components were introduced in V6.2.0, and if you upgrade from an earlier version, you must install them first.

Before you begin

Worklight Server V6.2.0 introduced a new architecture for the unified console based on several core elements that are described in “Introduction to the MobileFirst Server components” on page 6-17.

If you upgrade from IBM Worklight V6.1.0 or earlier, you must install the following new components as part of the upgrade process: the Administration Services, and the MobileFirst Operations Console.

The present topic lists the items that you must plan before you perform that upgrade process. The actual installation procedure for the Administration Services, and optionally the MobileFirst Operations Console, is at “Installation or upgrade of MobileFirst Server Administration Services” on page 7-58.

Note: If your application server is WebSphere Application Server V7.0, you must add the configuration property

“com.ibm.ws.webcontainer.invokerequestlistenerfilter = true”. For more information about how to add this property, see “Configuring WebSphere Application Server V7.0” on page 6-70.

About this task

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-7. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	No
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	No
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	No
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

Table 7-8. System status after this step.

Module	Status
Application Center	All instances are kept running.
MobileFirst Server	All instances are kept running.

If you upgrade from V6.1.0 or earlier, install the Administration Services as part of the upgrade process.

To minimize downtime or issues while you follow the upgrade procedure, start with reviewing the installation procedure and configuration options:

1. Review the topic “Planning deployment of administration components and runtimes” on page 6-19.
2. Define your upgrade strategy if multiple MobileFirst runtimes are installed (project WAR files).
3. Prepare the configuration of the application.
4. Set up the MobileFirst administration database.
5. Review the configuration of the application server.

The following procedure emphasizes important items that you must prepare before running an upgrade. You must also review the installation instructions at “Installing the MobileFirst Server administration” on page 6-58.

The following steps are for planning only, and you do not have to start the installation of the MobileFirst Server administration at this stage. The actual installation is described later in the upgrade procedure, at “Installation or upgrade

of MobileFirst Server Administration Services” on page 7-58.

Procedure

1. Review the topic “Planning deployment of administration components and runtimes” on page 6-19 to define the application server where you can install the MobileFirst Server administration components.
2. Define your upgrade strategy if multiple MobileFirst runtimes are installed (project WAR files).

Note: You must perform this step only if you have more than one MobileFirst runtimes (project WAR files) to upgrade. If you have only one MobileFirst runtime to upgrade, you can skip this test.

You can either manage all the runtimes with the same MobileFirst Administration Services and Console runtime environment or install this environment for each runtime.

- Manage all the runtimes with the same MobileFirst Administration Services and Console runtime environment: This is the default setting. Carefully review the context root of each runtime. The context root is used to identify a runtime in the administration database. After the MobileFirst administration data is migrated to the administration database, you can no longer change the context root of a MobileFirst Server runtime. For more information, see “Upgrade the runtime database” on page 7-61.
 - Install a MobileFirst Administration Services and Console environment for each runtime: In this case, define the environment IDs as follows:
 - If you install by running an Ant file, add an environmentID attribute to the Ant tasks for installation administration: `<installworklightadmin>`, `<updateworklightadmin>`, `<uninstallworklightadmin>`, `<configureapplicationserver>`, `<updateapplicationserver>`, `<unconfigureapplicationserver>`. For more information, see “Ant tasks for installation of MobileFirst runtime environments” on page 16-42 and “Ant tasks for installation of MobileFirst Operations Console and Administration Services” on page 16-34.
 - If you install manually, update the `ibm.worklight.admin.environmentid` JNDI property as documented in “List of JNDI properties for MobileFirst Server administration” on page 6-111 and “JNDI environment entries for MobileFirst projects in production” on page 12-68.
3. Prepare the configuration of the application.

Since IBM Worklight Foundation V6.2.0, the protection of the Administration Services and the MobileFirst Operations Console is configured by security roles that are managed in the application server. For more information, see “Configuring user authentication for MobileFirst Server administration” on page 6-106. To prepare the installation and configuration of the Administration Services and the MobileFirst Operations Console, you must identify the users who need access to the console, and verify that these users are declared in the application server. This way, you can configure their access to the Administration Services and MobileFirst Operations Console when the applications are installed.
 4. Set up the MobileFirst administration database.

A MobileFirst administration database is necessary for the Administration Services. This database can be created at installation time, if you have an administrator access to the database server. Otherwise, you must contact your database administrator so that the database is created in advance, and you

must provide your database administrator with the information listed at “Optional creation of the administration database” on page 6-58.

5. Review the configuration of the application server.

For IBM MobileFirst Platform Foundation V7.1.0, you must configure your application server to enable Java Management Extensions (JMX) communication between the Administration Services and the MobileFirst Server runtime. Review the topic “Configuration of the application server” on page 6-63 to see if there is a need to configure your application server to support JMX for a production environment. For example, in the case of WebSphere Application Server Liberty profile, the Ant tasks that you use to install the Administration Services can configure a default secure JMX connection, which includes the generation of a self-signed SSL certificate with a validity period of 365 days. But this configuration is not intended for production use.

Identify the MobileFirst WAR file and prepare the Ant deployment script

In this task, you identify the MobileFirst project WAR file that contains numerous resources and configuration settings for MobileFirst Server and prepare the Ant script that is used to deploy it.

About this task

The MobileFirst project WAR file, also referred to as the MobileFirst runtime environment, is a web application archive that contains server-specific configuration settings, and other resources that can be required to run MobileFirst applications and adapters. You produce this file with MobileFirst Studio, or IBM MobileFirst Platform Command Line Interface, and it is the end point for mobile applications. Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-9. Is this step required for your upgrade path?.

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-10. System status after this step.

Module	Status
Application Center	Running
MobileFirst Server	Running

Procedure

In the upgrade process, the MobileFirst runtime environment must be migrated, and redeployed to the application server. It is important to deploy the same WAR file than the one you previously deployed to your production server. This WAR file might have been updated since the last installation of MobileFirst Server, or the last upgrade. To ensure this, you must complete the following steps:

1. Find the WAR file that was previously deployed to the application server.
 - If you are upgrading from Worklight Server V6.0.0.x or later, find the JNDI properties that were set for the deployed Worklight project to override the default `worklight.properties` file. If you used an Ant script with the **`configureapplicationserver`** task to deploy the WAR file, you can find in that script the JNDI properties that were set at installation time. For more information, see “Configuration of MobileFirst applications on the server” on page 12-50.

For upgrading from Worklight Server V6.0.0.x or later, the procedure to deploy the WAR file is described at “Deploying the project WAR file” on page 12-5.

- When you upgrade from Worklight Server V5.0.6.x, a MobileFirst WAR file is installed by the installer. If you have not modified this WAR file on your production server, you must create a modified file by following the instructions at “Building a project WAR file with Ant” on page 12-4.

When you modify the WAR file, use Worklight Studio V5.0.6.x or the Ant tasks (`worklight-ant.jar`) from an installation of Worklight Studio V5.0.6.x that was used to build the apps previously deployed to the server. The version of Worklight Studio that was used to build the project WAR file must exactly match the version of Worklight Studio that was used to build the apps previously deployed to the server.

The WAR file is automatically migrated to MobileFirst Server V7.1.0 format during the deployment procedure that is described in later steps.

2. Prepare the Ant deployment script that you use to upgrade this WAR file to MobileFirst Server V7.1.0 and to deploy this WAR file to the application server, with the upgraded MobileFirst runtime library.
 - a. Depending on the version from which you want to upgrade to V7.1.0, you must select one of the following options to prepare your Ant tasks.
 - Use the Ant samples provided in the `WorklightServer/configuration-samples/` directory of the MobileFirst Server V7.1.0 distribution. Compared to previous versions, these Ant tasks do not install or upgrade the deprecated reports database. This method is preferred when you upgrade from V5.0.6.x, V6.0.0 or V6.1.0, when you do not want to upgrade your reports database, or if you cannot find the Ant tasks you used to install previous versions.
 - Reuse the Ant files that you used to install previous versions. The Ant files provided by previous versions do install and upgrade the reports database. This method is preferred when you upgrade from V6.2.0, V6.3.0, or V7.0.0, and you want to keep you reports database. You cannot use this method if you upgrade from V6.0.0 or V6.1.0, because the Ant tasks that are provided in these versions are not compatible with MobileFirst Server V7.1.0.

If you upgrade from V6.0.0 to V6.1.0, you can encounter the following incompatibilities: The name of the `worklight-ant-deployer.jar` file is modified (`taskdef` element), and new targets are added to perform an upgrade without losing configuration (`minimal-update`).

If you upgrade from V6.1.0 to V6.2.0, you can encounter the following incompatibilities: New targets are added to install the MobileFirst Administration Services, the MobileFirst Operations Console, and their databases. A new element is added to the configuredatabase task.

- b. To use a sample ant file that is provided in the WorklightServer/configuration-samples/ directory:
 - 1) You must install MobileFirst Server V7.1.0 on your computer, without installing Application Center.
 - 2) Review the sample configuration files in "Sample configuration files" on page 16-77, and copy the Ant sample file that corresponds to your application server and your database. For more information, see the table Table 16-83 on page 16-78.
 - 3) There are two different cases, depending on the version to be upgraded:
 - For an upgrade from V6.0.0 and later, the files for upgrading your runtime and your database are named after the following pattern:
configure-appServer-database.xml
 - For an upgrade from V5.0.6.x, the files for upgrading your runtime and your database are named after the following pattern:
redeploy506-appServer-database.xml

Note: These files have some parameters that are already entered to match the installation settings of IBM Installation Manager for IBM Worklight V5.0.6, especially for the database settings.

- c. You find the following kind of properties in your configuration sample file:

```
<property name= "database.db2.wladmin.password" value= "*****" />
<propertyname="database.db2.worklight.password" value="*****"/>
<property name= "worklight.server.install.dir" value= "****UPDATE**** - MobileFirst Server ins
<property name= "worklight.project.war.file" value= "****UPDATE**** - MobileFirst Project WAR
<property name= "worklight.contextroot" value= "****UPDATE**** - Context Root for the MobileF
<property name= "database.db2.host" value= "****UPDATE**** - DB2 host name (example: proddb.ex
<property name= "database.db2.port" value= "****UPDATE**** - DB2 port, by default 50000 (exam
<property name= "database.db2.instance" value= "****UPDATE**** - DB2 database instance (exam
<property name= "database.db2.driver.dir" value= "****UPDATE**** - DB2 JDBC driver directory
<property name= "database.db2.wladmin.dbname" value= "****UPDATE**** - Database name for Mobi
<property name= "database.db2.wladmin.schema" value= "****UPDATE**** - Database schema for M
<property name= "database.db2.wladmin.username" value= "****UPDATE**** - DB2 user name (exam
<property name= "database.db2.worklight.dbname" value= "****UPDATE**** - Database name for M
<property name= "database.db2.worklight.schema" value= "****UPDATE**** - Database schema for M

<property name= "appserver.was.installdir" value= "****UPDATE**** - Installation directory of
<property name= "appserver.was85liberty.serverInstance" value= "****UPDATE**** - The name of t
```

You must specify precisely the values of these properties. For example, for the property named "worklight.server.install.dir", you must replace the following string with the actual directory where you installed MobileFirst Server:

```
****UPDATE**** - MobileFirst Server installation directory (example: /opt/IBM/MobileFirst_Pl
```

For passwords, such as "database.db2.wladmin.password", if you do not specify them in the Ant sample, then you are asked to enter them when it is required by the upgrading process.

Note: The properties in the previous example are for WebSphere Application Server Liberty profile, and DB2 database. For a different application server, or a different database, you have different properties to set.

If you are not familiar with the MobileFirst component, the meaning of the properties is as follows:

- the MobileFirst project WAR file is a WAR file that is built by your development team with MobileFirst Studio, or with MobileFirst Platform Command Line Interface.
- The database for the Administration Services is a database that was introduced in V6.2.0, which contains applications, adapters, and other administration data. If you upgrade from V6.2.0 or later, you must use the same parameters as the ones you used at installation time, so that the upgrade is performed. If you upgrade from V6.1.0 or earlier, a new database must be created. For more information about the creation of this database, see “Installation or upgrade of MobileFirst Server Administration Services” on page 7-58.
- The database for the MobileFirst runtime environment is a database used by the MobileFirst project WAR file. Use the same parameters as the ones you used at installation time, so that the upgrade is performed.

Since V7.1.0, the Ant samples that are provided do not upgrade your reports database. If you still need to keep your reports database, and you want to upgrade it to V7.1.0, you must do extra customization of the Ant sample, in addition to the modification performed in this step. For more information, see “Using Ant tasks to upgrade the reports database” on page 14-126.

3. Verify that the **environmentID** attribute for the MobileFirst runtime environments matches the **environmentID** attribute that is used to install the MobileFirst Server administration Ant file.

If you install the MobileFirst Server administration components with a different Ant file than the one that you used to install the MobileFirst runtime environment, for example if you install the MobileFirst Server administration with the Server Configuration Tool, you might have a different **environmentId** for the administration and the runtime. In this case, the MobileFirst Server administration components would not find the MobileFirst runtime environments.

The **environmentID** is an attribute of the following Ant tasks:

- `installworklightadmin`, `updateworklightadmin`, and `uninstallworklightadmin` Ant tasks, which are documented at “Ant tasks for installation of MobileFirst Operations Console and Administration Services” on page 16-34.
- `configureapplicationserver`, `updateapplicationserver`, and `unconfigureapplicationserver` Ant tasks, which are documented at “Ant tasks for installation of MobileFirst runtime environments” on page 16-42.

Review and note the application server configuration for MobileFirst Server and Application Center

In this task, if it is required for your upgrade path, you prepare for the undeployment and redeployment of applications to the application server to correct information that can potentially be modified or deleted by IBM Installation Manager.

About this task

In some upgrade scenarios, the applications that are deployed to the application server must be undeployed, and then redeployed. As a consequence, the

configurations that were previously made to these applications are erased and must be reconfigured after the application is deployed again to the application server.

The applications to review are as follows:

- For Application Center:
 - The Application Center Console and Application Center Services
- For Worklight Server or MobileFirst Server:
 - The Administration Console and Administration Services
 - Each project runtime

The JDBC data sources to review are as follows:

- For Application Center: the Application Center database
- For Worklight Server or MobileFirst Server:
 - The runtime database
 - The reports database
 - The administration database

If these items were previously configured, note the configuration details so you can reconfigure them after the applications are reinstalled and redeployed. The configurations affected can include security settings, lists of users authorized to use the application, startup behaviors, connection pool settings, JNDI properties, and other items.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-11. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	No
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	No
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	No
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

Table 7-12. System status after this step.

Module	Status
Application Center	All instances are kept running.
MobileFirst Server	All instances are kept running.

Procedure

To review the configuration of the data sources and applications:

- For WebSphere Application Server full profile, use the console.
- For WebSphere Application Server Liberty profile:
 - Open the `server.xml` file. The settings that can be modified or removed by IBM Installation Manager are between the marker comments, as shown in the following sample:

```
<!-- Begin of configuration added by IBM Worklight installer. -->
...
<!-- End of configuration added by IBM Worklight installer. -->
```
- For Apache Tomcat:
 - Open the `server.xml` and the `tomcat-users.xml` files. The settings that can be modified or removed by IBM Installation Manager are between the marker comments, as shown in the following sample:

```
<!-- Begin of Context and Realm configuration added by IBM Worklight installer. -->
...
<!-- End of Context and Realm configuration added by IBM Worklight installer. -->
```

Verify environments of deployed apps

Before you upgrade to MobileFirst Server V7.1.0, verify that all of the environments that are targeted in your MobileFirst applications are still supported.

About this task

After the migration is completed, your MobileFirst applications contain only the environments that are supported by the current version of MobileFirst Server.

Since IBM Worklight V6.1.0, some of the MobileFirst environments such as iGoogle, Facebook, Apple OS X Dashboard, Vista that were supported in IBM Worklight V5.0.6 are no longer supported. If a target mobile device has an application that is installed on it which requires an environment that is no longer supported by a version of MobileFirst Server prior to V7.1.0, the application on this device stops working after an upgrade of MobileFirst Server to V7.1.0.

Therefore, if you upgrade Worklight Server from V6.0.0.x or earlier to MobileFirst Server V7.1.0, you must pay particular attention to the following procedure. Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-13. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	No
Worklight Server V6.2.x to MobileFirst Server V7.1.0	No
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	No

Table 7-13. Is this step required for your upgrade path? (continued).

Product or component versions	Required?
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	No
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

Table 7-14. System status after this step.

Module	Status
Application Center	Running
MobileFirst Server	Running

Procedure

If your current version of MobileFirst Server includes existing applications that target environments that are no longer supported by MobileFirst Server V7.1.0:

- For old, no-longer-supported environments, your application developers must update the MobileFirst application to run with an environment supported by MobileFirst Server V7.1.0 before you can run it.
- For new environments for which support is added after the release of MobileFirst Server V7.1.0, check for the availability of a fix pack release that provides support for this environment.

The following table can help to determine the IBM Worklight versions in which support for older environments was discontinued, and to suggest possible replacement environments for those environments.

Environment	Support removed in	Suggested replacement path
Facebook	IBM Worklight V6.0.0	Desktop web app
iGoogle	IBM Worklight V6.0.0	Review environments supported by IBM MobileFirst Platform Foundation V7.1.0
Apple OS X Dashboard	IBM Worklight V6.0.0	Review environments supported by IBM MobileFirst Platform Foundation V7.1.0
Windows 7 and Vista	IBM Worklight V6.0.0	Review environments supported by IBM MobileFirst Platform Foundation V7.1.0
Windows Phone 7.5	IBM Worklight V6.1.0	Review environments supported by IBM MobileFirst Platform Foundation V7.1.0

Related concepts:

“Version compatibility” on page 7-1

Compatibility among different versions of the IBM MobileFirst Platform Foundation client and server depends on several factors.

In-place upgrade or rolling upgrade to MobileFirst Server V7.1.0

You can upgrade to a new version of the product in one of two ways: as an *in-place upgrade* or as a *rolling upgrade*. An in-place upgrade replaces the previous version while a rolling upgrade does not.

You can replace the previous version by the new one or you can install the new version alongside the previous one.

In-place upgrade

An upgrade by which the old version of Worklight Server or MobileFirst Server is no longer installed after the new version of MobileFirst Server is installed.

In-place upgrades require some downtime of the service.

Rolling upgrade

An upgrade that installs the new version of MobileFirst Server such that it runs side-by-side with the old version of Worklight Server or MobileFirst Server in the same application server or in a different application server.

The procedure for a rolling upgrade to apply a fix pack to IBM MobileFirst Platform Foundation V7.1.0 is documented in “Rolling upgrade procedure to apply a fix pack to IBM MobileFirst Platform Foundation V7.1.0 in stateful mode” on page 7-83.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-15. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.0 to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.0 to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.0 to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.0 to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-16. System status after this step

Module	Status

MobileFirst Server	Running

Packaging change of WebSphere Application Server Liberty profile in IBM Worklight V6.x

Important information about how WebSphere Application Server Liberty profile is delivered since IBM Worklight V6.0.0, and what is the impact on the upgrade of your production MobileFirst Server.

About this task

Important: The information on this page applies to you if you previously installed Worklight Server V5.x with the embedded WebSphere Application Server Liberty profile option.

Since IBM Worklight V6.1.0, WebSphere Application Server Liberty Core is not embedded in the IBM Installation Manager wizard of MobileFirst Server. Instead, it is provided as a separate IBM Installation Manager wizard.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-17. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	No
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	No
Worklight Server V6.2.x to MobileFirst Server V7.1.0	No
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	No
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	No
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

Table 7-18. System status after this step.

Module	Status
Application Center	All instances are kept running.
MobileFirst Server	All instances are kept running.

Procedure

As a result of this packaging, the MobileFirst Server upgrade process does not upgrade your installed version of WebSphere Application Server Liberty profile, and will not apply fix packs to it in the future. At the end of the upgrade process, your Liberty server remains installed in `<WorklightServerInstallationDirectory>/server/wlp`, but is considered as an external file from the perspective of upgrades, uninstall, and updates from the IBM Installation Manager wizard of MobileFirst Server.

To prevent this existing server from being uninstalled during the upgrade process, the IBM Installation Manager wizard temporarily renames its directory during the upgrade process. It is critical to apply the steps that are defined in section Special steps for WebSphere Application Server Liberty profile before you start the upgrade process. The result of not completing these steps can be a non-functional server.

Alternate Method: Move your MobileFirst apps and data to a new Liberty server

This alternate upgrade method migrates your MobileFirst Operations Console and Application Center to a new WebSphere Application Server Liberty profile server installed by IBM Installation Manager. This server can be updated by IBM Installation Manager when new updates for Liberty are made available.

1. Stop the Liberty server that was installed with the previous version of IBM MobileFirst Platform Foundation.
2. Install WebSphere Application Server Liberty Core with IBM Installation Manager. The installer for WebSphere Application Server Liberty Core is part of the IBM MobileFirst Platform Foundation package.
3. Create a server in this new WebSphere Application Server Liberty profile installation. If you are not familiar with the creation of a server for Liberty, see the “Tutorial for a basic installation of MobileFirst Server” on page 6-35.
4. Configure the Liberty server for your production environment.
5. Modify the Ant files created in section “Identify the MobileFirst WAR file and prepare the Ant deployment script” on page 7-30 to point to the newly installed WebSphere Application Server Liberty Core.
6. When you reach the step “Running IBM Installation Manager and completing the Application Center upgrade” on page 7-48, follow the instructions for “Upgrading from Worklight Server V5.0.6.x (changing the Liberty server)” on page 7-53.

Become familiar with IBM Installation Manager before you start

Before you start the actual installation, verify that you have all the products that you want to install and that you are familiar with IBM Installation Manager procedures.

About this task

You use IBM Installation Manager to complete the actual upgrade. Before you start, verify that you have all of the necessary installation components, and that you understand the installation procedure.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-19. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes

Table 7-19. Is this step required for your upgrade path? (continued).

Product or component versions	Required?
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-20. System status after this step.

Module	Status
Application Center	Running
MobileFirst Server	Running

Procedure

Before you use IBM Installation Manager to upgrade your production server, familiarize (or refamiliarize) yourself with how it works:

1. Make sure that you have the appropriate version of IBM Installation Manager installed on the installation workstation.

Verify that your version of IBM Installation Manager is supported by IBM MobileFirst Platform Foundation V7.1.0. For more information, see the prerequisite software in “System requirements” on page 2-15. For more information about IBM Installation Manager procedures, see the IBM Installation Manager user documentation.

IBM Installation Manager updates are available at Installation Manager and Packaging Utility download links.

Important: If you are performing an in-place upgrade, and you have IBM Installation Manager installed on your computer in several different modes, for example, administrator mode and nonadministrator (single user) mode, you must use the same mode used to install the previous version of Worklight Server or MobileFirst Server.

2. Download the repositories that are required for the update from Passport Advantage, or have them available if they are on physical media.
For more information about the types of upgrade repositories available, see “Information about the repositories” on page 7-41.
3. Verify that the products that you want to update are contained in the IBM Installation Manager repositories.
4. If you do not plan to use IBM Installation Manager in graphical mode but in silent install mode, review the procedures for a silent install as documented in “Command-line installation with XML response files (silent installation)” on page 6-45 and “Working with sample response files for IBM Installation Manager” on page 6-46 and prepare your response file.

To prepare your response file from sample response files, create a response file based on the following versions of MobileFirst Server, and sample files:

Table 7-21. Sample upgrade response files in the *Silent_Install_Sample_Files.zip*

Initial version of MobileFirst Server	Sample file
Worklight Server V5.x	upgrade-initially-worklightv5.xml
Worklight Server V6.x	upgrade-initially-worklightv6.xml
IBM MobileFirst Platform Server V6.x	upgrade-initially-mfpserverv6.xml
IBM MobileFirst Platform Server V7.x	upgrade-initially-mfpserver.xml

In the <offering> element in the <install> element, set the version attribute to match the release you want to upgrade to, or remove the version attribute if you want to upgrade to the newest version available in the repositories.

Information about the repositories

There are three types of repositories: base repositories, delta repositories, and interim fix repositories:

- A *base repository* is an installation package that is available on Passport Advantage or on physical media. It is self-contained.
- A *delta repository* is an installation package that is available from FixCentral and is labeled as an *update pack*. It requires a base repository of the previous release version to be functional.
- An *interim fix repository* is an installation package that is available from FixCentral and is labeled as an interim fix, and that is only versioned by a build number. It requires the repositories of the previous release version to be functional: either a base repository, or both a base repository and a delta repository.

To install a major release (for example, MobileFirst Server V7.1.0), you need only:

- The base repository V7.1.0 installation package from Passport Advantage or physical media.

To install a fix pack release (for example, MobileFirst Server V7.1.0.1), you need:

- The corresponding base repository (such as MobileFirst Server V7.1.0) installation package from Passport Advantage or physical media. The corresponding base repository for V7.1.0.x fix packs is the V7.1.0 release.
- The appropriate V7.1.0.x installation package from FixCentral.

For a fix pack installation, you must add both repositories to the list known to IBM Installation Manager. Then, in the example given, IBM Installation Manager recognizes the V7.1.0 release as an **Install** choice and the V7.1.0.x release (or interim fix) as an **Update** choice.

To install an interim fix release, you can need up to three repositories:

- The repositories for the release to which the fix applies.
- The repository for the fix.

For installing an interim fix, you must add all these repositories to the list known to IBM Installation Manager. Then IBM Installation Manager recognizes the interim fix as an Update choice.

Review of the basic IBM Installation Manager steps

Attention: The following steps are not the actual installation. They are preparatory tasks to help you ensure that you have everything that is required for the upgrade. Be sure to click **Cancel** in the last step.

1. Start IBM Installation Manager.
2. Click **File > Preferences > Repositories** to add references to the repositories that you downloaded and extracted on a local disk, or that you can access through the internet.
See Repository preferences for details.
3. Click **Install**.
4. Verify that the products list contains everything that you need.
5. Click **Cancel**. Do not proceed with the installation.

Starting the MobileFirst Server V7.1.0 upgrade process

In this phase of the upgrade process, you shut down and back up the application server and MobileFirst databases and perform other pre-installation tasks.

When you finish the tasks that are listed in “Preparation for upgrades to MobileFirst Server” on page 7-25, you can begin the actual upgrade process.

Note: After you complete this phase of the upgrade process, your MobileFirst Server, Application Center, databases, and application server(s) are (or can be) offline. They are no longer available to support existing apps or provide service to existing users of those apps. The upgrade process itself can take several hours. Therefore, you must plan the timing of this process for non-critical hours to have minimal impact on users.

The following topics present the steps, in the order in which they must be completed.

Verify the ownership of your MobileFirst Server files

Before you begin the actual installation, check the ownership of all MobileFirst Server files.

About this task

The upcoming step “Running IBM Installation Manager and completing the Application Center upgrade” on page 7-48 attempts to remove and replace many files in the MobileFirst Server installation directory. This step can fail if the single-user mode of IBM Installation Manager is used and some of the files or directories are not owned by that user. Therefore, it is useful to guard against this case.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-22. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes

Table 7-22. Is this step required for your upgrade path? (continued).

Product or component versions	Required?
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-23. System status after this step.

Module	Status
Application Center	All instances are kept running.
MobileFirst Server	All instances are kept running.

Procedure

If you previously installed MobileFirst Server with the nonadministrator (single-user) mode of IBM Installation Manager, check whether all files and directories in the `product_install_dir` installation directory are owned by the current user.

For more information about Installation Manager administrator and nonadministrator modes, see Administrator, nonadministrator, and group mode. Group mode is not supported for MobileFirst Server installation.

On UNIX, you can use the following command to list the files and directories that do not fulfill this condition.

```
cd product_install_dir
find . '!'-user "$USER" -print
```

This command is expected to return nothing.

What to do next

See also: “File system prerequisites” on page 6-16

Back up your application server

Back up the directory that contains the application server and its configuration.

About this task

Back up your application server so that you can recover in case of an unsuccessful server upgrade. This strategy covers the rare cases in which the new application server version fails to work correctly if errors occur in the forthcoming configuration changes.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-24. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-25. System status after this step.

Module	Status
Application Center	All instances are running.
MobileFirst Server	All instances are running.

Procedure

Back up all the application servers (or network deployment nodes) where the Application Center and MobileFirst Server administration applications are installed.

For WebSphere Application Server Liberty profile:

- Back up the `usr` directory. By default this directory is located in `<LibertyInstallDir>/usr`, but its location can be redefined by the `WLP_USER_DIR` variable in `<LibertyInstallDir>/env/server.env`.

For WebSphere Application Server full profile:

- If your original installation was to one or more servers under the control of a deployment manager, and not a single stand-alone server:
 - Either use the WebSphere `backupConfig` command to back up the deployment manager node.
 - Or back up the `config` directory inside the deployment manager profile directory.
- If your original installation was to a stand-alone server:
 - Either use the WebSphere `backupConfig` command to back up the entire node.
 - Or back up the application server profile directory.

See the documentation for Apache Tomcat to determine the directories to back up for this application server.

Shutting down the application server

If you upgrade from IBM Worklight V5.0.6, or if you installed Application Center with IBM Installation Manager, and if you use WebSphere Application Server Liberty profile or Apache Tomcat, you must shut down the application server.

About this task

When it is running, IBM Installation Manager removes the Worklight application from the application server if you upgrade from V5.0.6. It also updates Application Center if you installed Application Center with IBM Installation Manager. If you upgrade from V5.0.6, or if you installed Application Center with Installation Manager, you must shut down the application server before running IBM Installation Manager in the following three cases:

- If your application server is Apache Tomcat.
- If your application server is WebSphere Application Server Liberty Core.
- If your application server is the embedded version of WebSphere Application Server Liberty profile that is installed by the Worklight Server V5.0.6 or earlier installer.
 - In this case, you must also shut down all processes that have either their current working directory inside or opened files inside the MobileFirst installation directory hierarchy.
 - On Windows, you must also shut down all such processes inside the Liberty MobileFirst Server directory hierarchy, which is in C:\ProgramData\IBM\Worklight\WAS85\liberty-server.

Otherwise, if the application server is running when IBM Installation Manager starts the upgrade, some upgrade operations might fail, leaving the MobileFirst Server installation in an inconsistent state.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-26. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes (if you installed Application Center with IBM Installation Manager)
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes (if you installed Application Center with IBM Installation Manager)
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes (if you installed Application Center with IBM Installation Manager)
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes (if you installed Application Center with IBM Installation Manager)
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes (if you installed Application Center with IBM Installation Manager)
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes (if you installed Application Center with IBM Installation Manager)

Table 7-27. System status after this step.

Module	Status
Application Center	Liberty and Tomcat are stopped. All other instances are kept running.
MobileFirst Server	Liberty and Tomcat are stopped. All other instances are kept running.

Procedure

For Apache Tomcat and WebSphere Application Server Liberty Core, use the administration commands to shut down the application server as you would normally.

For the embedded version of WebSphere Application Server Liberty Server, you can use the following procedure:

1. Ensure that the `JAVA_HOME` environment variable points to the installation directory of a Java 6 or 7 implementation (JRE or JDK), or that the `PATH` environment variable contains a java program from a Java 6 or 7 implementation.
2. Shut down the server.
 - a. On UNIX, enter the following commands, changing the installation location if necessary:

```
cd /opt/IBM/Worklight
cd server/wlp/bin
./server stop worklightServer
```
 - b. On Windows, enter the following commands, changing the installation location if necessary:

```
cd C:\Program Files (x86)\IBM\Worklight
cd server\wlp\bin
server.bat stop worklightServer
```
3. Verify that no other runaway Liberty server processes are running in the same directory. On Linux and AIX, you can list such processes with the following command:

```
ps auxww | grep java | grep /wlp/
```

Stop all instances of the Application Center applications

Stop the applications currently running on Application Center.

About this task

If you have installed Application Center on multiple servers, networked or not, then all instances of the IBM Application Center Console and IBM Application Center Services must be stopped before you run IBM Installation Manager to upgrade the MobileFirst Server installation.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-28. Is this step required for your upgrade path?.

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes (if installed on multiple servers)

Table 7-28. Is this step required for your upgrade path? (continued).

Product or component versions	Required?
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes (if installed on multiple servers and if you installed Application Center with IBM Installation Manager)
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes (if installed on multiple servers and if you installed Application Center with IBM Installation Manager)
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes (if installed on multiple servers and if you installed Application Center with IBM Installation Manager)
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes (if installed on multiple servers and if you installed Application Center with IBM Installation Manager)
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes (if installed on multiple servers and if you installed Application Center with IBM Installation Manager)
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes (if installed on multiple servers and if you installed Application Center with IBM Installation Manager)

Table 7-29. System status after this step.

Module	Status
Application Center	All instances are stopped.
MobileFirst Server	Liberty and Tomcat are stopped. All other instances are kept running.

Procedure

This step is required because IBM Installation Manager migrates the schema of the database so that it can be used with MobileFirst Server V7.1.0. No instance of Application Center can be running while this operation is performed.

After the database is migrated, only migrated Application Center applications must be run, because only migrated applications are able to read and write to the new databases. Otherwise, the Application Center database might be corrupted.

If you installed Application Center only once, this operation is done automatically by IBM Installation Manager.

Back up the Application Center database

Before you run IBM Installation Manager to install MobileFirst Server V7.1.0, back up your Application Center database.

About this task

In the upgrade process, the Application Center database is updated and migrated to a schema compatible with MobileFirst Server V7.1.0. This operation cannot be undone. If, for any reason, you decide to roll back the upgrade of MobileFirst Server, you need this backup.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-30. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes (if you installed Application Center with IBM Installation Manager)
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes (if you installed Application Center with IBM Installation Manager)
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes (if you installed Application Center with IBM Installation Manager)
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes (if you installed Application Center with IBM Installation Manager)
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes (if you installed Application Center with IBM Installation Manager)
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

Table 7-31. System status after this step.

Module	Status
Application Center	All instances are stopped.
MobileFirst Server	Liberty and Tomcat are stopped. The other instances keep running.

Procedure

Use the standard procedures for your DBMS (IBM DB2, Oracle, or MySQL) to back up the Application Center database. The default name for the Application Center database, unless you modified it at install time, is as follows:

- For IBM DB2, MySQL, and Oracle, if you installed IBM Worklight V5.0.6: APPCNTR
- For IBM DB2 and MySQL if you installed IBM Worklight V6.0.0 or later: APPCNTR
- For Oracle, if you installed IBM Worklight V6.0.0 or later: ORCL

The runtime and reports databases are backed up as well, but in a later step of this procedure. For more information, see step “Back up the runtime database” on page 7-59 of this upgrade procedure.

Running IBM Installation Manager and completing the Application Center upgrade

Use IBM Installation Manager to install the new MobileFirst Server version.

Before you continue, make sure that you completed all of the steps in the “Preparation for upgrades to MobileFirst Server” on page 7-25 and “Starting the MobileFirst Server V7.1.0 upgrade process” on page 7-42 sections that preceded this step.

It is also possible to run IBM Installation Manager in silent install mode, using response files that are either generated by using it in wizard mode on a machine where a GUI is available, or by working with sample response files supplied with IBM MobileFirst Platform Foundation. For more information, see “Command-line installation with XML response files (silent installation)” on page 6-45 and “Working with sample response files for IBM Installation Manager” on page 6-46.

Upgrading from MobileFirst Server V6.3.0, or later

In this step, you run IBM Installation Manager to perform the upgrade to MobileFirst Server V7.1.0.

About this task

IBM Installation Manager completes the following tasks:

- It installs on your disk the files and tools that are required to deploy IBM MobileFirst Platform Foundation on your application server.
- If Application Center was installed in the previous version of MobileFirst Server, the installer also:
 - Undeploys the previous version of the Application Center from the application server.
 - Upgrades the databases of Application Center to the format used by the current version of IBM MobileFirst Platform Foundation V7.1.0. To see a copy of the upgrade scripts, you can install MobileFirst Server in a new package group and review a copy of the upgrade scripts in `<product_install_dir>/ApplicationCenter/databases`.
 - Deploys the new version of Application Center to the application server and connects it to the upgraded database.
 - Configures the application server for running the Application Center.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-32. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	No
Worklight Server V6.0.0.x to MobileFirst Server V7.1.0	No
Worklight Server V6.1.0.x to MobileFirst Server V7.1.0.x	No
Worklight Server V6.2.0.x to MobileFirst Server V7.1.0	No
MobileFirst Server V6.3.0.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-33. System status after this step.

Module	Status
Application Center	All instances are stopped.

Table 7-33. System status after this step (continued).

Module	Status
MobileFirst Server	Liberty and Tomcat are stopped. All other instances are kept running.

Procedure

Having prepared for this step by becoming familiar with IBM Installation Manager and ensuring that you have all the proper repositories for the upgrade, start the actual installation using the following steps:

1. Start IBM Installation Manager.
2. Click **Update**.
3. Step through the installation wizard, following the onscreen prompts to complete the upgrade.

Upgrading from Worklight Server V6.0.0, V6.1.0, or V6.2.0

In this step, you run IBM Installation Manager to perform the actual upgrade from IBM Worklight V6.x to MobileFirst Server V7.1.0.

About this task

IBM Installation Manager completes the following tasks:

- It installs on your disk the files and tools that are required to deploy IBM MobileFirst Platform Foundation on your application server.
- If Application Center was installed in the previous version of IBM Worklight, the installer also:
 - Undeploys the previous version of the Application Center from the application server.
 - Upgrades the databases of Application Center to the format used by IBM MobileFirst Platform Foundation V7.1.0. To see a copy of the upgrade scripts, you can install MobileFirst Server in a new package group and review a copy of the upgrade scripts in *product_install_dir/ApplicationCenter/databases*.
 - Deploys the new version of Application Center to the application server and connects it to the upgraded database.
 - Configures the application server for running the Application Center.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-34. Is this step required for your upgrade path?.

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	No
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes

Table 7-34. Is this step required for your upgrade path? (continued).

Product or component versions	Required?
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	No
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	No
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

Table 7-35. System status after this step.

Module	Status
Application Center	Stopped (all instances)
MobileFirst Server	Stopped (Liberty and Tomcat) Running (others)

Procedure

Having prepared for this step by becoming familiar with IBM Installation Manager and ensuring that you have all the proper repositories for the upgrade, start the actual installation using the following steps:

1. Start IBM Installation Manager.
2. Click **Install**.

Note: In IBM MobileFirst Platform Foundation, you must upgrade by clicking **Install**, because the package name for Worklight Server changed between Worklight Server and MobileFirst Server.

3. Select the package group that contains your Worklight Server installation.
4. Step through the installation wizard, following the onscreen prompts to complete the upgrade.

Upgrading from Worklight Server V5.0.6.x

Use this procedure to upgrade from Worklight Server V5.0.6.x to MobileFirst Server V7.1.0 in a stand-alone WebSphere Application Server or Apache Tomcat environment.

About this task

If you originally installed IBM Worklight on the following application servers, use the IBM Installation Manager **Install** function as explained in the steps:

- A stand-alone WebSphere Application Server Liberty profile server
- A stand-alone WebSphere Application Server full profile server
- A stand-alone Apache Tomcat server

Read from the tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-36. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Worklight Server V5.0.6.x to MobileFirst Server V7.1.0

Table 7-36. Is this step required for your upgrade path? (continued).

Product or component versions	Required?
Worklight Server V6.0.x to MobileFirst Server V7.1.0	No
Worklight Server V6.1.x to MobileFirst Server V7.1.0	No
Worklight Server V6.2.x to MobileFirst Server V7.1.0	No
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	No
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	No
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

Table 7-37. System status after this step.

Module	Status
Application Center	All instances are stopped.
MobileFirst Server	Uninstalled.

Procedure

1. Start IBM Installation Manager.
2. Click **Install**. The package name for MobileFirst Server has changed between Worklight Server V5.x and MobileFirst Server V7.1.0, so the upgrade must be done with the 'Install' process.
3. If you are doing an in-place upgrade (see “In-place upgrade or rolling upgrade to MobileFirst Server V7.1.0” on page 7-37), select the package group that contains your Worklight Server installation. If you are doing a rolling upgrade, select **Create a new package group**.
4. Step through the installation wizard. If you are doing an in-place upgrade, most choices are disabled (displayed in gray). But you can change the passwords for the database or for WebSphere Application Server access if they are different from the original installation.
5. IBM Installation Manager completes the following tasks:
 - It installs on your disk the files and tools that are required to deploy IBM MobileFirst Platform Foundation in your application server.
 - It undeploys the previous version of IBM Worklight from the Application Server.
 - It removes the application server configurations that were set by the previous installer of Worklight Server.
 - If Application Center was installed in the previous version of Worklight Server, the installer also:
 - Undeploys the previous version of the Application Center from the application server.
 - Upgrades the databases of Application Center to the format used by the current version of MobileFirst Server. To see a copy of the upgrade scripts, you can install MobileFirst Server in a new package group and review a copy of the upgrade scripts in `<product_install_dir>/ApplicationCenter/databases`.

- Deploys the new version of Application Center to the application server and connects it to the upgraded database.
- Configure the application server for running the Application Center.

Upgrading from Worklight Server V5.0.6.x (changing the Liberty server)

This step contains special instructions if you are migrating to a new instance of WebSphere Application Server Liberty profile.

About this task

This task is part of the “Alternate Method: Move your MobileFirst apps and data to a new Liberty server” on page 7-39 section of the “Packaging change of WebSphere Application Server Liberty profile in IBM Worklight V6.x” on page 7-38 step. Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-38. Is this step required for your upgrade path?.

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes (if Liberty server was installed by Worklight Server V5.0.6)
Worklight Server V6.0.x to MobileFirst Server V7.1.0	No
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	No
Worklight Server V6.2.x to MobileFirst Server V7.1.0	No
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	No
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	No
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

Table 7-39. System status after this step.

Module	Status
Application Center	Stopped (all instances)
MobileFirst Server	Uninstalled

Procedure

Having prepared for this step by becoming familiar with IBM Installation Manager and ensuring that you have all the proper repositories for the upgrade, start the actual installation using the following steps:

1. Start IBM Installation Manager.
2. Click **Install**.
3. Select a new package group.
4. Step through the installation wizard. Enter the database settings used to install Application Center for V5.0.6.

- For the Application Server choice, select the newly installed WebSphere Application Server Liberty Core.

Restore the Application Center configurations and restart the application server

In this step, you restore the required configurations of Application Center that you made note of in a previous step.

About this task

Restore the configurations that you previously identified in step “Review and note the application server configuration for MobileFirst Server and Application Center” on page 7-33.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-40. Is this step required for your upgrade path?.

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	No
Worklight Server V6.2.x to MobileFirst Server V7.1.0	No
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	No
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	No
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

Table 7-41. System status after this step.

Module	Status
Application Center	Embedded Liberty, Liberty on Windows, and Tomcat on Windows are stopped. All other instances are upgraded.
MobileFirst Server	After an upgrade from V6.0.x or later, all instances are running. After an upgrade from V5.0.6.x, all instances are stopped.

Procedure

- For the applications, restore the Application Center console and services.
- For the JDBC data sources, restore the Application Center database.
- When you have restored these configurations, restart the application server that was upgraded.

Results

At the end of this step, Application Center is upgraded. All applications previously loaded in Application Center should be available.

However, if this Application Center is running on the same application server as a MobileFirst Operations Console, that application server is shut down again in a later step, and is restarted only in subsequent steps.

Upgrading the MobileFirst runtime environment for MobileFirst Server V7.1.0 manually, or with Ant tasks

In these post-installation steps, you upgrade the MobileFirst Server, its databases, its MobileFirst runtime environment or environments, and restart the application server.

This topics in this section describe the steps to upgrade MobileFirst Server and MobileFirst runtime environments with Ant tasks, or manually. If you installed MobileFirst Server and the MobileFirst runtime environments with the Server Configuration Tool, you can follow the procedure “Upgrading with the Server Configuration Tool” on page 7-81 instead.

Complete each of the following steps, as required for your particular upgrade path.

Stop all MobileFirst Server instances

Before you complete subsequent upgrade steps, you must shut down all runtime environments. You must also disable the auto start mode of the Worklight Console if you upgrade from IBM Worklight V6.0.0.x on WebSphere Application Server full profile.

About this task

If you installed Worklight Server or MobileFirst Server on multiple servers, whether networked or not, you must stop all runtime environments before you move on to the next steps.

Note: You must do so even if you installed only one runtime environment.

This step is mandatory because in step “Upgrade the runtime database” on page 7-61, you upgrade the schema of the databases so that it can be used with MobileFirst Server V7.1.0. No database schema can be upgraded while a runtime environment is running.

After the database is upgraded, only upgraded runtime environments can run, because only upgraded applications can read and write to the new databases. Otherwise, the database might be corrupted.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-42. Is this step required for your upgrade path?.

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes

Table 7-42. Is this step required for your upgrade path? (continued).

Product or component versions	Required?
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-43. System status after this step.

Module	Status
Application Center	All instances are upgraded.
MobileFirst Server	All instances are stopped.

Important: In addition to stopping all runtime environments, if you upgrade from IBM Worklight V6.0.0.x on WebSphere Application Server full profile, you must also disable the auto start mode of the Worklight Console application during the upgrade before you shut down the Worklight Server. If the auto start mode is not disabled, the Worklight Console modifies the database when the server is started in step “Upgrading the MobileFirst runtime environment for MobileFirst Server V7.1.0 manually, or with Ant tasks” on page 7-55 and prevents the new MobileFirst runtime environment from starting.

To disable the auto start mode:

1. Log in to the WebSphere Console.
2. Go to the menu **Applications > Application Types > WebSphere enterprise applications**, and list the applications.
3. In the table, click Worklight Console application, whose default name is **IBM_Worklight_Console**.
4. In **Detail Properties** click **Target Specific Application Status**.
5. Select all the target servers, or the cluster where the application is installed.
6. Click **Disable Auto Start**.
7. Click **Save** to save the configuration.
8. Verify that the **Auto Start** property in the table is set to **No**.

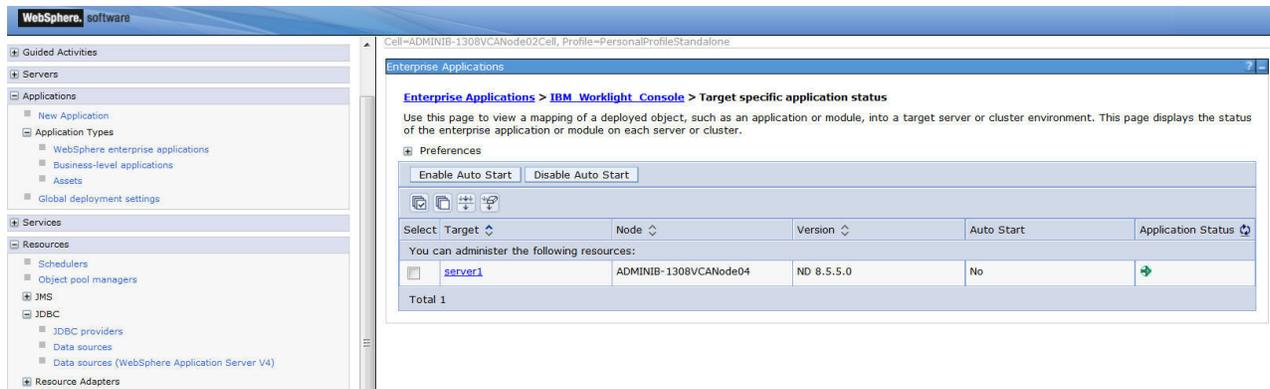

Figure 7-2.

Shutting down the application server to be upgraded

For certain configurations, in this step you shut down the application server before completing subsequent steps.

About this task

For certain types of application servers (see the following table and “Procedure” on page 7-58 section), you must shut down the application server before proceeding to subsequent steps.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-44. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-45. System status after this step.

Module	Status
Application Center	Embedded Liberty, Liberty on Windows, and Tomcat on Windows are stopped. All other instances are upgraded.
MobileFirst Server	All instances are stopped.

Procedure

In the following cases, you must shut down the application server before you undeploy applications from the MobileFirst Operations Console application:

- If the application server is WebSphere Application Server Liberty profile and the OS is Windows.
- If the application server is Apache Tomcat, and the OS is Windows or the database type is Apache Derby.

If these application servers are not shut down, the undeploy operations might fail.

Installation or upgrade of MobileFirst Server Administration Services

As part of the MobileFirst Server upgrade, you must install the Administration Services, and optionally the MobileFirst Operations Console.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-46. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-47. System status after this step.

Module	Status
Application Center	Embedded Liberty, Liberty on Windows, and Tomcat on Windows are stopped. All other instances are upgraded.
MobileFirst Server	All instances are stopped.

The procedure is different depending on whether you upgrade from a previous version to V6.2.0, or from a previous version to V7.1.0, or to a fix pack or interim fix.

For an upgrade from Worklight Server V6.1.0 or earlier to MobileFirst Server V7.1.0 Follow the steps in “Installing the MobileFirst Server administration” on page 6-58.

For an upgrade from Worklight Server V6.2.0, or later, to MobileFirst Server V7.1.0 (but not for an upgrade from MobileFirst Server V7.1.0 to a fix pack)

1. Back up the administration database
2. Find the Ant file that you created in “Identify the MobileFirst WAR file and prepare the Ant deployment script” on page 7-30.
3. Make sure that the taskdef for the `worklight-ant-deployer.jar` file uses the correct directory. The correct directory is the directory that contains the upgraded installation of MobileFirst Server V7.1.0.
4. Upgrade the administration database:

```
product_install_dir/shortcuts/ant -f your_file admatabases
```

Note: For a manual upgrade of the administration database, instead of running the Ant tasks, see “Manually upgrading the MobileFirst Server V7.1.0 databases” on page 7-71.

5. Run the **minimal-admupdate** target of the Ant file:

```
product_install_dir/shortcuts/ant -f your_file minimal-admupdate
```

Note: For a manual upgrade of the applications server, instead of running the Ant task, review the manual installation instructions at “Deploying the Administration Services and MobileFirst Operations Console and configuring the application server manually” on page 6-92, and update the installed WAR files for `worklightconsole.war`, and `worklightadmin.war` in your installation.

For an upgrade from MobileFirst Server V7.1.0 to a fix pack or to an interim fix

1. Find the Ant file that you created in “Identify the MobileFirst WAR file and prepare the Ant deployment script” on page 7-30.
2. Make sure that the taskdef for the `worklight-ant-deployer.jar` file uses the correct directory. The correct directory is the directory that contains the upgraded installation of MobileFirst Server V7.1.0.
3. Run the **minimal-admupdate** target of the Ant file:

```
product_install_dir/shortcuts/ant -f your_file minimal-admupdate
```

Note: For a manual upgrade of the applications server, instead of running the Ant task, review the manual installation instructions at “Deploying the Administration Services and MobileFirst Operations Console and configuring the application server manually” on page 6-92, and update the installed WAR files for `worklightconsole.war`, and `worklightadmin.war` in your installation.

Back up the runtime database

Back up the contents of your MobileFirst project database.

About this task

Important: Before performing this step, verify that you have completed step “Stop all MobileFirst Server instances” on page 7-55, and that no instance of MobileFirst Server is still running, and thus still using this database.

If you upgrade from IBM Worklight V6.1.0 or earlier, during the upgrade process in the steps “Upgrade the runtime database” on page 7-61 and “Upgrade the MobileFirst Server runtime environment” on page 7-63, the data that is specific to administration and runtime environments are split into distinct databases:

- The MobileFirst data that is related to administration is moved to the administration database.

- The runtime database that you previously updated is migrated to a schema compatible with MobileFirst Server V7.1.0.

If you upgrade from V6.2.0, or later, the database schema is modified and some data might be modified.

The previous operations cannot be undone.

If, for some reason, you decide to roll back the upgrade of MobileFirst Server, you need this backup.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-48. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

Table 7-49. System status after this step.

Module	Status
Application Center	Embedded Liberty, Liberty on Windows, and Tomcat on Windows are stopped. All other instances are upgraded.
MobileFirst Server	Embedded Liberty, Liberty on Windows, and Tomcat on Windows are stopped. All other instances are partially upgraded.

Procedure

The default names for the databases, unless you modified them at installation time, are as follows:

- For IBM DB2, Derby, MySQL, and Oracle, if you installed IBM Worklight V5.0.6.x: WRKLGHT and WLREPORT
- For IBM DB2, Derby, and MySQL, if you installed IBM Worklight V6.x: WRKLGHT and WLREPORT
- For Oracle, if you installed IBM Worklight V6.x, for Oracle: ORCL

Note: The reports database and the sample BIRT reports are deprecated since IBM MobileFirst Platform Foundation V7.0.0. Use “Operational analytics” on page 14-9 instead.

Upgrade the runtime database

If you upgrade from IBM Worklight V6.1.0 or earlier, you must move the data that is related to administration to the administration database. In all cases, you must also upgrade the runtime database to a schema that is compatible with MobileFirst Server V7.1.0.

Before you begin

1. Make sure that you complete step “Stop all MobileFirst Server instances” on page 7-55, and that no instance of Worklight Server or MobileFirst Server is still running, and therefore is still using these databases.
2. Make sure that you complete step “Installation or upgrade of MobileFirst Server Administration Services” on page 7-58 and that the administration database exists.

Note: This procedure explains how to upgrade the database with Ant tasks. For a manual upgrade of the databases, see “Manually upgrading the MobileFirst Server V7.1.0 databases” on page 7-71 instead.

Remember: To upgrade from V6.1.0 or earlier with Oracle as a database, the Oracle user must have the CREATE VIEW privilege.

About this task

In this step, you run Ant scripts to perform operations on your MobileFirst Server databases.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-50. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

Table 7-51. System status after this step.

Module	Status
Application Center	Embedded Liberty, Liberty on Windows, and Tomcat on Windows are stopped. All other instances are upgraded.
MobileFirst Server	All instances are stopped.

Procedure

1. If you upgrade from IBM Worklight V6.0.0.x, and the application server is WebSphere Application Server full profile, make sure that you disabled the auto start mode for all instances of the Worklight Console application, as specified in “Stop all MobileFirst Server instances” on page 7-55.
2. Locate the Ant file that you created in section “Identify the MobileFirst WAR file and prepare the Ant deployment script” on page 7-30.
3. Verify that taskdef for the worklight-ant-deployer.jar uses the directory that contains the upgraded installation of MobileFirst Server V7.1.0.

In this example, check the value of the **worklight.server.install.dir** property because this property defines the directory of the worklight-ant-deployer.jar in the taskdef tag:

```
<property name="worklight.server.install.dir" value="c:/Program File/IBM/Worklight"/>
```

[...]

```
<taskdef resource="com/worklight/ant/defaults.properties">
  <classpath>
    <fileset dir="{worklight.server.install.dir}/WorklightServer">
      <include name="worklight-ant-deployer.jar"/>
    </fileset>
  </classpath>
</taskdef>
```

Important: This verification step defines the version of IBM MobileFirst Platform Foundation that you use to upgrade the databases, to deploy the WAR file, and to install the MobileFirst runtime library for the MobileFirst Operations Console.

4. If you upgrade from IBM Worklight V6.1.0 or earlier, make sure that the Ant task `<configuredatabase kind="Worklight">` in the Ant file contains an `<admindatabase>` sub-element.

Note: In the following example code, DB2 is the DBMS. The **`\${contextRoot}** property contains the value of the context root of the MobileFirst project.

```
<configuredatabase kind="Worklight">
  <db2 database="WRKLGHT" server="proddb.example.com"
    user="w16admin" password="w16pass" schema="WLRT">
    <dba user="db2inst1" password="db2IsFun"/>
  </db2>
  <driverclasspath>
    <fileset dir="/opt/database-drivers/db2-9.7">
      <include name="db2jcc4.jar"/>
      <include name="db2jcc_license_*.jar"/>
    </fileset>
  </driverclasspath>
  <admindatabase runtimeContextRoot=${contextRoot}>
    <db2 database="WLADMIN" server="proddb.example.com"
      user="w16admin" password="w16pass" schema="ADMIN">
    </db2>
  </admindatabase>
</configuredatabase>
```

```

        <fileset dir="/opt/database-drivers/db2-9.7">
            <include name="db2jcc4.jar"/>
            <include name="db2jcc_license_*.jar"/>
        </fileset>
    </driverclasspath>
</admindatabase>
</configuredatabase>

```

5. Start the **databases** target of the Ant file with this command:

```
product_install_dir/shorcuts/ant -f your_file databases
```

Note: If you created an Ant file with your own target names, the Ant task to start is **configuredatabase**.

6. If you use push notifications and you want to upgrade from V6.1.0 or earlier, configure your runtime database manually for push notifications by following the instructions in “Runtime database configuration for Push notifications” on page 7-78.

This procedure loads the administration database and upgrades the database schemas for the runtime database to V7.1.0.

Upgrade the MobileFirst Server runtime environment

In this step, you run the Ant script to upgrade MobileFirst runtime environment to V7.1.0. You must repeat this procedure as many times for each runtime environment to upgrade.

Before you begin

Note: If your application server is WebSphere Application Server V7.0, you must add the configuration property “com.ibm.ws.webcontainer.invokerequestlistenerforfilter = true”. For more information about how to add this property, see “Configuring WebSphere Application Server V7.0” on page 6-70.

About this task

Note: This procedure explains how to upgrade the applications that you deployed to the application server with Ant tasks. For a manual upgrade of the applications that you deployed in the application server, see “Manually upgrading the application server” on page 7-79.

In this step, you run the same Ant script as in the previous step, but with a different parameter to indicate the Ant target and the nature of the upgrade.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-52. Is this step required for your upgrade path?.

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes

Table 7-52. Is this step required for your upgrade path? (continued).

Product or component versions	Required?
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-53. System status after this step.

Module	Status
Application Center	Embedded Liberty, Liberty on Windows, and Tomcat on Windows are stopped. All other instances are upgraded.
MobileFirst Server	Embedded Liberty, Liberty on Windows, and Tomcat on Windows are stopped. All other instances are partially upgraded.

Procedure

1. Locate the Ant file that you created in section “Identify the MobileFirst WAR file and prepare the Ant deployment script” on page 7-30.
2. Verify that the taskdef for the worklight-ant-deployer.jar uses the correct directory containing the upgraded installation of MobileFirst Server V7.1.0.

In this example, you need to check the value of the property **worklight.server.install.dir** because this property is used to define the directory of the worklight-ant-deployer.jar in the taskdef tag:

```
<property name="Worklight.server.install.dir" value="c:/Program File/IBM/Worklight"/>
```

[...]

```
<taskdef resource="com/worklight/ant/defaults.properties">
  <classpath>
    <fileset dir="${product_install_dir}/WorklightServer">
      <include name="worklight-ant-deployer.jar"/>
    </fileset>
  </classpath>
</taskdef>
```

This verification step is extremely important. It defines the version of IBM MobileFirst Platform Foundation that you use to migrate the databases, to deploy the WAR file, and to install the MobileFirst runtime library for the MobileFirst Operations Console.

3. Verify that the **environmentID** attribute for the MobileFirst runtime environment matches the **environmentID** attribute that you used to install the MobileFirst Server administration file. For more information, see “Identify the MobileFirst WAR file and prepare the Ant deployment script” on page 7-30.

Note:

- If the **environmentID** is defined in the Administration Services, and not in the runtime, or if it has different values in each, the Administration Services application does not detect the runtime. The MobileFirst Operations Console would display “No runtime found”.

- If you installed the MobileFirst Server administration with the Server Configuration Tool, it might have added an **environmentID** attribute, whose value you can see in the **Configuration Details** of the Server Configuration Tool).
4. Select the Ant target.
 - To upgrade from V5.0.6.x, use **install**.
 - To upgrade from V6.0.0.x, or V6.1.0.x, use **uninstall**, then **install**.
 - To upgrade from V6.2.0.x, or later (including from V7.1.0 to a fix pack), use **minimal-update**.
 5. Run Ant with the selected target:

```
product_install_dir/shortcuts/ant -f your_file_target_defined_in_step_4
```

 This scripts have the following effects:
 - Target **uninstall**: see the definition for the task <unconfigureapplicationserver> in the *Task effects* section of the page Ant tasks for installation of MobileFirst runtime environments.
 - Target **install**: see the definition for the task <configureapplicationserver> in the *Task effects* section of the page Ant tasks for installation of MobileFirst runtime environments.
 - Target **minimal-update**: see the definition for the task <updateapplicationserver> in the *Task effects* section of the page Ant tasks for installation of MobileFirst runtime environments.

Upgrading server farms for MobileFirst Server V7.1.0

About this task

If you run multiple servers, and if you do not use WebSphere Application Server Network Deployment, the configuration of server farms is required since V6.2.0. The configuration of server farms has also changed in V7.0.0. In this step, you upgrade or define your server farms to be compatible with MobileFirst Server V7.1.0. Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-54. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.2.0.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.0.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0.x to MobileFirst Server V7.1.0	No
MobileFirst Server V7.1.0 to MobileFirst Server V7.1.0.x (fix pack or interim fix)	No

Table 7-55. System status after this step.

Module	Status
Application Center	Embedded Liberty, Liberty on Windows, and Tomcat on Windows are stopped. All other instances are upgraded.
MobileFirst Server	Embedded Liberty, Liberty on Windows, and Tomcat on Windows are stopped. All other instances are partially upgraded.

For more information, see “List of JNDI properties for MobileFirst Server administration” on page 6-111.

If you upgrade from V6.1.0 or earlier, see “Installing a server farm” on page 6-138.

If you upgrade from V6.2.0 or V6.3.0, and you already defined a farm configuration, update your farm configuration as follows:

WebSphere Application Server Liberty

Optionally, you can remove some unused JNDI properties and configure the heartbeat rate and timeout values.

- The following JNDI properties in the server.xml file are not used any more. You can remove them.

```
<jndiEntryjndiName="ibm.worklight.farm.type"
value="File"/>
<jndiEntryjndiName="ibm.worklight.farm.definition.location" value="<plugin xml file location>"/>
```

- You can configure the heartbeat rate and timeout values by defining the following JNDI properties in the server.xml file.

```
<jndiEntryjndiName="worklight.admin.farm.heartbeat"
value="<heartbeat rate in minutes>"/>
<jndiEntryjndiName="ibm.worklight.admin.farm.missed.heartbeats.timeout"
value="<number of missed heartbeats before considering the server as being down>"/>
```

Tomcat

Optionally, you can remove some unused JNDI properties and configure the heartbeat rate and timeout values.

- The following JNDI properties in the server.xml file are not used any more. You can remove them.

```
<Environment name="ibm.worklight.farm.type" value="File" type="java.lang.String"
override="false"/>
<Environment name="ibm.worklight.farm.definition.location"
value="<plugin xml file location>"
type="java.lang.String" override="false"/>
```

- You can configure the heartbeat rate and timeout values by defining the following JNDI properties in the server.xml file.

```
<Environment name="worklight.admin.farm.heartbeat" value="<heartbeat rate in minutes>"
type="java.lang.String" override="false"/>
```

```
<Environmentname="ibm.worklight.admin.farm.missed.heartbeats.timeout"
value="<number of missed heartbeats before considering the server as being down>"
type="java.lang.String"override="false"/>
```

WebSphere Application Server

Required modifications

You must set new JNDI properties in MobileFirst Administration Services applications and every MobileFirst runtime application.

1. Open the WebSphere Application Server administration console.
2. On the navigation pane, select **Applications > Application Types > Websphere enterprise applications**.
3. Select the application that you want to configure.
4. In **Web Module Properties**, click **Environment entries for Web Modules** to display the JNDI properties.
5. Set the **ibm.worklight.admin.jmx.user** property to a user name that has access to the SOAP connector.
6. Set the **ibm.worklight.admin.jmx.pwd** property to the password of the user that you declared in the **ibm.worklight.admin.jmx.user** property.
7. Verify that the **ibm.worklight.admin.jmx.connector** property is set to **SOAP**.

Optional modifications

You can configure the heartbeat rate and timeout values by defining the **worklight.admin.farm.heartbeat** and **ibm.worklight.admin.farm.missed.heartbeats.timeout** JNDI properties in the MobileFirst Administration Services application.

Restore the MobileFirst Server configuration

In this step you restore the required configurations of MobileFirst Server that you made note of in a previous step.

About this task

Restore the configurations that you previously identified in step “Review and note the application server configuration for MobileFirst Server and Application Center” on page 7-33.

Restore as follows:

- For the applications: The MobileFirst runtime environments.
- For the JDBC data source: The runtime and reports database.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-56. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	No
MobileFirst Server V7.0.0.x to MobileFirst Server V7.1.0	No

Table 7-56. Is this step required for your upgrade path? (continued).

Product or component versions	Required?
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

Table 7-57. System status after this step.

Module	Status
Application Center	Embedded Liberty, Liberty on Windows, and Tomcat on Windows are stopped. All other instances are upgraded.
MobileFirst Server	Embedded Liberty, Liberty on Windows, and Tomcat on Windows are stopped. All other instances are upgraded.

Restart the application server

In this final step, you restart the application server.

About this task

Now that the upgrade of MobileFirst Server is completed, restart your application server.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-58. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0.x to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-59. System status after this step

Module	Status
Application Center	All instances are upgraded.
MobileFirst Server	All instances are upgraded.

Procedure

1. Use your standard procedures to start the application server, or restart the application server if it was running in this step, so that all changes are taken into account.

At the end of this step, the MobileFirst Server is upgraded. All applications that you previously deployed are available, along with their environments (those that are supported by MobileFirst Server V7.1.0).

The URL of the MobileFirst Operations Console changed. If you did not specify a context root in the Ant file, its context root is /worklightconsole.

Updating deployment scripts

If you use Ant tasks **app-deployer** or **adapter-deployer** to deploy apps or adapters, you must update the Ant scripts to use the Ant task **wladm**.

Read from the following tables whether this step is required for your upgrade path.

Table 7-60. Is this step required for your upgrade path?.

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.0.x to MobileFirst Server V7.1.0	Yes
Worklight Server V6.1.x to MobileFirst Server V7.1.0.x	Yes
Worklight Server V6.2.x to MobileFirst Server V7.1.0	No
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	No
MobileFirst Server V7.0.0.x to MobileFirst Server V7.1.0	No
V7.1.0 to V7.1.0.x (fix pack or interim fix)	No

If you have Ant scripts that deploy apps or adapters by using the Ant tasks **app-deployer** or **adapter-deployer**, you must update them to use the Ant task **wladm**. The Ant tasks **app-deployer** or **adapter-deployer** no longer apply in IBM MobileFirst Platform Foundation V7.1.0.

Note: In the following code samples, *mf_install_dir* is the directory where you installed MobileFirst Server.

1. In the initialization commands of the Ant script, replace the path as follows:

```
<taskdef resource="com/worklight/ant/defaults.properties">
  <classpath>
    <pathelement location="mf_install_dir/WorklightServer/worklight-ant-deployer.jar"/>
  </classpath>
</taskdef>
```

With

```

<taskdef resource="com/worklight/ant/deployers/antlib.xml">
  <classpath>
    <pathelement location="mf_install_dir/WorklightServer/worklight-ant-deployer.jar"/>
  </classpath>
</taskdef>

```

2. Replace <app-deployer> calls.

```

<app-deployer deployable="myApp.wlapp"
  worklightserverhost="http://server-address:port/project-name"
  userName="username" password="password"/>

```

With

```

<wladm url="https://server-address:secure-port/worklightadmin" user="username" password="password"
  <deploy-app runtime="project-name" file="myApp.wlapp"/>
</wladm>

```

Set the placeholders as follows:

- For *worklightadmin*, substitute the actual context root of the MobileFirst administration services web application
- For *username* and *password*, pick a user that is in the role **worklightadmin** or **worklightdeployer**.

3. Replace <adapter-deployer> calls.

```

<adapter-deployer deployable="myAdapter.adapter"
  worklightserverhost="http://server-address:port/project-name"
  userName="username" password="password"/>

```

With

```

<wladm url="https://server-address:secure-port/worklightadmin" user="username" password="password"
  <deploy-adapter runtime="project-name" file="myAdapter.adapter"/>
</wladm>

```

Set the placeholders as follows:

- For *worklightadmin*, substitute the actual context root of the MobileFirst administration services web application.
- For *username* and *password*, you need to pick a user that is in the role **worklightadmin** or **worklightdeployer**.

For more information about the **wladm** Ant task, see “Administering MobileFirst applications through Ant” on page 13-12.

Additional MobileFirst Server V7.1.0 upgrade information

This section contains additional information that may be of use if you have additional test or pre-production databases that must be updated, if you need to update HTTP redirections on networked servers, if you are manually upgrading the application server, or in the event of a failed upgrade.

Recovering from an unsuccessful upgrade to MobileFirst Server V7.1.0

Instructions for how to recover from a failed installation or to revert to the previous version of Worklight Server or MobileFirst Server.

About this task

If the MobileFirst Server upgrade fails for any reason, use the following procedure to restore the previous Worklight Server or MobileFirst Server version.

Procedure

The **Roll Back** button of IBM Installation Manager is not supported for MobileFirst Server. Therefore, to return to the previous version:

1. Uninstall MobileFirst Server, with IBM Installation Manager.
2. Install the old version of Worklight Server or MobileFirst Server with IBM Installation Manager, specifying the same installation parameters that you used previously.
3. Restore the databases. For more information, see “Back up the runtime database” on page 7-59.
4. Restore the application server. For more information, see “Back up your application server” on page 7-43.
5. If the server fails to start and load the applications, delete workarea of the server before starting it again. For example, for a WebSphere Application Server Liberty profile backup, the workarea is the directory `<LibertyInstallDir>/usr/servers/<serverName>/workarea`.

Manually installing the MobileFirst Server administration during the upgrade

You can manually install the MobileFirst Server administration as part of the MobileFirst Server upgrade.

Since IBM Worklight Foundation V6.2.0, you must install the administration components. To manually set up the MobileFirst Server administration, follow the steps detailed in “Manually installing MobileFirst Server administration” on page 6-76.

Manually upgrading the MobileFirst Server V7.1.0 databases

Follow these instructions to manually update the MobileFirst project databases. First set up the MobileFirst Server administration environment.

Note: The reports database, referenced as WLREPORT, was deprecated in IBM MobileFirst Platform Foundation V7.0.0. Use “Operational analytics” on page 14-9 instead. Note that setting up the reports database is optional in this release and previous releases. Also note that the use of the reports database is redundant with the MobileFirst Operational Analytics console in this release and previous releases, because of the deprecation of the reports database.

If you prefer to update databases manually instead of using the Ant tasks, you must update their sets of tables and columns manually. For example, if you have test or preproduction databases as part of your production environment, each served by a different runtime database or schema, you can use this procedure to update their schemas.

Procedure

Updating the reports (by default WLREPORT) and Application Center (by default APPCNTR) databases is done by running a sequence of database scripts.

Updating the runtime database (by default WRKLGHT) and administration (by default WLADMIN) databases is done by running a sequence of database scripts, if you upgrade from IBM Worklight Foundation V6.2.0 or later.

For the WRKLGHT database, if you upgrade from IBM Worklight V6.1.0 or earlier, you must apply the proper sql scripts to upgrade the databases to IBM MobileFirst

Platform Foundation V7.1.0. If you migrate the database from V6.1.0 to V6.2.0, you have some additional steps to perform, which are detailed in the following sections for each database.

For the WRKLGHT and WLADMIN databases, if you upgrade from V6.2.0 or later, you must apply the proper sql scripts to upgrade the databases to IBM MobileFirst Platform Foundation V7.1.0.

For the WLREPORT and APPCNTR databases: apply the proper sql scripts to upgrade the databases to IBM MobileFirst Platform Foundation V7.1.0.

Scripts for DB2

For an upgrade from IBM Worklight V5.0.6.x to V6.0.0:

- WorklightServer/databases/upgrade-worklight-506-60-db2.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-506-60-db2.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-506-60-db2.sql (for APPCNTR)

For an upgrade from IBM Worklight V6.0.0.x to V6.1.0:

- WorklightServer/databases/upgrade-worklight-60-61-db2.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-60-61-db2.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-60-61-db2.sql (for APPCNTR)

For an upgrade from IBM Worklight V6.1.0.x to IBM Worklight Foundation V6.2.0:

Important:

- First, you must install the MobileFirst Server, so that the administration database exists. Then, you must run the data migration tool, and run the following sql scripts. For more information, see the section data migration tool.
- If you manually added an index I_USERPRF_USERID to the runtime database to solve the performance problem that is described in the technote IBM Worklight queries on the GADGET_USER_PREF table might take time, you must comment the corresponding index, as described in “Commenting the I_USERPRF_USERID index from the sql scripts” on page 7-76.
- WorklightServer/databases/upgrade-worklight-61-62-db2.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-61-62-db2.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-61-62-db2.sql (for APPCNTR)

For an upgrade from IBM Worklight Foundation V6.2.0.x to IBM MobileFirst Platform Foundation V6.3.0:

- WorklightServer/databases/upgrade-worklightadmin-62-63-db2.sql (for WLADMIN)
- WorklightServer/databases/upgrade-worklight-62-63-db2.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-62-63-db2.sql (for REPORTS)

- ApplicationCenter/databases/upgrade-appcenter-62-63-db2.sql (for APPCNTR)

For an upgrade from IBM MobileFirst Platform Foundation V6.3.0.x to IBM MobileFirst Platform Foundation V 7.0.0:

- WorklightServer/databases/upgrade-worklightadmin-63-70-db2.sql (for WLADMIN)
- WorklightServer/databases/upgrade-worklight-63-70-db2.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-63-70-db2.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-63-70-db2.sql (for APPCNTR)

For an upgrade from IBM MobileFirst Platform Foundation V7.0.0.x to IBM MobileFirst Platform Foundation V7.1.0:

- WorklightServer/databases/upgrade-worklightadmin-70-71-db2.sql (for WLADMIN)
- WorklightServer/databases/upgrade-worklight-70-71-db2.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-70-71-db2.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-70-71-db2.sql (for APPCNTR)

These scripts are applied similarly to steps 4 and 6 in “Setting up your DB2 database manually” on page 12-21

Note: If you are using Application Center, the size limit for applications stored on Application Center with IBM DB2 is 1 GB. If you have applications larger than 1 GB in the Application Center, remove them before starting the upgrade process.

Scripts for MySQL

For an upgrade from IBM Worklight V5.0.6.x to V6.0.0:

- WorklightServer/databases/upgrade-worklight-506-60-mysql.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-506-60-mysql.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-506-60-mysql.sql (for APPCNTR)

For an upgrade from IBM Worklight V6.0.0.x to V6.1.0:

- WorklightServer/databases/upgrade-worklight-60-61-mysql.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-60-61-mysql.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-60-61-mysql.sql (for APPCNTR)

For an upgrade from IBM Worklight V6.1.0.x to IBM Worklight Foundation V6.2.0:

Important:

- First, you must install the MobileFirst Server, so that the administration database exists. Then, you must run the data migration tool, and run the following sql scripts. For more information, see the section data migration tool.
- If you manually added an index I_USERPRF_USERID to the runtime database to solve the performance problem that is described in the technote IBM Worklight queries on the GADGET_USER_PREF table might take time, you must comment the corresponding index, as described in “Commenting the I_USERPRF_USERID index from the sql scripts” on page 7-76.
- WorklightServer/databases/upgrade-worklight-61-62-mysql.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-61-62-mysql.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-61-62-mysql.sql (for APPCNTR)

For an upgrade from IBM Worklight Foundation V6.2.0.x to IBM MobileFirst Platform Foundation V6.3.0:

- WorklightServer/databases/upgrade-worklightadmin-62-63-mysql.sql (for WLADMIN)
- WorklightServer/databases/upgrade-worklight-62-63-mysql.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-62-63-mysql.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-62-63-mysql.sql (for APPCNTR)

For an upgrade from IBM MobileFirst Platform Foundation V6.3.0.x to IBM MobileFirst Platform Foundation V7.0.0:

- WorklightServer/databases/upgrade-worklightadmin-63-70-mysql.sql (for WLADMIN)
- WorklightServer/databases/upgrade-worklight-63-70-mysql.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-63-70-mysql.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-63-70-mysql.sql (for APPCNTR)

For an upgrade from IBM MobileFirst Platform Foundation V7.0.0.x to IBM MobileFirst Platform Foundation V7.1.0:

- WorklightServer/databases/upgrade-worklightadmin-70-71-mysql.sql (for WLADMIN)
- WorklightServer/databases/upgrade-worklight-70-71-mysql.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-70-71-mysql.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-70-71-mysql.sql (for APPCNTR)

These scripts are applied similarly to step 1.b in “Setting up your MySQL database manually” on page 12-29.

Scripts for Oracle

Remember: To upgrade from V6.1.0 or earlier, the Oracle user must have the CREATE VIEW privilege.

For an upgrade from IBM Worklight V5.0.6.x to V6.0.0:

- WorklightServer/databases/upgrade-worklight-506-60-oracle.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-506-60-oracle.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-506-60-oracle.sql (for APPCNTR)

For an upgrade from IBM Worklight V6.0.0.x to V6.1.0:

- WorklightServer/databases/upgrade-worklight-60-61-oracle.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-60-61-oracle.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-60-61-oracle.sql (for APPCNTR)

For an upgrade from IBM Worklight V6.1.0.x to IBM Worklight Foundation V6.2.0:

Important:

- First, you must install the MobileFirst Server, so that the administration database exists. Then, you must run the data migration tool, and run the following sql scripts. For more information, see the section data migration tool.
- If you manually added an index I_USERPRF_USERID to the runtime database to solve the performance problem that is described in the technote IBM Worklight queries on the GADGET_USER_PREF table might take time, you must comment the corresponding index, as described in “Commenting the I_USERPRF_USERID index from the sql scripts” on page 7-76.
- WorklightServer/databases/upgrade-worklight-61-62-oracle.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-61-62-oracle.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-61-62-oracle.sql (for APPCNTR)

For an upgrade from IBM Worklight Foundation V6.2.0.x to IBM MobileFirst Platform Foundation V6.3.0:

- WorklightServer/databases/upgrade-worklightadmin-62-63-oracle.sql (for WLADMIN)
- WorklightServer/databases/upgrade-worklight-62-63-oracle.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-62-63-oracle.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-62-63-oracle.sql (for APPCNTR)

For an upgrade from IBM MobileFirst Platform Foundation V6.3.0.x to IBM MobileFirst Platform Foundation V7.0.0:

- WorklightServer/databases/upgrade-worklightadmin-63-70-oracle.sql (for WLADMIN)
- WorklightServer/databases/upgrade-worklight-63-70-oracle.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-63-70-oracle.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-63-70-oracle.sql (for APPCNTR)

For an upgrade from IBM MobileFirst Platform Foundation V7.0.0.x to IBM MobileFirst Platform Foundation V7.1.0:

- WorklightServer/databases/upgrade-worklightadmin-70-71-oracle.sql (for WLADMIN)
- WorklightServer/databases/upgrade-worklight-70-71-oracle.sql (for WRKLGHT)
- WorklightServer/databases/upgrade-worklightreports-70-71-oracle.sql (for REPORTS)
- ApplicationCenter/databases/upgrade-appcenter-70-71-oracle.sql (for APPCNTR)

These scripts are applied similarly to step 3 in “Setting up your Oracle database manually” on page 12-33.

Commenting the I_USERPRF_USERID index from the sql scripts

Before you apply the sql scripts that upgrade the WRKLGHT database from the previous version V6.1.0 to V6.2.0, you must check whether the index I_USERPRF_USERID, in column USER_ID of the table GADGET_USER_PREF, exists. You might have added it manually to solve the performance problem that is described in the technote IBM Worklight queries on the GADGET_USER_PREF table might take time.

If this index exists, you must comment the statement that creates this index, in the script WorklightServer/databases/upgrade-worklight-61-62-*<dbms>*.sql.

Comment the following line that refers to its creation before running it:

```
INDEX I_USERPRF_USERID ON GADGET_USER_PREF (USER_ID);
```

The data migration tool

In IBM Worklight Foundation V6.2.0, the process of updating the runtime database (by default WRKLGHT) required to move the runtime administrative data to the administration database. When you upgrade from IBM Worklight V6.1.0 or older, before you call the script WorklightServer/databases/upgrade-worklight-61-62-*<dbms>*.sql, run the data migration tool to migrate the administration database to the new administration database. Then, run the SQL scripts from V6.2.0 to the current release to update the WRKLGHT database schema. If you forgot to run the data migration tool before you run the SQL script, WorklightServer/databases/upgrade-worklight-61-62-*<dbms>*.sql is likely to fail, and indicates that the data migration was not run. In that case, the WRKLGHT schema is not updated, or the production data might be corrupted or lost.

The data migration tool and the database upgrade scripts are both contained in the MobileFirst Server directory that you just installed.

Running the data migration tool

Before you run the tool in command line, make sure that the library `worklight-ant-deployer.jar` of the MobileFirst version that you installed is in your current directory, or that your `CLASSPATH` variable references the directory it is in. Example on a Unix/Linux machine:

```
# Go to the directory library that worklight-ant-deployer.jar is in
$ cd $product_install_dir/WorklightServer
# Print the usage
$ java -cp worklight-ant-deployer.jar com.ibm.worklight.config.dbmigration.MigrationTool usage
Usage:
    java -cp worklight-ant-deployer.jar com.ibm.worklight.config.dbmigration.MigrationTool [op
```

Options:

```
-p <project>          The name of the project to create.
-sourceurl            The path to the source database.
-sourceschema        The name of the schema of the source database.
-sourcedriver        The fully qualified driver class name of the source
                    database. This driver must be in the class path.
-sourceuser          The user name of the source database.
-sourcepassword      The password of the source database.
-sourceproperty <key> <value>  Adds additional OpenJPA properties to the connection
                    of the source database.
-targeturl           The path to the target database.
-targetschema        The name of the schema of the target database.
-targetdriver        The fully qualified driver class name of the target
                    database. This driver must be in the class path.
-targetuser          The user name of the target database.
-targetpassword      The password of the target database.
-targetproperty <key> <value>  Adds additional OpenJPA properties to the connection
                    of the target database.
```

```
# Example with DB2 as DBMS
$ java -cp worklight-ant-deployer.jar com.ibm.worklight.config.dbmigration.MigrationTool
-p worklight
-sourceurl jdbc:db2://proddb.example.com:50000/WRKLGHT
-sourceschema WLRT
-sourcedriver com.ibm.db2.jcc.DB2Driver
-sourceuser wuser1
-sourcepassword wuser1_pswd
-targeturl jdbc:db2://proddb.example.com:50000/WLADMIN
-targetschema ADMIN
-targetdriver com.ibm.db2.jcc.DB2Driver
-targetuser wuser2
-targetpassword wuser2_pswd
```

To run the data migration tool, you must add the database drivers to the class path. For example, to migrate a DB2 database, you must add the `db2jcc4.jar` file and the license JAR file (for example `db2jcc_license_cu.jar`), to the class path:

```
$ java -cp worklight-ant-deployer.jar:/path/to/db2jcc4.jar:/path/to/db2jcc_license_cu.jar
com.ibm.worklight.config.dbmigration.MigrationTool usage
```

Note:

- The name of the project to create (worklight in the example) must be the context root where the MobileFirst runtime component (project WAR file) is deployed. For example, if the runtime component is deployed in the application server with a context root `/worklight`, then the project name must be `worklight`. The applications will be assigned to this project name. When a runtime component starts, it contacts the administration service to get the applications and the adapters it needs to serve. The runtime component uses its project name, computed by removing the initial `/` from its context root, to indicate which

applications it needs. If the project name is not the same as the context root without the initial slash, then the migrated applications and the adapters are not visible by the runtime component.

- For MySQL databases, the schema options '-sourceschema' and '-targetschema' must be left unspecified. The name of the schema to use will be the name of the database specified in the connection URL.

Runtime database configuration for Push notifications

Note: The following section applies if you use push notifications and you upgrade from V6.1.0 or earlier.

To ensure that push notifications work as expected, you must complete some additional manual configuration. After your migration to V7.1.0 is complete (this includes a complete migration of both the runtime database and the runtime environment) and the application server is restarted, complete the steps in the section for your database type.

This task requires the use of a database account that can modify the content of the runtime database. It also requires basic knowledge to run SQL scripts on the database. For DB2, you need to know how to run the DB2 command line processor or the command line program. For Oracle, make sure that you know how to run SQLPlus. This task is only needed for Oracle or DB2. It is not needed for MySQL.

DB2

1. Change *SCHEMANAME* instances to actual names.
2. Replace X and Y values based on the given description.

```
SELECT MAX(ID) FROM SCHEMANAME.PUSH_DEVICES;  
SELECT MAX(ID) FROM SCHEMANAME.PUSH_SUBSCRIPTIONS;
```

```
--Value of X = Result of the selected query of PUSH_DEVICES + 1. For example, if SELECT  
--SCHEMANAME.PUSH_DEVICES returns 100, then X = 101;  
--Value of Y = Result of the selected query of PUSH_SUBSCRIPTIONS + 1. For example, if SE  
--SCHEMANAME.PUSH_SUBSCRIPTIONS returns 100, then Y = 101;
```

```
ALTER SEQUENCE SCHEMANAME.PUSHDEVICE_SEQ RESTART WITH X ;  
ALTER SEQUENCE SCHEMANAME.PUSHSUBSCRIPTION_SEQ RESTART WITH Y ;
```

```
VALUES NEXT VALUE FOR SCHEMANAME.PUSHDEVICE_SEQ;  
VALUES NEXT VALUE FOR SCHEMANAME.PUSHSUBSCRIPTION_SEQ;
```

Oracle

1. Change *SCHEMANAME* instances to actual names.
2. Replace X and Y values (based on the given description) while running the query.

```
SELECT MAX(ID) FROM SCHEMANAME.PUSH_DEVICES;  
SELECT MAX(ID) FROM SCHEMANAME.PUSH_SUBSCRIPTIONS;
```

```
SELECT LAST_NUMBER FROM ALL_SEQUENCES WHERE SEQUENCE_NAME='PUSHDEVICE_SEQ';  
SELECT LAST_NUMBER FROM ALL_SEQUENCES WHERE SEQUENCE_NAME='PUSHSUBSCRIPTION_SEQ';
```

```
--Take note of the resulting value of each query above to use in the following X and Y ca
```

```
--Value of X = (MAX(ID) OF PUSH_DEVICES - LAST_NUMBER OF PUSHDEVICE_SEQ) + 20. For exampl  
--SCHEMANAME.PUSH_DEVICES returned 100 and SELECT LAST_NUMBER FROM ALL_SEQUENCES  
--(where SEQUENCE_NAME='PUSHDEVICE_SEQ' is 50), then X=100-50+20 = 70
```

```
--Value of Y = (MAX(ID) OF PUSH_SUBSCRIPTIONS - LAST_NUMBER OF PUSHSUBSCRIPTION_SEQ) + 20  
--MAX(ID) FROM SCHEMANAME.PUSH_SUBSCRIPTIONS returned 100, then Y = 101 and SELECT --LAST  
--FROM ALL_SEQUENCES (where SEQUENCE_NAME='PUSHSUBSCRIPTION_SEQ' is 50), then Y=100-50+20
```

```
ALTER SEQUENCE SCHEMANAME.PUSHDEVICE_SEQ INCREMENT BY X ;
SELECT SCHEMANAME.PUSHDEVICE_SEQ.NEXTVAL FROM dual;
ALTER SEQUENCE SCHEMANAME.PUSHDEVICE_SEQ INCREMENT BY 1;

ALTER SEQUENCE SCHEMANAME.PUSHSUBSCRIPTION_SEQ INCREMENT BY Y ;
SELECT SCHEMANAME.PUSHSUBSCRIPTION_SEQ.NEXTVAL FROM dual;
ALTER SEQUENCE SCHEMANAME.PUSHSUBSCRIPTION_SEQ INCREMENT BY 1;
```

MySQL

No action is required.

Manually upgrading the application server

Follow these instructions to manually upgrade the application server.

The recommended way to upgrade MobileFirst Server is to use IBM Installation Manager, either in its graphical mode or in silent mode with a response file, and the Ant tasks, as described previously.

However, if this is not applicable to your installation and you must update your application server manually, use a different series of steps.

Instead of completing the tasks “Running IBM Installation Manager and completing the Application Center upgrade” on page 7-48 and “Upgrade the MobileFirst Server runtime environment” on page 7-63, use the following procedure:

- Upgrade the databases manually as specified in section “Manually upgrading the MobileFirst Server V7.1.0 databases” on page 7-71.
- Review the manual installation procedures at:
 - “Manually installing Application Center” on page 6-243
 - “Deploying a project WAR file and configuring the application server manually” on page 12-37
- Update the items manually. This includes, at a minimum:
 - The WAR file for the Application Center console, Application Center services, and the MobileFirst Operations Console.
 - The MobileFirst library `worklight-jee-library.jar`.
 - The MobileFirst runtime environment, which must be migrated to the current version of the server using the migrate Ant task described at “Migrating a project WAR file for use with a new MobileFirst Server” on page 12-38.
- If you upgrade from IBM MobileFirst Platform Foundation V6.3.0 or earlier, and you use DB2 as a DBMS, you must update the schemas as described in “Updating DB2 schema names in the case of a manual installation” on page 7-80.

Verifying and updating the HTTP redirections for MobileFirst Server V7.1.0

If you are upgrading from IBM Worklight V6.1.0 or earlier, to MobileFirst Server on a clustered application server environment, you must also update IBM HTTP Server after you install IBM MobileFirst Platform Foundation V7.1.0.

If your MobileFirst Server upgrade is to be installed on a WebSphere Application Server Network Deployment clustered environment or a WebSphere Application Server Liberty profile farm, you might have to update IHS after you install MobileFirst Server V7.1.0. For general information about installing these types of application server, see:

- “Setting up IBM MobileFirst Platform Foundation in WebSphere Application Server cluster environment” on page 6-328
- “Setting up HTTP Server in a WebSphere Application Server Liberty profile farm” on page 6-339

If your application server receives HTTP requests forwarded by an HTTP server, the HTTP server configuration may require updating.

For IBM HTTP Server, in the IHS plugin file the context root of the applications must be updated especially for the session affinity configuration section. The following example is a configuration for Application Center that is deployed with its default settings, and a project that is deployed with a root context of /worklight.

```
<UriGroup Name="default_host_defaultServer_default_node_Cluster_URIs">
  <Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid"
    Name="/worklight/*"/>
  <Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid"
    Name="/applicationcenter/*"/>
  <Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid"
    Name="/apcenterconsole/*"/>
</UriGroup>
```

Updating DB2 schema names in the case of a manual installation

If you are upgrading manually from IBM MobileFirst Platform Foundation V6.3.0, or earlier, to MobileFirst Server on a clustered application server environment, and if you are using DB2 for the runtime database or the reports database, you must update the DB2 schema.

About this task

Since IBM MobileFirst Platform Foundation V7.0.0, for the runtime database and the reports database, IBM MobileFirst Platform Foundation expects the schema name without surrounding double quotation marks.

Procedure

Perform one of the following steps, based on your installation.

1. WebSphere Application Server Liberty profile:
 - a. Edit the server.xml file in the `usr/servers/serverName` directory.
 - b. Look for the `<properties.db2.jcc .../>` element in the `<dataSource jndiName="contextroot/jdbc/WorklightDS" ...>` and `<dataSource jndiName="contextroot/jdbc/WorklightReportsDS" ...>` elements.
 - c. Optional: If there are double quotation marks around the value of the `currentSchema` attribute, you must remove them. For example, change `currentSchema="wrkschem"` or `currentSchema=""wrkschem"` to `currentSchema='wrkschem'`.
2. WebSphere Application Server full profile:
 - a. Sign in to WebSphere Application Server administrative console.
 - b. Click **Resources > JDBC > Data sources**
 - c. For each database with the JNDI name `jdbc/WorklightDS` or `jdbc/WorklightReportsDS`, possibly with a suffix:
 - 1) Select the data source
 - 2) Click **Additional properties > Custom properties**.
 - 3) Select the `currentSchema` property.

- 4) If the value is not empty, remove the double quotation marks around the value. For example, change the value "wrkschem" to wrkschem.
 - 5) Click **OK**.
 - 6) Click **Save** to save the changes.
3. Tomcat:
- a. Edit the server.xml file in the conf directory.
 - b. In the <Resource name="jdbc/WorklightDS" .../> and <Resource name="jdbc/WorklightReportsDS" .../> elements, remove the double quotation marks around the value of the currentSchema connection property in the url attribute, if this property is present. For example, change url='jdbc:db2://dbserver.example.com:50000/WRKLGHT:currentSchema="wrkschem";' to url='jdbc:db2://dbserver.example.com:50000/WRKLGHT:currentSchema=wrkschem;'.

Upgrading with the Server Configuration Tool

Upgrade an older configuration that was deployed with the Server Configuration Tool.

Before you begin

Before you start to upgrade, you must complete the following steps:

- Prepare the passwords of the databases that are to be upgraded, and the passwords for the WebSphere Application Server, if this is the application server that you use in your configuration. For more information, see “Gathering information for MobileFirst Server V7.1.0 upgrades” on page 7-25.
- Shut down your application server. This is mandatory if you use Apache Tomcat, or Liberty stand-alone servers. For more information, see “Shutting down the application server to be upgraded” on page 7-57.

To be able to restore your previous deployment if the upgrade fails, you must complete the following steps:

- Back up your administration and runtime databases. For more information, see “Back up the runtime database” on page 7-59.
- Find your previous project WAR file, or project WAR files, which are already deployed. You can then redeploy them. For more information, see “Identify the MobileFirst WAR file and prepare the Ant deployment script” on page 7-30.
- Back up your application server configuration. For more information, see “Back up your application server” on page 7-43.

About this task

Since IBM MobileFirst Platform Foundation V7.1.0, you can upgrade an older configuration that is already deployed, by using the Server Configuration Tool. You can perform this upgrade with the Server Configuration Tool only on a configuration that uses the architecture of MobileFirst Server that was introduced in V6.2.0. You can then upgrade from V6.2.0 or later.

Read from the following tables whether this step is required for your upgrade path and what the system status is afterward if both Application Center and MobileFirst Server are on the same application.

Table 7-61. Is this step required for your upgrade path?

Product or component versions	Required?
Worklight Server V5.0.6.x to MobileFirst Server V7.1.0	No
Worklight Server V6.0.x to MobileFirst Server V7.1.0	No
Worklight Server V6.1.x to MobileFirst Server V7.1.0	No
Worklight Server V6.2.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V6.3.x to MobileFirst Server V7.1.0	Yes
MobileFirst Server V7.0.0 to MobileFirst Server V7.1.0	Yes
V7.1.0 to V7.1.0.x (fix pack or interim fix)	Yes

Table 7-62. System status after this step.

Module	Status
Application Center	STOPPED (embedded Liberty, Liberty on Windows, Tomcat on Windows), UPGRADED (other cases)
MobileFirst Server	STOPPED (all instances)

Limitations

- This procedure concerns only the MobileFirst Server upgrade, not the Application Center upgrade.
- You can perform an upgrade with the Server Configuration Tool only if the configuration was deployed with the Server Configuration Tool from IBM Worklight Foundation V6.2.0, or later.
- You cannot perform an upgrade with the Server Configuration Tool on a configuration that was deployed manually, or with Ant tasks.
- You cannot perform an upgrade with the Server Configuration Tool on a server farm installation.

Procedure

To perform this upgrade, a new button **Upgrade a previous configuration** is defined in the Server Configuration Tool. This button is only available when you select a deployed configuration.

1. Select the previously deployed configuration.
2. Start the upgrade by right-clicking the configuration in the navigation tree, then selecting **Configurations > Upgrade a previous Configuration**.
3. A modal dialog opens.
 - a. Select the configuration to upgrade.
 - b. If you decide to upgrade the reports database for each runtime that is deployed, select the **Upgrade the Runtime REPORT database** check-box. By default, the upgrade of the reports database is not activated.
 - c. If your installation is on WebSphere Application Server, and the security of the server is activated, you must enter the administration password of the application server.

- d. Enter the passwords of the users that have the privileges to upgrade the administration and runtime databases.
 - e. Enter or confirm the WAR file path for each runtime. The WAR file must have the same base name as the WAR file that was initially deployed.
 - f. Click **OK**.
4. The upgrade procedure begins. The procedure includes a database upgrade. If the database contains a large number of entries, this step might require one hour or more to complete.

What to do next

If your upgrade fails, you can complete the following steps to solve the issue, as the execution of the upgrade is reentrant:

1. Analyze the issues that you can find in the log file, or directly in the console.
2. Correct the issues that you found. If the Server Configuration Tool was interrupted in the middle of a database upgrade script, you must complete that upgrade script manually. The upgrade scripts can be found in `product_install_dir/WorklightServer/databases`.
3. Start the upgrade again. The upgrade can be run twice on the same configuration.

If the upgrade fails definitively, you must restore your previous deployment with the databases and application server back-ups that you did before starting the upgrade procedure (see section *Before you begin*).

Rolling upgrade procedure to apply a fix pack to IBM MobileFirst Platform Foundation V7.1.0 in stateful mode

If your installation of MobileFirst Server V7.1.0 is configured in stateful mode, meaning that it uses sticky sessions with an attribute store of type HTTPSESSION, you can perform a rolling upgrade to apply a fix pack or an interim fix to an installation of MobileFirst Server V7.1.0, without downtime of the MobileFirst runtime environment. Performing this rolling upgrade ensures that there is no interruption of service for the mobile applications that query the MobileFirst Server.

Note: Since MobileFirst Server V7.1.0, new MobileFirst runtime environments are configured in stateless mode by default (distributed attribute store, or type DATABASE or EXTREMESCALE). The following procedure, which runs both a previous, and a more recent installation of MobileFirst in parallel for some time, must not be used for a stateless installation. In a stateless installation, HTTP requests of a same session can be sent indifferently to the previous, or the more recent installation. If there is a different behavior in both installations, this can prevent mobile applications from working correctly.

To perform this rolling upgrade, you must install the upgraded version of IBM MobileFirst Platform Foundation in a different environment, for example a new cluster in WebSphere Application Server Network Deployment. This environment must be connected to the same databases as the initial IBM MobileFirst Platform Foundation installation. You must then switch HTTP traffic progressively from the old environment to the new environment.

The procedure for an in-place upgrade, with interruption of service, is documented at “Upgrading to IBM MobileFirst Platform Foundation V7.1.0” on page 7-1.

Important: This procedure applies to a MobileFirst Server installation, including the Administration Services, the MobileFirst Operations Console, and the MobileFirst runtime environment, but does not apply to the Application Center.

The following topics explain what you must plan for your production environment, and the steps of the rolling upgrade procedure for IBM MobileFirst Platform Foundation, installed in one cluster in IBM WebSphere Application Server, with the HTTP traffic routed by an IBM HTTP Server, and web server plug-ins for IBM WebSphere Application Server.

Planning the rolling upgrade procedure

You must plan the steps of the rolling upgrade procedure to install a fix pack to IBM MobileFirst Platform Foundation without downtime.

You must review, adapt, and test this upgrade procedure for your production environment. Other components that interact with IBM MobileFirst Platform Foundation in your production environment might require extra steps or changes to that procedure.

The goal of this procedure is to switch HTTP-based traffic from a previous installation of MobileFirst Server to an upgraded installation of MobileFirst Server. This is done without losing any data in the former databases, and without visible impact for users of applications that have an active session while this procedure is applied.

If other protocols than HTTP are used by some components of your application to interact with the MobileFirst Server, then you must include in your upgrade plan a way to route that traffic during a rolling upgrade procedure.

For example, if you use a pull mechanism for push notifications, you must review the risk of double notification or lost notification in a rolling upgrade procedure. For more information, see “Possible MobileFirst push notification architectures” on page 8-497.

Verify that your installation of MobileFirst Server V7.1.0 is configured in stateful mode (attribute store of the type HTTPSESSION).

Since MobileFirst Server V7.1.0, new MobileFirst runtime environments are configured in stateless mode by default (distributed attribute store, or type DATABASE or EXTREMESCALE). The following rolling upgrade procedure, which runs both a previous, and a more recent installation of MobileFirst in parallel for some time, must not be used for a stateless installation. In a stateless installation, HTTP requests of a same session can be sent indifferently to the previous, or the more recent installation. If there is a different behavior in both installations, this can prevent mobile applications from working correctly.

You must review, with the development team, the code of all your adapters to identify extra steps that might be required for a rolling upgrade procedure. This is the case especially if these adapters require external resources, or use other communication protocols than HTTP, such as JMS or WebSphere MQ.

During the rolling upgrade, you must also stop management operations, such as uploading a new application or a new adapter to the console. If a new version of a MobileFirst application or adapter is uploaded to the MobileFirst Server during the upgrade procedure, some servers on the clusters might not be notified of this

change and might continue to operate with the old artifact. If a new MobileFirst application is uploaded to the MobileFirst Server and the runtimes do not all have the same version, it might trigger arbitrary direct update sessions for the users of MobileFirst apps, depending on the server to which they were routed. Identify all MobileFirst administration users that have a privilege to upgrade an application. Their role is defined as `worklightadmin` or `worklightdeployer`. You can then notify them of the beginning and the end of the rolling upgrade. During that period, they must not upload any adapter or application.

This procedure requires to temporarily duplicate the environment. You might find it convenient to apply this procedure at a period of low traffic, so that you can use existing hardware resources for the servers of the new environment. You must double the number of instances of WebSphere Application Server during the rolling upgrade, and the hardware must have enough memory to run these servers without paging. The CPU requirements must not increase significantly during that procedure because the use on the servers that are being brought online would ramp up as new sessions get routed to the new version of the application. The CPU use on the servers that run the old version of the application must ramp down as existing sessions end.

Overview of the rolling upgrade procedure

Learn about the steps of a rolling upgrade procedure.

You must perform the following actions to complete a rolling upgrade procedure. These steps are detailed in the following topics.

- Stop management operations while you apply the rolling upgrade procedure. No management operation, such as uploading a new application version or a new adapter, must be performed during a rolling upgrade.
- Duplicate the application server environment and install the fix pack IBM MobileFirst Platform Foundation V7.1.0.x in that duplicated environment, for example in a new cluster. You must use the existing administration database, MobileFirst runtime database, and MobileFirst reports database.
- Start a server in the duplicated environment.
- Direct some of the new HTTP sessions to the new servers and drain the servers of the previous installation so that they do not receive new HTTP sessions.

Note: IBM MobileFirst Platform Foundation uses session affinity and locally stores data about the state of sessions in a server. When routing traffic to the new cluster, existing sessions must continue to be routed to the old server with which they started.

- When the old servers are all drained and there is no longer any active session, and the new MobileFirst Server is confirmed to work correctly, shut down the old servers. If required, uninstall the old IBM MobileFirst Platform Foundation version from those servers.
- When the old environment is shut down, you can authorize management operations again.

Performing a rolling upgrade to install a fix pack

Learn how to perform a rolling upgrade to install a fix pack to IBM MobileFirst Platform Foundation, assuming the following topology: IBM MobileFirst Platform Foundation is installed in one cluster in IBM WebSphere Application Server, and the HTTP traffic is routed by an IBM HTTP Server and web server plug-ins for IBM WebSphere Application Server.

About this task

The following topics present the steps of the rolling upgrade procedure, in the order in which they must be completed.

Note: The cluster in which your current installation of the product is installed is called **cluster_WL61** in the following topics.

Stopping management operations

Managements operations must not be performed during a rolling upgrade.

Procedure

You must ensure that all management operations, such as uploading a new application or a new adapter, are stopped while you perform the rolling upgrade procedure.

Notify users with the privilege `worklightadmin` or `worklightdeployer` that they cannot deploy any artifact until the upgrade procedure is complete.

Installing the IBM MobileFirst Platform Foundation fix pack in a new cluster

You must create a new cluster, in which you install the IBM MobileFirst Platform Foundation fix pack. Here, the procedure targets an installation in a WebSphere Application Server Network Deployment environment, in a single cell, with IBM HTTP Server and web server plug-ins for IBM WebSphere Application Server.

Procedure

1. Create a cluster in IBM WebSphere Application Server. In the rest of this document, this cluster is called **cluster_WL61FP1**.
2. Create servers in this cluster.
3. For each server, set a weight of 0.
4. Install the IBM MobileFirst Platform Foundation fix pack in this cluster. You can install this fix pack with the IBM MobileFirst Platform Foundation Ant tasks, or manually.
 - To install this fix pack with the IBM MobileFirst Platform Foundation Ant tasks, follow the steps 5 - 9 on page 7-87.
 - To install this fix pack manually, follow the steps 10 on page 7-87 - 14 on page 7-88.

Installing the fix pack with the IBM MobileFirst Platform Foundation Ant tasks:

5. With IBM Installation Manager, install the IBM MobileFirst Platform Foundation fix pack on the computer where the WebSphere Application Server Deployment Manager is installed.

Note: Do not install the Application Center.

6. Verify that WebSphere Application Server is not set to automatically generate and propagate the web plug-in. To be sure that the installation of the product fix-pack does not generate and propagate a new web plug-in that you did not review, perform the following steps.
 - a. Open the WebSphere Application Server administration console.
 - b. Go to **Servers > Server Types > Web Servers**.
 - c. In the table, click the web server.
 - d. Under **Additional Properties**, click **Plug-in properties**.

- e. Make sure that the check box for **Automatically generate the plug-in configuration file** is not selected.
 - f. Make sure that the check box for **Automatically propagate plug-in configuration file** is not selected.
7. Copy the Ant file that you used to install IBM MobileFirst Platform Foundation in the cluster **cluster_WL61**.
- a. Modify the cluster name, for example `${was.nd.cluster.name}` in the code example in step 8.
 - b. Modify the environment ID.
You use this environment ID to distinguish the Administration Services and MobileFirst runtime environment from the two clusters. The new ID also generates different application names to avoid name conflicts in the WebSphere Application Server cell.
 - c. You must make these modifications for the following Ant tasks. Use the same environment ID in all the tasks.
 - `configureapplicationserver`
 - `updateapplicationserver`
 - `unconfigureapplicationserver`
 - `installworklightadmin`
 - `updateworklightadmin`
 - `uninstallworklightadmin`

Important: The environment ID determines which instance of Administration Services manages the deployed runtime environments. All runtime environments must have the same environment ID as the MobileFirst Server administration components.

8. Run the `admininstall` target of the Ant file.
9. Run the `install` target of the Ant file that installs the MobileFirst runtime environment. If you have more than one MobileFirst runtime environment, repeat this operation for all of them:

Note: Do not change the database settings, the context roots, or the other parameters of the installation.

```
<!-- Start of the install target Generated by IBM MobileFirst Platform Foundation -->
<target name="install">
  <configureapplicationserver environmentId="${worklight.environment.id}" contextroot="${wo
  <project warfile="${worklight.project.war.file}"/>
  <applicationserver>
    <websphereapplicationserver installldir="${appserver.was.installldir}"
                                profile="${appserver.was.profile}"
                                user="${appserver.was.admin.name}"
                                password="${appserver.was.admin.password}">
      <cluster name="${appserver.was.nd.cluster}"/>
    </websphereapplicationserver>
  </applicationserver>
</target>
```

Installing the fix pack manually:

10. Install the data sources that point to the administration and MobileFirst runtime databases in the cluster.
 - For instructions about the administration database, see the following documentation:
 - “Configuring WebSphere Application Server for DB2 manually for MobileFirst Server administration” on page 6-78

- “Configuring WebSphere Application Server for Oracle manually for the MobileFirst Server administration” on page 6-89
 - For instructions about the runtime database, see the following documentation:
 - “Configuring WebSphere Application Server for DB2 manually” on page 12-23
 - “Configuring WebSphere Application Server for Oracle manually” on page 12-34
11. Select a name for an environment ID that is used for all the web applications that you installed in step 12.
For example, FP1.

Note: You must not have any other installation of IBM MobileFirst Platform Foundation in the WebSphere Application Server cell that is using the same environment ID.
 12. Install the Administration Services as documented in “Configuring WebSphere Application Server for MobileFirst Server administration manually” on page 6-95, with the following change:
In **Environment entries for Web modules** for the Administration Services, set the value of **ibm.worklight.admin.environmentid** to the environment ID that you selected in step 11.
 13. Install the MobileFirst runtime environment as documented in “Configuring WebSphere Application Server for MobileFirst Server administration manually” on page 6-95, with the following change:
In **Environment entries for Web modules** for the MobileFirst runtime environment, set the value of **ibm.worklight.admin.environmentid** to the environment ID that you selected in step 11.
 14. Use a different name for the WebSphere applications than the one that you used in the first cluster.

Completing the configuration of the new installation of IBM MobileFirst Platform Foundation

You must complete the configuration of the new installation of IBM MobileFirst Platform Foundation with security settings, update of the JNDI properties, and other configuration settings.

About this task

This configuration includes the following parameters for the Administration Services application, and for the MobileFirst Operations Console application. For more information, see “Configuring MobileFirst Server” on page 6-147.

Procedure

1. Configure the security settings that define the users for each of the following roles: `worklightadmin`, `worklightdeployer`, `worklightmonitor`, `worklightoperator`.
2. Update the JNDI properties that you modified during the installation in the **WL61FP1** cluster:
 - For the Administration Services and the MobileFirst Operations Console.
 - For each MobileFirst runtime environment.

Verifying the new installation of IBM MobileFirst Platform Foundation

You must make sure that IBM MobileFirst Platform Foundation is installed properly.

Procedure

1. Start all the servers in the **Worklight61FP1** cluster. This action starts all the MobileFirst runtime environments. They synchronize with the Administration Services, and download the application and adapter artifacts they need to be ready to serve requests.
2. Log to the MobileFirst Operations Console. At this stage, IBM HTTP Server must not route traffic to that installation, so you must connect directly to the host name and port of a server. If the MobileFirst Operations Console is installed with the default context root, which is `worklightconsole`, the URL looks like the following example: `http://<hostname>:<httpPortOfServer>:/worklightconsole/`
3. Verify that the MobileFirst runtime environments are present and that they do not report any error.
4. Optional: You might also perform an additional smoke test of the adapters that are specific to your IBM MobileFirst Platform Foundation installation.

Switching progressively the HTTP traffic to the new cluster, with session affinity

You must modify the HTTP plug-in file to route the HTTP traffic to the new installation of IBM MobileFirst Platform Foundation

Before you begin

The following procedure requires modifications of the HTTP plug-in file, `plugin-cfg.xml`. Before you perform this procedure in production, you must test it in a test environment.

Important: If errors occur during these steps, it would result in incorrect traffic routing and might impact all applications in the cell of the WebSphere Application Server.

About this task

The procedure to route the traffic is based on the following properties of the web plug-in:

- The plug-in routes traffic to a server cluster that is based on the definition of the cluster members in its `<ServerCluster>` listing. The HTTP plug-in has no other information about the target servers other than what is defined in the plug-in configuration file. Even if a collection of servers is defined in a WebSphere cell as being in two separate clusters, they can be defined in one cluster from the point of view of the plug-in. With this property, you can use the plug-in to route traffic between the clusters `cluster_WL61` and `cluster_WL61FP1`.
- The `LoadBalanceWeight` attribute of the Server element is used to statically assign a weighting factor that is associated with the round-robin distribution of new requests among the servers that are in a cluster. When this attribute is set to zero, this is a signal to the plug-in to stop sending new requests to that application server. Requests that are associated with existing sessions on that server continue to flow to it, but as those sessions get terminated, the server stops having any active sessions.

- The plugin-cfg.xml file is re-read periodically by the plug-in to the HTTP server, with a default refresh interval of 1 minute.

For more information about updating the plugin-cfg.xml file, see “Setting up IBM MobileFirst Platform Foundation in WebSphere Application Server cluster environment” on page 6-328.

Procedure

1. Progressively, set the weight of a server in the **cluster_WL61** to 0.
2. Move a server of the cluster **cluster_WL61FP1** to the definition of **cluster_WL61**, with a weight of 2.
3. Wait for the server in cluster **cluster_WL61** to drain so that most of the session terminates and that it stops using CPU resources.
4. Repeat the procedure for the next server.

Example

Before you start the procedure:

```
<ServerCluster LoadBalance="Round Robin" Name="cluster_WL61">
  <Server CloneID="a8er1kj2" LoadBalanceWeight="2" Name="ServerWL61_1">
    <Transport Hostname="test1.ibm.com" Port="9081" Protocol="http"/>
  </Server>
  <Server CloneID="a8er2kd3" LoadBalanceWeight="2" Name="ServerWL61_2">
    <Transport Hostname="test2.ibm.com" Port="9082" Protocol="http"/>
  </Server>
  <Server CloneID="a8es3as1" LoadBalanceWeight="2" Name="ServerWL61_3">
    <Transport Hostname="test3.ibm.com" Port="9083" Protocol="http"/>
  </Server>
  <PrimaryServers>
    <Server Name="ServerWL61_1"/>
    <Server Name="ServerWL61_2"/>
    <Server Name="ServerWL61_3"/>
  </PrimaryServers>
</ServerCluster>
[...]
```

```
<ServerCluster LoadBalance="Round Robin" Name="cluster_WL61FP1">
  <Server CloneID="a8sd1kj2" LoadBalanceWeight="0" Name="ServerWL61FP1_1">
    <Transport Hostname="test1.ibm.com" Port="9084" Protocol="http"/>
  </Server>
  <Server CloneID="a8as2kd3" LoadBalanceWeight="0" Name="ServerWL61FP1_2">
    <Transport Hostname="test2.ibm.com" Port="9085" Protocol="http"/>
  </Server>
  <Server CloneID="a8qa3as1" LoadBalanceWeight="0" Name="ServerWL61FP1_3">
    <Transport Hostname="test3.ibm.com" Port="9086" Protocol="http"/>
  </Server>
  <PrimaryServers>
    <Server Name="ServerWL61FP1_1"/>
    <Server Name="ServerWL61FP1_2"/>
    <Server Name="ServerWL61FP1_3"/>
  </PrimaryServers>
</ServerCluster>
[...]
```

```
<!-- Example of the UriGroups and Routes. They are not changed while you switch the traffic -->
<UriGroup Name="prod_vhost_cluster_WL61_URIs">
  <Uri AffinityCookie="JSESSIONID"
    AffinityURLIdentifier="jsessionid" Name="/worklightconsole/*"/>
  <Uri AffinityCookie="JSESSIONID"
    AffinityURLIdentifier="jsessionid" Name="/worklightadmin/*"/>
  <Uri AffinityCookie="JSESSIONID"
    AffinityURLIdentifier="jsessionid" Name="/worklight/*"/>
</UriGroup>
<Route ServerCluster="ClusterX"
```

```

    UriGroup="prod_vhost_cluster_WL61_URIs" VirtualHostGroup="default_host"/>
<UriGroup Name="test_vhost_cluster_WL61FP1_URIs">
  <Uri AffinityCookie="JSESSIONID"
    AffinityURLIdentifier="jsessionid" Name="/worklightconsole/*"/>
  <Uri AffinityCookie="JSESSIONID"
    AffinityURLIdentifier="jsessionid" Name="/worklightadmin/*"/>
  <Uri AffinityCookie="JSESSIONID"
    AffinityURLIdentifier="jsessionid" Name="/worklight/*"/>
</UriGroup>
<Route ServerCluster="ClusterY" UriGroup="test_vhost_cluster_WL61FP1_URIs"
  VirtualHostGroup="test_host"/>

```

Moving a server:

```

<ServerCluster LoadBalance="Round Robin" Name="cluster_WL61">
  <!-- Server ServerWL61_1 has a weight of 0 -->
  <Server CloneID="a8er1kj2" LoadBalanceWeight="0" Name="ServerWL61_1">
    <Transport Hostname="test1.ibm.com" Port="9081" Protocol="http"/>
  </Server>
  <Server CloneID="a8er2kd3" LoadBalanceWeight="2" Name="ServerWL61_2">
    <Transport Hostname="test2.ibm.com" Port="9082" Protocol="http"/>
  </Server>
  <Server CloneID="a8es3as1" LoadBalanceWeight="2" Name="ServerWL61_3">
    <Transport Hostname="test3.ibm.com" Port="9083" Protocol="http"/>
  <!-- Server ServerWL61F1_1 added to the cluster_WL61 in the plugin-cfg file -->
  <Server CloneID="a8sd1kj2" LoadBalanceWeight="2" Name="ServerWL61FP1_1">
    <Transport Hostname="test1.ibm.com" Port="9084" Protocol="http"/>
  </Server>
  <PrimaryServers>
    <Server Name="ServerWL61_1"/>
    <Server Name="ServerWL61_2"/>
    <Server Name="ServerWL61_3"/>
    <Server Name="ServerWL61FP1_1"/>
  </PrimaryServers>
</ServerCluster>
[...]
<ServerCluster LoadBalance="Round Robin" Name="cluster_WL61FP1">
  <Server CloneID="a8as2kd3" LoadBalanceWeight="0" Name="ServerWL61FP1_2">
    <Transport Hostname="test2.ibm.com" Port="9085" Protocol="http"/>
  </Server>
  <Server CloneID="a8qa3as1" LoadBalanceWeight="0" Name="ServerWL61FP1_3">
    <Transport Hostname="test3.ibm.com" Port="9086" Protocol="http"/>
  </Server>
  <PrimaryServers>
    <Server Name="ServerWL61FP1_2"/>
    <Server Name="ServerWL61FP1_3"/>
  </PrimaryServers>
</ServerCluster>

```

End of the transition:

```

<ServerCluster LoadBalance="Round Robin" Name="cluster_WL61">
  <!-- Server ServerWL61_X have a weight of 0 -->
  <Server CloneID="a8er1kj2" LoadBalanceWeight="0" Name="ServerWL61_1">
    <Transport Hostname="test1.ibm.com" Port="9081" Protocol="http"/>
  </Server>
  <Server CloneID="a8er2kd3" LoadBalanceWeight="0" Name="ServerWL61_2">
    <Transport Hostname="test2.ibm.com" Port="9082" Protocol="http"/>
  </Server>
  <Server CloneID="a8es3as1" LoadBalanceWeight="0" Name="ServerWL61_3">
    <Transport Hostname="test3.ibm.com" Port="9083" Protocol="http"/>
  <!-- Server ServerWL61F1_X added to the cluster_WL61 in the plugin-cfg file -->
  <Server CloneID="a8sd1kj2" LoadBalanceWeight="2" Name="ServerWL61FP1_1">
    <Transport Hostname="test1.ibm.com" Port="9084" Protocol="http"/>
  </Server>
  <Server CloneID="a8as2kd3" LoadBalanceWeight="2" Name="ServerWL61FP1_2">
    <Transport Hostname="test2.ibm.com" Port="9085" Protocol="http"/>
  </Server>

```

```

</Server>
</Server>
<Server CloneID="a8qa3as1" LoadBalanceWeight="2" Name="ServerWL61FP1_3">
  <Transport Hostname="test3.ibm.com" Port="9086" Protocol="http"/>
</Server>
<PrimaryServers>
  <Server Name="ServerWL61_1"/>
  <Server Name="ServerWL61_2"/>
  <Server Name="ServerWL61_3"/>
  <Server Name="ServerWL61FP1_1"/>
  <Server Name="ServerWL61FP1_2"/>
  <Server Name="ServerWL61FP1_3"/>
</PrimaryServers>
</ServerCluster>
[...]
<ServerCluster LoadBalance="Round Robin" Name="cluster_WL61FP1">
  <PrimaryServers>
  </PrimaryServers>
</ServerCluster>

```

Performing a rollback procedure

You might want to perform a rollback procedure to restore your initial configuration if a problem occurs.

Procedure

If a problem is detected while you are switching the traffic, you must restore the `plugin-cfg.xml` to its initial state so that the HTTP traffic is routed again to the initial installation of IBM MobileFirst Platform Foundation.

Uninstalling IBM MobileFirst Platform Foundation from the old cluster

You must uninstall IBM MobileFirst Platform Foundation from the cluster that it was previously installed in, and update the appropriate settings accordingly.

Procedure

1. When the migration is complete and the sessions are stopped, shutdown the `cluster_WL61` cluster.
2. You can allow management operations to start again and notify users with privilege `worklightadmin` or `worklightdeployer` that they are allowed to deploy MobileFirst artifacts because the upgrade procedure is complete.
3. Uninstall IBM MobileFirst Platform Foundation from the cluster `cluster_WL61`.
4. Update the `plugin-cfg.xml` so that it no longer references the old cluster `cluster_WL61`.
5. Verify that the HTTP traffic is routed correctly to the new cluster. For example, you can activate the log file of the web plug-in, and review the log.

Upgrading, or applying a fix pack to the MobileFirst Data Proxy

Follow these steps to upgrade the MobileFirst Data Proxy and the Trust Association Interceptor (TAI).

Before you begin

You must run IBM Installation Manager to upgrade the installation directory of IBM MobileFirst Platform Foundation. For more information, see “Running IBM Installation Manager and completing the Application Center upgrade” on page 7-48.

The following procedure installs the upgraded versions of the MobileFirst Data Proxy WAR file and the TAI (Trust Association Interceptor) on your disk.

Note: If you installed Application Center, you might want to upgrade or apply a fix pack only to the MobileFirst Data Proxy, and not to the Application Center. To do this, you can run IBM Installation Manager to install IBM MobileFirst Platform Foundation in a different location, without installing Application Center:

- For a graphic installation, in the window **Configuration Choice**, select **No** to the question **Install the IBM MobileFirst Platform Application Center**.
- For a command-line installation, use the silent installation file that is named `install-no-appcenter.xml`, which is described in “Working with sample response files for IBM Installation Manager” on page 6-46.

About this task

If you installed the MobileFirst Data Proxy with Ant tasks, follow the steps 1 to 6.

If you installed the MobileFirst Data Proxy manually, follow the steps 7 to 11.

Procedure

For an installation with Ant tasks:

1. Locate the Ant file that you used to perform the installation.
2. Verify that the **taskdef** for the `worklight-ant-deployer.jar` uses the correct directory, which contains the upgraded installation of MobileFirst Server V7.1.0.

Review the following example. You must check the value of the property `worklight.server.install.dir`, because this property is used to define the directory of the `worklight-ant-deployer.jar` file in the **taskdef** tag:

```
<taskdef resource="com/worklight/ant/defaults.properties">
  <classpath>
    <fileset dir="${worklight.server.install.dir}/WorklightServer">
      <include name="worklight-ant-deployer.jar"/>
    </fileset>
  </classpath>
</taskdef>
```

Important: This verification step must not be overlooked because it defines the version of IBM MobileFirst Platform Foundation that you use to deploy the WAR file and update the TAI.

3. Stop your application server.
4. Run the following command:

```
product_install_dir/shortcuts/ant -f <your file> minimal-update
```

This command has the following effects:

- It updates the WAR file of the MobileFirst Data Proxy web app.
 - On WebSphere Application Server Liberty profile, and WebSphere Application Server stand-alone server, it updates the TAI.
5. On WebSphere Application Server Network Deployment, replace the TAI JAR file by the new JAR file, which is in `product_install_dir/WorklightServer/external-server-libraries`, on all nodes of your WebSphere Application Server cell.

For more information, see the instructions to install the MobileFirst Data Proxy manually.

6. Restart the application server.

For a manual installation:

7. Replace the MobileFirst Data Proxy WAR file in your application server.

You find the WAR file in *product_install_dir/Datastore/imf-data-proxy.war*.

8. Stop the application server.

9. Replace the TAI JAR file in your application server.

You find the JAR file in *product_install_dir/WorklightServer/external-server-libraries/com.ibm.worklight.oauth.tai_*.jar*.

10. On WebSphere Application Server Liberty profile, replace the TAI feature manifest in your application server.

You find the manifest in *product_install_dir/WorklightServer/external-server-libraries/OAuthTai-1.0.mf*.

11. Restart the application server.

Applying a fix pack to IBM MobileFirst Platform Operational Analytics

Learn how to use Ant tasks to upgrade MobileFirst Operational Analytics V7.1.0 to a fix pack or interim fix, if you installed this component with Ant tasks.

Before you begin

On WebSphere Application Server, applying a fix pack creates a significant peak of memory usage in the heap. If WebSphere Application Server has insufficient memory heap, this might cause OutOfMemory issues, and seriously impact the performance of the application server. Before you perform the following procedure, verify that your server on WebSphere Application Server has the memory settings that are described at “Setting up a production cluster” on page 14-90.

About this task

Use this procedure if you installed MobileFirst Operational Analytics with Ant tasks, as documented in “Installing MobileFirst Operational Analytics with Ant tasks” on page 6-216.

If you installed MobileFirst Operational Analytics manually, you must perform a manual update of the WAR file, or EAR file. For more information, see “Installing the IBM MobileFirst Platform Operational Analytics” on page 6-216.

Procedure

For an upgrade from MobileFirst Server V7.1.0 to a fix pack or an interim fix

1. Find the Ant file that you created in “Sample configuration files for MobileFirst Operational Analytics” on page 16-82..
2. Make sure that the taskdef for the *worklight-ant-deployer.jar* file uses the correct directory. The correct directory is the directory that contains the upgraded installation of MobileFirst Server V7.1.0.
3. Run the *minimal-update* target of the Ant file on the system where you installed MobileFirst Operational Analytics:

```
product_install_dir/shortcuts/ant -f your_file minimal-update
```
4. Restart the server.

What to do next

If you installed more than one MobileFirst Operational Analytics servers that are connected to your MobileFirst runtime environment, then you must repeat this procedure on each server where MobileFirst Operational Analytics is installed.

Applying a fix pack to Application Center installed with Ant tasks

If you installed Application Center with Ant tasks, learn how to use Ant tasks to upgrade Application Center V7.1.0 to a fix pack or interim fix.

Before you begin

You must run IBM Installation Manager to upgrade the installation directory of IBM MobileFirst Platform Foundation, without installing Application Center.

During the installation process with IBM Installation Manager, in the window **Configuration Choice**, select **No** to the question *Install the IBM MobileFirst Platform Application Center*.

For more information, see “Running IBM Installation Manager and completing the Application Center upgrade” on page 7-48.

With the following procedure, you install the upgraded versions of the Application Center Console and Services web applications on your disk.

About this task

Use this procedure if you installed Application Center with Ant tasks, as documented in “Installing the Application Center with Ant tasks” on page 6-241.

If you installed Application Center manually, you must perform a manual update of the WAR file, or EAR file. For more information, see “Manually installing Application Center” on page 6-243.

Procedure

For an upgrade from Application Center V7.1.0 to a fix pack or an interim fix:

1. Find the Ant file that you created in “Deploying the Application Center console and services with Ant tasks” on page 6-242.
2. Run the **minimal-update** target of the Ant file, on the system where you installed Application Center:

```
product_install_dir/shortcuts/ant -f your_file minimal-update
```
3. Restart the server.

Developing MobileFirst applications

You use either MobileFirst Platform Command Line Interface or MobileFirst Studio, and the MobileFirst client- and server-side APIs to develop cross-platform mobile applications, desktop applications, or web applications.

This information is designed to help users develop applications for various channels by using IBM MobileFirst Platform Foundation. It is intended for developers who are familiar with web, or native application development.

This section covers client-side development and server-side development topics, such as the integration with back-end services, and push notifications.

Development framework features

IBM MobileFirst Platform Foundation provides a framework that enables the development, optimization, integration, and management of secure apps. This framework provides the following features:

- Guidelines and design patterns that promote compatibility across multiple consumer environments.
- Automatic packaging and provisioning of application resources to multiple consumer environments.
- A flexible UI optimization and globalization scheme.
- Tools that provide uniform access to back-end enterprise data, processes, and transactions.
- Uniform persistence.
- A uniform personalization model.
- A flexible authentication model and automatic application protection from web attacks.

IBM MobileFirst Platform Foundation does not introduce a proprietary programming language or model that users must learn. You can develop apps by using HTML5, CSS3, and JavaScript. You can optionally write native code (Java, Objective-C, or C#), and IBM MobileFirst Platform Foundation provides an SDK that includes libraries that you can access from native code.

Seamlessly mix web and native components in your application

You can mix web and native components in your application, allowing you to build a hybrid application with any composition of web and native capabilities. The following features support this flexibility in hybrid app development.

- The architecture of hybrid applications (iOS and Android) allows you to easily use native code when the application starts. You can add code at the beginning of the application lifecycle, before the MobileFirst framework is initialized, and have full control over when to initialize the MobileFirst framework, including being able to initialize it in the background. This flexibility allows you, for example, to add a custom splash screen or to control the default splash screen behavior, and to start an application with a native screen.

- You can navigate seamlessly between the native and web parts of your application without having to reauthenticate, and you can invoke both native and JavaScript WLClient APIs in any order. For example, the following scenarios are possible:
 - Start the application in a web view page, connect to the MobileFirst Server, and then login to access protected resources. You can then switch to a native view and access the same protected resources without the need to reauthenticate.
 - Start the application in a native page, connect to the MobileFirst Server, and then login to access protected resources. You can then switch to a web view and access the same protected resources without the need to reauthenticate.
- The MobileFirst API allows you to easily send actions (events) and data between the native and web modules of your app. This makes it easier to build applications that mix hybrid and web components, for example:
 - You have an application with a JavaScript communication module and a native presentation layer. You can use the MobileFirst API to easily send the data acquired by the communication module to the native layer, so that you can present it to the user in a native screen.
 - You can easily trigger complex native actions using JavaScript, without implementing a Cordova plugin. You can also call JavaScript code from native code.
 - You can easily show native and web components on the same screen, using the MobileFirst API for communication.

MobileFirst projects, environments, and skins

Develop mobile applications within projects, build your applications, and create skins for specific devices.

MobileFirst projects

To develop your mobile applications, you must first create a project.

You can develop one or several mobile applications, which you can build for different environments.

In your project, when you create an application, you have a main application folder, in which you can find several subfolders and files:

- A common folder, for you to store the code that is shared between all environments, such as HTML, CSS, or JavaScript code.
- One folder for each environment that is supported by the application, and where you store the code that is specific to this environment, such as Java code for Android or Objective-C code for iOS.
- A legal folder, for you to store all the license-related documents.
- An application-descriptor.xml file that contains the application metadata. For more information about this file, see “The application descriptor” on page 8-50.
- A build-settings.xml file, for you to prepare minification and concatenation configurations for each environment. For more information about this file, see “MobileFirst application build settings” on page 8-369.

Within your project, you can create the graphical user interface of your mobile application by using the Rich Page Editor (deprecated). The Rich Page Editor is a WYSIWYG editor in MobileFirst Studio.

When the application is finished, you can test it with the Mobile Browser Simulator in MobileFirst Studio. However, you cannot test native code with MobileFirst Studio. To test native code, you must test it with a real device or with the development kit of the appropriate environment.

MobileFirst environments

You can build your mobile applications for different environments, such as:

- Mobile environments, which include iPhone, iPad, Android phones and tablets, BlackBerry 6 and 7 (deprecated. See Table 3-2 on page 3-21), BlackBerry 10, Windows Phone Silverlight 8, and Windows 8 Universal.
- Desktop environments, which include Adobe AIR.
- Web environments, which include Mobile web app and Desktop Browser web page.

There is a difference between the Mobile web app environment and the Desktop Browser web page environment.

- Mobile web apps are only used in a mobile device browser. Choose the Mobile web app environment when you want your users to surf to your application by using their mobile device.
- Desktop browser web pages are used only in a desktop web browser. With the Desktop Browser web page environment, you can develop an application that you then embed inside your website, but this application is not meant for use in a mobile device.
 - For example, since Facebook uses iframes as containers to its apps, you can use the Desktop Browser web page environment to create Facebook apps by setting `https://host:port/apps/services/www/application_name/desktopbrowser/` as the canvas URL in the Facebook dashboard.

If your web application is not based on IBM MobileFirst Platform Foundation, you must first port it to IBM MobileFirst Platform Foundation. If your web application is based on IBM MobileFirst Platform Foundation, you can add the Desktop Browser web page environment to your existing project.

MobileFirst skins

Different types of devices exist for a same environment. If you want to write a piece of code that is specific to a certain device, you must create a skin. Skins are subvariants of an environment and they provide support for multiple form factors in a single executable file for devices of the same OS family. Skins are packaged together in one app. At run time, only the skin that corresponds to the target device is applied.

Note: Cordova applications do not support application skins.

MobileFirst Studio overview

IBM MobileFirst Platform Studio is an Eclipse-based integrated development environment (IDE). You can use MobileFirst Studio to create mobile applications for various mobile operating systems, and to integrate applications with existing services.

With MobileFirst Studio, you can add custom plug-ins to Eclipse. For instance, you can use a Rational Team Concert plug-in to control your source code, track changes, and create daily builds without installing an extra development

application. You can also build server applications, and applications for different mobile device operating systems, from a single IDE.

Note: If you use non-Latin characters in your application, you must make sure that your Eclipse editor uses UTF-8 encoding. To set the Eclipse text file encoding to UTF-8:

1. In MobileFirst Studio, go to **Window > Preferences > General > Workspace**.
2. In **Text file encoding**, select **Other**, and select **UTF-8** from the list.

Native and web development technologies

MobileFirst Studio supports native and web development technologies such as HTML5, Apache Cordova, and Java. With these development technologies, you can use the following capabilities:

- Develop mobile applications with pure HTML5.
- Use a compatible JavaScript framework, such as jQuery Mobile, Dojo Mobile, or Sencha Touch. You can use the user interface widgets and functions that are provided by these frameworks.
- Use Apache Cordova so that your mobile application can access native device functionality. To access a special device module, such as one for near field communication (NFC), you can develop a native extension that you expose to JavaScript through an Apache Cordova plug-in, which is a small native-to-JavaScript wrapper.

Shell development

For hybrid mobile applications, MobileFirst Studio uses a default hybrid shell that provides you with capabilities to use web and native technologies. With shell development, you can use the following capabilities:

- Separate native-component implementation from web-based implementation, and split this work between different developers. For example, you can create a custom shell, and add third-party native libraries, implement custom security, or provide extended features that are specific to your company.
- Use shells to restrict or enforce specific corporate guidelines, such as design or security rules. For example, you can use a shell to add a default style to your mobile application, or to disable the camera of the device.

Runtime skinning

With MobileFirst Studio, you use a common environment as a basic development point and all environments can share base code. You can then create a version of this environment that is specific to a device, for example an iPad, by creating a variant of the base and implementing only the required changes. At run time, an extra function that is called runtime skinning makes your mobile application switch between different sets of customization.

Integration of device-specific SDKs

Each vendor of mobile devices supplies its own development environment as part of a software development kit (SDK). MobileFirst Studio generates a project for each supported SDK, such as Xcode for iOS development. Some vendors require that you use their SDK for specific tasks, such as building the binary application. The integration of device-specific SDKs within MobileFirst Studio links your MobileFirst Studio project with the native development environment (such as

Xcode). You can then switch between a native development environment and MobileFirst Studio. Any change in the native development environment is reflected to your MobileFirst Studio project, which reduces manual copying steps.

Third-party library integration

Depending on your programming approach, your mobile application can include several JavaScript frameworks, such as Sencha Touch, jQuery Mobile, or Dojo Mobile. This third-party library integration facilitates code reuse and reduces implementation times. If you have a shell project, several types of compatible native code or libraries can be included.

Integrated build engine

The build chain of MobileFirst Studio combines common implementation code, which is used on all target platforms, with platform-unique implementation code, which is used on a specific target platform. At build-time, the integrated build engine combines these implementations into a complete mobile application. You can then use a single, common implementation for as much of the mobile application function as possible, instead of a unique implementation for every supported platform.

Integrated development tools

You can extend the Eclipse IDE with custom plug-ins, and use MobileFirst Studio to develop all components of your application from within the same development environment. These components include the mobile application and the integration code, which is called MobileFirst adapters. With integrated development tools, you can develop and test these MobileFirst adapters within MobileFirst Studio.

Mobile Browser Simulator

MobileFirst Studio includes a Mobile Browser Simulator that you can use during the development cycle. You can use the Mobile Browser Simulator to test mobile web and hybrid applications that are displayed in a desktop browser. This Mobile Browser Simulator support cross-platform browser testing for mobile devices.

Many desktop browsers and mobile browsers use the WebKit engine as their underlying core technology, which provides a common platform for developing applications that support HTML5, CSS3, and JavaScript. If you use a desktop browser that is based on WebKit, such as Chrome or Safari, to host the Mobile Browser Simulator, you can validate the behavior of the application in the browser before you deploy it on the device. When you test your application on the device or mobile emulator, you can verify that the core WebKit engine provides the same consistent user experience that you verify when you test with the browser.

The Mobile Browser Simulator also provides default implementations of the various Apache Cordova APIs. You can then use these default implementations to test hybrid applications that leverage the device features, without having to run the applications on the actual device.

Ant tasks

MobileFirst Studio provides a set of Ant tasks that you can use to run a mobile application build for various platforms. For example, you can distribute build tasks to various build machines that run Apple OS X (for an Apple iOS binary file), or

Microsoft Windows (for a Microsoft Windows Phone 8 binary file). If you use this mechanism, you do not need to access multiple build machines to create several builds for specific mobile platforms.

Startup behavior

Every project has an associated WAR file. In MobileFirst Studio, you deploy the WAR file to MobileFirst Development Server during standard development activities. MobileFirst Studio remembers the last deployed project to the server. When MobileFirst Studio restarts, all deployed MobileFirst WAR applications are deleted from the server, except from the last one. The behavior is to avoid a Timeout error with the MobileFirst Development Server during server startup in case there are many WAR applications deployed.

Note: You can inhibit this behavior and make it work exactly like IBM Worklight V6.1 by using the following steps:

- Close MobileFirst Studio.
- Go to the following path: `<workspace_path>/metadata/.plugins/org.eclipse.core.runtime/.settings`
- Open `com.worklight.studio.plugin.prefs` file with a text editor.
- Add `com.worklight.studio.plugin.avoidServerCleanup=true`.
- Save the file and restart MobileFirst Studio.

Creating MobileFirst projects with MobileFirst Studio

You can use MobileFirst Studio to create a project.

About this task

With MobileFirst Studio, you create a project as a place where you develop your apps.

Note: You can also use the IBM MobileFirst Platform Command Line Interface **create** command to create projects. For more information see “**create**” on page 16-15.

When you create a project, you create a first app in it. This first app can be of the following types:

- *Hybrid application:* A hybrid application can target multiple environments. You can write it primarily in HTML5, CSS, and JavaScript. It can access device capabilities by using the MobileFirst JavaScript API. You can also extend it with native code.
- *Inner application:* An Inner application contains the HTML, CSS, and JavaScript parts that run within a Shell component. Before you can deploy this application, you must package it within a shell component to create a full hybrid application.
- *Native application:* A Native application targets a specific environment, and can use the MobileFirst API for integration, security, and application management.
- *Shared Templates:* A project based on existing templates that were created for sharing and reuse. You select those templates from your download folder.
- *Shell component:* A Shell component provides custom native capabilities and security features that an Inner application can use.

After you create a MobileFirst project, you can later add further apps to it.

Procedure

To create a project and a first app in it:

1. In Eclipse **Design** perspective, click **File > New > MobileFirst Project**.
2. In the **Name** field, enter a name for your new project.
3. From the list of project templates, select the template that applies to the first application in your project:

Table 8-1. List of project templates

Application type	Purpose
Hybrid Application	To create a project with an initial hybrid application
Inner Application	To create a project with an initial inner application and point to a built shell component
Native Application	To create a project with an initial native application
Shared Templates	To create a project that is based on an existing template. For more information, see “Creating MobileFirst projects from MobileFirst project templates” on page 8-416.
Shell Component	To create a project with an initial shell component application

4. Click **Next**, and in the field **Application name** or **Component name**, set the name of your application or component.
5. Set the properties of your application, as described in the following sections:
 - Hybrid application:
 - a. Optional: To add JavaScript libraries to your application, click **Configure JavaScript Libraries**, and select the check boxes that correspond to the layers that you need:

Table 8-2. JavaScript libraries.

Library	Effect
Add jQuery Mobile	To add jQuery Mobile support to the application. You must identify the directory where the required files for jQuery Mobile are located.
Add Dojo Toolkit	To add the Dojo facet and Dojo support to the application. When you build a mobile web application, Dojo is included to create the native application, such as an iPhone or Android application.
Add Sencha Touch (deprecated)	To add Sencha Touch support to the application. You must identify the directory where the required files for Sencha Touch are located.

Note: If you add jQuery Mobile to your application, and you use Windows Phone Silverlight 8, you must ensure that the following conditions are met:

- The **\$.mobile.allowCrossDomainPages** option is set to true (in jQuery Mobile).
- An absolute URL is used for file, for example `x-wmapp0:/www/default/app-pages/myPage.html`.

- b. Optional: Click **Environments** in the left pane, and select the environments that you want to add to your new application.

Note: You can also add new environments later by clicking **File > New > MobileFirst Environment**. For more information about how to add an environment to an existing app, see “Setting up a new MobileFirst environment for your application” on page 8-58.

- Inner application:
 - a. In the field **Shell archive name**, set the path of your Shell archive file. The path can be either absolute or relative, if a Shell archive exists within your project.
 - b. Optional: To add JavaScript libraries to your application, click **Configure JavaScript Libraries**, and select the check boxes that correspond to the layers that you need: **jQuery Mobile**, **Dojo Toolkit**, **Sencha Touch** (see Table 8-2 on page 8-7).
 - Native API:
 - In the field **Environment**, select the environment that you need: **Android**, **iOS**, **Java ME**, **WindowsPhone8 - Silverlight**, **Windows8 - Universal**, or **WindowsPhone8 - Universal**.
 - Shared Templates:
 - Select one of the templates available from the list.
 - Shell component:
 - Select the check boxes that correspond to the layers that you need: **jQuery Mobile**, **Dojo Toolkit**, **Sencha Touch** (see Table 8-2 on page 8-7).
6. Click **Finish** to close the wizard.

Creating an application in a MobileFirst project with MobileFirst Studio

With MobileFirst Studio, you can create different types of applications within an existing project.

About this task

You create and develop an application in an existing MobileFirst Studio project.

Note: You can also use the IBM MobileFirst Platform Command Line Interface to create applications. For more information see “**add api**” on page 16-3.

Procedure

1. In Eclipse **Design** perspective, click **File > New**, and select the type of application that you want to create:
 - **MobileFirst Hybrid Application**
 - **MobileFirst Inner Application**
 - **MobileFirst Native API**
 - **MobileFirst Shell Component**A dialog opens, based on the type of application that you selected.
2. Depending on the selected type of application, set the properties of your application, as described in the following sections.
 - Hybrid application:
 - a. In the field **Project name**, select your existing project.

- b. In the field **Application name**, set the name of your application.
- c. Optional: To add JavaScript libraries to your application, click **Configure JavaScript Libraries**, and select the check boxes that correspond to the layers that you need: **jQuery Mobile**, **Dojo Toolkit**, **Sencha Touch (deprecated)**.

Note: If you add jQuery Mobile to your application, and you are using Windows Phone 8, you must ensure that the following conditions are met:

- The `$.mobile.allowCrossDomainPages` option is set to true (in jQuery Mobile).
 - An absolute URL is used for file, for example `x-wmapp0:/www/default/app-pages/myPage.html`.
- Inner application:
 - a. In the field **Project name**, select your existing project.
 - b. In the field **Application name**, set the name of your application.
 - c. In the field **Shell archive name**, set the path of your Shell archive file. The path can be either absolute or relative, if a Shell archive exists within your project.
 - d. Optional: To add JavaScript libraries to your application, click **Configure JavaScript Libraries**, and select the check boxes that correspond to the layers that you need: **jQuery Mobile**, **Dojo Toolkit**, **Sencha Touch (deprecated)**.
 - Native API:
 - a. In the field **Project name**, select your existing project.
 - b. In the field **Application name**, set the name of your application.
 - c. In the field **Environment**, select the environment that you need: **Android**, **iOS**, **Java ME**, **WindowsPhone8 - Silverlight**, **Windows8 - Universal**, or **WindowsPhone8 - Universal** .
 - Shell component:
 - a. In the field **Project name**, select your existing project.
 - b. In the field **Component name**, set the name of your component.
 - c. Select the check boxes that correspond to the layers that you need: **jQuery Mobile**, **Dojo Toolkit**, **Sencha Touch (deprecated)**.
3. Click **Finish** to save your choices.

Results

An application of the type that you selected is now visible in your MobileFirst project, and the application descriptor opens.

Creating the client side of a MobileFirst application with MobileFirst Studio

You can use MobileFirst Studio to create the client side of a MobileFirst application.

In MobileFirst Studio, you have two methods to create the client side of a MobileFirst application:

- Use an existing MobileFirst project, and create your application in it, as described in “Creating an application in a MobileFirst project with MobileFirst Studio” on page 8-8.

- Create a MobileFirst project, and your application in it as its first application, as described in “Creating MobileFirst projects with MobileFirst Studio” on page 8-6

You can build your MobileFirst application for specific mobile, desktop, and web environments that you can select in MobileFirst Studio.

- To learn about the available environments, see “MobileFirst environments” on page 8-3
- To learn how to set up environments for your MobileFirst application, see “Setting up a new MobileFirst environment for your application” on page 8-58

After you create your MobileFirst application, you can develop its code by using different APIs:

- “JavaScript client-side API for hybrid apps”
- “Objective-C client-side API for native iOS apps”
- “Objective-C client-side API for hybrid apps”
- “Objective-C client-side API for migrated Bluemix iOS apps” on page 8-11
- “Java client-side API for native Android apps” on page 8-11
- “Java client-side API for Java ME apps” on page 8-11
- “C# client-side API for Windows Phone Silverlight 8 apps” on page 8-11
- “C# client-side API for Windows 8 Universal apps” on page 8-11

You can also use your own custom libraries or third-party libraries when you create mobile applications in MobileFirst Studio.

For more information about how to develop your applications, see “Developing hybrid and web apps” on page 8-39 and “Developing native applications ” on page 8-182.

JavaScript client-side API for hybrid apps

With the JavaScript client-side API, you can develop hybrid applications that target all environments. You can use the capabilities of the MobileFirst runtime client API for mobile applications, desktop, and web to develop your applications.

For more information, see “JavaScript client-side API” on page 11-2.

Objective-C client-side API for native iOS apps

IBM MobileFirst Platform Foundation provides the MobileFirst Objective-C client-side API that you can use to develop native iOS applications.

For more information, see “Objective-C client-side API for iOS apps” on page 11-5.

Objective-C client-side API for hybrid apps

IBM MobileFirst Platform Foundation provides the MobileFirst Objective-C client-side API that you can use to develop hybrid applications.

For more information, see “Objective-C client-side API for hybrid apps” on page 11-6.

Objective-C client-side API for migrated Bluemix iOS apps

IBM MobileFirst Platform Foundation provides the MobileFirst Objective-C client-side API that you can use for translating the code that is in your original Bluemix application to code that is recognized by MobileFirst. For more information, see “Objective-C client-side API for migrated Bluemix iOS apps” on page 11-6.

Java client-side API for native Android apps

IBM MobileFirst Platform Foundation provides the MobileFirst Java client-side API that you can use to develop native Android applications.

For more information, see “Java client-side API for Android apps” on page 11-6.

Java client-side API for Java ME apps

IBM MobileFirst Platform Foundation provides the MobileFirst Java client-side API that you can use to develop native Java ME applications.

For more information, see “Java client-side API for Java Platform, Micro Edition (Java ME) apps” on page 11-6.

C# client-side API for Windows Phone Silverlight 8 apps

IBM MobileFirst Platform Foundation provides the MobileFirst C# client-side API that you can use to develop native Windows Phone Silverlight 8 applications.

For more information, see “C# client-side API for Windows Phone Silverlight 8 apps” on page 11-6.

C# client-side API for Windows 8 Universal apps

IBM MobileFirst Platform Foundation provides the MobileFirst C# client-side API that you can use to develop native Windows 8 Universal applications.

For more information, see “C# client-side API for Windows 8 Universal and Windows Phone 8 Universal apps” on page 11-7.

Features of MobileFirst Studio

MobileFirst Studio provides the facilities to automatically complete attribute values, validate adapters on three levels, and to fix errors in adapter configuration.

Auto-complete

The auto-complete feature offers a list of possible values for attribute values. In the following example, the JavaScript Editor displays a list of values for the possible field types of a record field. In this way, the auto-complete feature helps correct configuration of an adapter.

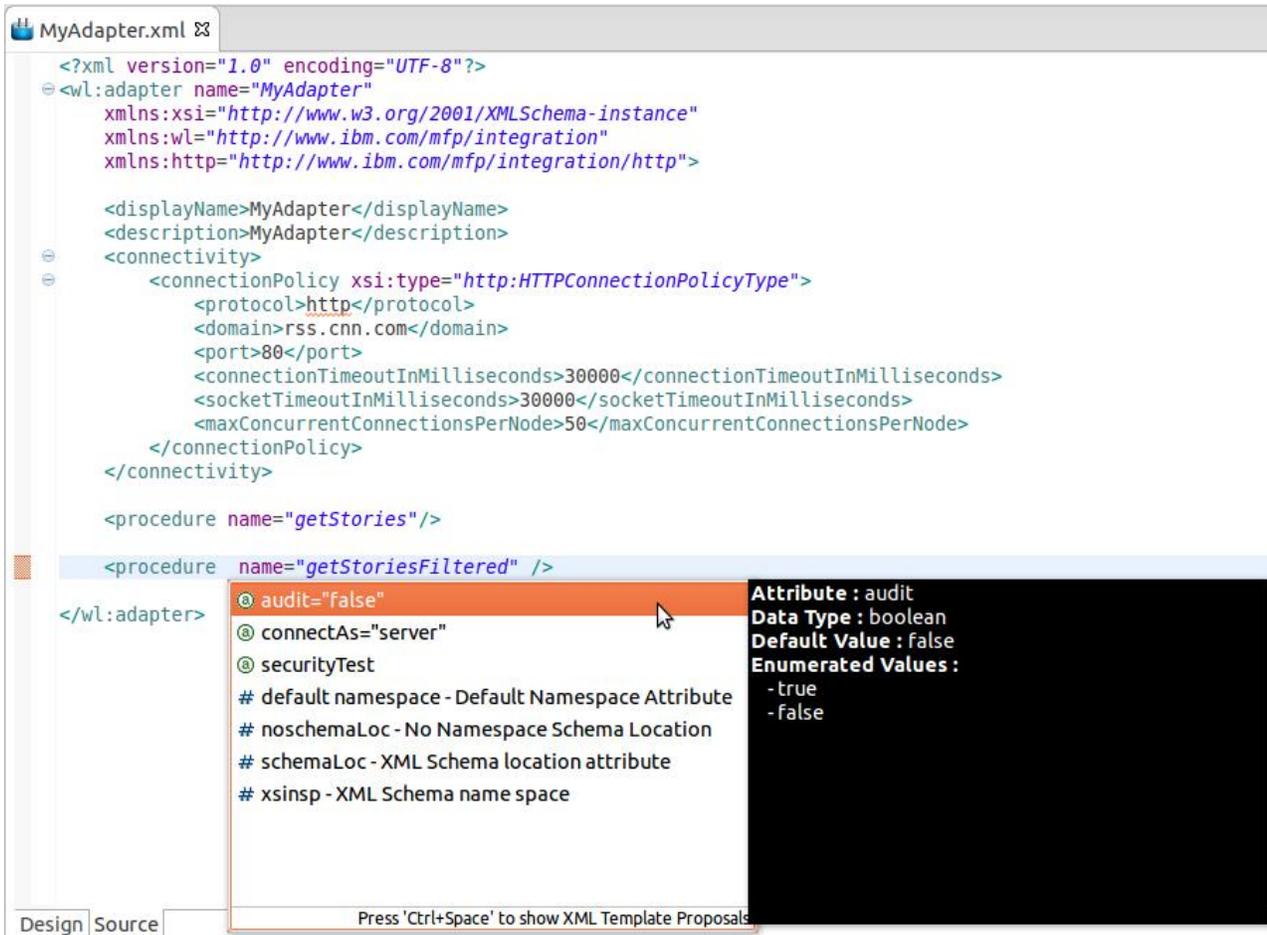

Figure 8-1. Adapter configuration through the auto-complete feature.

For example, in the screen capture, the left template lists Attribute: Audit, Data Type: boolean, Default Value: false, Enumerated Values: - true -false. The right template lists @audit=false @connectAs=server @requestTimeoutInSeconds=30 @requiresAuthentication=false followed by default namespace, noschemaLoc, schemaLoc, xsinsp with their attributes.

Adapter validation

MobileFirst Studio provides adapter validation on three levels:

Schema validation

The XML Editor validates the XML file as well-formed and conforming to the rules defined in the validating schema.

Logical validation of the XML

MobileFirst Studio provides logical validation of the XML, based on MobileFirst adapter constraints. For example, if a procedure is a JavaScript procedure, then field mapping is not permitted.

XML/JavaScript validation

MobileFirst Studio provides validation between XML and JavaScript. It verifies that each declared JavaScript procedure has a corresponding procedure in the adapter JavaScript file with the appropriate signature (that is, input parameters and return values).

Quick fix

The MobileFirst Studio provides Quick Fix options for adapter configuration errors.

Whenever an error is detected, the error console displays the offending code. To activate the Quick Fix window, right-click the error in the console and select **Quick Fix**. Alternatively, press Ctrl+1.

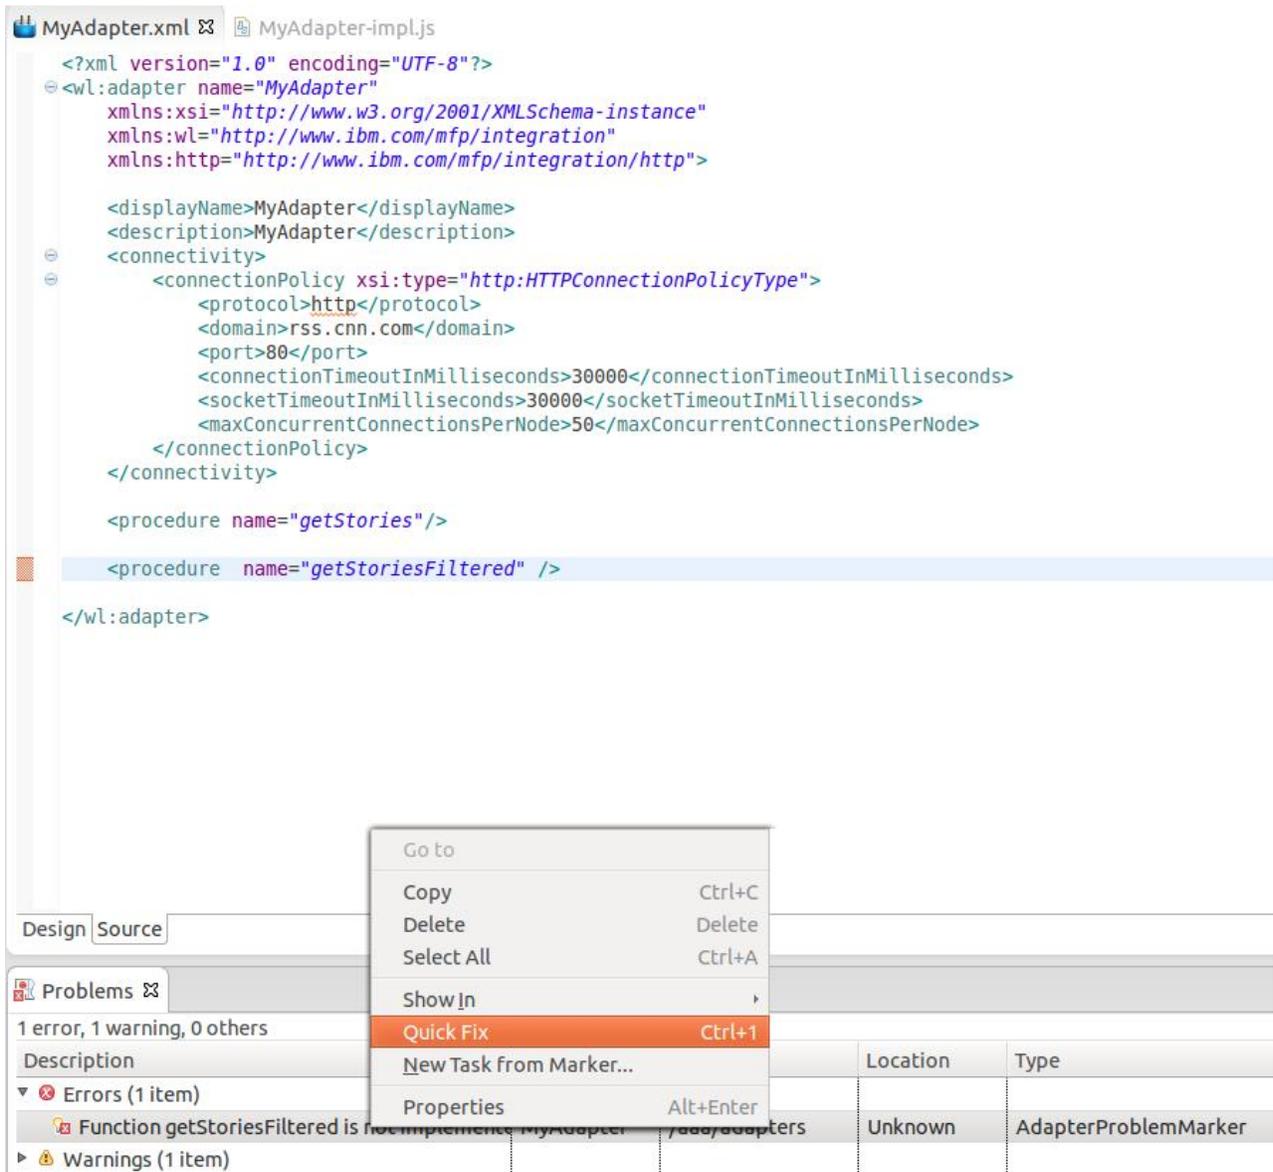

Figure 8-2. Quick Fix options for adapter configuration problems.

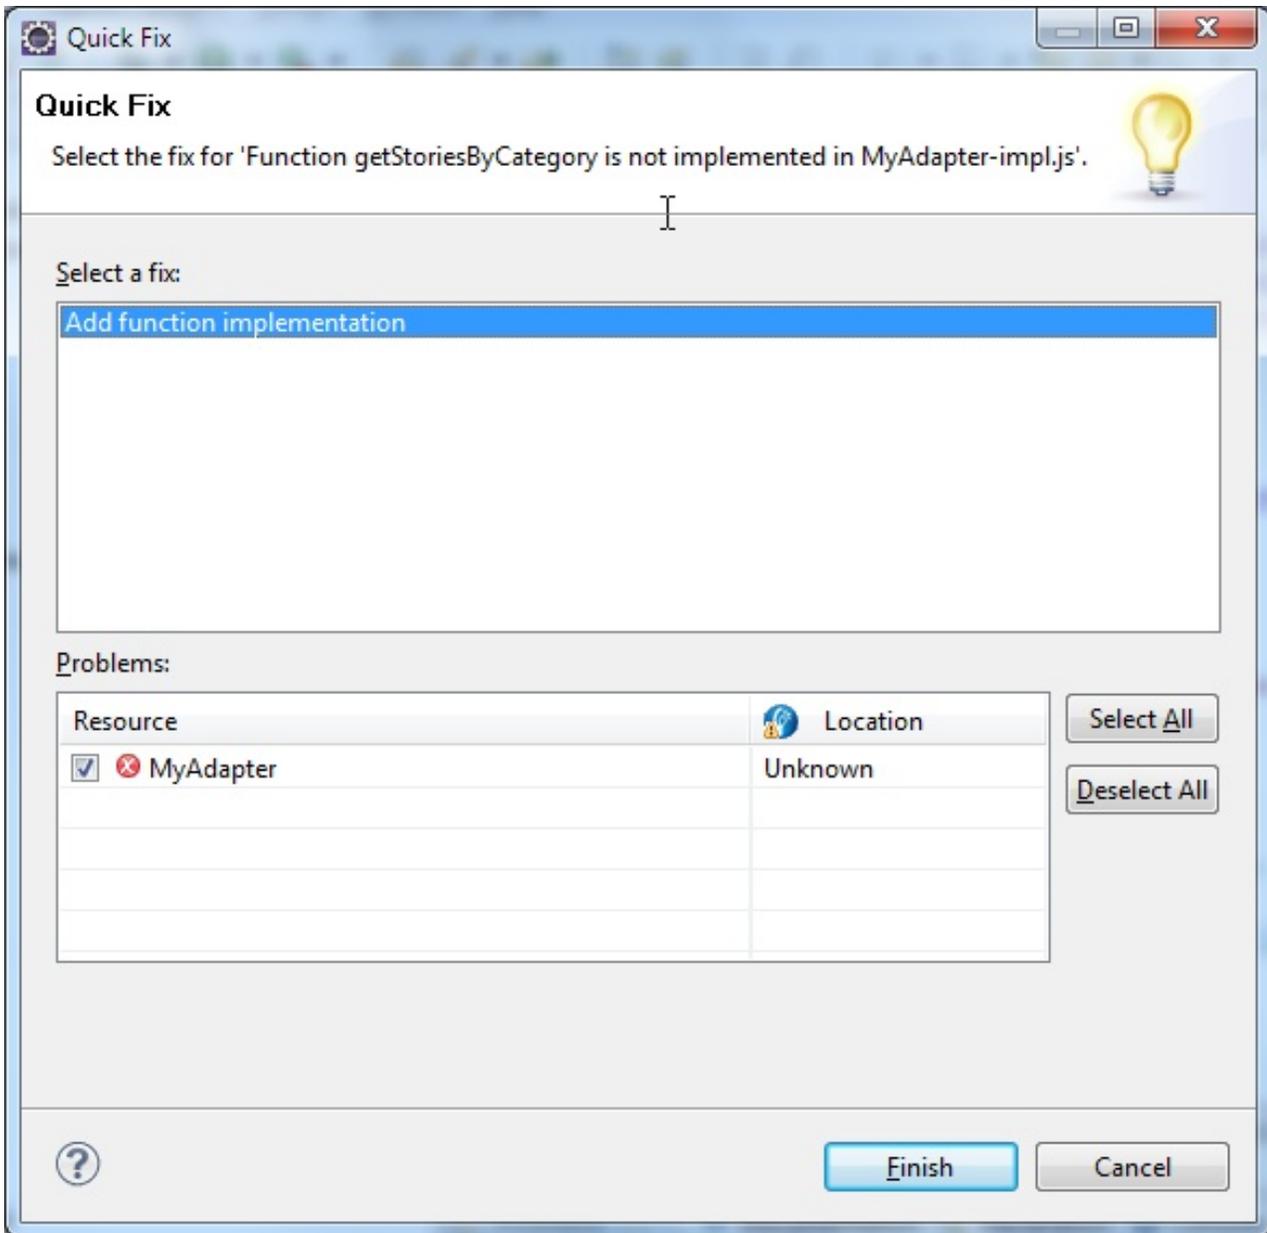

Figure 8-3. Quick Fix option for missing JavaScript functions.

Specifically, MobileFirst Studio provides a Quick Fix option for missing JavaScript functions. The Quick Fix creates the missing function in the corresponding JavaScript file (also creating the file if one does not exist).

```

- /*****
  * Implementation code for procedure - 'getStoriesByCategory'
  *
  *
  * @return - invocationResult
  */
- function getStoriesByCategory() {
  }

```

Building and deploying in MobileFirst Studio

After you create your IBM MobileFirst project, you must build the application and deploy it to MobileFirst Server to run and test it.

In “Developing hybrid and web apps” on page 8-39 and “Developing native applications ” on page 8-182, you learned the basics of creating and working with your projects in MobileFirst Studio. Here is an overview of the process for building these projects, deploying them to an instance of MobileFirst Server, and running them.

During development, to build and deploy your application, you right-click either your application or an environment in the Project Explorer view of MobileFirst Studio, select **Run As** from the menu, and then select one of its options.

- When you select the **Run As** action on an *environment*, it builds only *this* environment of the MobileFirst application. It transforms your JavaScript, HTML, and CSS code into a mobile application for the specified environment, such as iOS or Android. The build process produces several elements:
 - A native project for the target platform that is stored in the native folder of the environment.
 - A MobileFirst application file (.wlap) that contains the application metadata and web resources from which MobileFirst Server identifies and services the mobile application. This file is named *app_name-environment_name-version.wlap*.

For more information about the iOS, Android, BlackBerry, and Windows Phone development environments, see the Getting Started page of the Developer Center.

The generated native project depends on the target environment:

iPhone and iPad

The build process creates a native Xcode project, which is placed under the native folder of the environment. You can then use Xcode to build the final iOS application. If you are working in MobileFirst Studio on a Mac computer, you can also right-click the **iphone** or **ipad** environment and use the **Run As > Xcode project** option to build the environment and open Xcode for that project.

Android

The native folder under the android folder contains automatically generated Android application code that is imported into the Eclipse workspace as an Android project. You use the ADT plug-in (Android

Development Tools for Eclipse) to build the final Android application. If you are working in MobileFirst Studio on a computer with ADT installed, you can also right-click the android environment and use the **Run As > Android Studio project** option to open that project.

BlackBerry

The native folder contains BlackBerry code that you can compile by using the Ripple development environment.

Windows Phone

The native folder contains a Visual Studio project that you compile to build the final Windows Phone application.

- When you select the **Run As** action on an *application* in the Project Explorer view, it builds *all* environments of the MobileFirst application at once.

The resulting files are stored in the MobileFirst Studio project hierarchy in the *project_name*\bin directory, with the following naming conventions:

- *project_name.war* is the WAR file for the project.
- *app_name-environment_name-version.wlapp* is a WLAPP file for each environment in the project, for example: MyApp-ipad-1.0.wlapp.
- *app_name-common.wlapp* is a WLAPP file that contains all common resources for the project.
- *app_name-all.wlapp* is a WLAPP file that contains one or more environments for the project. This is a ZIP file that contains the WLAPP files that were generated most recently.

Note: Only the latest build is contained in the *project_name*\bin directory at any time. If you create multiple builds for different target servers for deployment by using the MobileFirst Operations Console, the supplied Ant tasks, or the Server Configuration Tool, you must deploy them after each build operation because the next build overwrites the existing files.

You can modify the generated native projects if, for example, you want to add native code or Cordova plug-ins to the application. If you modify the HTML, JavaScript, CSS, the application descriptor file, or any application resources, you must rebuild the environment by using the appropriate **Run As > Build ...** command to update the MobileFirst application file (.wlapp) and the native project.

After the build of the application completes, it is deployed or not deployed depending on which **Run As** command you used:

- The **Run As > Run on MobileFirst Development Server** option deploys the application metadata and web resources (the .wlapp file) to the internal MobileFirst Development Server. If you have defined an alternative test server by using the **Run As > Build Settings and Deploy Target** option, you can also deploy directly to that instance of MobileFirst Server. In this case, the command name changes to include the name of the target server. For example, if you add a local instance of MobileFirst Server, name it Group Test Server and designate it as your default test server, this command appears in the menus as **Run As > Run on Group Test Server**.
- The **Run As > Build ...** options builds the application or environment but does not deploy it. To deploy, you use the MobileFirst Operations Console, the supplied Ant scripts, or the Server Configuration Tool. For more information about deploying MobileFirst apps to remote servers, see “Deploying MobileFirst projects” on page 12-1.

The Run on MobileFirst Development Server command

Information about the menu command that is used to build and run an application or environment on your designated test server.

About this task

You use this menu option when you want to build your project in MobileFirst Studio and run it on the internal MobileFirst Development Server. This instance of MobileFirst Server is created automatically when you install MobileFirst Studio, and is described in “The MobileFirst Development Server and the MobileFirst Operations Console” on page 8-339.

Note: This command name is context-sensitive in that it does not always display the name **Run on MobileFirst Development Server**. If you use the Configure MobileFirst Build and Deploy Target dialog to choose a different test server, the name of the server that is selected in the **MobileFirst server to test applications** area is displayed in the command name instead. For example, if you add a local instance of MobileFirst Server, name it "Group Test Server" and designate it as your default test server, this command appears as **Run As > Run on Group Test Server**. For consistency, when referring to this menu command in this IBM MobileFirst Platform Foundation user documentation, the default name of this command (**Run on MobileFirst Development Server**) is used throughout.

Procedure

When you choose the **Run As > Run on MobileFirst Development Server** option, MobileFirst Studio performs the following actions:

- It starts the MobileFirst Development Server, if it is not already running.
- It builds your app and all of its included environments.
- It deploys the app to the MobileFirst Development Server (or designated test server), reporting success, failure, and any error messages in the Console view of MobileFirst Studio.
- When you open the MobileFirst Operations Console that is associated with the MobileFirst Development Server (or designated test server), that console displays the successfully deployed app and all of its environments. The console also displays detailed build and deployment messages, if required.

Note: .If you select more than one application node in the same project, all these applications are built and deployed to the MobileFirst Development Server.

Note: If your MobileFirst Operations Console is secured, an Authentication Required dialog appears, prompting you to enter the **User Name** and **Password**.

If you enter the correct credentials, the deployment continues when you click **OK**.

The dialog also contains a **Save user credentials** check box. If you select it before you click **OK**, the credentials are stored in Eclipse secure storage. This information can be edited in Eclipse by selecting **Preferences > General > Security > Secure Storage**. If you enter incorrect credentials, the deployment fails and the credentials are not saved.

You can also use this menu command to run and test individual MobileFirst environments by right-clicking on the environment in the Project Explorer and clicking **Run As > Run on MobileFirst Development Server**. This option runs and tests the selected environment on the designated test server.

Important: This menu command always uses as its target server the MobileFirst Server instance currently selected in the **MobileFirst server to test applications** area of the Configure MobileFirst Build and Deploy Target dialog. It ignores any server information that is entered in the **Build the application to work with a different MobileFirst server** area of the Configure MobileFirst Build and Deploy Target dialog.

OutOfMemoryError exceptions

If you get an OutOfMemoryError exception while deploying a large application to the MobileFirst Development Server, consider increasing the heap size of the server. To increase the heap size, edit the `jvm.options` file by double-clicking it in the Servers view in MobileFirst Studio, then either increase the value of the flag `-Xmx` if it already exists, or add this flag with the value `1024m` if it does not exist yet: `-Xmx1024m`.

The Build All Environments command

Information about the menu command that is used to build or rebuild an application or an environment, without deploying and running it to a server.

About this task

You use this menu option when you want to build or rebuild your application or environments in MobileFirst Studio, but not deploy them to the test server. This feature is useful when you are preparing to deploy for QA or Production environments.

Note: This command name is context-sensitive in that it does not always display the name **Build All Environments**. If you right-click the name of one of your environments, the name of that environment is displayed in the command name instead. For example, if you right-click the `android` folder in your project hierarchy, this command appears as **Run As > Build Android Environment**. For consistency, when referring to this menu command in this IBM MobileFirst Platform Foundation user documentation, the default name of this command (**Build All Environments**) is used throughout.

Procedure

When you choose this command, MobileFirst Studio performs the following actions, depending on the project element that is selected:

- If you right-click the main application node and choose **Run As > Build All Environments**, MobileFirst Studio builds your application and all of its included environments.

Note: If you select multiple application nodes, all environments for all applications are built.

- If you right-click on only a single environment and choose (for example) **Run As > Build iPhone Environment**, MobileFirst Studio builds only the selected environment.
- No deployment takes place, either to the designated test server or to a different MobileFirst Server.

Important: If you checked the **Build the application to work with a different MobileFirst server** option in the Configure MobileFirst Build and Deploy Target dialog, then this menu option triggers a build using that MobileFirst Server

information, and recognizes it over the test server setting. If this option is cleared, the build occurs using the build settings for the designated test server.

The Preview command

Information about the menu command that is used to preview an application or an environment.

About this task

You use this menu option when you want to preview an application or one of its environments, without triggering a rebuild and redeployment of it to the designated test server.

Note: The Preview feature requires that your designated test server is running and that the application was built at least once for current test server configuration.

Procedure

When you select **Run As > Preview**, MobileFirst Studio displays an instant preview, depending on the project element that is selected:

- **Common preview** – If you right-click the common folder in your project hierarchy and choose this command, MobileFirst Studio previews all common resources. This action opens a browser with a simple preview of your application, independent of any development environment you might have installed.
- **Single environment preview** – If you right-click an environment folder in your project hierarchy and choose this command, MobileFirst Studio previews that environment with the Mobile Browser Simulator.
- **All environments preview** – If you right-click the main application node in your project hierarchy and choose this command, MobileFirst Studio previews that environment with the Mobile Browser Simulator, displaying a preview for every environment you added to your application.

Important: If you use a MobileFirst Shell Component in your inner application, you might see incorrect results with a browser-based preview of the application.

In MobileFirst Studio V6.1.0, the preview feature that you can start by selecting **Run As > Preview** or from the MobileFirst Operations Console, changed. As an unintended side-effect, the preview of an inner application that references a shell component might not render as expected. Specifically, the fragments that normally get injected into the HTML page for the inner application are missing. As a result, any additional links, such as scripts, or CSS, are omitted during the preview. Also, if an extra user interface is defined in the shell, it is omitted as well.

To see a correct preview for an inner application that uses a shell, build the application and start it by using either a device emulator (Android or iOS) or an actual native device.

The Build Settings and Deploy Target command

Information about the menu command that is used to create build and deploy settings for MobileFirst applications.

In previous versions of MobileFirst Studio, you accessed the build and deploy settings for a given MobileFirst project through a number of different dialogs. Since IBM Worklight 6.1.0, those settings are consolidated in a single dialog. As a result,

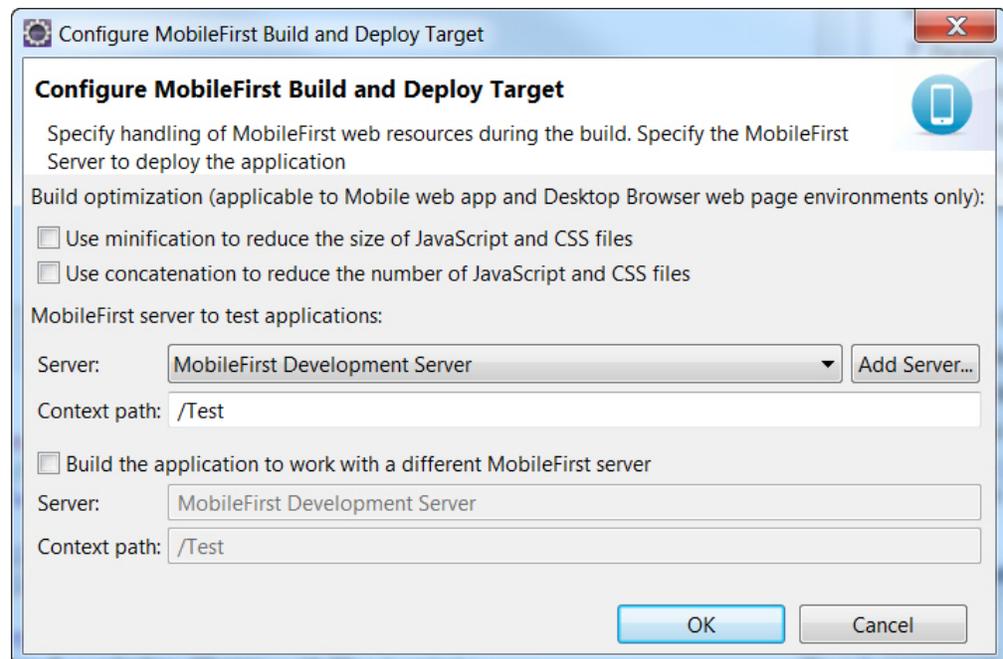

configuring a project to build and deploy to a local test server or to build for a remote server are available through the same dialog, along with other build settings options.

This new dialog, which is accessed by choosing the **Run As > Build Settings and Deploy Target** menu command, takes the place of several commands or dialogs in previous versions of MobileFirst Studio. It replaces:

- The **Run As > Build for Remote Server** menu command and its associated dialog.
- The **Run As > Apply Build Settings** menu command and its associated dialog.
- The **Change Target Server** menu command and its associated dialog.

The Build Settings and Deploy Target dialog

When you right-click on an application or an environment and select **Run As > Build Settings and Deploy Target**, the following dialog is displayed:

Important: This dialog is used only to specify configurations and settings; clicking **OK** does not trigger a build. Any time that you make a modification with this dialog, you must rebuild your application and environments for your changes to take effect, using either the **Run As > Run on MobileFirst Development Server** or the **Run As > Build...** menu commands.

The dialog contains three main areas, used to perform different actions. Each of these areas is covered in the sections that follow.

Apply build optimization settings

Build optimizations are useful to reduce the size of an application, improve its performance, or reduce its load time. The available optimizations, minification, and concatenation, are disabled by default for every project, but you can enable them by checking the appropriate option in the following screen capture.

Build optimization (applicable to Mobile web app and Desktop Browser web page environments only):

- Use minification to reduce the size of JavaScript and CSS files
- Use concatenation to reduce the number of JavaScript and CSS files

You use this area of the dialog if you want to change the build settings for the environments for the currently selected server, and want to apply these new minification and concatenation settings to future builds.

Important: The build optimization settings that you choose apply to the MobileFirst Server selected in the rest of the dialog. That is, if **Build the application to work with a different server** is selected, these optimization settings apply to that server when you click **OK**. If **Build the application to work with a different server** is not selected, they apply to the test server selected in the **Server** field of the **MobileFirst server to test applications** area.

For more information about build settings, see “MobileFirst application build settings” on page 8-369.

For more information about minification, see “Minification of JS and CSS files” on page 8-371.

For more information about concatenation, see “Concatenation of JS and CSS files” on page 8-373.

MobileFirst Server to test applications

In this area of the dialog, you can set the MobileFirst Server that you want to use to test your applications and environments. The default setting is **MobileFirst Development Server**. This name refers to the embedded instance of WebSphere Application Server Liberty profile and MobileFirst Server that is created when you install MobileFirst Studio.

But you can have other test servers that you want to use. For example, you can have a local or shared instance of MobileFirst Server running on WebSphere Application Server Liberty profile or Apache Tomcat. Using this area of the dialog, you can choose which of these servers you want to use as a default for testing during development.

MobileFirst server to test applications:

Server:	MobileFirst Development Server ▼	Add Server...
Context path:	/Test	

The **Server** field enables you to select from a list of configured test servers in your MobileFirst Studio development environment. You can also add a test server by clicking **Add Server**.

The **Context path** field enables you to specify the web application context path to be used when you deploy and run on the selected test server. By default this field is set to `/<your_project_name>`.

Note: If you use this area of the Configure MobileFirst Build and Deploy Target dialog to choose a different test server than the internal MobileFirst Development Server, the name of the server that is selected in the **Server** field is displayed in the command name instead. For example, if you add a local instance of MobileFirst Server, name it Group Test Server and designate it as your default test server, this command appears in the menus as **Run As > Run on Group Test Server**.

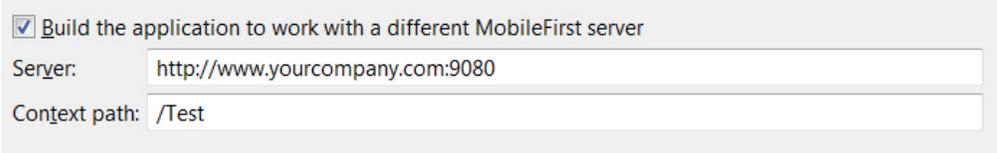

Important: When you change your designated test server, the new server remains the default for the **Run As > Run on <name of test server>** command until you change it again. All subsequent builds created with this command are deployed to and run on the test server you selected.

Build the application to work with a different MobileFirst Server

You use this option when you want to build your project in MobileFirst Studio and run it on another instance of MobileFirst Server that is running externally to your Eclipse development environment. For example, after you test locally, you use this area of the dialog to build your application for deployment to a production server.

Note: Both MobileFirst Studio Consumer Edition and MobileFirst Studio Enterprise Edition provide the capability to deploy to the internal MobileFirst Development Server, and, using this area of the dialog, to a remote server. The MobileFirst Studio Developer Edition is provided for evaluation purposes, and you can deploy only to the internal MobileFirst Development Server.

This area of the Configure MobileFirst Build and Deploy Target dialog becomes active when you select **Build the application to work with a different server**:

Build the application to work with a different MobileFirst server

Server:

Context path:

The **Server** field is required, and contains the URL for the remote target server. The entry must use the format: `http(s)://<hostname>:<port>`.

The **Context path** field specifies the web application context path to be used when deploying to this server.

To deploy the resulting WAR file and other artifacts, you must use the MobileFirst Operations Console, the supplied Ant tasks, or the Server Configuration Tool, following the procedures that are listed in “Deploying the project WAR file” on page 12-5.

Additional Run As menu options

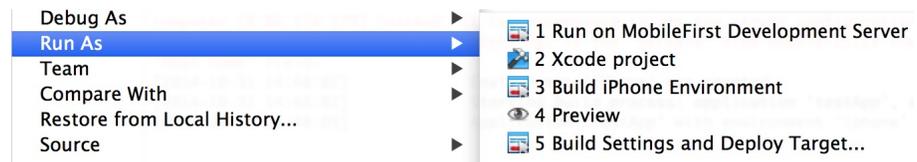

Depending on the platform and the external development environments that you installed, specific menu commands are available in **Run As** menus.

The commands that are available from the **Run As** menus depend on context-sensitivity, on the computer platform that you are working on, and on which external development environments you installed on your computer.

For more information about the iOS, Android, and Windows Phone Silverlight 8 development environments, see the Setting up your development environments tutorial category on the Getting Started page of the Developer Center.

You are working in MobileFirst Studio on a Mac computer

Right-click the iphone or ipad environment and use the **Run As > Xcode project** option to build the environment and open the Xcode development environment for that project.

You are working in MobileFirst Studio on a computer with the ADT plug-in (Android Development Tools for Eclipse) installed

Right-click the **android** environment and use the **Run As > Android Studio project** option to open that project in the Android development environment.

You are working in MobileFirst Studio on a computer that runs Windows 8, with Microsoft Visual Studio installed

Right-click the **windowsphone8** or **windows8** environment and use the **Run As > Visual Studio project** option to open that project in the Visual Studio development environment.

Working with multiple MobileFirst Server instances in MobileFirst Studio

Information about how to work in MobileFirst Studio in a development environment with multiple instances of MobileFirst Server.

As noted in “The MobileFirst Development Server and the MobileFirst Operations Console” on page 8-339, in IBM Worklight V6.0.0 the embedded Jetty test server was replaced with an instance of WebSphere Application Server Liberty Profile. This server is referred to as the MobileFirst Development Server and is associated with MobileFirst projects as the default development server. The **Open MobileFirst Operations Console** menu item enables you to view it in the MobileFirst Operations Console. You can think of this instance of Liberty profile as the *embedded* or *internal* development server.

MobileFirst Studio can also work with additional *external* MobileFirst Server instances, for example, an instance of Liberty profile that is installed on your development computer. These external servers are defined in Eclipse's **Servers** view. This topic covers the information that you need to know to work with these external servers.

Starting and stopping MobileFirst Server

Because MobileFirst Server can support multiple MobileFirst projects, there are no longer **Start Server** and **Stop Server** menu options that are associated directly with the MobileFirst project. Instead, the server that is associated with a MobileFirst project is started automatically (if the server is not already running) when you perform an action against that server or adapter. For example, the target server starts when you use the MobileFirst Studio command **Run As > Run on MobileFirst Development Server**.

Path to the MobileFirst Development Server and its console

As previously noted, the default server that is associated with MobileFirst projects is the embedded MobileFirst Development Server. The default path for this server is: `http://localhost:10080/PROJECT_NAME`. The path to the MobileFirst Operations Console for this embedded server is: `http://localhost:10080/worklightconsole`.

There are two consoles now. The first is the MobileFirst Operations Console, which contains the builder and plug-in logs. The second is the MobileFirst Development Server console, which contains the MobileFirst Server logs and Liberty profile logs. For more information about setting logging levels for these consoles, see “Configuring logging in the development server” on page 14-4.

Working with multiple development servers

You can create and run multiple MobileFirst projects against the same MobileFirst Server. Therefore, if you have an additional instance of Liberty profile that is installed in your development environment, you must ensure that the project you are working with is pointing to the correct server when building, deploying, or viewing it in the console.

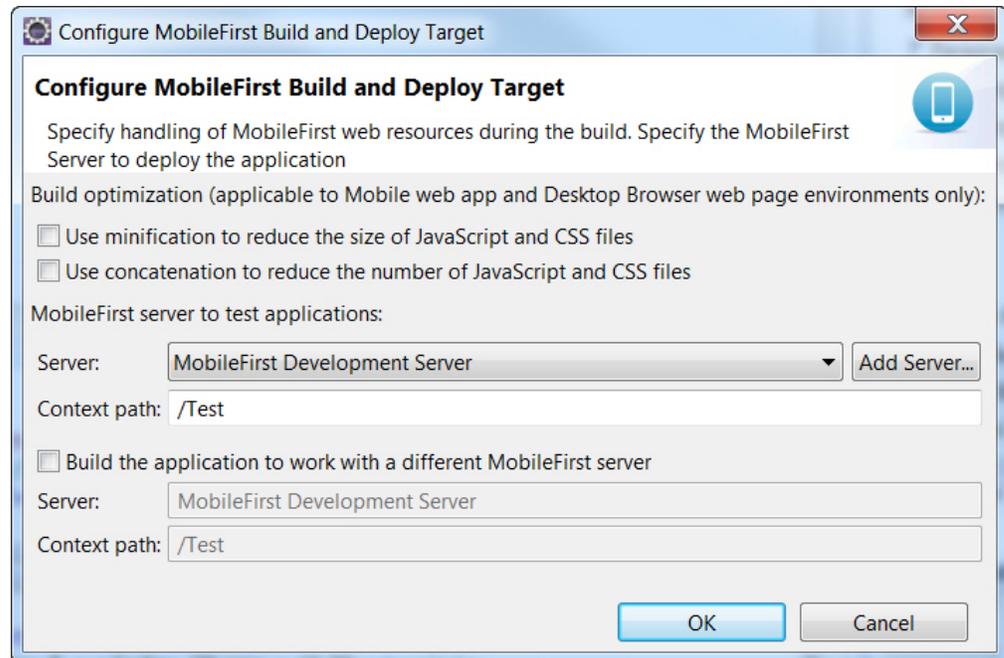

Every change that is made to the project source that is related to the project WAR file (under the `/server` folder) is automatically built and deployed to the current target server. The database connector JAR files and MobileFirst JAR file are also automatically deployed to this target server when you deploy the WAR file. That means that the project WAR file (not applications or adapters) is always updated on the target server. Every time that the project WAR file is built, it also gets deployed to the server associated with that project.

Note: The status of the server and its projects as it appears in the Eclipse **Servers** view does not always reflect its current status. This is a known issue.

Changing the MobileFirst Server associated with a project

You can change the target test server or change the MobileFirst project *context root* (which MobileFirst Server it is associated with) by right-clicking the application and selecting **Run As > Build Settings and Deploy Target**.

This action displays the following window:

If the MobileFirst Server instance you want to associate with this project is visible in the **Server** drop-down list, select it, update the **Context path** if necessary, and click **OK**. The outcome of this action is:

1. The project WAR file is automatically updated with the new context root value the next time you build.
2. After rebuilding and deploying the application, the new context root is also saved in the client-side files.

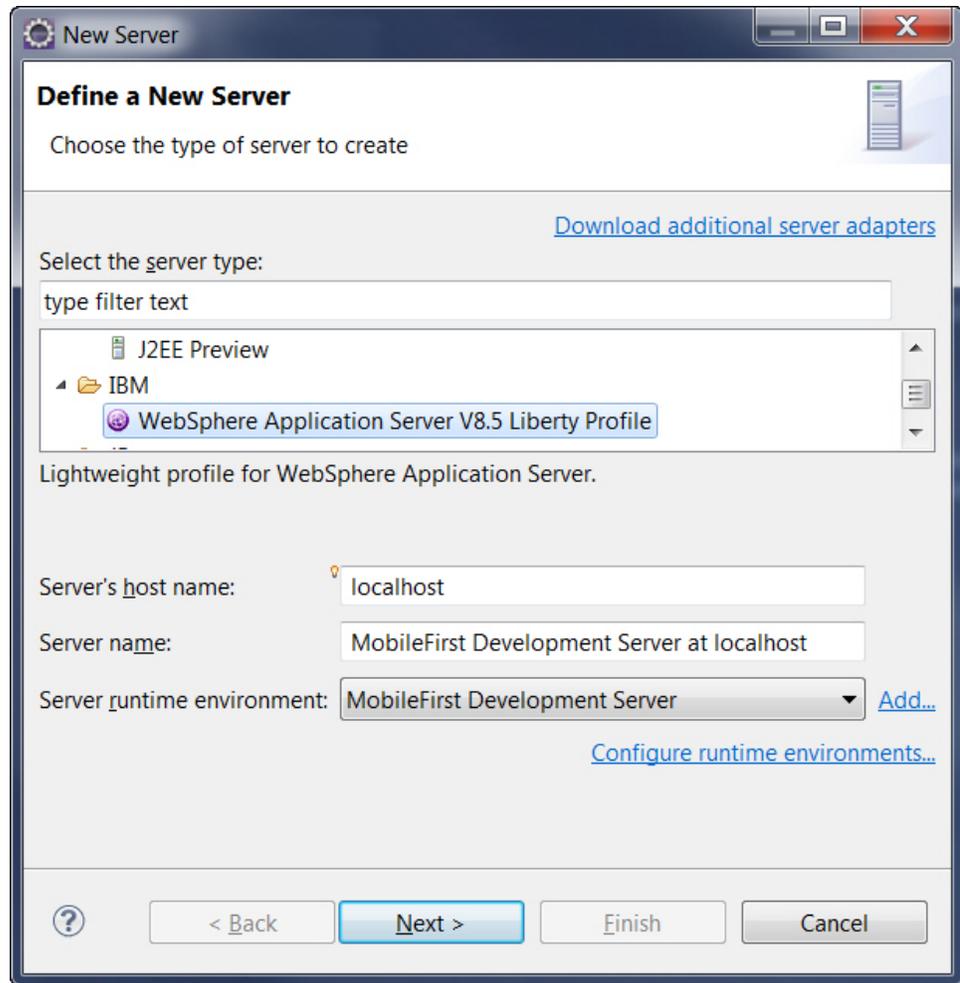

The selected server now becomes your default test MobileFirst Server. This action also changes the URL under the **Open MobileFirst Operations Console** menu command, so that it now points to the new server.

Note: If the MobileFirst Server instance you want is not displayed in the list on this Configure MobileFirst Build and Deploy Target window, use the following procedure to add it.

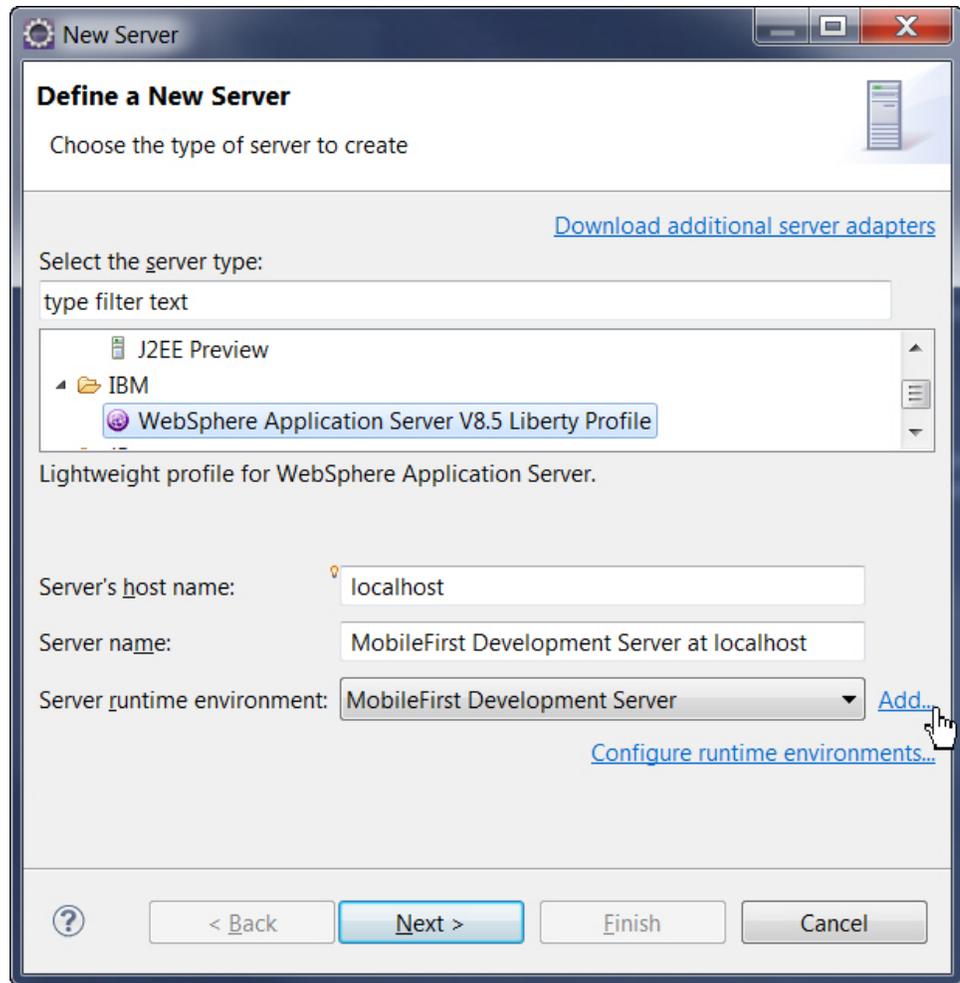

Adding a new MobileFirst Server

If the MobileFirst Server instance that you want to select is not visible in the **Server** dropdown list, you can add a new MobileFirst Server by using the following procedure. In this example, the user creates a new server entry for an instance of WebSphere Application Server Liberty Profile that is installed on his development computer.

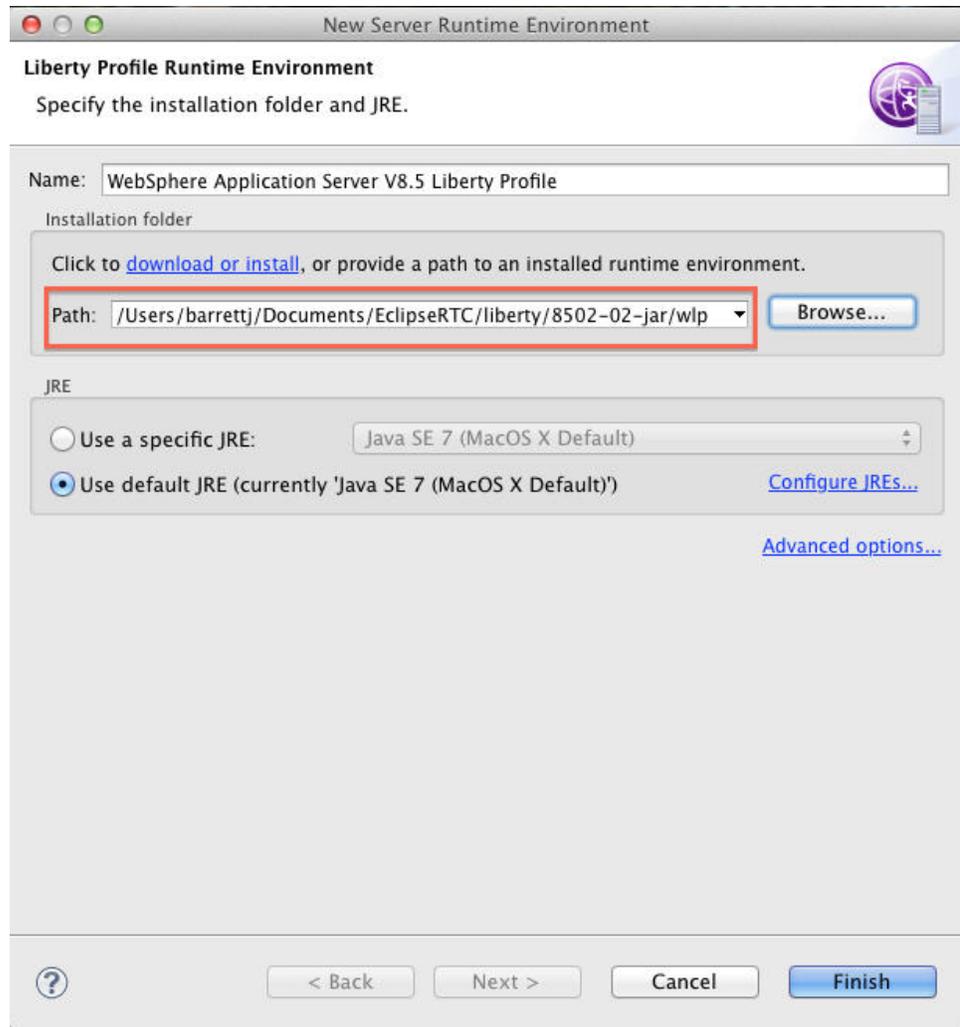

1. First, on the Configure MobileFirst Build and Deploy Target window, click **Add Server** to display the following window:

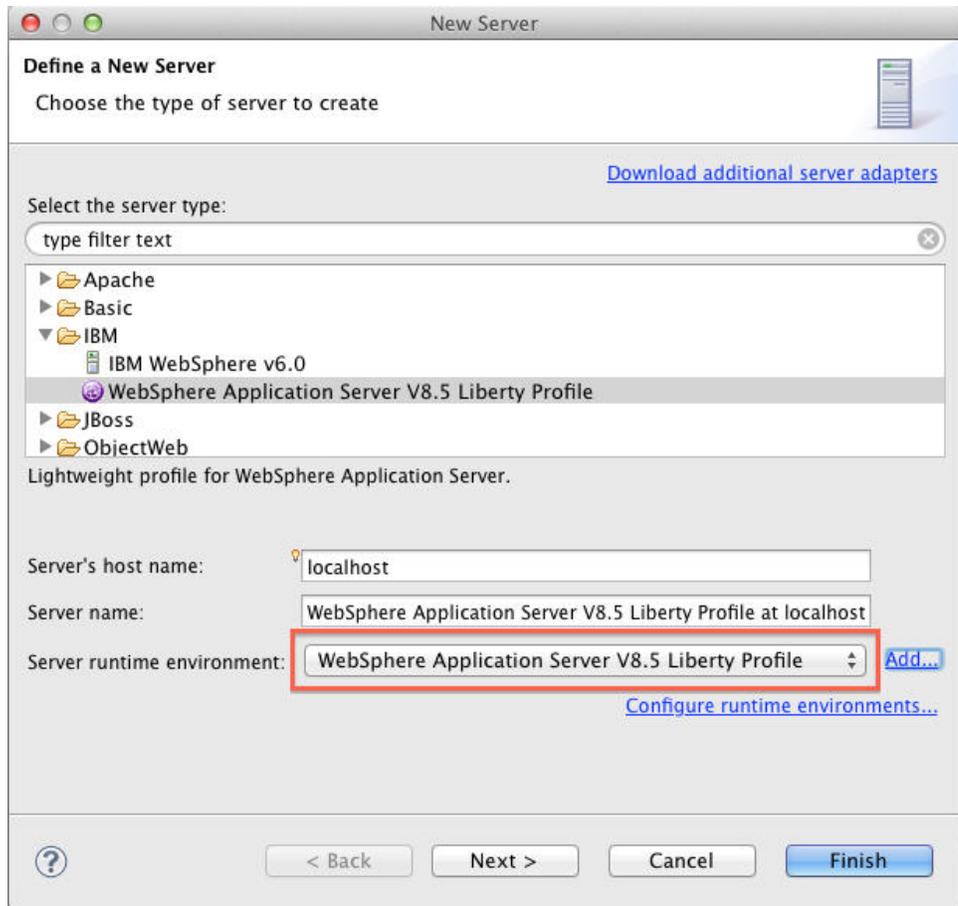

2. Select the server type that you want (in this example, **WebSphere Application Server V8.5 Liberty Profile**), and click **Add**:

3. On the resulting screen, set **Path** to point to the directory containing the new external Liberty profile server.

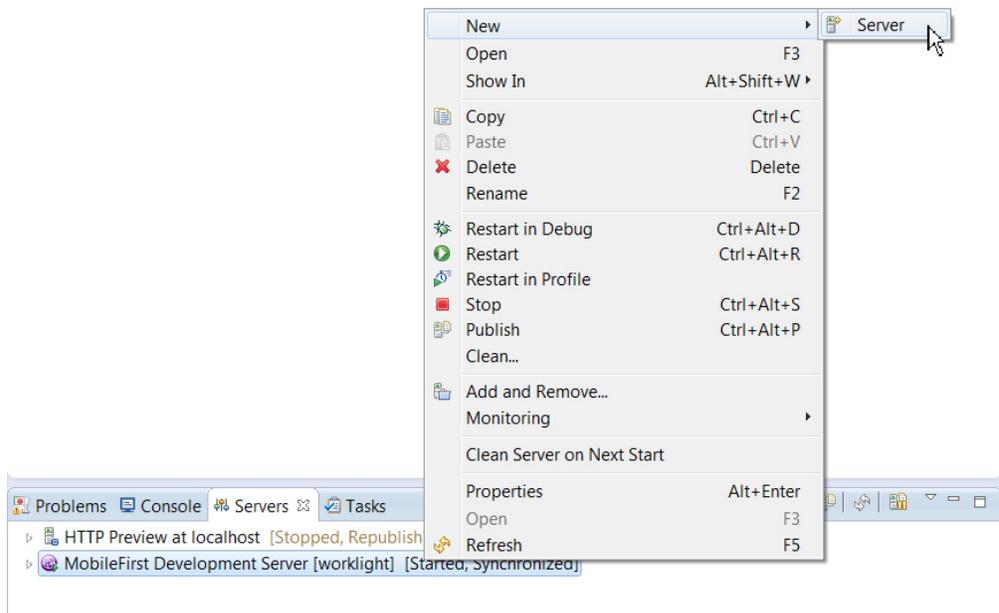

4. After you add the new server, it displays under Server runtime environment.

5. The new external server now is displayed in the **Server** field of the Configure MobileFirst Build and Deploy Target window. If you select the new server on the Configure MobileFirst Build and Deploy Target window, it becomes the default target test server, and all builds, deployments, and updates of the project WAR files made using the **Run As > Run on MobileFirst Development Server** command will go there.

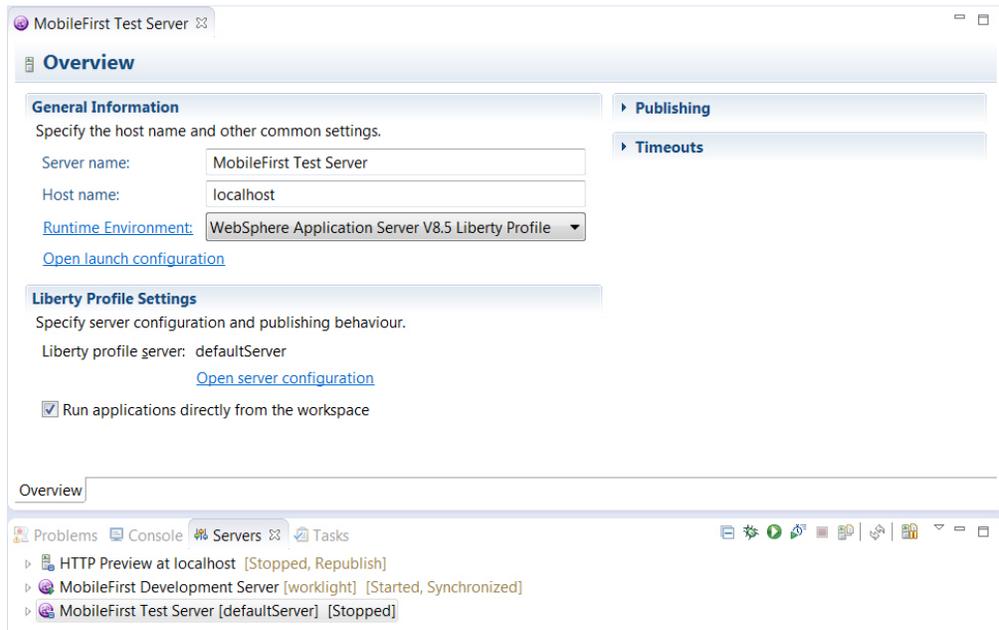

An alternate method of reaching this New Server window is to right-click the entry for an existing server in the Eclipse Servers view and select **New > Server** from the menu, as shown in the following screen capture:

In the New Server window, select the type of server you want to add and click **Next**. Continue with the remaining screens of the New Server wizard to define your new server.

Setting the port for new MobileFirst Server instances

When your new server is added, you can see it in the Eclipse **Servers** view. When you double-click it, you can view an **Overview** page on which you can change the **Server Name**, change the **Host name**, and other settings.

When you connect a project in MobileFirst Studio to an existing Liberty profile server (not the MobileFirst Development Server), you must check one thing before you attempt to build and deploy MobileFirst applications:

- In the `server.xml` file of the target server, inside the `httpEndpoint` element, make sure that the Liberty server listens on an external network interface host. Either use a wildcard symbol (for example, `host="*"`) or use a true public listening IP. Do not use `localhost`.

Any change that is done directly in the Liberty `server.xml` file and is related to the Liberty configuration causes a server restart.

Writing server-side Java code in a MobileFirst project

Server-side Java code can be added to a MobileFirst project under the `<project>/server/java` folder. If that code uses specific server runtime classes, be sure to add the Server Runtime Library to the Project Build Path:

1. Right-click the project and select **Build Path > Configure Build Path**.
2. Then, on the **Libraries** tab, click **Add Library**.
3. On the Add Library window, select **Server Runtime** and click **Next**.
4. On the next screen, select a server runtime library to add to the path and click **Finish**.

Otherwise, compilation markers can appear in the Java code.

MobileFirst Filtered Export

You can use the MobileFirst Filtered Export option to export only the required MobileFirst project resources to an archive file on the local system. Filtered Export ignores the files that are generated at build time, resulting in a smaller file than the previous method of exporting.

Before you begin

To complete this export, you must select a valid MobileFirst project. Any other project is not eligible for Filtered Export.

Procedure

1. Right-click the MobileFirst project, then select **Export**.
2. In the Export window that appears, expand **IBM MobileFirst**.
3. Select **MobileFirst Filtered Export**.
4. Click **Next**.
5. Click **Browse** to complete the file path of the **To archive file** field. The only valid file extension is `.zip`.
6. Click **Finish**.

MobileFirst CLI overview

To help developers get a better tools experience, IBM MobileFirst Platform provides a command-line interface (CLI) tool, the IBM MobileFirst Platform Command Line Interface, to easily create and manage both native and hybrid apps. The CLI enables developers to use their preferred text editors or alternative IDEs to create mobile applications.

The command-line interface does not require MobileFirst Studio for most standard activities. The commands support tasks such as creating, adding, and configuring with the MobileFirst API library, adding the client-side MobileFirst properties file and performing the build and deploy of the MobileFirst application. From the command-line, you can create and deploy adapters, and test them locally. You can

administer your MobileFirst project from CLI or REST services, or the Console, where you can easily control the local server and observe the logs. You can use command-line tools on their own, or in parallel with the MobileFirst Studio tools.

Everything that is generated by using the command-line interface is compatible with MobileFirst Studio. You can also use the CLI to integrate third-party tools such as ANT or Grunt to create your own tool chain for automated testing, build, and deployment flows.

To install command-line tools, see “Installing CLI” on page 6-8.

CLI commands usage

The CLI commands are intended for IT developers to create MobileFirst projects separately from the Eclipse MobileFirst Studio.

Use the command-line interface (CLI) keywords and options from a command line window. To run the commands, you can use either **mfp** or **mobilefirst**.

You can run the commands in either of the following ways:

- The direct method: You enter the command and set its options on one line and press Enter. For example: **\$ mfp add adapter MyAdapter --type http**.
- The interactive method: You enter the command with no arguments and press Enter. For example: **\$ mfp add adapter**. Then, you are prompted to set the available parameters one by one.

Examples:

```
$ mfp create MyProject
$ cd MyProject
$ mfp add api MyiOS --environment ios
$ mfp add adapter MySQLAdapter --type sql
$ cd MySQLAdapter
$ mfp push localDevServer
```

Global options

You can use the following options on any MobileFirst Platform Command Line Interface command:

Option	Description
-v, --version	Prints this utility's version
-d, --debug	Produces debug log output
-dd, --ddebug	Produces verbose debug log output
--no-color	Suppresses use of special text colors for all command line output. When specified, the color settings for your operating system's console are used for all error messages, status messages and other CLI prompts.

For a complete list of the CLI commands with descriptions of their functions, see “CLI Commands” on page 16-1.

Getting started with CLI

To get started with the CLI, configure your global commands, create one MobileFirst Server definition, and create your MobileFirst project.

Procedure

1. Configure global commands. Run **mfp config**. For more information about the **mfp config** command, see “**config**” on page 16-7.
2. Create at least one MobileFirst Server definition.
 - For a local Development Server, run **mfp server create**. For more information, see “**server create**” on page 16-22.
 - For a remote server, run **mfp server add**. For more information, see “**server add**” on page 16-21.
3. Create a MobileFirst project to manage your back-end assets. Run **mfp create**. For more information, see “**create**” on page 16-15.
4. Change directories into your project. Run **cd YourProject**.
5. If you are using the local development server, start the MobileFirst Server. For the local development server, run **mfp start**. This should take between 1 and 5 minutes. For the remote server, verify with the administrator that the server is running. For more information, see “**start**” on page 16-24.
6. Verify server access by opening the Console. Run **mfp console**. For more information, see “**console**” on page 16-8.
7. Push your app to the MobileFirst Server. Run **mfp push**.
8. Preview your app by using the **mfp preview** command. For more information, see “**preview**” on page 16-18

Creating an app back-end runtime

To create an application back-end runtime, use the **mfp create** command.

Procedure

1. To create your MobileFirst back-end project, run the following command:
mfp create myProject
where *myProject* is the name of your project. For more information, see “**create**” on page 16-15.
2. Enter **cd myProject** to change into your MobileFirst back-end project directory.
3. Create at least one MobileFirst Server definition.
 - For a local MobileFirst Development Server:
 - If this is the first time that you are creating a project or the existing server is stopped, run the **mfp start** command. For more information, see “**start**” on page 16-24.
 - If an existing server is already running, run the **mfp restart** command. For more information, see “**restart**” on page 16-21.

Tip: To find out if a server is running, run the **mfp status** command. For more information, see “**status**” on page 16-24.

 - For a remote server, run **mfp server add**. For more information, see “**server add**” on page 16-21.
4. Deploy the back-end runtime.
 - For a local MobileFirst Development Server, run **mfp push**. For more information, see “**push**” on page 16-19.

- For a remote server, follow the instructions to build and deploy the back-end runtime WAR file. For more information, see “Deploying the project WAR file” on page 12-5.
5. Verify that the back-end runtime has been successfully deployed by obtaining the list of runtimes that are running on the MobileFirst Server. To obtain this list, run the following command:

```
mfp server info MyServerDefinition
```

 where *MyServerDefinition* is the name of the server definition that represents the target server. For example, run

```
mfp server info local
```

 to obtain the list of runtimes on the local MobileFirst Development Server.

Results

The application back-end runtime that is deployed on the MobileFirst Server starts. You can now deploy your apps and adapters to this back-end runtime.

Optimizing applications with CLI

You can reduce the size of your application, obfuscate its JavaScript, reduce its load time, or otherwise improve its performance by using IBM MobileFirst Platform Command Line Interface (CLI).

By using minification and concatenation, you optimize your application to maximize performance and to make your application more secure. If you obfuscate and minimize JavaScript, your hybrid apps become difficult to read by humans, which discourages exploitation. Additionally, the minification of JavaScript code reduces the app package size.

For more information about minification and concatenation, see “Minification of JS and CSS files” on page 8-371 and “Concatenation of JS and CSS files” on page 8-373.

Creating a build-settings entry by using CLI

There is no command to explicitly create an entry in the `build-settings.xml` file. But, you can indirectly create an entry.

Procedure

Add an environment to the application by using the `mfp add environment` command. For more information about this command, see “`add environment`” on page 16-4.

Results

An entry is added to the `build-settings.xml` file. For example, the command `$ mfp add environment android --app appName` results in the following entry addition.

```
<android>
  <minification includes="*" level="none"/>
  <concatenation includes="*" />
</android>
```

Updating a build-settings entry by using CLI

You can update an entry in the `build-settings.xml` file by using IBM MobileFirst Platform Command Line Interface (CLI).

Procedure

Use the `mfp build-config update-env` command to modify the optimization setting for any existing configuration. For more information about using the `mfp build-config` command, see “`build config`” on page 16-6.

Deleting a build-settings entry by using CLI

There is no IBM MobileFirst Platform Command Line Interface (CLI) command to delete an entry from the `build-settings.xml` file. But, you can remove the entry directly from the file.

Procedure

Manually edit the `build-settings.xml` file to delete the entry.

Troubleshooting a Request Timeout error

You can often resolve a Request Timeout error that you receive when you use the IBM MobileFirst Platform Command Line Interface by increasing the default timeout value.

Symptom

You receive a Request Timeout error while you are using the IBM MobileFirst Platform Command Line Interface.

Cause

This error occurs when the IBM MobileFirst Platform Command Line Interface does not receive a response from the IBM MobileFirst Platform Server (MobileFirst Server) within 30 seconds. This communication error is caused by one of the following situations:

- The MobileFirst Server is experiencing a high traffic load.
- There is network latency between your development system and the MobileFirst Server.
- Your MobileFirst Server failed.

Resolving the problem

To confirm that the problem is being caused by basic network latency, run a `ping` command to the MobileFirst Server. If the response time is longer than expected, it is a latency issue. Contact your network administrator.

Increasing the default timeout value on the system that is running the IBM MobileFirst Platform Command Line Interface can resolve this problem. The built-in default value is 30000 milliseconds (30 seconds). Increasing the value allows more time for the communication to take place, so it resolves some latency issues. To override the built-in default timeout value, you can set or increase the value of an environment variable, `MFP_HTTP_DEFAULT_TIMEOUT`. To set or modify this value, complete the following steps:

1. Determine if your system already has an environment variable, MFP_HTTP_DEFAULT_TIMEOUT.
 - If this variable already exists, increase the value to higher than the built-in default value of 30000.
 - If this variable does not already exist, create the variable and set it to higher than the built-in default value of 30000.
2. Rerun the failing MobileFirst Platform Command Line Interface command after you increase this environment variable.

If you still receive the Request Timeout error after you increase the timeout value to 90 seconds or longer and the ping latency is low, contact your MobileFirst Server administrator to confirm that the MobileFirst Server is running correctly.

Developing cross-platform apps

You can develop both MobileFirst hybrid apps and Cordova apps as detailed here.

Cordova apps versus MobileFirst hybrid apps

Discover the similarities and differences between Cordova apps and MobileFirst hybrid apps.

Table 8-3. Cordova versus MobileFirst hybrid apps

Feature	MobileFirst hybrid app	Cordova app
IDE Eclipse Studio		
Eclipse plug-in and integration	Yes	Unsupported
Rich Page Editor	Yes	Unsupported
Application Components	Yes	Yes Note: Create your own Cordova plug-ins to manage application components in your organization. For more information, see Apache Cordova Plugin Development Guide.
Project Templates	Yes	Yes Note: Create Cordova applications by using the MobileFirst Platform Command Line Interface when you create a new app: use the --template argument or provide the path during interactive mode by using mfp cordova create .
Dojo and jQuery IDE instrumentation	Yes	Yes Note: Dojo and jQuery Mobile are JavaScript frameworks that you can use in Cordova apps. For more information, see Dojo Documentation and jQuery Mobile documentation.
Mobile UI Patterns	Deprecated	Unsupported

Table 8-3. Cordova versus MobileFirst hybrid apps (continued)

Feature	MobileFirst hybrid app	Cordova app
Application sub types		
Shell Component	Yes	Unsupported
Inner Hybrid Application	Yes	Unsupported
Application Features		
Mobile OS	iOS, Android, Windows Phone 8 BlackBerry 10	iOS 7 or higher, Android 4 or higher. See “System requirements” on page 2-15 for supported operating system details.
Direct Update	Yes	Yes
MobileFirst Security Framework	Yes	Yes
Certificate pinning	Yes	No
JSONStore	Yes	Yes
FIPS 140-2	Yes	No
IBM Tealeaf SDK	Yes	Unsupported
Encryption of web resources that are associated with the application within the application binary file. (<EncryptWebResources>) in the application descriptor)	Yes	No
Verification of the integrity of web resources by using a checksum each time the app starts running. (<testWebResourcesChecksum> in the application descriptor)	Yes	Unsupported
Specification of app target category (B2E or B2C) for addressable device license tracking. (<targetCategory> in application descriptor)	Yes	No
MobileFirst application skins	Yes	No Note: To detect and handle different device screen sizes, use standard web development practices such as responsive web design.
Environment optimizations	Yes	Yes via Cordova hooks and merges
Push Notifications	Yes	Yes
Cordova plug-ins management	No	Yes
Mobile Browser Simulator	Yes	Yes
Simple browser preview	Yes	Yes

Table 8-3. Cordova versus MobileFirst hybrid apps (continued)

Feature	MobileFirst hybrid app	Cordova app
Cordova platform management	Yes	Yes
MESSAGES (i18n)	Yes	Yes
Application optimizations		
Minification	Yes	Yes Note: Use common open source tools.
Concatenation of JS and CSS	Yes	Yes Note: Use common open source tools.
Obfuscation	Yes	Yes Note: Use common open source tools.
Android Pro Guard	Yes	Yes Note: See Android documentation to enable Pro Guard.
Client-side JavaScript API		
WL.App.openURL	Yes	No Note: Instead, use standard Cordova APIs for this functionality in the In App Browser plugin.
WL.App.close	Deprecated	Unsupported
WL.App.copyToClipboard	Yes	Unsupported
WL.App.getDeviceLocal	Yes	No Note: Instead, use standard Cordova APIs for this functionality in the Globalization Plugin.
WL.App.getDeviceLanguage	Yes	No Note: Instead, use standard Cordova APIs for this functionality in the Globalization Plugin.
WL.App.overrideBackButton	Yes	No Note: Instead, use the standard Cordova APIs for backButton event listener.
WL.App.resetBackButton	Yes	No Note: Instead, use the standard Cordova APIs for backButton event listener.

Table 8-3. Cordova versus MobileFirst hybrid apps (continued)

Feature	MobileFirst hybrid app	Cordova app
WL.App.BackgroundHandler	Yes	No Note: To run a custom handler function, use the standard Cordova pause event listener. Use a Cordova plug-in that provides privacy and prevents iOS and Android systems and users from taking snapshots or screen captures: https://github.com/devgeeks/PrivacyScreenPlugin .
WL.Client.getAppProperty	Yes	No Note: Only the APP_VERSION property is supported.
WL.Client.getEnvironment	Yes	No Note: Use the standard Cordova API <code>cordova.platformId</code> .
WL.Client.reloadApp	Yes	Unsupported
WL.Badge.setNumber	Yes	Unsupported
WL.EncryptedCache	Deprecated	Unsupported
WL.OptionsMenu	Yes	No Note: Use a web UI framework or standard HTML 5 to create the UI.
WL.Item	Yes	No Note: Use a web UI framework or standard HTML 5 to create the UI.
WL.NativePage	Yes	No Note: Use a web UI framework or standard HTML 5 to create the UI.
WL.TabBar	Yes	No Note: Use a web UI framework or standard HTML 5 to create the UI.
WL.TabBarItem	Yes	No Note: Use a web UI framework or standard HTML 5 to create the UI.
WL.Toast	Yes	No Note: Use a web UI framework or standard HTML 5 to create the UI.

Developing hybrid and web apps

Develop hybrid and web applications as detailed here.

Anatomy of a MobileFirst project

The file structure of a MobileFirst project helps you organize the code that is required for your apps.

When you develop mobile apps with IBM MobileFirst Platform Foundation, all development assets including source code, libraries, and resources are placed in a MobileFirst project folder.

Table 8-4. A MobileFirst project has the following structure:

Folder name		Description	
<project-name>		Root project folder	
	adapters	Source code for all adapters belonging to the project	
	apps	Source code for all applications belonging to the project	
	bin	Artifacts resulting from building adapters, apps, and server-side configuration and libraries	
	components	Source code for all shell components belonging to the project	
	externalServerLibraries	Libraries to be placed in external service servers and used for access token validation	
	www	Source code of the Dojo JavaScript framework, if installed as part of MobileFirst Studio	
	server		
		conf	MobileFirst Server configuration files, such as <code>worklight.properties</code> and <code>authenticationConfig.xml</code>
		java	Java code that must be compiled and packaged into jar files deployable to the MobileFirst Server
		lib	Pre-compiled libraries that must be deployed to the MobileFirst Server

Table 8-4. A MobileFirst project has the following structure: (continued)

Folder name		Description
	services	Description, at development stage, of back-end services discovered for consumption by the applications in the project

Initialization options

The `initOptions.js` file is included in the project template. It is used to initialize the MobileFirst JavaScript framework. It contains a number of tailoring options, which you can use to change the behaviour of the JavaScript framework. These options are commented out in the supplied file. To use them, uncomment and modify the appropriate lines.

The `initOptions.js` file calls `WL.Client.init`, passing an `options` object that includes any values you have overridden.

Content of the `www` folder

If you installed the Dojo JavaScript framework, the `www` folder contains a minified version of Dojo Mobile libraries. This minified version contains all the Dojo mobile components. If you need to add more Dojo components or Dojo features to your application, see the topic “Creating Dojo-enabled projects” on page 8-93.

Anatomy of a MobileFirst application

This collection of topics describes the files within a MobileFirst application

With IBM MobileFirst Platform Foundation, you can write applications by using web technologies or native technologies, or combine both types of technology in a single app. All client-side application resources, both web and native, must be located under a common file folder with a predefined structure. MobileFirst Studio builds these resources into various targets, depending on the environments supported by the application.

The application folder:

The application folder contains all application resources.

Table 8-5. The folder has the following structure:

Folder name		Description	
<app-name>		Main application folder	
	common	Application resources common to all environments	
		css	Style sheets to define the application view
		images	Thumbnail image and default icon

Table 8-5. The folder has the following structure: (continued).

Folder name		Description
	js	JavaScript files
	index.html	An HTML5 file that contains the application skeleton
	android	Web and native resources specific to Android
	blackberry10	Web and native resources specific to BlackBerry 10
	blackberry	Web and native resources specific to BlackBerry 6 and 7
	ipad	Web and native resources specific to iPad
	iphone	Web and native resources specific to iPhone
	windowsphone8	Web and native resources specific to Windows Phone Silverlight 8
	air	Resources specific to Air
	desktopbrowser	Resources specific to desktop browsers
	mobilewebapp	Web resources specific to mobile web applications
	windows8	Resources specific to Windows 8 Universal and Windows Phone 8 Universal
	certificates	Contains any X.509 digital certificates, in DER format, that are used for certificate pinning.
	legal	License documents for the application or third-party software used in the application
	application-descriptor.xml	
	build-settings.xml	

Application resources:

You must provide various types of resources if you are to create applications that can run in multiple environments.

You must provide the following resources to create applications that can run in multiple environments. IBM MobileFirst Platform Foundation automatically generates any missing resources that are not supplied. However, for production quality, you must provide all resources that are required by the environments in which the application runs.

Application descriptor

The application descriptor is a mandatory XML file that contains application metadata, and is stored in the root directory of the app. The file is automatically generated by MobileFirst Studio when you create an application, and can then be manually edited to add custom properties.

Main file

The main file is an HTML5 file that contains the application skeleton. This file loads all the web resources (scripts and style sheets) necessary to define the general components of the application, and to hook to required document events. This file is in the `\common` folder of the app directory and optionally in the `optimization` and `skin` folders.

The main file contains a `<body>` tag. This tag must have an `id` attribute that is set to content. If you change this value, the application environment does not initialize correctly.

Style sheets

The app code can include CSS files to define the application view. Style sheets are placed under the `\common` folder (normally under `\common\css`) and optionally in the `optimization` and `skin` folders.

Scripts

The app code can include JavaScript files that implement interactive user interface components, business logic and back-end query integration, and a message dictionary for globalization purposes. Scripts are placed under the `\common` folder (normally under `\common\js`) and optionally in the `optimization` and `skin` folders.

Thumbnail image

The thumbnail image provides a graphical identification for the application. It must be a square image, preferably of size 128 by 128 pixels. It is used to identify the app in the MobileFirst catalog.

MobileFirst Studio creates a default thumbnail image when the app is created. You can override this default image (using the same file name) with a replacement image that matches your application. The file is in the `\common\images` folder of the app.

Splash image

The splash image applies for mobile environments. The splash image (or *splash screen*) is displayed while the application is being initialized. It must be in the exact dimensions of the app.

MobileFirst Studio creates a default splash image when you create an application environment. These **default** images are stored in the following locations:

- For Apple iOS platforms, the default splash images are stored as follows:
 - For iPhone, under `iphone\native\Resources`
 - For iPad, under `ipad\native\Resources`

The file names of the default splash images are as follows, and vary according to iOS version and target device:

- For iPhone Non-Retina display (iOS 6.1 - deprecated, see “Deprecated features and API elements” on page 3-20 - and earlier): `Default~iphone.png` 320 by 480 pixels
 - For iPhone Retina display (iOS 6.1 - deprecated - and earlier): `Default@2x~iphone.png` 640 by 960 pixels
 - For iPhone 4-inch Retina display (iOS 6.1 - deprecated - and earlier): `Default568h@2x~iphone.png` 640 by 1136 pixels
 - For iPhone Retina display (iOS7): `Default@2x~iphone.png` 640 by 960 pixels
 - For iPhone 4-inch Retina display (iOS7): `Default568h@2x~iphone.png` 640 by 1136 pixels
 - For iPad (iOS 6.1 - deprecated - and earlier): `Default-Portrait~ipad.png` 768 by 1004 pixels
 - For iPad Retina display (iOS 6.1 - deprecated - and earlier): `Default-Portrait@2x~ipad.png` 1536 by 2008 pixels
 - For iPad (iOS 6.1 - deprecated - and earlier): `Default-Landscape~ipad.png` 1024 by 748 pixels
 - For iPad Retina display (iOS 6.1 - deprecated - and earlier): `Default-Landscape@2x~ipad.png` 2048 by 1496 pixels
 - For iPad (iOS7): `Default-Portrait~ipad.png` 768 by 1004 pixels
 - For iPad Retina display (iOS7): `Default-Portrait@2x~ipad.png` 1536 by 2008 pixels
 - For iPad (iOS7): `Default-Landscape~ipad.png` 1024 by 748 pixels
 - For iPad Retina display (iOS7): `Default-Landscape@2x~ipad.png` 2048 by 1496 pixels
- For Android platforms, the file name of the default splash image is `splash.9.png`; it is stored:
 - For all resolutions, under `android\native\res\drawable`
 - For BlackBerry 10, under `blackberry10\native\www`. The file must be in `.png` format and there are four different splash screen sizes:
 - splash 1024 pixels width by 600 pixels height: `splash-1024x600.png`
 - splash 1280 pixels width by 768 pixels height: `splash-1280x768.png`
 - splash 600 pixels width by 1024 pixels height: `splash-600x1024.png`
 - splash 768 pixels width by 1280 pixels height: `splash-768x1280.png`
 - For BlackBerry 6 and 7 (deprecated. See Table 3-2 on page 3-21), the file name of the splash image is `splash.png`, stored under `blackberry\native`.

- For Windows Phone Silverlight 8, the file name of the splash image is `SplashScreenImage.jpg`, stored under `windowsphone8\native`. This file must be in .jpg format, with a width of 768 pixels and height of 1280 pixels.
- For Windows 8 Universal, the file name of the splash image is `splashscreen.png`, stored under `windows8\native\images`. This file must be in .png format, with a width of 620 pixels and height of 300 pixels.

Adding a custom splash image

You can override the default images that are created by MobileFirst Studio with a splash image that matches your application.

The procedures for doing this differ, depending on the target platform. But in all cases, your custom splash image must match the size of the default splash image you are replacing, and must use the same file name.

- For Apple iOS platforms:
 - There are two ways of creating a custom splash image:
 1. Replace the default image in `ipad\native\Resources` (or `iphone\native\Resources`), **OR**
 2. Add the new (replacement) image to `ipad\nativeResources\Resources` (or `iphone\nativeResources\Resources`).
 3. Rebuild the application by clicking **Run As > Run on MobileFirst Development Server** or **Run As > Build...**

The second method (step 2) is preferable because it does not delete any files from the native directory, which is often not backed up in a source code control system. When you add your image to the `nativeResources` directory, it is copied to the native directory during the build. The replacement splash image must not be placed in any folder other than `Resources`.

- For Android:
 - There are two ways of creating a custom splash image:
 1. Replace the default image in `android\native\res\drawable`, **OR**
 2. Add the new (replacement) image to `android\nativeResources\res\drawable`.
 3. Rebuild the application by clicking **Run As > Run on MobileFirst Development Server** or **Run As > Build...**

The second method (step 2) is preferable because it does not delete any files from the native directory, which is often not backed up in a source code control system. When you add your image to the `nativeResources` directory, it is copied to the native directory during the build. The replacement splash image must not be placed in any folder inside the `res` folder other than `drawable`.

- For BlackBerry 10:
 - There are two ways of creating a custom splash image:
 1. Replace the default image in `blackberry10\native\www`, **OR**
 2. Add the new (replacement) image to `blackberry10\nativeResources\www`.
 3. Rebuild the application by clicking **Run As > Run on MobileFirst Development Server** or **Run As > Build...**

The second method (step 2) is preferable because it does not delete any files from the native directory, which is often not backed up in a source code control system. When you add your image to the `nativeResources` directory, it is copied to the native directory during the build.

- For BlackBerry 6 and 7:
 1. Replace the default image in blackberry\native. If the original splash image is not backed up in a source code control system, it is advisable to rename or back up the original image first.
 2. Rebuild the application by clicking **Run As > Run on MobileFirst Development Server** or **Run As > Build...**
- For Windows Phone Silverlight 8:
 - There are two ways of creating a custom splash image:
 1. Replace the default image in windowsphone8\native, **OR**
 2. Add the new (replacement) image to windowsphone8\nativeResouces.
 3. Rebuild the application by clicking **Run As > Run on MobileFirst Development Server** or **Run As > Build...**

The second method (step 2) is preferable because it does not delete any files from the native directory, which is often not backed up in a source code control system. When you add your image to the nativeResources directory, it is copied to the native directory during the build.
- For Windows 8 Universal:
 1. Replace the default image in windows8\native\images. If the original splash image is not backed up in a source code control system, it is advisable to rename or back up the original image first.
 2. Rebuild the application by clicking **Run As > Run on MobileFirst Development Server** or **Run As > Build...**

Application icons

MobileFirst Studio creates default application icons when you create the app. You can override them with images that match your application. For Android, iPad, and iPhone, put your replacement icons (using the same file names, except as noted with an asterisk * in this table) in the location indicated by the Location of overriding icon column in the following table.

The following table summarizes the sizes and location of each application icon.

Table 8-6. Application icons

Environment	File name	Description	Location of default icon	Location of overriding icon
Adobe AIR	icon16x16.png icon32x32.png icon48x48.png icon128x128.png	Application icons of various sizes that are attached to the AIR version of the application. The dimensions of each icon are specified in its name.	air\images	

Table 8-6. Application icons (continued)

Environment	File name	Description	Location of default icon	Location of overriding icon
Android	icon.png	An icon that is displayed on the device springboard. You can provide a different icon for each device density that you want to support.	android\native\ res\drawable	\android\ nativeResources\ res\drawable or android\ nativeResources\ res\drawable- ldpi -hdpi or other options.
BlackBerry 10	icon.png	An icon that is displayed on the device. Its dimensions are 114 by 114 pixels. For best practices on creating application icons, see https://developer.blackberry.com/devzone/design/application_icons.html .	blackberry10\ native\www	blackberry10\ nativeResources\ www
BlackBerry 6 and 7	icon.png	An icon that is displayed on the device. Its dimensions are 80 by 80 pixels.	blackberry\ native	

Table 8-6. Application icons (continued)

Environment	File name	Description	Location of default icon	Location of overriding icon
iPad	icon-xxxx.png * Filename varies by size and target device. Exact file name can change as long as it is listed in the plist file.	An icon that is displayed on the device springboard. Size depends on iOS version and target device. iOS 6.1 (deprecated) and earlier: <ul style="list-style-type: none"> • Non-Retina display: 72 by 72 pixels • Retina display: 144 by 144 pixels iOS7: <ul style="list-style-type: none"> • Non-Retina display: 76 by 76 pixels • Retina display: 152 by 152 pixels 	ipad\native\resources	\ipad\nativeResources\Resources
iPhone	icon-xxxx.png * Filename varies by size and target device. Exact file name can change as long as it is listed in the plist file.	An icon that is displayed on the device springboard. Size depends on iOS version and target device. iOS 6.1 (deprecated) and earlier: <ul style="list-style-type: none"> • Non-retina display: 57 by 57 pixels • Retina display: 114 by 114 pixels iOS7: <ul style="list-style-type: none"> • 120 by 120 pixels 	iphone\native\resources	\iphone\nativeResources\Resources

Table 8-6. Application icons (continued)

Environment	File name	Description	Location of default icon	Location of overriding icon
Windows Phone Silverlight 8	Background.png ApplicationIcon.png	Both icons are used to identify the application. Background.png is displayed on the device home screen, and must be 300 by 300 pixels. ApplicationIcon.png is displayed in the list of applications, and must be 100 by 100 pixels.	windowsphone8\native	

Table 8-6. Application icons (continued)

Environment	File name	Description	Location of default icon	Location of overriding icon
Windows 8 Universal	storelogo.png logo.png smalllogo.png	<p>All icons are used to identify the application.</p> <p>storelogo.png is the image the Windows Store uses when it displays the app listing in search results and with the app description in the listing page. The image must be 50 by 50 pixels.</p> <p>logo.png represents the square tile image of the app in the Start screen. The image must be 150 by 150 pixels.</p> <p>smalllogo.png is displayed with the app display name in search results on the Start screen. smalllogo.png is also used in the list of searchable apps and when the Start page is zoomed out. The image must be 30 by 30 pixels.</p>	windows8\ native\images	

The application descriptor:

The application descriptor is a metadata file that is used to define various aspects of the application. It is in the application root directory and has the name application-descriptor.xml.

<application>

The root element of the descriptor.

```
<application id="App_Test" platformVersion="7.1.0"
  xmlns="http://www.worklight.com/application-descriptor"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
```

Attributes

id The identifier of the application. The identifier must be identical to the application folder name. It must be an alphanumeric string that starts with a letter. It can also contain underscore ("_") characters. It must not be a reserved word in JavaScript.

platformVersion

The product version on which the application was developed.

Elements

<accessTokenExpiration>

Optional.

Defines the expiration period (in seconds) of OAuth access tokens. The default is 3600 seconds (one hour).

Client applications can use the token to access protected resources as long as the token has not expired. When the token expires, the client application has to obtain a new access token to access a protected resource. Obtaining a new access token may happen automatically without user intervention if all the realms by which the resource is protected have not expired. However, if one of the realms that is included in the security test of the resource has expired, and the realm requires user input (such as a form-based authenticator), the user has to re-authenticate.

```
<accessTokenExpiration>360</accessTokenExpiration>
```

<author>

Provides information about the application author. This data is copied to the descriptor files of the web and desktop environments that require it.

<description>

Description of the application. The description is displayed in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

<directUpdateAuthenticityPublicKey>

Optional.

<displayName>

The name of the application. The name is displayed in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

Note: This element supports English only.

<environment>

Each environment on which the application can run must be declared with a dedicated XML element: For example, `iphone`, or `windowsPhone8`. The following example shows the possible values for *environment*:

```
<iphone version="1.0" />
<android version="1.0" />
<blackberry10 version="1.0" />
<blackberry version="1.0" />
<windowsphoneuniversal version="1.0" />
  <uuid>34e026eb-6652-4ab-9f66-m68195re2931</uuid>
<windowsPhone8 version="1.0">
  <uuid>87e096eb-6882-4cef-9f66-e68769de3926</uuid>
</windowsPhone8>
```

```

<windows8 version="1.0">
  <certificate PFXFilePath="Path to certificate file" password="certificate password"/>
  <uuid>556a98a3-63fb-4602-827c-0b6bd9d00490</uuid>
</windows8>
<ipad version="1.0" />
<mobileWebApp />
<air version="1.0" />

```

Each such *environment* element has one mandatory attribute: **version** (except for web apps). See **version** for details.

<features>

Controls which features are included in your application. This capability gives you a finer degree of control over the size of your application, and therefore over its capacity to download and start quickly.

This element is added automatically with no contents when the application is first created. If later you add JSONStore features and want to include these resources in the application build, you can edit the <features> element.

If you do not include JSONStore in the build but use it in your code, an error is raised when you run the app, and you can add it to the <features> element with a QuickFix.

If, during the testing phase, you find that your application does not use the JSONStore resources, you can reduce the size of your Android app by removing the JSONStore argument from the <features> element. When you add or remove a feature, build the application again for the change to take effect.

Note: The JSONStore resources are still included in your iOS application builds.

For more information about the <features> element, see Including and excluding application features.

<licenseAppType>

Declares the application type for token licensing. This element is ignored if the MobileFirst Server does not have token licensing activated.

Possible values (values are case-sensitive; must be all uppercase):

- **NON_PRODUCTION:** Use this while you are developing and testing the application on the production server.

Important: Using NON_PRODUCTION for a production app is a breach of the license terms.

- **APPLICATION:** Use this for most applications when you are ready to deploy the app on a production server. This is the default. The production server must have token licensing activated, and enough tokens must be available.
- **ADDITIONAL_BRAND_DEPLOYMENT:** Use this when you are ready to deploy an additional brand deployment app on a production server. The app must be an additional brand deployment of an existing app for which an APPLICATION token has already been used. Your organization must have purchased an Additional Brand Deployment license for you to use this option. In addition, the code in the similar application must meet specific requirements such as the percentage of code that is different.

Refer to your IBM MobileFirst Platform Foundation - Additional Brand Deployment software license for details.

The production server must have token licensing activated, and enough tokens must be available.

If token licensing is activated on the server and this element is not present in the application descriptor, then the default setting APPLICATION is used.

For more information, see “Licensing in MobileFirst Server” on page 2-16 and your IBM MobileFirst Platform Foundation software license.

Note: Token licensing, as defined by <licenseAppType> is not related to OAuth access tokens, as defined by <accessTokenExpiration>.

<languagePreferences>

Contains a comma-separated list of languages to display system messages. For more information, see “Enforce language preference for MobileFirst messages” on page 8-168.

<loginPopupHeight> and <loginPopupWidth>

When login is configured as popup, you must provide the dimensions of the login window.

```
<loginPopupHeight> Height in pixels </loginPopupHeight>  
<loginPopupWidth> Width in pixels </loginPopupWidth>
```

<mainFile>

Contains the name of the main HTML file of the application.

<smsGateway>

Defines the SMS gateway to be used for SMS push notifications. It has one mandatory attribute, **id**, which contains the identifier of the SMS gateway. The ID must match one of the gateway identifiers that are defined in the SMSConfig.xml file.

```
<smsGateway id="kannelgw"/>
```

<targetCategory>

Declares the target category of your application. You can generate more accurate license reports for the ADDRESSABLE DEVICE license metric. This element is added automatically when the application is created. By default, the target category is set to UNDEFINED. If your application is licensed under the ADDRESSABLE DEVICE metric, you must edit this element to specify the relevant target category.

Possible values:

- UNDEFINED
- B2E: IBM MobileFirst Platform Foundation Enterprise
- B2C: IBM MobileFirst Platform Foundation Consumer

<thumbnailImage>

Contains the path to the thumbnail image for the application, including the image file name. The path is relative to the main application folder.

```
<mainFile>index.html</mainFile>  
<thumbnailImage>common/images/thumbnail.png</thumbnailImage>
```

<userIdentityRealms>

A comma-separated ordered list of user identity realms for OAuth authentication. The realms should be ordered by preference. The first successfully authenticated realm in this list is selected as the user identity

realm. If the list is empty, or no realm in the list was authenticated, the ID token contains no identity information. This element is optional and the default value is an empty list.

```
<userIdentityRealms>WASLTPRealm, CustomAuthenticatorRealm</userIdentityRealms>
```

Note: This attribute is used to set user identity in the OAuth-based flows. For the classic (pre-V7.0) flows, see the documentation for the `customSecurityTest` security test.

Sub-attributes

applicationId

Optional.

This attribute specifies the name of the application, as specified in the `worklight.plist` file. The values in the `application-descriptor.xml` and `worklight.plist` must match, and the value of **applicationId** must be the same as the value of **id**. This attribute is required if you use the IBM MobileFirst Platform Foundation classic security model. For more information, see “MobileFirst application authenticity overview” on page 8-564.

bundleId

Mandatory for iOS target environments. Not applicable to other target environments.

This attribute is copied to the appropriate native configuration file in the Xcode project of the application. Do not modify this value directly in the native configuration file because it is overridden by the builder with the value that you indicate in this attribute.

cacheManifest

Manages and edits the contents of the application cache for Desktop Browser and Mobile Web applications, and controls which resources are fetched when the application starts. Unused resources such as large images or unused files, when included in the Cache Manifest file, increase the startup time for these applications. If you edit this file, you can remove these unnecessary resources and speed up your application.

The following values are valid modes.

no-use Default mode. The cache manifest is not included in the application HTML files. There is no cache manifest, so decisions about which resources are cached are decided by the browser.

generated

The builder generates a default cache manifest and includes it in the application HTML files.

- For Desktop Browser environments, all resources are under NETWORK, which means: no cache at all.
- For Mobile Web environments, all resources are under CACHE, which means: cache everything.

The builder also creates a backup of the previous cache manifest, called `worklight.manifest.bak`. This file is overwritten in every build.

user The builder does not generate the cache manifest, but it does include it in the application HTML files. You must maintain the cache manifest manually.

If you open the application descriptor in Design view, you can view and set the current mode of this element with the DDE editor.

In Design view, each option is given a description:

- **Not Included in the application (default): no-use** mode
- **Managed by Worklight: generated** mode
- **Managed by user: user** mode

For more information about the cache manifest, see “Application cache management in Desktop Browser and Mobile Web apps” on page 8-364.

showInTaskbar

Determines behavior of the AIR application on the task bar. For more information, see “Specifying the application taskbar for Adobe AIR applications” on page 8-141.

version

The value of the version attribute is a string of the form *x.y*, where *x* and *y* are digits (0-9).

- For mobile apps, the version is shown to users who download the app from the app store or market.
- For desktop apps, the version determines whether MobileFirst Server automatically downloads a new version of the app to the user's desktop.

Sub-elements

<allowedDomainsForRemoteImages>

- **<windowsPhone8>**: Enables the application tile to access remote resources. Use subelement **<domain>** to define the list of allowed remote domains from which to access remote images. Each domain in the list is limited to 256 characters.

Note: You cannot add this subelement to the application descriptor by using the Design editor. You must use the Source editor instead.

<certificate>

- **<air>**: Sign the AIR application before you publish it. For more information, see “Signing Adobe AIR applications” on page 8-142.
- **<windows8>**: Sign the Windows 8 Universal application before you publish it. For more information, see “Signing Windows 8 Universal apps” on page 8-143.

<height>

Determine the height of the application on desktop environments.

<pushSender>

- **<iphone>** or **<ipad>**: For iOS apps that use the Apple Push Notification Service (APNS). Defines the password to the SSL certificate that encrypts the communication link with APNS. The password attribute can refer to a property in the `worklight.properties` file and can therefore be encrypted.
- **<android>**: For Android apps that use Google Cloud Messaging (GCM), use the **<pushSender>** element to define the connectivity details to GCM.

The **key** is the GCM API key, and the **senderId** is the GCM Project Number. For more information about GCM API key and GCM Project Number, see the Enabling the GCM Service page on the Android website for developers.

- `<windowsPhone8>`: For apps that use the Microsoft Push Notification Service (MPNS), you can indicate that the app is a "pushable" application. That is, the app subscribes to event sources and receives push notifications. You can also set attributes for authenticated push. For more information, see "Setting up push notifications for Windows Phone Silverlight 8" on page 8-506.

<security>

A subelement of the `<iphone>`, `<ipad>`, `<android>`, `<windowsPhone8>`, `<windows8>`, and `<windowsphoneuniversal>` elements. It is used to configure security mechanisms for protecting your apps against various malware and repackaging attacks. The element has the following structure:

<encryptWebResources>

Controls whether the web resources that are associated with the application are packaged and encrypted within the application binary file (a file with the `.apk` or `.app` name extension). If its **enabled** attribute is set to true, the builder encrypts the resources. The application decrypts them when it first runs on the device. Not supported on Windows Phone Silverlight 8, Windows 8 Universal, and Windows Phone 8 Universal.

<testWebResourcesChecksum>

Controls whether the application verifies the integrity of its web resources each time it starts running on the mobile device. If its **enabled** attribute is set to true, the application calculates the checksum of its web resources and compares the checksum with a value that was stored when the application was first run. Checksum calculation can take a few seconds, depending on the size of the web resources. To make it faster, provide a list of file extensions to be ignored in this calculation. Supported on Android, iOS, Windows 8 Universal, and Windows Phone 8 Universal.

<publicSigningKey>

Valid only in the Android environment, under `<android>/<security>`. This element contains the public key of the developer certificate that is used to sign the Android app. For instructions on how to extract this value, see "Extracting a public signing key" on page 8-69.

<productId>

Valid only in the Windows Phone Silverlight 8 environment, under `<windowsPhone8>/<security>`. The default value is the GUID for the project (128 bit). During the app submission process, a new product ID is inserted into the `WMAppManifest.xml` file.

<applicationId>

Valid in the Windows Phone Silverlight 8 environment, under `<windowsPhone8>/<security>`. This element is also valid in the Windows 8 Universal environment, under `<windows8>/<security>` and in the Windows Phone 8 Universal environment, under `<windowsphoneuniversal>/<security>`. The application ID value must match the value of the `wlAppId` property that is located in the `wlclient.properties` file.

<packageName>

Valid only in the Android, Windows 8 Universal, and Windows Phone 8 Universal environments. For Android, this element is required under `<android>/<security>`. This element is optional for all Windows platforms. If used for Windows 8 Universal, add it under `<windows8>/<security>`. If used for Windows Phone 8 Universal, add it under `<windowsphoneuniversal>/<security>`. This element is the family name of the package and the value can be picked up from the package.appxmanifest file.

For example:

```
<security>
  <encryptWebResources enabled="false"/>
  <testWebResourcesChecksum enabled="false" ignoreFileExtensions="png, jpg, jpeg, gif, mp4
  <!-- publicSigningKey is valid only for Android -->
  <publicSigningKey> value </publicSigningKey>
  <!-- productId is valid only for Windows Phone Silverlight 8 -->
  <productId>22cbbacb-e323-4419-befb-d3aff42f2126</productId>
  <!-- applicationId is valid for Windows Phone Silverlight 8, Windows 8 Universal, and W
  <applicationId>MyProj</applicationId>
  <!-- packageName is valid for Android, Windows 8 Universal and Windows Phone 8 Universal
  <packageName>4d0fb885-07fd-4d16-897d-255ab527486e_vr9ykqv283qqw</packageName>
</security>
```

<tags>

Supported by Android, iOS, Windows Phone Silverlight 8, Windows 8 Universal, and Windows Phone 8 Universal environments. During application deployment, the specified tags are created, updated, or deleted on the management database tables. In the following example, the `<tags>` specifies customer categories. Tags represent topics of interest to the user and provide user with an ability to receive notifications according to the chosen interest. This feature enables ability for sending and receiving messages by tags. A message is targeted to only the devices subscribed for a tag.

```
<tags>
  <tag>
    <name>Silver</name>
    <description>Silver customers</description>
  </tag>
  <tag>
    <name>Gold</name>
    <description>Gold customers</description>
  </tag>
</tags>
```

For more information about the setting of Tag-based notification, see “Setting up Tag-based notifications” on page 8-513.

<width>

Set the width of the application on desktop environments.

<worklightSettings>

You can use the settings page to change the address of the MobileFirst Server with which the app communicates. By default, the settings page is disabled. To enable it for the app, change the `include` attribute element to `true`. When the settings page is enabled, that page is accessible by using the settings app on the iOS device.

<uuid>

Uniquely identifies an application. The UUID is automatically generated when you create the environment for the application. Required for the following target environments:

- Windows Phone Silverlight 8
- Windows 8 Universal
- Windows Phone 8 Universal

Deprecated elements

The following table lists deprecated and removed elements:

Table 8-7. Deprecated and removed elements in application descriptors

Element	IBM MobileFirst Platform Foundation version
<provisioning> <viralDistribution> <adapters> <mobile>	Deprecated as of V4.1.3
<worklightRootURL	Deprecated as of V5.0
<usage>	Deprecated as of V5.0.0.3
<worklightServerRootURL>	This element was a replacement for <worklightRootURL> and was removed in IBM Worklight V6.0.0.

Login form and authenticator:

If your application needs a login form, you can use the default one as is or change it as necessary.

Applications that require user authentication might have to display a login form as part of the authentication process. In web widgets, the login form is not part of the widget resources. It can be triggered by the authentication infrastructure that is used by the organization or by the MobileFirst Server.

For more information about authentication, see the Form-based authentication tutorial on the Getting Started page of the Developer Center.

Setting up a new MobileFirst environment for your application

With MobileFirst Studio, you can build applications for different mobile, desktop, or web environments within your project.

Before you begin

Note: Starting with IBM Worklight V6.1.0, the structure of Project Explorer is simplified and focuses on three main components that the user is interested in: adapters, apps, and services. The following figure shows the directory structure.

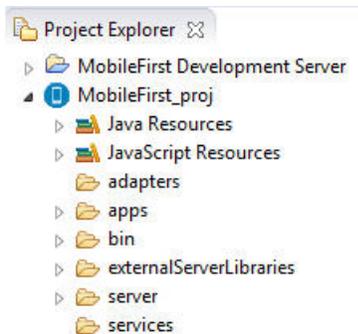

Figure 8-4. Project Explorer showing simplified structure

About this task

With MobileFirst Studio, you can add environments to your application, and write code that is specific to one or several mobile, desktop, or web environments. If you want to create a version of your application for a specific platform, you must add the environment that corresponds to that platform to your application. For example, if you want to create an iPhone version of your application, you must add an iPhone environment. When you add an environment to your application, a new folder for that environment is created. This folder contains the resources of the new environment:

images: This folder contains images that override the images in the common environment that have the same name.

css: This folder contains files that extend or override the CSS files in the common environment.

js: This folder contains JavaScript files that extend the common application instance JavaScript object. The class that is defined in this environment folder extends the common app class.

HTML: This HTML file overrides the HTML file in the common environment that has the same name.

Note: The **common** folder in your MobileFirst application folder contains the code and resources that are common to several environments.

You can add environments to your application either while you create your application, or later, when your application is created and already located in your project. This procedure only describes how to add environments to an existing app. To learn how to create a project, a first hybrid application, and to add environments to this app, see “Creating MobileFirst projects with MobileFirst Studio” on page 8-6. To learn how to create a hybrid application and to add environments to this app, see “Creating an application in a MobileFirst project with MobileFirst Studio” on page 8-8.

Note: The **Keychain Sharing** capability is mandatory while running iOS apps in the iOS Simulator when using Xcode 8. You need to enable this capability manually before building the Xcode project.

Procedure

1. In MobileFirst Studio, go to your application, which is in your project.

You can see your application within your project in the Project Explorer.

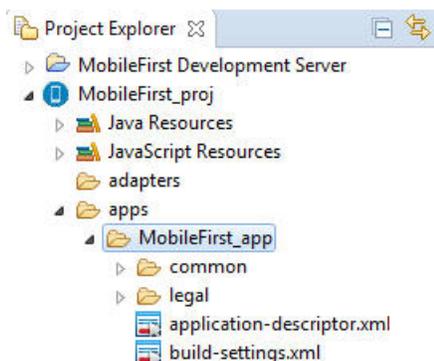

Figure 8-5. Your MobileFirst application folder

2. Click **File > New > MobileFirst Environment**.
A window opens where you can select the environment that you want to add.
3. In the **Project name** list, select your project.
4. In the **Application/Component** list, select your application.
5. Select the environments that you want to add. You can see the folders corresponding to the environments you added in your application folder. For example, the following figure shows the folders that are created if you select the iPhone, iPad, Blackberry 6 and 7, windows8 (Windows 8 Universal), and Desktop Browser web page environments.

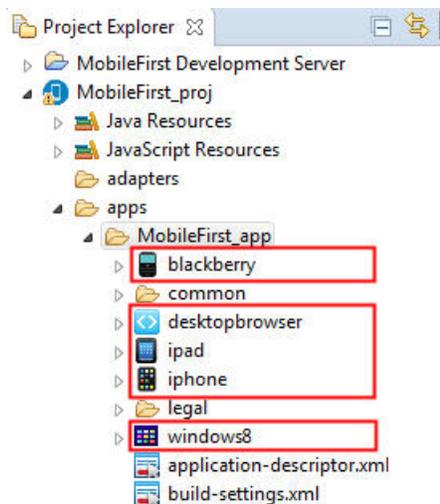

Figure 8-6. MobileFirst application folder that contains folders for the environments you selected

Developing hybrid applications

Use IBM MobileFirst Platform Foundation to create hybrid applications.

With IBM MobileFirst Platform Foundation, you can perform the following tasks:

- Add MobileFirst capabilities into existing native applications
- Show your splash screen as soon as the application starts
- Generally control the application startup flow and control the business logic of your apps, by running native code in your apps before they start the web view

By default, hybrid applications start the web view immediately. However, you can use native code in the startup process and start the web view later.

- Call a MobileFirst hybrid web view from native code and call a native page from a web view
- Send actions and data objects between JavaScript code and native code. The actions are received by action receivers. Actions that cannot be delivered immediately are queued by the MobileFirst framework and delivered after a suitable action receiver is registered.

Developing hybrid applications for iOS:

Develop hybrid applications for iOS as detailed here.

Note: The MobileFirst iOS SDK supports ARC (Automatic Reference Counting). The default MobileFirst application that is generated for the iPhone/iPad environment also supports ARC. Refer to the Apple documentation for more details on ARC.

Default startup process in iOS-based hybrid applications:

By default, the MobileFirst framework is initialized to display a web view in the iOS-based hybrid application.

The `initializeWebFrameworkWithDelegate` method is called to start the initialization process. After the initialization process is complete, the `wlInitWebFrameworkDidCompleteWithResult` method is called. In case of success, this method creates the Cordova `ViewController` instance and loads the main HTML file (through `mainHtmlFilePath`) into the Cordova `WebView`. In case of failure, an error dialog is displayed.

The `appName.h` file

```
@interface MyAppDelegate : WAppDelegate <WlInitWebFrameworkDelegate> {  
  
}  
  
@end
```

Note: Starting with version V6.2 of the product, `WLCordovaAppDelegate`, `CDVMainViewController`, and `didFinishWLNativeInit` APIs are deprecated.

The `appName.m` file

```
@interface Compatibility50ViewController : UIViewController  
@end  
  
@implementation Compatibility50ViewController  
/**  
 In iOS 5 and earlier, the UIViewController class displays views in portrait mode only.  
 To support additional orientations, you must override the shouldAutorotateToInterfaceOrientation: method  
 and return YES for any orientations your subclass supports.  
 */  
- (BOOL)shouldAutorotateToInterfaceOrientation:(UIInterfaceOrientation)interfaceOrientation {  
    return YES;  
}  
@end  
  
@implementation MyAppDelegate  
  
- (BOOL)application:(UIApplication *)application didFinishLaunchingWithOptions:  
    (NSDictionary *)launchOptions
```

```

{
    BOOL result = [super application:application didFinishLaunchingWithOptions:launchOptions];

    // A root view controller must be created in application:didFinishLaunchingWithOptions:
    self.window = [[UIWindow alloc] initWithFrame:[UIScreen mainScreen] bounds];
    UIViewController* rootViewController = [[Compatibility50ViewController alloc] init];

    [self.window setRootViewController:rootViewController];
    [self.window makeKeyAndVisible];

    [[WL sharedInstance] showSplashScreen];

    [[WL sharedInstance] initializeWebFrameworkWithDelegate:self];

    return result;
}

// This method is called after the WL web framework initialization is complete and web resources are ready to be used.
-(void)wInitWebFrameworkDidCompleteWithResult:(WLWebFrameworkInitResult *)result
{
    if ([result statusCode] == WLWebFrameworkInitResultSuccess) {
        [self wInitDidCompleteSuccessfully];
    } else {
        [self wInitDidFailWithResult:result];
    }
}

-(void)wInitDidCompleteSuccessfully
{
    UIViewController* rootViewController = self.window.rootViewController;

    // Create a Cordova View Controller
    CDVViewController* cordovaViewController = [[CDVViewController alloc] init] ;

    cordovaViewController.startPage = [[WL sharedInstance] mainHtmlFilePath];

    // Adjust the Cordova view controller view frame to match its parent view bounds
    cordovaViewController.view.frame = rootViewController.view.bounds;

    // Display the Cordova view
    [rootViewController addChildViewController:cordovaViewController];
    [rootViewController.view addSubview:cordovaViewController.view];
}

-(void)wInitDidFailWithResult:(WLWebFrameworkInitResult *)result
{
    UIAlertView *alertView = [[UIAlertView alloc] initWithTitle:@"ERROR"
        message:[result message]
        delegate:self
        cancelButtonTitle:@"OK"
        otherButtonTitles:nil];

    [alertView show];
}

```

Implementing a custom startup process for iOS-based hybrid applications:

You can implement a custom startup process to first display a native page in iOS-based hybrid applications.

About this task

The following application demonstrates the flexibility of the MobileFirst architecture: The application starts from a native page that runs custom native code. The MobileFirst and Cordova frameworks are used only later in the flow:

- The user clicks a button to initialize the MobileFirst framework. A second button is enabled only when initialization completes successfully,
- The second button loads the Cordova web view with the main HTML file of the application.

Procedure

1. Create a hybrid app, which creates the .h file that extends WAppDelegate. For example:

```
@interface MyAppDelegate : WAppDelegate
{
}
@end
```

Note: WLCordovaAppDelegate, CDVMainViewController, and didFinishWLNativeInit APIs are deprecated since V6.2.0.

2. Create a custom native view.

Note: The MobileFirst framework is not used at this point.
For example:

```
@implementation MyAppDelegate
// Create a custom view before initializing the MobileFirst framework
- (BOOL)application:(UIApplication *)application didFinishLaunchingWithOptions:(NSDictionary *)launchOptions
{
    BOOL res = [super application:application didFinishLaunchingWithOptions:launchOptions];

    // code for building a window

    // Build custom native UI
    MyCustomViewController* customViewController = [[MyCustomViewController alloc] init];

    // Set root view controller
    self.window.rootViewController = customViewController;

    // Show window
    [self.window makeKeyAndVisible];

    return res;
}
@end
```

3. Create a custom view controller. The view controller performs some custom business logic, and contains two buttons:

- one to trigger the MobileFirst initialization
- one to load the Cordova Webview

A custom delegate is used to handle the UI actions and to respond to the initialization completion For example:

```
@interface MyCustomViewController : UIViewController
{
}
@property (retain, nonatomic) MyWDelegate* wDelegate;
@end

@implementation MyCustomViewController
//
- (id)initWithNibName:(NSString *)nibNameOrNil bundle:(NSBundle *)nibBundleOrNil
{
    self = [super initWithNibName:nibNameOrNil bundle:nibBundleOrNil];
    init wDelegate
    return self;
}

- (void)viewDidLoad
{
```

```

        [super viewDidLoad];
        //Run some business logic here
    }
    //Run some more business logic

    // Start MobileFirst initialization
    - (IBAction)onInitWLClicked:(id)sender {
        [[WL sharedInstance] initializeWebFrameworkWithDelegate:self.wlDelegate];}

    // Load the Cordova web view
    - (IBAction)onShowWebViewClicked:(id)sender {
        [self.wlDelegate showCordovaWebView];
    }
}
@end

```

4. Create the custom delegate that implements `WLInitWebFrameworkDelegate` and some custom logic. For example:

```

@interface MyWLDelegate : NSObject <WLInitWebFrameworkDelegate>
//
@end

@implementation MyWLDelegate

// Implement WLInitWebFrameworkDelegate protocol
-(void)wlInitWebFrameworkDidCompleteWithResult:(WLWebFrameworkInitResult *)result
{
    if ([result statusCode] == WLWebFrameworkInitResultSuccess) {
        [self wlInitDidCompleteSuccessfully];
    } else {
        [self wlInitDidFailWithResult:result];
    }
}

-(void)wlInitDidCompleteSuccessfully{
    // Enable the button on the viewController
}

// load and show the Cordova WebView
-(void)showCordovaWebView
{
    // build the cordova view controller
    CDVViewController* cordovaViewController = [[[CDVViewController alloc] init]];

    // Set URL of main HTML file
    cordovaViewController.startPage = [[WL sharedInstance ]mainHtmlFilePath];

    // Show the Cordova web view
    UIViewController* rootViewController = self.window.rootViewController;
    [rootViewController addChildViewController:cordovaViewController];
    [rootViewController.view addSubview:cordovaViewController.view];
}

// Handle initialization failure
-(void)wlInitDidFailWithResult:(WLWebFrameworkInitResult *)result
{
    UIAlertView *alertView = [[UIAlertView alloc] initWithTitle:@"ERROR" message:[result message]
delegate:self cancelButtonTitle:@"OK" otherButtonTitles:nil];
    [alertView show];
    [alertView release];
}
@end

```

Specifying the icon for an iPhone application:

Put the icon in your application's `/iphone/nativeResources/Resources` folder. It is copied from there at build time.

About this task

You want to use a particular icon for your application in the iPhone environment.

Procedure

1. Place the icon that you want to use in the *project/apps/application/iphone/nativeResources/Resources* folder.
2. Build and deploy your application.

Results

The icon is copied to the *project/apps/application/iphone/native/Resources* folder.

Though you can place the icon directly into the *project/apps/application/iphone/native/Resources* folder, you risk losing the icon if that folder is deleted for any reason.

Customizing iOS applications:

You can further customize your iOS application by extending a different class than the default MobileFirst class.

Before you begin

These features require you to create your application in IBM Worklight Foundation V6.2.0 or IBM MobileFirst Platform Foundation and later. If you created your application in a previous version of IBM Worklight, follow the upgrade procedures to upgrade your application to V6.2.0.

About this task

By default, the application delegate extends the `WLAppDelegate` class, which gives access to various features provided by the product, such as push notifications and local notifications. However, if your application delegate extends a class other than `WLAppDelegate`, you can still access MobileFirst features by following these steps.

Procedure

1. Create a hybrid iOS application
2. In `MyAppDelegate.h`, have `MyAppDelegate` extend a different class than `WLAppDelegate`. For example,

```
MyAppDelegate : UIResponder <WLInitWebFrameworkDelegate,UIApplicationDelegate>
```

3. Add the **window** property to `MyAppDelegate.h`, following iOS guidelines.

```
@property (nonatomic, retain) IBOutlet UIWindow* window;
```

4. Add the **launchOptions** property to `MyAppDelegate.h`

```
@property (nonatomic, retain) NSMutableDictionary* launchOptions;
```

5. Synthesize the two properties in `MyAppDelegate.m`.

```
@synthesize window, launchOptions;
```

6. In `MyAppDelegate.m`, make the following changes to `applicationDidFinishLaunchingWithOptions`:

- a. Make necessary changes to the super call. In this example, remove the line

```
BOOL result = [super application :application didFinishLaunchingWithOptions:launchOptions]
```

and return **YES** instead of result.

- b. Add the following line to keep the launchOptions. For example,
`self . launchOptions = [NSMutableDictionary dictionaryWithDictionary :launchOptions];`

Results

You can now run your application and access most of the MobileFirst features. Some features, such as custom URL schemas, local notifications, and push notifications require extra steps.

What to do next

To enable the use of custom URL schemas, add the following method to your application delegate (MyAppDelegate) and follow the Cordova documentation on **handleOpenURL**.

```
- (BOOL)application:( UIApplication*)application handleOpenURL:(NSURL *)url
{
    [[ NSNotificationCenter defaultCenter ] postNotificationName: WApplicationHandleOpenURL object :url];
    return YES;
}
```

To use local notifications, add the following method to your application delegate (MyAppDelegate) and follow the Cordova documentation on sending local notifications to Cordova plug-ins.

```
- (void)application:( UIApplication*)application
didReceiveLocalNotification:( UILocalNotification*)notification
{
    [[NSNotificationCenter defaultCenter ] postNotificationName: WApplicationDidReceiveLocalNotification
object:notification];
}
```

To enable MobileFirst hybrid push notifications, add the following three methods to your application delegate (MyAppDelegate) and follow the MobileFirst documentation on hybrid push notifications.

```
- (void)application:( UIApplication *)application didRegisterForRemoteNotificationsWithDeviceToken:( NSData *)deviceToken
{
    [[ NSNotificationCenter defaultCenter ]
postNotificationName :WApplicationDidRegisterForRemoteNotificationsWithDeviceToken object:deviceToken];
}
- ( void)application:(UIApplication *)application didFailToRegisterForRemoteNotificationsWithError:( NSError *)error {
    [[ NSNotificationCenter defaultCenter ]
postNotificationName :WApplicationDidFailToRegisterForRemoteNotificationsWithError object:error];
}
- ( void)application:(UIApplication *)application didReceiveRemoteNotification:( NSDictionary *)userInfo {
    [[ NSNotificationCenter defaultCenter ]
postNotificationName :WApplicationDidReceiveRemoteNotification object:userInfo];
}
```

Developing hybrid applications for Android:

Develop hybrid applications for Android as detailed here.

Note: When Android runs in debuggable mode, which can be set in the application's manifest file, unintended consequences can occur. One consequence is that SSL errors are not displayed by Cordova, such as when the server certificate is not trusted.

Important: When building an Android application for deployment to a production environment, do not build it to run in debuggable mode. Ensure that the `AndroidManifest.xml` file does not include an `android:debuggable` attribute, or set its value to `false`. For more information, see [Configuring Your Application for Release](#).

Note: If you are targeting devices on API level below 14, add the following permission to your `AndroidManifest.xml` file: `<uses-permission android:name="android.permission.GET_TASKS"/>`. This permission is required for the heartbeat functionality to function properly.

Understanding the Default startup process in Android-based Hybrid applications:

By default, the MobileFirst framework is initialized to display a web view in the Android-based hybrid application. The default startup process for Android-based hybrid applications is described here.

The default activity

The default activity for the Android environment extends `CordovaActivity` and implements `WLInitWebFrameworkListener`.

For example:

```
public class AndroidWebview extends CordovaActivity implements WLInitWebFrameworkListener {  
  
    @Override  
    public void onCreate(Bundle savedInstanceState){  
        super.onCreate(savedInstanceState);  
    }  
}
```

Note: The `WLDroidGap` API is deprecated since V6.2.

WL APIs

The WL APIs are called before any other IBM MobileFirst Platform Foundation API to initialize the IBM MobileFirst Platform Foundation framework.

For example:

```
//Create Worklight framework, show splash screen, and initialize  
//the web framework, passing 'this' as the listener for the web  
//initialization process  
  
WL.createInstance(this);  
  
WL.getInstance().showSplashScreen(this);  
  
WL.getInstance().initializeWebFramework(getApplicationContext(), this);  
  
// Add additional code here  
}
```

Initialization status

If the initialization status is **SUCCESS**, the webpage is loaded with the `WL.getMainHtmlFilePath()` method. For example:

```
@Override  
  
//Start the Cordova web view using the main HTML file path that it gets  
//from Worklight framework
```

```
public void onInitWebFrameworkComplete(WLInitWebFrameworkResult result){
    if(result.getStatusCode() == WLInitWebFrameworkResult.SUCCESS) {
        super.loadUrl(WL.getInstance().getMainHtmlFilePath());
    }
}
```

Initialization failure

The initialization status can be:

- FAILURE_INTERNAL
- FAILURE_UNZIP
- FAILURE_CHECKSUM
- FAILURE_NOT_ENOUGH_SPACE

For example:

```
    } else {
        AlertDialog.Builder alertDialogBuilder = new AlertDialog.Builder(this);
        alertDialogBuilder.setNegativeButton(R.string.close, new OnClickListener() {
            @Override
            public void onClick(DialogInterface dialog, int which) {
                finish();
            }
        });

        alertDialogBuilder.setTitle(R.string.error);
        alertDialogBuilder.setMessage(result.getMessage());
        alertDialogBuilder.setCancelable(false);
        alertDialogBuilder.create();
        alertDialogBuilder.show();
    }
}
```

Implementing a custom startup process in Android-based hybrid applications:

You can display a native page when you start an Android-based hybrid application.

About this task

You can choose to initialize the MobileFirst framework whenever you want to display a web view.

Procedure

1. Create the main launcher activity that extends Activity and implements WLInitWebFrameworkListener. For example:

```
public class NativeCustomActivity extends Activity implements WLInitWebFrameworkListener {

    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        WL.createInstance(this);
        WL.getInstance().initializeWebFramework(getApplicationContext(), this);
    }

    public void onInitWebFrameworkComplete(WLInitWebFrameworkResult result){
        if (result.getStatusCode() == WLInitWebFrameworkResult.SUCCESS) {
            openMainNativeActivity();
        } else {
            handleWebFrameworkInitFailure(result);
        }
    }
}
```

Note: The WLDroidGap API is deprecated since V6.2.

2. Create the main UIActivity that extends Activity. For example:

```
public class NativeMainActivity extends Activity {  
  
    public void onStart(){  
        super.onStart();  
        // The rest of the code for regular native activity,  
        // and opening a CordovaActivity when ever it's needed  
        openHybridPage();  
    }  
  
}
```

Specifying the icon for an Android application:

Put the icon in your application's /android/nativeResources/res folder. It is copied from there at build time.

About this task

You want to use a particular icon for your application in the Android environment.

Procedure

1. Place the icon that you want to use in the *project/apps/application/android/nativeResources/res* folder.
2. Build and deploy your application.

Results

The icon is copied to the *project/apps/application/android/native/res* folder.

Though you can place the icon directly into the *project/apps/application/android/native/res* folder, you risk losing the icon if that folder is deleted for any reason.

Extracting a public signing key:

Copy the public signing key from the keystore to the application descriptor.

Procedure

1. In the Eclipse project explorer, right-click the android folder for the application and then click **Extract public signing key**.

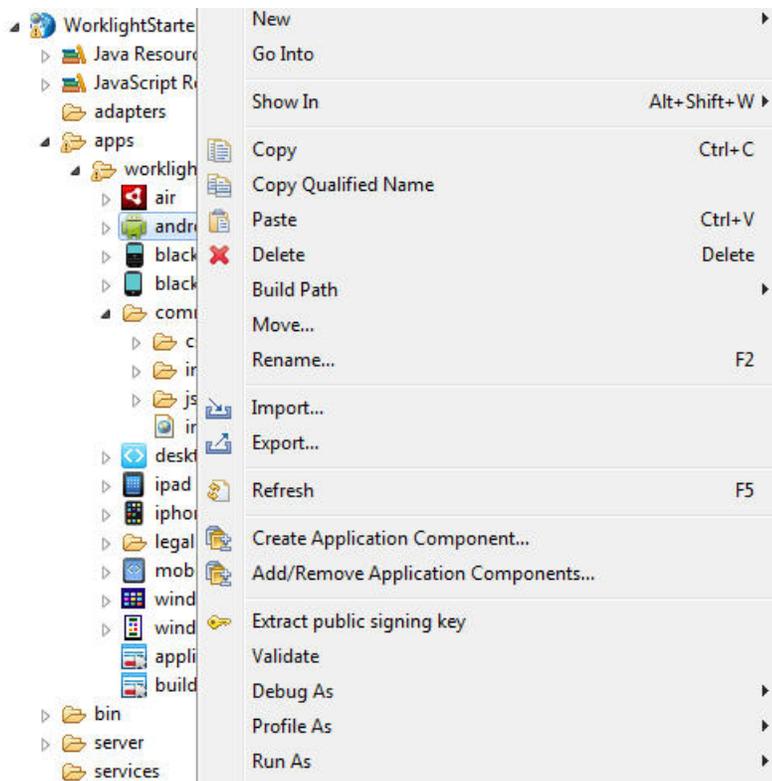

Figure 8-7. Extracting the public signing key

A wizard window opens.

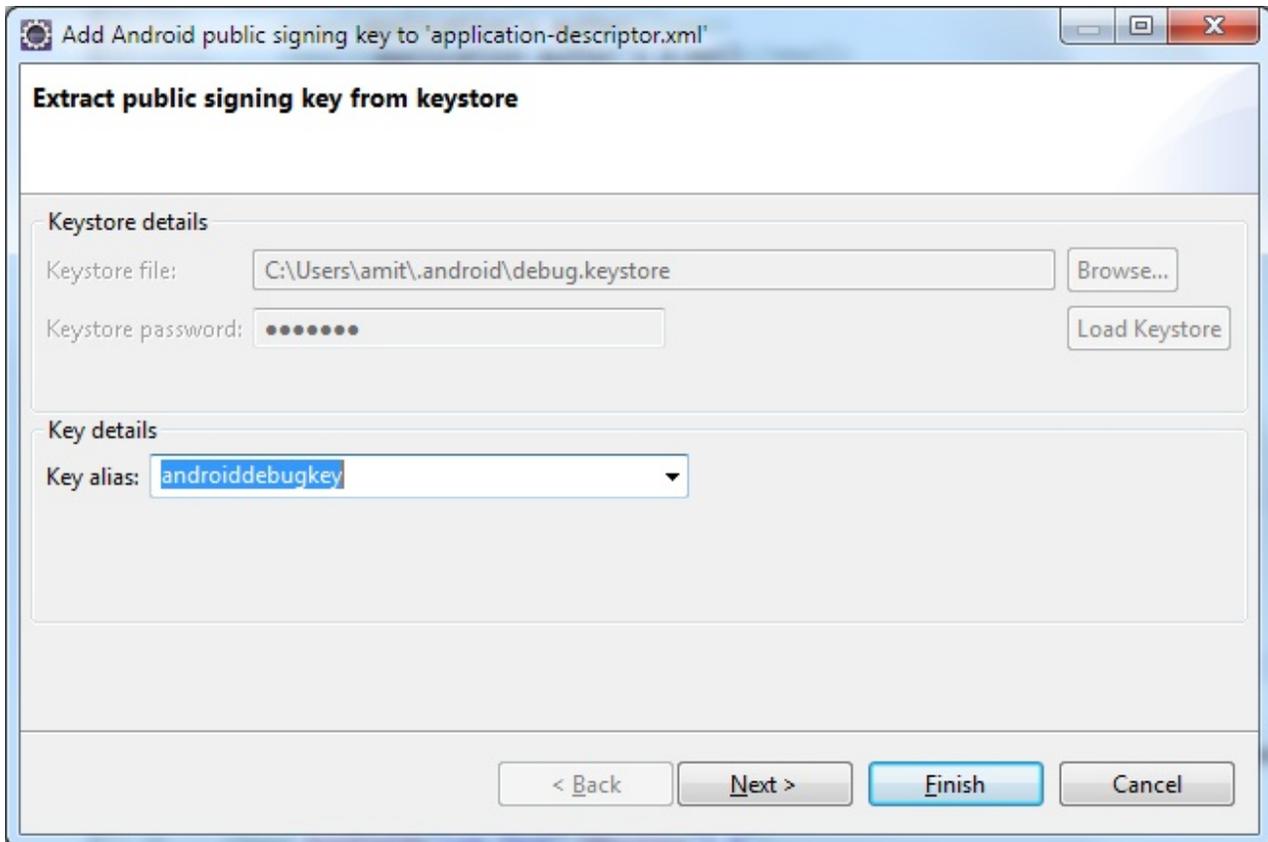

Figure 8-8. Adding the Android public signing key

- In this window, enter the path to your keystore.
The keystore is usually in one of the following directories, depending on operating system.

Option	Description
Windows	C:\Documents and Settings\user_name\ .android\
OS X and Linux	~/.android/

- Enter the password to your keystore and click **Load Keystore**.
The password is usually android.
- When the keystore is loaded, select an alias from the **Key alias** menu and click **Next**. For more information about the Android keystore, see the *Signing Your Applications* page of the Android site at <http://developer.android.com/guide/publishing/app-signing.html> .
- In the window, click **Finish** to copy the public signing key directly into the application descriptor.

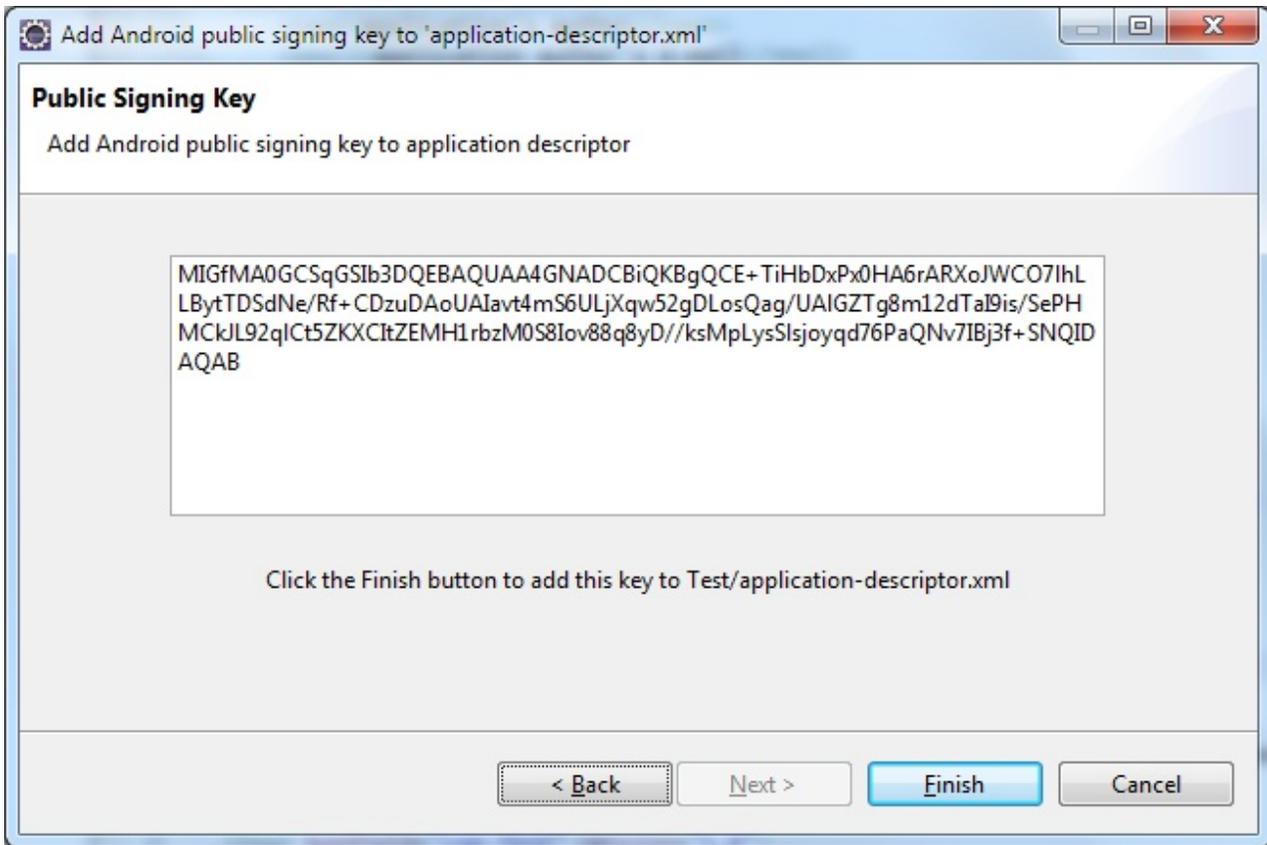

Figure 8-9. Android public signing key

Results

The public key is copied to the application descriptor. See the following code example:

```
<android version="1.0">
  <worklightSettings include="false"/>
  <security>
    <testAppAuthenticity enabled="false"/>
    <encryptWebResources enabled="false"/>
    <testWebResourcesChecksum enabled="false" ignoreFileExtensions="png, jpg, jpeg, gif, mp4, mp3"/>
    <publicSigningKey>MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQCE+TiHbDxPx0HA6rARXoJWC071hLLBytTDSdNe/>
  </security>
</android>
```

Managing device orientation:

When you develop Android applications that target an API level equal or higher than 13, you must include the screenSize value to the android:configChanges attribute in the AndroidManifest.xml file. Otherwise, the application fails to run properly when the device orientation changes.

Assuming that IBM MobileFirst Platform Foundation is the first main activity in the AndroidManifest.xml file of your application:

- If your target API is equal or higher than 13, you must add the screenSize value to the android:configChanges attribute of the <activity> element, as shown in the following example:

```
<activity android:name=".worklightStarter" android:label="@string/app_name" android:configChanges=
```

- If your target API is smaller than 13, your activity always handles this configuration change itself, and you do not need to add the screenSize value to the <activity> element.

Preparing a project that uses the Cordova camera plug-in with the Android platform:

You must complete extra steps for the Cordova camera plug-in to work correctly with your IBM MobileFirst Platform Foundation Cordova app for the Android platform.

About this task

Starting with Android N, the Cordova camera plug-in requires a fix that enables the file URI of the photo to be accessed by the camera plug-in. The fix requires some extra setup steps for the camera plug-in to work correctly. You must complete these steps when you create a Cordova app that uses the Cordova camera plug-in with the Android platform or when you modify an existing Cordova app to use the camera plug-in. If you do not complete the steps, your app crashes when it starts, and returns the following error messages:

```
java.lang.RuntimeException: Unable to get provider android.support.v4.content.FileProvider
java.lang.ClassNotFoundException: Didn't find class "android.support.v4.content.FileProvider"
```

Complete the following steps to prepare the project:

Procedure

1. Add the android-support-v4.jar file to your project.
 - a. In a file explorer, browse to your Android SDK directory, which is where your Android SDK Manager downloads the updates.

Tip: If you are using Android Studio, you can open the SDK Manager from the toolbar.

- b. If it is not already installed, install the Android Support Repository in your Android environment.
- c. Browse to extras/android/m2repository/com/android/support/support-core-utils.
- d. Select version 24.2.0, or higher, of the support-core-utils repository.
- e. Extract the classes.jar file from the support-core-utils-24.2.0.aar package.

Tip: If you do not have a file archive tool, you can change the .aar file extension to .zip to extract the classes.jar file.

- f. Add the classes.jar file to the libs directory of your Android platform.
2. Update the AndroidManifest.xml file.

- a. Open the AndroidManifest.xml file that is in the platforms/android folder.

- b. Add the following lines inside of the ending <application> tag:

```
<provider android:authorities="{PACKAGE_ID}.provider" android:exported="false"
android:grantUriPermissions="true" android:name="android.support.v4.content.FileProvider">
<meta-data android:name="android.support.FILE_PROVIDER_PATHS" android:resource="@xml/provi
</provider>
```

Where {PACKAGE_ID} is replaced with the Android Package ID of your project.

- c. Save the AndroidManifest.xml file.

3. Update the config.xml file.
 - a. Open the config.xml file that is in your project folder.
 - b. Inside the <platform name="android"> tag, add the following tag:

```
<preference name="applicationId" value="{PACKAGE_ID}"/>
```

Where {PACKAGE_ID} is replaced by the Android Package ID of your project.
 - c. Save the config.xml file.

Building MobileFirst Android applications with Android Studio:

From MobileFirst Studio, point to the directory that contains your Android Studio installation, and run your Android application as an Android Studio project.

About this task

You want to use Android Studio as the IDE to customize and build your MobileFirst Android application.

Procedure

1. In MobileFirst Studio, go to **Window > Preferences > MobileFirst** (or **Eclipse > Preferences > MobileFirst** on Mac OS), click **Browse**, and specify the directory where your Android Studio is installed.
2. Right-click the Android environment folder of your project, and click **Run As > Android Studio project** to start Android Studio.

Converting a MobileFirst project to an Android Studio-based project:

Follow these instructions if you want to work with a project created either with the MobileFirst Platform Command Line Interface or with MobileFirst Studio in Android Studio, and use Gradle building capabilities.

About this task

This procedure enables you to make changes to your project, build and deploy to MobileFirst Server, go to Android Studio, and build and deploy your app to an emulator or a device.

Procedure

1. Only for projects created with MobileFirst Platform Command Line Interface (for projects created with MobileFirst Studio, go directly to step 2), import your project into MobileFirst Studio:
 - a. In MobileFirst Studio, go to **File > Import > Android > Existing Android Code into Workspace**, and click **Next**.
 - b. In **Root Directory**, click **Browse** and go to *your_project_name* > **apps** > *your_app_name* > **android** > **native**, and click **OK**.
 - c. Select your project from **Project to Import**, and click **Finish**.
2. Export the Gradle file:
 - a. In MobileFirst Studio, go to **File > Export > Android > Generate Gradle build files**
 - b. Follow the wizard instructions to select your Android project, and click **Finish** when the export is completed.

The build.gradle file is now generated in your Android project.

3. Import the build.gradle file from your project to Android Studio:
 - a. In Android Studio, click **Import project (Eclipse ADT, Gradle, etc.)**.
 - b. Go to your MobileFirst project under **apps > android > native**, and click build.gradle.

Note: Make sure to click build.gradle and not the native folder.

- c. Click **OK** and accept any Gradle configuration that Android Studio prompts for.

You might now have to fix sync errors.

4. Optional: After your Gradle file is imported, an error message might report that your Gradle plug-in version is out of date. To fix the issue, you can either:
 - Select the auto-fix by clicking **Fix plugin version and sync project**.
 - Or manually edit the build.gradle file:
 - a. From the **Project** tab, expand the **Gradle Scripts** drop-down menu, and open build.gradle.
 - b. Change the version of Gradle tools to classpath 'com.android.tools.build:gradle:1.5.0' and sync Gradle again.
5. Optional: To fix a Gradle sync error about the Gradle wrapper version:
 - a. Open the **Project** drop-down menu, go to **native > gradle > wrapper**, and open the gradle-wrapper.properties file.
 - b. Set the distributionUrl version to 2.8: distributionUrl = https \: //services.gradle.org/distributions/gradle-2.8-all.zip
6. Optional: If other errors prevent Gradle from syncing, fix them before you go to the next step.

The most common issues that you must resolve are dependencies issues. To know how to fix those problems, see the Gradle documentation:

https://docs.gradle.org/current/userguide/dependency_management.html and https://docs.gradle.org/current/userguide/java_plugin.html#sec:java_plugin_and_dependenc%20y_management

7. Run your application in Android Studio. If the application is deployed successfully, continue with this procedure. If you have other build errors, you might have to edit the build.gradle file again to adapt it to your project.
8. Edit the index.html file from the **common** folder of your project, make a change and save the file, either in MobileFirst Studio or with any other editor.
9. Build the environment:
 - For a project created with the MobileFirst Platform Command Line Interface, run the **mfp push** command.
 - For a project created with MobileFirst Studio, go to your android app folder in the MobileFirst hybrid project directory, right-click **android**, click **Run as** and select any of the first three options.

Note: Build Android Environment is the fastest option, but you can also choose to deploy your app to MobileFirst Server. If you want to open your app automatically in Android Studio, you can also click **Android Studio project**. All three options build the hybrid Android project.

10. In Android Studio, from the **Project** drop-down menu, go to **native > assets > www > default**, open the index.html file, and make sure the changes that you made in step 8 are present.

Note: If your changes are not there, refresh your project in Android Studio
11. Run the application.

Results

The application is now deployed successfully in Android Studio.

Developing hybrid applications for BlackBerry:

Develop hybrid applications for BlackBerry as detailed here.

IBM MobileFirst Platform Foundation supports development of BlackBerry 6 and 7 (deprecated; see Table 3-2 on page 3-21), and 10 hybrid mobile applications.

Important: Blackberry 6 and 7 hybrid mobile application performance might not be on par with the latest BlackBerry 10 operating system due to older embedded browser technologies and hardware. It is best to use prototypes to validate that applications meet your performance targets on Blackberry 6 and 7. When advanced performance is needed, native development should be preferred.

Creating a MobileFirst BlackBerry 10 environment:

Follow these instructions to create a MobileFirst BlackBerry 10 environment.

About this task

For WebWorks SDK 1.x:

The BlackBerry 10 environment uses the latest version of Cordova. Use either Ripple or Cordova Ant scripts to create a MobileFirst BlackBerry 10 environment, and follow the steps in the Procedure section to ensure that your program runs correctly.

For WebWorks SDK 2.x:

Follow the instructions of BlackBerry documentation. For more information, see Building and Testing.

Note: BlackBerry OS 10 is not supported by the current version of the Application Center.

Procedure

1. Follow all instructions to install WebWorks SDK, described at HTML5 WebWorks.
2. Install Ant Version 1.8 (or later) if it is not already installed. You can obtain Ant Version 1.8 from <http://ant.apache.org/>.
3. Download the `ant-contrib-1.0b3.jar` file from <http://central.maven.org/maven2/ant-contrib/ant-contrib/1.0b3/ant-contrib-1.0b3.jar>, and save the `.jar` file in the `lib` folder of the Ant installation folder, `ANT_HOME`.
4. If you use Ant scripts, manually modify the `project.properties` file. Provide values for the following variables in `project.properties`. This step is not relevant if you are using Ripple.

```
# BB10 Code Signing Password  
qnx.sigtool.password=
```

```
For simulator:  
# QNX Simulator IP  
#
```

```
# If you leave this field blank, then
# you cannot deploy to simulator
#
qnx.sim.ip=
```

```
# QNX Simulator Password
#
# If you leave this field blank, then
# you cannot deploy to simulator
#
qnx.sim.password=
```

for device:

The initial device ip is 169.254.0.1, that is, the one that is usually given when connected via USB to the computer; you

```
# QNX Device IP
#
# If you leave this field blank, then
# you cannot deploy to device
#
qnx.device.ip=169.254.0.1
```

```
You also must change
# QNX Device Password
#
# If you leave this field blank, then
# you cannot deploy to device
#
qnx.device.password=
```

```
# QNX Device PIN
#
# Fill this value in to use debug tokens when debugging on the device
qnx.device.pin=
```

5. Do **not** delete or change the following elements in config.xml:

```
<!-- start_worklight_host_server do not change this line-->
<access subdomains="true" uri="http://9.148.225.82" />
<!-- end_worklight_host_server do not change this line-->
```

The correct server TCP/IP address is automatically put in the <access> element on each MobileFirst build. If this element is deleted or changed, the TCP/IP address cannot be automatically updated.

6. BlackBerry 10 supports Ripple. If you intend to use Ripple, specify {project name}/apps/{app name}/blackberry10/native/www as the root folder in Ripple. Before you package or start the application with Ripple, perform the following steps:
 - a. Install Ant if it is not already installed.
 - b. Open a command window, and navigate to the {project name}/apps/{app name}/blackberry10/native folder.
 - c. In the {project name}/apps/{app name}/blackberry10/native folder, run the **ant qnx** copy-extensions command.

Note: If you uninstall and install back the WebWorks SDK, make sure to run the **ant qnx** copy-extensions command again.

7. BlackBerry 10 is based on QNX. To run the application on the phone by using Cordova Ant scripts, use **ant qnx** <command>, where <command> is one of the commands that are defined in the native/qnx.xml file. For example, use **ant qnx** debug-device to build, deploy, and run the app on the device.

Migrating a BlackBerry 10 WebWorks 1.x MobileFirst project to WebWorks 2.x:

Follow these instructions to make a MobileFirst BlackBerry 10 WebWorks 1.x project works with WebWorks SDK 2.x.

1. Set the **WEBWORKS_HOME** environment variable to the WebWorks SDK 2.x folder.
2. Create a MobileFirst project and MobileFirst application.
3. Add BlackBerry 10 environment to it. A BlackBerry 10 native folder is created with WebWorks SDK 2.x project structure.
4. Replace *new_project/new_app/blackberry10/native/www* folder with *old_app/blackberry10/native/www* folder of the old project. This old project has a BlackBerry 10 native folder with WebWorks SDK 1.0 project structure.

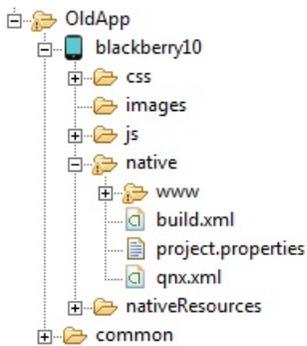

Figure 8-10. native folder of an old project with WebWorks SDK 1.0 project structure

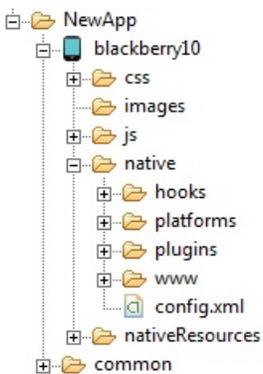

Figure 8-11. native folder of a new project with WebWorks SDK 2.x project structure

5. Replace *new_project/new_app/blackberry10/css*, *new_app/blackberry10/images*, *new_app/blackberry10/js*, and *new_app/common* folder with corresponding folders from the old project.
6. Modify *new_project/new_app/blackberry10/native/www/webresources/default/index.html* file with the following steps:
 - a. Remove `<script>` tag that includes `webworks.js`.
 - b. Change `src="worklight/cordova.js"` to `src="../../cordova.js"`. The path now points to *new_project/new_app/blackberry10/native/platforms/blackberry10/www/cordova.js*.
7. Remove unnecessary files and folders from *new_project/new_app/blackberry10* folder:
 - a. Delete `chrome`, `ext-qnx`, and `config.xml` from *native/www* folder.

- b. Delete `Plugins`, `cordova.js`, `cordova_plugin.js` from `native/www/webresources/default/worklight/` folder.
8. Reapply the custom changes that you made to the `config.xml` file. Modify the `new_app/blackberry10/native/config.xml` file with the changes made in the `config.xml` file of the old project. For example, changes in `rim:splash`, `content`, and `rim:permission` elements.
9. If any Cordova and BlackBerry plug-ins are added to your old project, add them to the new project.
10. The new project that you created is your migrated project. You can archive the old project for future reference.

For more information, see BlackBerry documentation: [Upgrading from WebWorks 1.0](#).

Specifying the icon for a BlackBerry application:

Put the icon in your application's folder. It is copied from there at build time.

About this task

You want to use a particular icon for your application in the BlackBerry environment.

Procedure

1. For BlackBerry 10, place the icon that you want to use in the `project/apps/application/blackberry10/nativeResources/www` folder.
2. For BlackBerry 6 and 7 (deprecated. See Table 3-2 on page 3-21), place the icon that you want to use in the `project/apps/application/blackberry/native` folder.
3. Build and deploy your application.

Results

For BlackBerry 10, the icon is copied to the `project/apps/application/blackberry10/native/www` folder.

For BlackBerry 6 and 7, the icon is copied to the `project/apps/application/blackberry/native` folder.

Though you can place the icon directly into the folder, you risk losing the icon if that folder is deleted for any reason.

Note: `nativeResources` is a feature that allows you to place replacement files in the BlackBerry 10 or BlackBerry 6 and 7 `nativeResources` directory. These files are copied to the `native` folder each time you build into the BlackBerry directory. It is easy to use, and if the `native` folder is accidentally deleted, you can go into the source control to retrieve it.

Developing hybrid applications for Windows Phone Silverlight 8:

Develop hybrid applications for Windows Phone Silverlight 8 as detailed here.

To develop applications for Windows Phones on IBM MobileFirst Platform Foundation, you must add a Windows Phone Silverlight 8 environment to your hybrid application. When you build a MobileFirst application with the Windows

Phone Silverlight 8 environment, a Visual C# Silverlight Windows Phone project is created. You can build and test this project from Microsoft Visual Studio.

Direct update consideration in development environment

You can get an unintended direct update in the development environment. This behavior is because IBM MobileFirst SDK stores the direct update resources in the isolated storage of the device or simulator. When you redeploy the app from Visual Studio, the isolated storage contents are not cleared. This leads to a mismatch in the version information of the app in the MobileFirst Server and what is in the isolated storage on the device or simulator. The solution is to explicitly uninstall the app in the device or simulator and proceed with reinstallation from Visual Studio. Alternately, you can accept the direct update and continue with the development.

This behavior occurs only when you have already done a direct update at least once. For more information about isolated storage, see [Isolated Storage](#).

Choosing a target platform

Depending on the target device or simulator, you must choose x86, or ARM from the **Configuration Manager**. The AnyCPU configuration is not supported.

Developing hybrid applications for Windows 8 Universal:

Develop hybrid applications for Windows 8 Universal as detailed here.

IBM MobileFirst Platform Foundation supports Windows Store Apps.

The MobileFirst Windows 8 Universal environment supports the Windows RT app development paradigm in Windows 8.1 called Windows Universal applications.

To develop applications for Windows 8 or 8.1 Universal phones, tablets and desktops on IBM MobileFirst Platform Foundation, you must add a Windows 8 Universal environment to your hybrid application. When you do so, the resultant application descriptor file includes elements for both desktops and tablets and for phones. When you build a MobileFirst application with the Windows 8 Universal environment, a WinJS (Windows Library for JavaScript) application is created. Two .wlapp files are created at build time: one for phones, the other for desktops and tablets. You can build and test this application from Microsoft Visual Studio.

WinJS versions

Visual Studio 2012

When you use Visual Studio 2012, the WinJS version is set to 1.0. This version is what Visual Studio 2012 supports.

Visual Studio 2013 Express

If you use Visual Studio 2013 Express, the first time you open your MobileFirst app project, you are prompted to retarget. This retarget operation upgrades the project to use WinJS 2.x.

Note: The retargeted apps work only on Windows 8.1 and later.

Visual Studio 2013 Commercial Editions

The first time when you open your MobileFirst app project, you are prompted to retarget. You can choose to retarget or not. If you choose to retarget, the project is upgraded to use WinJS 2.x. However, if you want to work with WinJS 1.0, then do not choose to retarget.

Note: The retargeted apps work only on Windows 8.1 and later.

Choosing a target platform

Depending on the target device, you must choose x86, x64, or ARM from the **Configuration Manager**. The AnyCPU configuration is not supported.

Managing the splash screen:

Show and hide the splash screen.

Managing the splash screen with JavaScript APIs:

You can choose to show and hide the splash screen with JavaScript.

In JavaScript code, you can use the `WL.App.showSplashScreen()` and `WL.App.hideSplashScreen()` methods to show and hide the splash screen.

By default, the MobileFirst JavaScript library auto-hides the splash screen when the application is launched. You can choose to disable the automatic hiding of the splash screen by setting the option **autoHideSplash** to `false` in the `initOptions.js` file and use the `WL.App.hideSplashScreen()` method to hide the splash screen after all of the page initialization tasks (including loading other JavaScript frameworks) are completed.

In case the application main web file is set to an external web page (the URL for the file starts with `http://` or `https://`), the splash screen is automatically hidden when the web view finishes loading the page.

Managing the splash screen in an Android-based hybrid application:

You can choose how to manage the splash screen for Android during application initialization.

Java APIs for showing and hiding the splash screen

In Java, you can use the methods `WL.getInstance().showSplashScreen(Activity activity)` and `WL.getInstance().hideSplashScreen()` to show and hide the splash screen from native code.

Changing the default splash image

You can change the default splash image that is located in the `res/drawable` folder and is named `splash.png`.

Disabling the splash screen in Android

For Android, you can disable the splash screen either by:

- Editing the Native Android App class and removing or commenting out the `WL.getInstance().showSplashScreen(this)` API call.
- Deleting the `splash.png` file in the `res/drawable` folder.

Cordova splash screen API

If you use the splash screen API offered in Cordova, do not use the MobileFirst splash screen APIs at the same time.

Showing a custom image

You can show a custom image when you use Cordova splash screen APIs by storing the image in the `res/drawable` folder and then either:

- Declaring it in the `config.xml` file.

```
<preference name="SplashScreen" value="splash_for_cordova_activity" />
<preference name="SplashScreenDelay" value="60000" />
```

- Adding it programmatically in the `CordovaActivity` class.

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    //Add these two lines to enable the Cordova splash screen

    this.splashscreen = R.drawable.splash_for_cordova_activity;
    this.showSplashScreen(60000);

    this.loadUrl(WL.getMainHtmlFilePath());
}
```

When the web view is ready to be shown, you can hide the splash screen by using: `navigator.splashscreen.hide();`

Showing a custom splash screen by adding a custom activity

You can implement a custom splash screen by adding a custom activity to be used as a splash screen. Here is an example of code where you to declare an activity in `AndroidManifest.xml`.

Note: The activity must have an intent-filter with **MAIN** and **LAUNCHER** properties that are defined in order to be launched.

```
<activity
    android:name="com.MyApp.MySplashScreen"
    android:label="@string/app_name"
    android:screenOrientation="portrait"
    android:theme="@android:style/Theme.Black.NoTitleBar" >
    <intent-filter>
        <action android:name="android.intent.action.MAIN" />
        <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
</activity>
```

In your activity `onCreate()` method, after you show the custom UI, you can use the `WL.createInstance().initializeWebFramework()` API to initialize IBM MobileFirst Platform Foundation. Once initialization is complete, you can hide your custom splash screen activity or move to a different `CordovaActivity` in order to show the application's web view.

Showing a custom loading spinner

You can enable a Cordova loading spinner by declaring it in the `custom.xml` file.

```
<preference name="LoadingDialog" value="Please wait while the application loads."/>
```

You can also set the Cordova Activity background color to transparent instead of the default black by declaring it in the `config.xml` file.

```
<preference name="BackgroundColor" value="0"/>
```

Note:

- By default, the MobileFirst JavaScript library auto-hides the splash screen when the application is launched. To have a smooth transition from the splash screen to the web view, set the option **autoHideSplash** to false in the `initOptions.js` file and use the `WL.App.hideSplashScreen()` method to hide the splash screen after all of the page initialization tasks (including loading other JavaScript frameworks) are completed.
- Make sure that your application initialization flow does not block the JavaScript call to hide the splash screen. For example, a problem can occur when you set the application to connect to the server on application startup, and you define form-based authentication that waits for the user to enter login credentials. In this case, the application shows a web login form behind the splash screen without a way for the user to interact with it.

Managing the splash screen in an iOS-based hybrid application:

You can choose how to manage the splash screen for iOS during application initialization.

By default, iOS hybrid applications show a splash screen image during application initialization. This image is selected at run time from the launch images that are supplied in the application Xcode project. You can also use a custom splash screen by replacing the default set of splash images in the `native/Resources` folder of your MobileFirst project.

The code that shows the splash screen is in the `{AppName}.m` class in the `didFinishLaunchingWithOptions` method. You can use the `[[WL.sharedInstance] showSplashScreen]` API to show the splash screen.

You must define a root view controller before you call this API. For example:

```
- (BOOL)application:(UIApplication *)application didFinishLaunchingWithOptions:(NSDictionary *)launchOptions
{
    ...
    UIViewController* rootViewController = ...
    [self.window setRootViewController:rootViewController];
    ...
    [[WL sharedInstance] showSplashScreen];
    ...
}
```

By default, the MobileFirst JavaScript library auto-hides the splash screen when the application is launched. To have a smooth transition from the splash screen to the web view, set the option **autoHideSplash** to false in the `initOptions.js` file and use the `WL.App.hideSplashScreen()` method to hide the splash screen after all of the page initialization tasks (including loading other JavaScript frameworks) are completed.

Note:

- Make sure that your application initialization flow does not block the JavaScript call to hide the splash screen. For example, a problem can occur when you set the application to connect to the server on application startup, and you define form-based authentication that waits for the user to enter login credentials. In

this case, the application shows a web login form behind the splash screen without a way for the user to interact with it.

- If you use the splash screen API offered in Cordova, do not use the MobileFirst splash screen APIs at the same time.
- iOS automatically displays the app's launch image when the app is launched and hides it when the app is ready (after `applicationDidFinishLaunchingWithOptions`). After this image is removed, you can use the MobileFirst splash screen as required by your application's logic. The documentation in this section describes the MobileFirst splash screen API.

Enabling high-resolution splash images for iPhone 6 and 6 Plus devices:

Use a **UILaunchImages** dictionary to enable high-resolution splash images.

During app startup on earlier versions of iPhone, iOS looked for splash images among application resources. IBM MobileFirst Platform Foundation looked for the same images and displayed them during WebView initialization. For iPhone 6 and 6 Plus, however, iOS is unable to automatically detect high-resolution images and IBM MobileFirst Platform Foundation is therefore not aware of them. To enable a high-resolution splash screen image on iPhone 6 and 6 Plus, developers must create a dictionary that references the set of images in the application resources. The dictionary comprises **UILaunchImages** key-value pairs and must be located in the `Info.plist` file. When the reference to the set appears in the `Info.plist`, both iOS and IBM MobileFirst Platform Foundation are able to select the splash image that is most suited to the device resolution.

The following code is a sample dictionary. To enable default MobileFirst splash images, copy the code as-is into the `Info.plist` file to enable high-resolution splash images for iPhone 6 or 6 Plus, along with low-resolution images for iPhone 3, 4, and 5.

Note: Images with lower resolutions must also appear in the dictionary. The code uses the following image names:

- `Default-667h.png`: image for iPhone 6
- `Default-736h.png`: image for iPhone 6 Plus
- `Default-736h-Landscape.png`: image for iPhone 6 Plus in landscape orientation

Of course, you can customize the code to use your own images.

Note: The name of the splash image must be identical in both the dictionary and the application resources.

```
<key>UILaunchImages</key>
<array>
  <dict>
    <key>UILaunchImageMinimumOSVersion</key>
    <string>8.0</string>
    <key>UILaunchImageName</key>
    <string>Default</string>
    <key>UILaunchImageOrientation</key>
    <string>Portrait</string>
    <key>UILaunchImageSize</key>
    <string>{320, 480}</string>
  </dict>
  <dict>
    <key>UILaunchImageMinimumOSVersion</key>
    <string>8.0</string>
    <key>UILaunchImageName</key>
    <string>Default-568h</string>
```

```

        <key>UILaunchImageOrientation</key>
        <string>Portrait</string>
        <key>UILaunchImageSize</key>
        <string>{320, 568}</string>
    </dict>
    <dict>
        <key>UILaunchImageMinimumOSVersion</key>
        <string>8.0</string>
        <key>UILaunchImageName</key>
        <string>Default-667h</string>
        <key>UILaunchImageOrientation</key>
        <string>Portrait</string>
        <key>UILaunchImageSize</key>
        <string>{375, 667}</string>
    </dict>
    <dict>
        <key>UILaunchImageMinimumOSVersion</key>
        <string>8.0</string>
        <key>UILaunchImageName</key>
        <string>Default-736h</string>
        <key>UILaunchImageOrientation</key>
        <string>Portrait</string>
        <key>UILaunchImageSize</key>
        <string>{414, 736}</string>
    </dict>
    <dict>
        <key>UILaunchImageMinimumOSVersion</key>
        <string>8.0</string>
        <key>UILaunchImageName</key>
        <string>Default-736h-Landscape</string>
        <key>UILaunchImageOrientation</key>
        <string>Landscape</string>
        <key>UILaunchImageSize</key>
        <string>{414, 736}</string>
    </dict>
</array>

```

Managing the splash screen in a Windows Phone Silverlight 8 based hybrid application:

You can choose how to manage the splash screen for Windows Phone Silverlight 8 during application initialization.

Java APIs for showing and hiding the splash screen

In C#, you can use the methods `WL.GetInstance().showSplashScreen()` and `WL.GetInstance().hideSplashScreen()` to show and hide the splash screen from native code (`App.xaml.cs`).

For example,

```

private void InitializePhoneAppliation()
{
    if (phoneApplicationInitialized)
        return;
    .....
    WL.GetInstance().showSplashScreen();
}

```

Changing the default splash image

You can change the default splash image that is in the application root folder and is named `SplashScreenImage.jpg`.

Disabling the splash screen in Windows Phone Silverlight 8

For Windows Phone Silverlight 8, you can disable the splash screen either by:

- Editing the native Windows Phone Silverlight 8 App.xaml.cs/MainPage.xaml.cs file and removing or commenting out the `WL.GetInstance().showSplashScreen()` API call.
- Deleting the `SplashScreenImage.jpg` file in the application root folder.

Note:

- By default, the MobileFirst JavaScript library auto-hides the splash screen when the application is started. To have a smooth transition from the splash screen to the web view, set the option **autoHideSplash** to `false` in the `initOptions.js` file. Use the `WL.App.hideSplashScreen()` method to hide the splash screen after all of the page initialization tasks (including loading other JavaScript frameworks) are completed.
- Make sure that your application initialization flow does not block the JavaScript call to hide the splash screen. For example, a problem can occur when you set the application to connect to the server on application startup, and you define form-based authentication that waits for the user to enter login credentials. In this case, the application shows a web login form behind the splash screen without a way for the user to interact with it.
- If you use the splash screen API offered in Cordova, do not use the MobileFirst splash screen APIs at the same time.

Sending actions and data objects between JavaScript code and native code:

Send actions and data objects from JavaScript code to native code and from native code to JavaScript code.

The actions are received by action receivers. Actions that cannot be delivered immediately are queued by the MobileFirst framework and delivered after a suitable action receiver is registered.

Sending actions and data objects from native code to JavaScript code:

IBM MobileFirst Platform Foundation lets you send actions with optional data objects from C#, iOS or Java code to JavaScript code.

About this task

You might want to send a custom action from native code to JavaScript code (for example, for updating the user interface).

Actions are received by action receivers. Actions that cannot be delivered immediately are queued by the MobileFirst framework and delivered as soon as a suitable action receiver is registered.

Procedure

1. Add action receiver function in JavaScript code. For example:
`WL.App.addActionReceiver ("MyActionReceiverId", actionReceiver);`
2. Send action from native code to JavaScript code. For example:

Android

```

JSONObject data = new JSONObject();
data.put("someProperty", 12345);
WL.getInstance().sendActionToJS("doSomething", data);

```

iOS

```

NSMutableDictionary *data = [[NSMutableDictionary alloc] init];
[data setValue:@"12345" forKey:@"testParam"];
[[WL sharedInstance] sendActionToJS:@"nativeToJsWithParams" withData:data];

```

Windows Phone Silverlight 8

```

JObject data = {someProperty:1234};
WL.getInstance().sendActionToJS("doSomething", data);

```

3. Implement a JavaScript action receiver function to receive and handle incoming actions and data. For example:

```

function actionReceiver(received){
  if (received.action === "doSomething" && received.data.someProperty === "12345"){
    //perform required actions, e.g., update web user interface
  }
}

```

Sending actions and data objects from JavaScript code to native code:

IBM MobileFirst Platform Foundation lets you send actions with optional data objects from JavaScript to C#, iOS or Java code.

About this task

You might want to send a custom action from JavaScript code to native code, for example, for updating the user interface.

Any object can receive actions. To do so, it must implement the `WLActionReceiver` interface (for Android, Windows Phone Silverlight 8) or protocol (for iOS).

Android

```

void onActionReceived (String action, JSONObject data);

```

Example

```

public class MyReceiver implements WLActionReceiver{
  void onActionReceived(String action, JSONObject data){
    //process received action
  }
}

```

Note: Actions are always delivered on a background thread. If you want to update the application user interface from the received action, do so on a main user interface thread, for example by using the `Context.runOnUiThread` method.

iOS

```

-(void)actionReceived:(NSString*)action withData:(NSDictionary*)data;

```

Example

```

// MyReceiver.h file
#import "WLActionReceiver.h";
@interface MyReceiver: NSObject <WLActionReceiver>{}
@end

// MyReceiver.m file
@implementation MyReceiver

```

```

-(void)onActionReceived:(NSString *)action withData:(NSDictionary *)data{
    // process received action
}
@end

```

Note: Actions are always delivered on a background thread. If you want to update the application user interface from the received action, do so on a main user interface thread, for example by using the `performSelectorOnMainThread` method.

Windows Phone Silverlight 8

```
void onActionReceived (String action, JObject data)
```

Example

```

public class MyReceiver : WActionReceiver {
    public void onActionReceived(string action, JObject data) {
        //process received action
    }
}

```

Actions are received by action receivers. Actions that cannot be delivered immediately are queued by the MobileFirst framework and delivered as soon as a suitable action receiver is registered.

Procedure

1. Add an action receiver in native code. For example:

Android

```
WL.getInstance().addActionReceiver(myReceiver);
```

iOS

```
[[WL sharedInstance] addActionReceiver:myReceiver];
```

Windows Phone Silverlight 8

```
WL.getInstance().addActionReceiver(myReceiver);
```

2. Send action from JavaScript code to native code. For example:

```

var data = {someproperty:1234};
WL.App.sendActionToNative("doSomething", data);

```

3. Implement the native `onActionReceived` method. For example:

Android

```

void onActionReceived(String action, JSONObject data){
    if (action.equals("doSomething")){
        //perform required actions, e.g., update native user interface
    }
}

```

iOS

```

-(void) onActionReceived:(NSString *)action withData:(NSDictionary *) data {
    if ([action isEqualToString:@"doSomething"]){
        // perform required actions, e.g., update native user interface
    }
}

```

Windows Phone Silverlight 8

```

void onActionReceived(string action, JObject data) {
    if (action == "doSomething") {
        //perform required action, e.g., update native user interface
    }
}

```

Guidelines for testing hybrid MobileFirst applications:

When you test hybrid applications, take into consideration several scenarios in which unexpected behaviors can manifest themselves.

Feature-specific scenarios

Certain features of a MobileFirst application, if not handled correctly, can cause unexpected behaviors. These behaviors, in turn, create unpleasant user experience. The features are:

- Remote Disable
- Adapter requests
- Direct Update
- Authentication flow

While the approach described in the coming sections relates to specific features, it is recommended you embrace the methodology for all aspects of your app. In so doing, you can verify the integrity of the app over the course of its lifecycle, as well as during runtime.

Remote Disable

Whenever an application is started, returns to the foreground, or sends an adapter request to the MobileFirst Server, a check for the Remote Disable state is first performed by the MobileFirst client-side framework against the MobileFirst Server.

If the MobileFirst Server determines that a request from an application must be blocked, a dialog is displayed to the user, by default. This dialog presents an OK button that upon tapping, returns the user to the application. Any further attempt to perform an operation that requires access to the server again displays the dialog. A possible scenario where this can cause annoying user experience is when the application performs an adapter request at the same time that the application is started, or returns to the foreground, expecting to display the result of the request. If access to the server is blocked, no response is received by the application, possibly leaving the screen blank and preventing the user from using the application.

The problem can be remedied either by avoiding dead-end scenarios such as the one just described, or, if required, by creating a custom Remote Disable behavior. For more information, see this [blog post](#).

Adapter requests

Most MobileFirst applications use adapters to retrieve data from back-end services. Using an adapter can cause connectivity errors such as timeouts that are caused by slow networks. To prevent such scenarios, take the following actions:

- Define a larger timeout value for the `WL.Client.invokeProcedure()` method.
- Use the `onSuccess` option to do data processing.
- Use the `onFailure` option to provide appropriate error messages.

Sometimes, even though a response was provided by the back end, processing may still fail. For more information on handling adapter invocation responses, see this [blog post](#).

Direct Update

There are two implementations of Direct Update:

- Default: The MobileFirst framework is responsible and controls the Direct Update lifecycle.
- Custom: The developer is responsible and controls the Direct Update lifecycle.

Whether you choose the default or custom implementation, it is important to test that updates to be deployed in future to the MobileFirst Server do not break the application. In addition, when implementing a custom Direct Update, the developer is responsible to verify the following outcomes:

- The way in which the update is presented to the end user
- The success condition of the update
- The failure condition of the update

For more information, see “Customizing the direct update interface and process” on page 8-390.

Authentication flow

Authentication can be performed in various ways, from form-based and custom-based authentication through to device provisioning. For all types of authentication, you must verify the following points:

- That the authentication form takes failure, timeout, and logout conditions properly into account and handles them.
- When and how failure, timeout, and logout conditions should be applied.
- That the user does not experience a malformed or non-functional UI on failure, timeout, or logout.

Network-specific scenarios

Most applications require a reliable Internet connection. This dependency makes apps prone to errors such as timeouts that are caused by slow networks or to complete breakdowns in connectivity. The issue can manifest itself at some point during the application runtime: when connecting to the MobileFirst Server, or when invoking adapters. To solve this problem, define a larger timeout value for any of the following:

- The `WL.Client.connect()` method
- The `WL.Client.invokeProcedure()` method
- The `connectionTimeoutInMilliseconds` element of the adapter XML file. For more information about this element, see “Structure of the adapter XML file” on page 8-247.

General error condition scenarios

In general, by implementing proper error conditions in the logic of the app, you protect it from crashes and other unexpected behaviors.

Developing user interface of hybrid applications

Develop the user interface of hybrid applications as detailed here.

JavaScript API for UI controls:

You can use a JavaScript API to call common user-interface controls, regardless of the environment.

With IBM MobileFirst Platform Foundation, you can use a JavaScript API to call user-interface controls that are common to most environments, such as modal pop-up windows, loading screens, or tab bars.

You can use the following API to render these controls automatically in a native way for each mobile platform.

For more information about common UI controls, see the Common UI controls tutorial on the Getting Started page of the Developer Center.

WL.BusyIndicator

The `WL.BusyIndicator` class implements a common API to display a modal activity indicator. This method uses native implementation on Android, iPhone, and Windows Phone platforms.

For more information about the functions of this API, see `WL.BusyIndicator`.

WL.OptionsMenu

The `WL.OptionsMenu` class implements a common API to display a menu of options for Android and Windows Phone.

For more information about the functions of this API, see `WL.OptionsMenu`.

WL.SimpleDialog

The `WL.SimpleDialog` class implements a common API for showing a dialog window with buttons. This method uses native implementation on mobile platforms. The dialog closes when the user presses any of the buttons.

For more information about the functions of this API, see `WL.SimpleDialog`.

WL.TabBar

The `WL.TabBar` class implements a common API to support tabbed application navigation with a tab bar component for Android and iOS environments.

For more information about the functions of this API, see “Fixing the Tab Bar on the screen – Android 2.2 and higher” and `WL.TabBar`.

Fixing the Tab Bar on the screen – Android 2.2 and higher:

Fix the position of the tab bar by updating HTML and CSS.

About this task

To fix the tab bar in one location on the screen on Android 2.2 and higher, perform the following steps:

Procedure

1. Add the following meta tag to the HTML HEAD section:

```
<meta name="viewport" content="width=device-width, initial-scale=1.0, maximum-scale=1.0, minimum-scale=1.0, user-scalable=no" />
```

2. Update the Android CSS BODY tag to also apply to the HTML tag, as follows:

```
html, body {  
    height: auto;  
    overflow: auto;  
}
```

Using JavaScript toolkits:

Learn how to use javascript toolkits such as JQuery, Dojo Mobile, Sencha Touch.

During the development process, you must design and implement the user interface of your application. You can achieve a high level of customization by writing entirely your own CSS style for each component. However, doing so requires a large amount of resources. You can also use existing JavaScript UI frameworks such as jQuery Mobile, Sencha Touch (deprecated. See “Deprecated features and API elements” on page 3-20), or Dojo Mobile to optimize your development process.

Dojo Mobile

IBM MobileFirst Platform Foundation supports Dojo Mobile for building the user interface of your hybrid mobile application. Dojo Mobile is a world class HTML5 open Source mobile JavaScript framework that you can use to develop mobile web and hybrid applications. Dojo Mobile is part of the Dojo Toolkit, which is developed and maintained by the Dojo Foundation. You can find information about Dojo Mobile, including its documentation, at <http://dojotoolkit.org/>.

You can use Dojo Mobile to develop mobile web applications that have the appearance of the native device on iPhone, iPod Touch, iPad, Android, and BlackBerry touch devices.

IBM MobileFirst Platform Foundation V7.1.0 supports the Dojo Toolkit version 1.10.1, which is embedded in MobileFirst Studio.

Note: To use Dojo 1.10.1 in MobileFirst Studio V7.1.0, you must be using Eclipse Luna SR1 for Java Developers (Eclipse 4.4.1) or higher. If you import an existing workspace with a previous version of Dojo, you do not need Eclipse Luna SR1 for Java Developers. This limitation exists only when you create a new project that targets Dojo 1.10.1.

When you create an IBM MobileFirst hybrid application, you can select Dojo Mobile among several JavaScript toolkit choices. If you select this option, a copy of Dojo Mobile is added in your project, and a Dojo library project is created in your workspace to support advanced usages of Dojo Mobile.

With MobileFirst Studio you can do the following tasks:

- Create a hybrid application that uses Dojo Mobile. For more information, see “Creating Dojo-enabled projects” on page 8-93.
- Create the user interface of your Dojo Mobile application with the Rich Page Editor, which is a WYSIWYG editor that MobileFirst Studio provides. The Rich Page Editor supports HTML, Dojo Mobile, and JQuery Mobile. For more information, see “Rich Page Editor” on page 8-117.
- Use predefined application templates to speed up the development of your application. For more information, see “Mobile patterns” on page 8-128.
- Use all the power of Dojo Mobile through the Dojo library project. For more information, see “Working with the Dojo Library Project that serves Dojo resources” on page 8-95.

- For information about how to use Dojo to create a globalized MobileFirst application, and how to achieve this process by using Dojo Mobile, see “Developing globalized hybrid applications” on page 8-144.
- For information about how to change Dojo versions that are used by your MobileFirst projects, see “Changing the Dojo version of projects” on page 8-105.

Sencha Touch

With Sencha Touch, developers can build mobile web applications that have the appearance of the native device on iPhone, Android, and BlackBerry touch devices. Sencha Touch is developed and maintained by Sencha Inc. To download the Sencha Touch package, see <http://www.sencha.com/products/touch/>. To begin the development of your application, you need the `sencha-touch.js`, and `sencha-touch.css` files.

jQuery Mobile

jQuery Mobile is a touch-optimized web framework for smartphones and tablets. You need jQuery to run jQuery Mobile.

Note: jQuery Core is provided in the MobileFirst library.

You can download the required jQuery Mobile components, which are in the `.js` and `.css` files, at <http://jquerymobile.com/download/>. Download the zip file, which has a version number as part of the file name, for example `jquery.mobile-1.4.2.zip`. New versions of jQuery are released frequently.

Note: The tools require the non-minified version of the scripts (if necessary, replace anything with a “min” segment in the file name with the corresponding “full” file).

1. Create a MobileFirst project.
2. Right-click the project and select Hybrid Application.
3. Name the application and configure.
4. Browse for the folder where you downloaded the `jquery.mobile-Version.zip`.

From the populated selection, choose the required jQuery Mobile components, as follows:

- `jquery.mobile-Version.css`, contains all the styling for the mobile widgets and framework
- `jquery.mobile-Version.js`, the jQuery mobile framework
- `images`, which is the whole folder of images that are used by the style sheet for jQuery's built-in icons

If your project is already created, go ahead and create an application.

Note: MobileFirst Studio also provides a WYSIWYG editor that supports HTML, Dojo Mobile, and JQuery Mobile. You can use this editor to create the JQuery Mobile user interface of your application. For more information, see “Rich Page Editor” on page 8-117.

Creating Dojo-enabled projects:

You can create Dojo-enabled projects that hold all of the resources that are created and used when you develop a Dojo mobile application.

Procedure

1. In the main menu, click **File > New > MobileFirst Project** to open the New MobileFirst Project wizard.
2. In the **Name** field, enter a name for your new project.
3. From the list of project templates, click one of the following templates to generate an application for your MobileFirst project, and then click **Next**.

Hybrid Application

Creates a project with an initial hybrid application.

Inner Application

Creates a project with an initial inner application and points to a built shell component.

Native API

Creates a project with a Native API.

Shell Component

Creates a project with an initial shell component application.

4. In the **Application name** field, enter a name for your application.
5. Click **Configure JavaScript Libraries**.
6. In the **Dojo installation** section, select **Add Dojo Toolkit** to add the Dojo facet and Dojo support to the application. When you build a mobile web application, Dojo is included to create the native application.
7. Specify the Dojo library project that you want to use in your project:

Select an existing Dojo library project

From the list of Dojo library projects, select the library that you want to use. For example, `dojoLib`.

Create a Dojo library project

- a. Click **New Dojo Library**. The Dojo Library Setup wizard opens.
 - b. In the **Name** field, enter a name for your Dojo library project.
 - c. Specify the version of Dojo that you want to install.
 - d. Configure how your Dojo library project accesses the Dojo Toolkit and which version of the toolkit to use:
 - Click **Provided** and select a Dojo Toolkit that is provided with the product.
 - Click **On Disk** and choose one of the following options:
 - Click **Archive File** to select an archive file of a compressed Dojo distribution. Click **Finish** to extract the contents of the archive file into your project.
 - Click **Folder** to browse to the root Dojo folder in another project in your workspace.
 - e. Expand the **Select the Dojo components to be included in the project** section and select the **Dojo components** that you want to include in your project.
 - f. Click **Finish**. The new project is now displayed as an option in the list of available Dojo library projects.
8. Click **Finish**. Both the MobileFirst project and the Dojo library project are created.

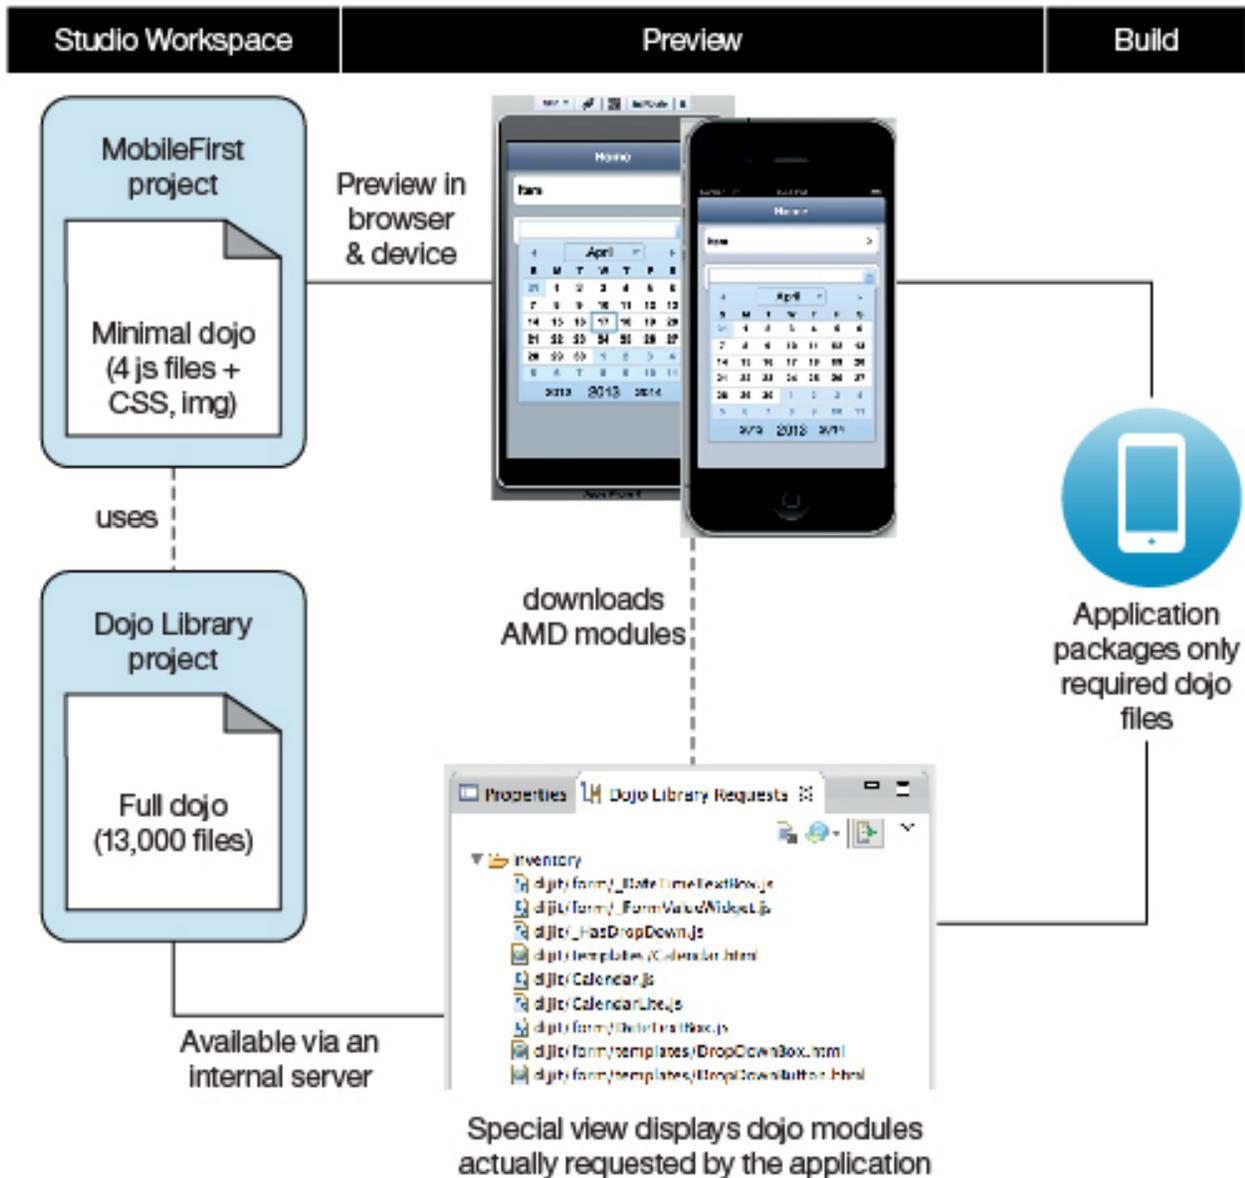

Working with the Dojo Library Project that serves Dojo resources:

IBM MobileFirst Platform Foundation projects that use Dojo contain a small subset of Dojo resources. This subset of Dojo resources is supplemented with resources (that might not be typical within mobile applications) from a separate Dojo library project.

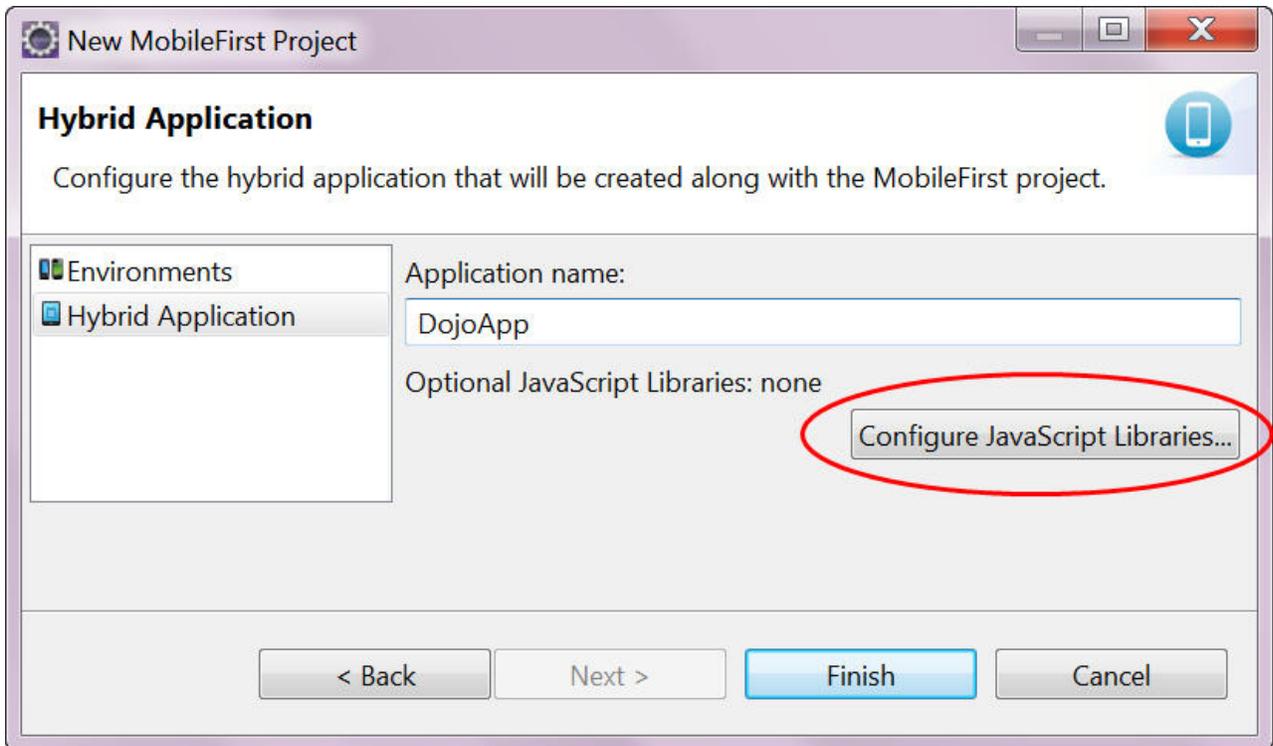

The Dojo library project contains a full distribution of Dojo. This version of Dojo includes both mobile and desktop Dojo resources. You can test your application by using any of the widgets from the Dojo library. The Dojo library project contains a full Dojo that you can use in a Dojo application. It is provided on an internal server, separate from your application.

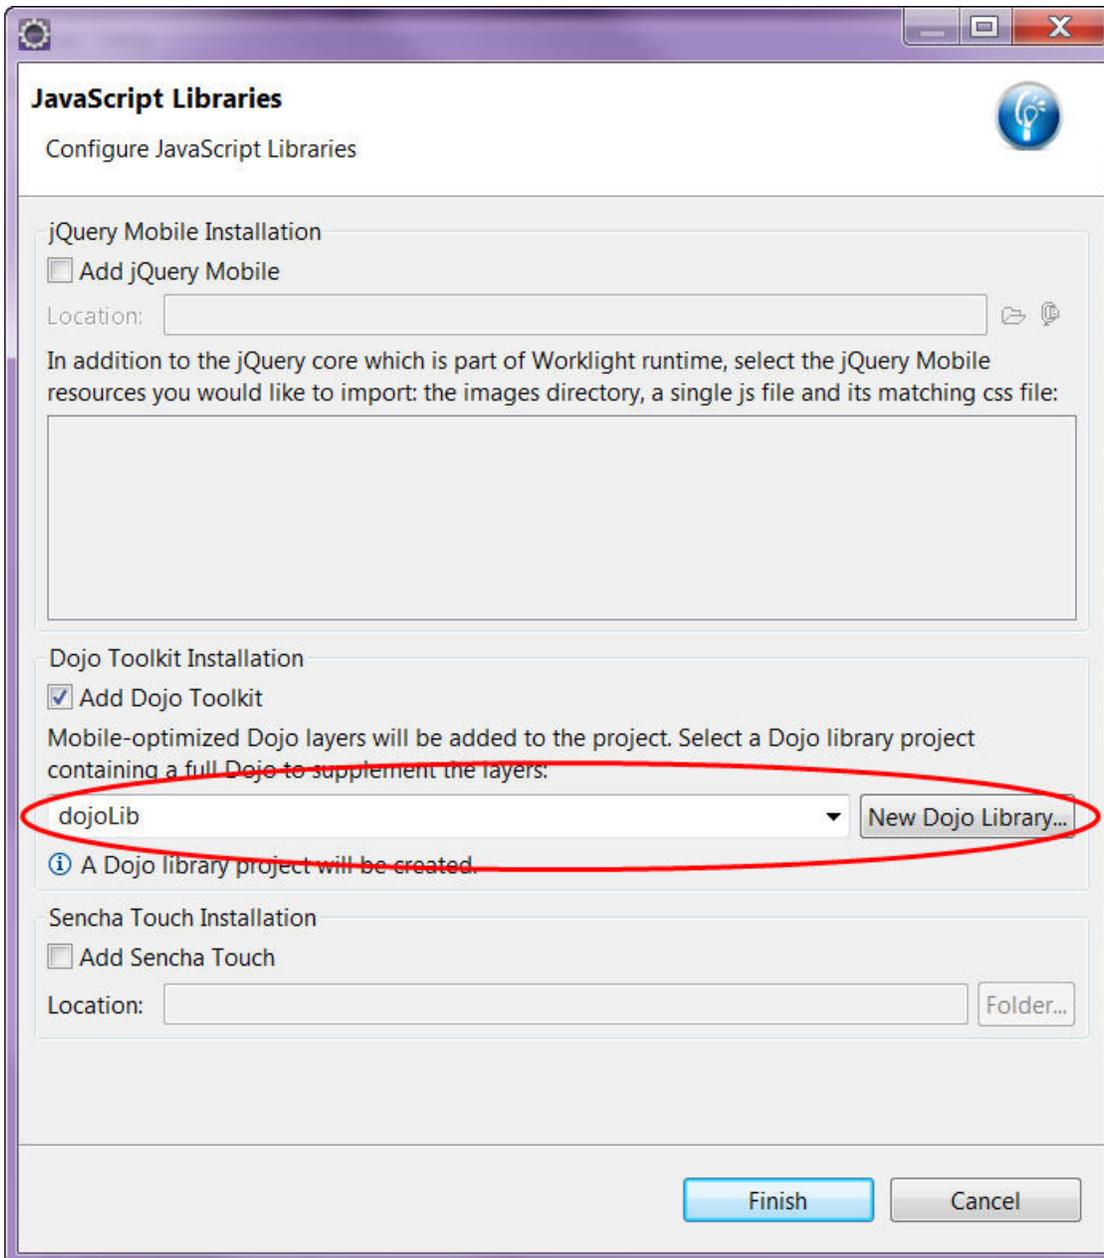

A project is initialized with only a minimal set of mobile layers and themes. It contains the Dojo resources that are deployed as part of the application. The Dojo that is contained in the project is optimized for size and includes only the features that are required for a basic mobile application.

The Dojo library project provides only the resources that are requested directly by the Dojo loader, such as the JavaScript modules, their template HTML fragments, and associated images. The Dojo library project, running separately on an internal server, provides faster builds, smaller projects, and accurate lists of the Dojo files that your application is requesting. Here is a view of the improved Dojo workflow for application size and development speed:

To demonstrate, here are illustrations that show the start of a new project. After you click **Configure JavaScript Libraries**, a wizard opens and you must click **Add Dojo Toolkit**. An extra field in the template is displayed called **New Dojo Library**.

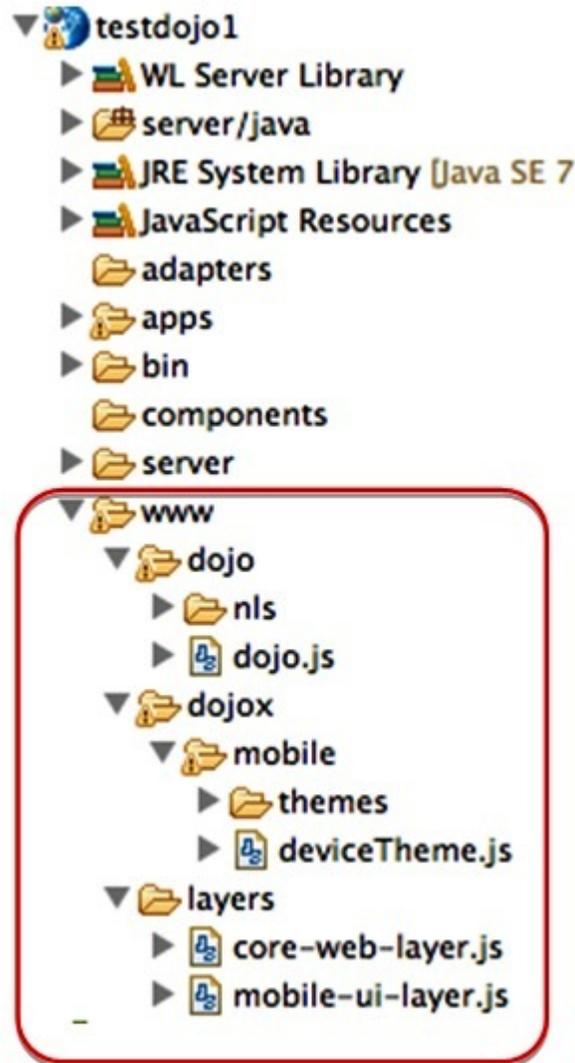

Note: You can create multiple libraries each for a different version of Dojo. A project is linked to one library.

The **New Dojo Library** feature is where access to the full distribution of Dojo is initiated by linking to the internal server. When you develop your application and test it, this feature supplies your **Dojo Library Requests** view with all the Dojo files requested during execution of your application. Select the files and move them to your project.

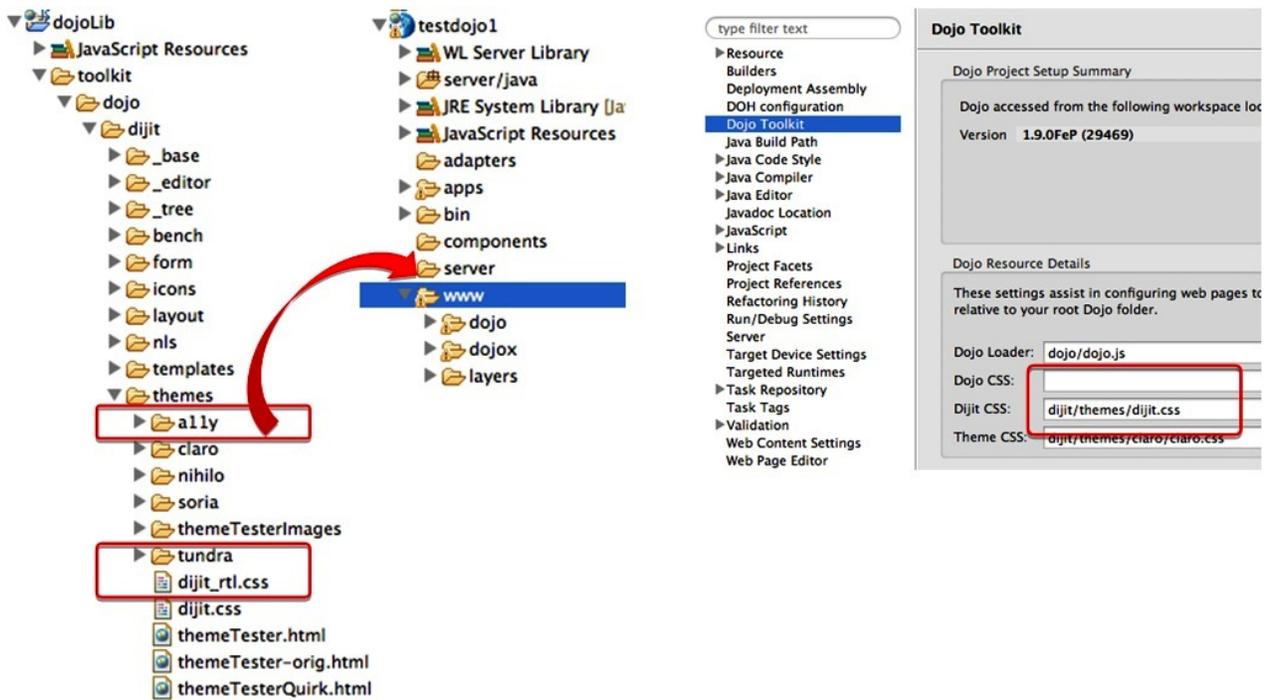

The minimum set of Dojo files that are provided in a project, are in a `www` folder in the navigation. It includes these files:

- Nano AMD loader (Dojo.js)
- Two layers for mobile widgets
- en-us NLS bundles for the two layers
- deviceTheme.js and mobile themes

Note: The deviceTheme.js.map file is not provided by the Dojo Library because of the way deviceTheme.js is requested by the main web page. deviceTheme.js is requested by a direct request instead of an asynchronous request. You can obtain this file from /dojoLib/toolkit/dojo/dojox/mobile only if dojoLib is the library project. You must copy the file manually.
With this formation, you can develop mobile pages by using Dojox mobile widgets.

You can manually set up more themes. First copy a theme into the www folder, and then set up the project CSS settings. Dijit widgets require a theme, Dojox widgets each bundle their own theme CSS.

You can start coding your application. Use any Dojo modules (you no longer need to consider what files to import into the project). In this example, the "DateTextBox" comes from dijit/form but this module and its dependencies are not in the project yet.

The Dojo loader is redirected to an internal server for modules in these packages:
Dojo, dijit and Dojox.

```

<script scr="worklight/cordova.js"></script>
<script scr="worklight/wljq.js"></script>
<script scr="worklight.js"></script>
<script scr="worklight/checksum.js"></script>
<script scr="worklight/plugins/org.apache.cordova.core.camera/www/ios/CameraPopoverHandle.js"></script>
<script scr="worklight/plugins/org.apache.cordova.core.contacts/www/ios/Contact.js"></script>
<script scr="worklight/plugins/org.apache.cordova.core.contacts/www/ios/contacts.js"></script>
<script scr="worklight/plugins/org.apache.cordova.core.file/www/ios/Entry.js"></script>
<script>windows.$ = window.jQuery = WLJQ;</script>
<script scr="http://192.168.0.100:9988/dojoLib/factory/inventory/iphone/dojo/dojo.js">
type="text/javascript" data-dojo-config=...></script>

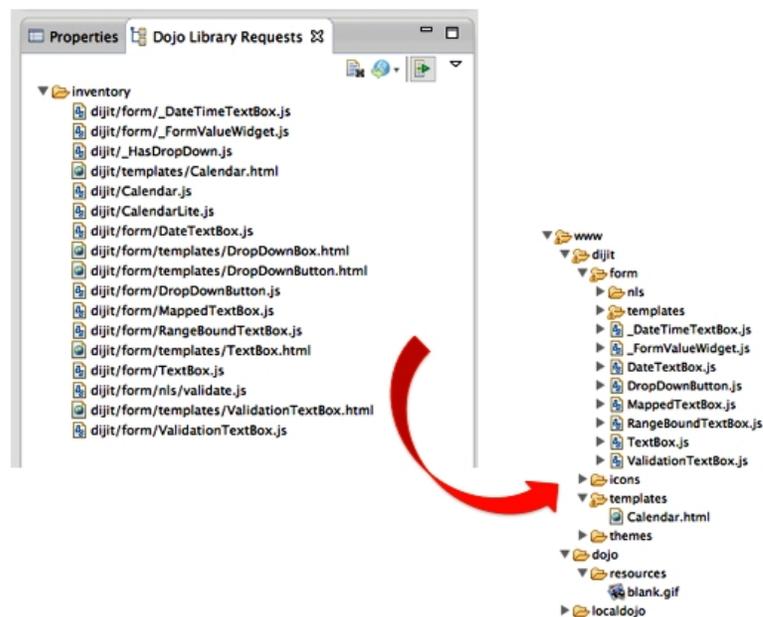

```

Turn on the **Provide Missing Dojo Resources** function first. This action injects code to redirect the Dojo Loader to the server during the build.

To do this open **Dojo Library Requests** view and then click **Provide Missing Dojo Resources**, as illustrated here:

The special view output gives an accurate list of the Dojo files that are requested by the application. You can use this output as a guide to use the **Copy to Project** or **Copy to application** actions to copy files from the library into the project.

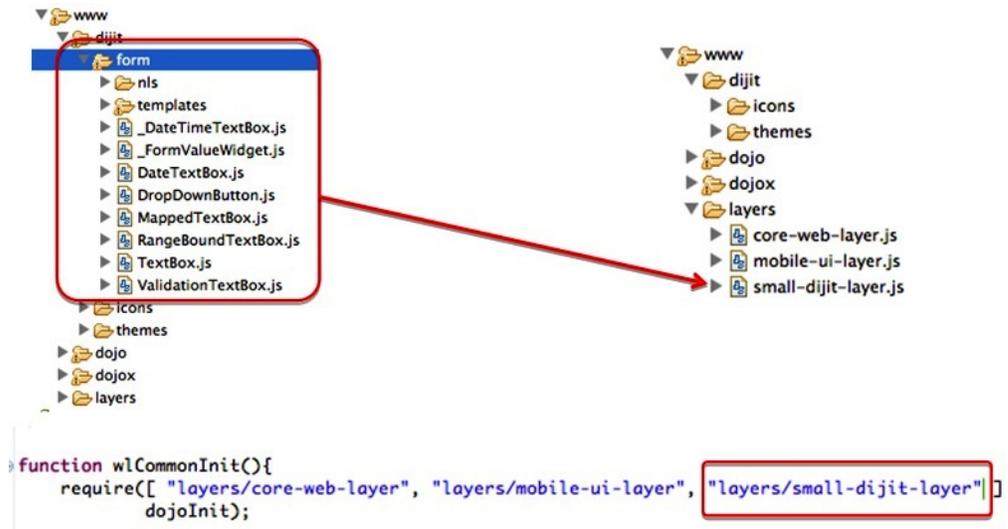

You must turn off the library and verify all the Dojo files are present in the application. Turn off the server

Then, rebuild the environment and deploy so that the injected Dojo loader config is removed. Run the application again.

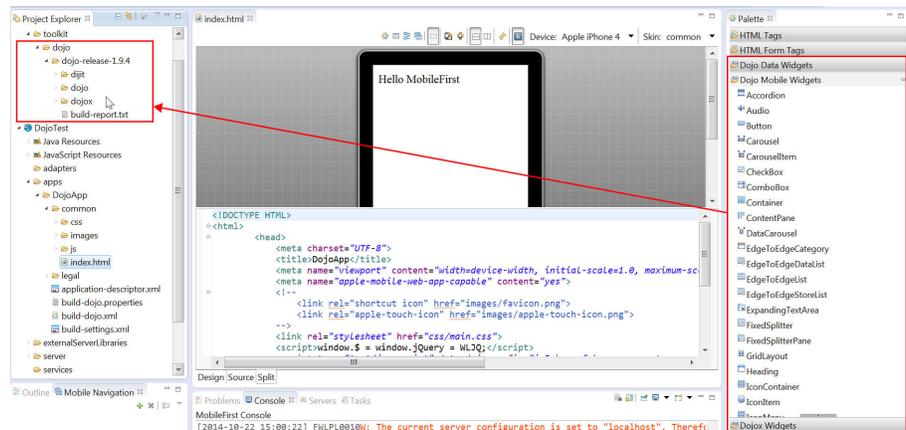

You can build the layers that are based on the code that is imported into the project (which is optional).

The IBM MobileFirst Platform Studio tools use the Dojo that is contained in the project and the associated Dojo Library project. The following MobileFirst Studio tools use the Dojo library content:

Rich Page Editor

The Rich Page Editor displays all of the widgets that are available in the Dojo library.

You can explore and test various Dojo artifacts. You could run and test your application outside of the Dojo library project. If you test on an external device or emulator, IDE must be running and must have Internet connectivity.

MobileFirst Studio provides the **Dojo Library Requests** view which shows what resources were requested from the Dojo library project. For example, if you add the `dijit.Calendar` Dojo widget (that is not part of the mobile layers) to the application HTML page, Rich Page Editor uses the Dojo library to display this widget.

Note: If you run and test your application on a mobile device or use a device emulator, Eclipse must be running to provide Dojo Library resources. To shut down Eclipse and test your application in an environment that is similar to a production environment, you must remove Dojo Library instrumentation. See “Removing Dojo library instrumentation” on page 8-105.

JavaScript source validation and content assist

Content assist suggests all of the Dojo widgets that are contained in the Dojo library, or contained within the project, and new widgets that you have added to either of these. For example, if you have added your own Dojo widgets in either project, these new widgets will show up on the palette and in content assist.

Mobile Browser Simulator

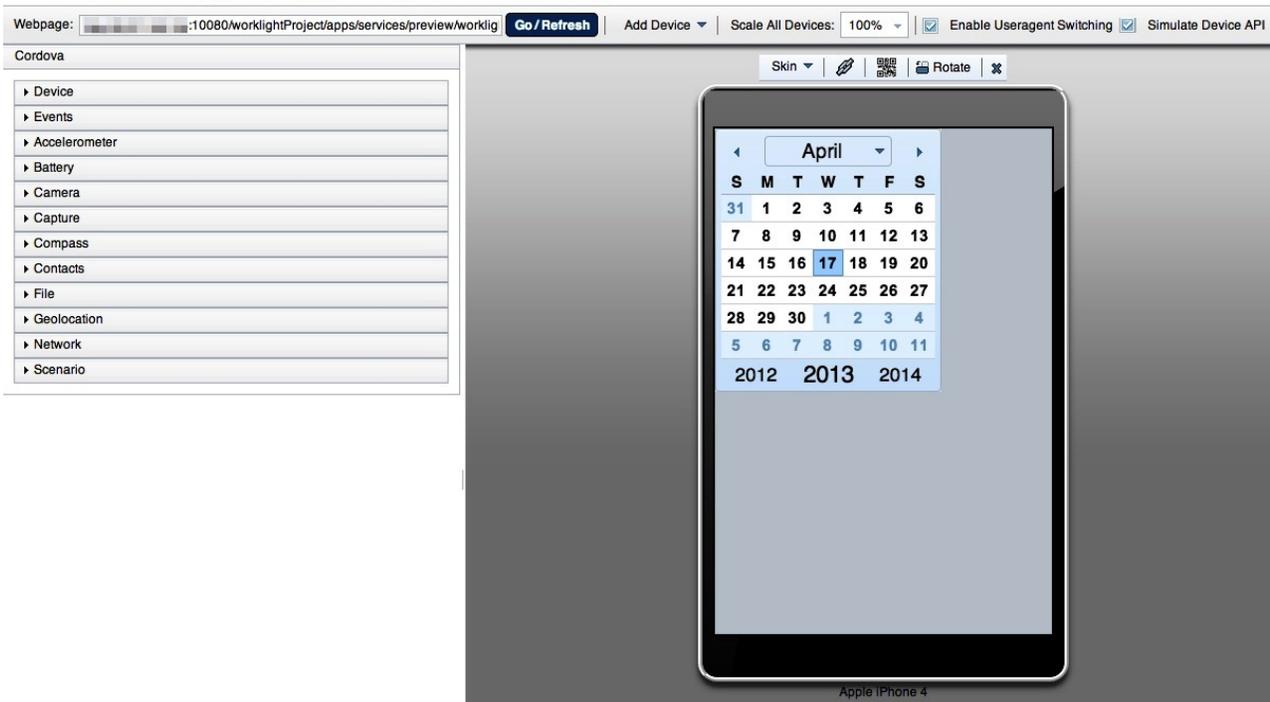

The Mobile Browser Simulator can run with or without the Dojo library resources. You can use the **Dojo Library Requests** view to turn on and off the Dojo library resources.

Select the **Provide Library Resources** option to specify that you want the Mobile Browser Simulator to use the Dojo library project when it runs. For example, when this option is selected the `dijit.Calendar` widget is displayed correctly.

Mobile Browser Simulator

The Mobile Browser Simulator displays mobile web pages in a variety of mobile browser sizes and shapes.

While the Mobile Browser Simulator is running, the **Dojo Library Requests** view shows which resources are served from the Dojo library project, which indicates the particular resources that are requested by the application but are not included as part of the application.

If the missing resources are required by the final application, you must add all of the missing resources to the project. The resources that are logged in the Dojo Library Requests are not available outside of the MobileFirst Studio development environment.

To add the missing resources to your application, the view provides two copy actions.

The **Copy to Project** action  copies selected resources into the project's `www` folder. Resources here are built into all Dojo-enabled applications in the project, which is useful when your applications use a common module or resource. The **Copy to application** action  copies selected resources into the requesting application's common folder, which is useful when an application uses resources that are unique to that application.

If you disable the **Provide Library resources** option , the Mobile Browser Simulator does not use the Dojo library project when it runs. The Mobile Browser Simulator uses only the resources that are contained in the project. For example, when this option is selected, the `dijit.Calendar` widget is not displayed. When the Mobile Browser Simulator runs in this mode, the preview emulates the mobile device. The preview provides only the resources that are available to the application when it is deployed to a mobile device. No entries are shown in the **Dojo Library Requests** view.

Removing Dojo library instrumentation:

If you run and test your application outside of the Dojo library project, you must remove the Dojo library instrumentation.

Procedure

1. Copy all resources that are provided by the Dojo library project and are required by the application into the `www` folder of the MobileFirst project. The Dojo Console view helps you determine which resources were provided by the Dojo library project. Only the resources in the `www` folder are available when an application is running on a native platform.
2. In the Dojo Library Requests console view, ensure that **Provide Library Resources** is cleared. When **Provide Library Resources** is cleared, the `dojoConfig` mapping that points to the Dojo library project is removed.
3. Run **Preview**. You can complete debugging actions in the Preview window.
4. Build and deploy the application. All required Dojo resources are in the MobileFirst project `www` folder.

Related concepts:

“Working with the Dojo Library Project that serves Dojo resources” on page 8-95 IBM MobileFirst Platform Foundation projects that use Dojo contain a small subset of Dojo resources. This subset of Dojo resources is supplemented with resources (that might not be typical within mobile applications) from a separate Dojo library project.

Changing the Dojo version of projects:

You can change the version of Dojo that is used by an existing project.

Before you begin

Note: A “pre-built” folder for versions of the Dojo toolkit is provided and is officially supported. If you download Dojo from <http://dojotoolkit.org/>, and use that for the Dojo library, Step 5 in the following procedure does not happen.

The procedure explains how to upgrade from the version of Dojo that is included with IBM MobileFirst Platform Foundation to a new version of Dojo. If you want to take advantage of a version of Dojo in open source that is not yet included in IBM MobileFirst Platform Foundation, extra steps are required, see **Alternate Procedure**.

Procedure

1. In the Project Explorer view, locate the MobileFirst project that you want to change the Dojo version for.
2. Right-click the project and select **Properties**. The Properties dialog opens.
3. In the left pane, click **Dojo Toolkit**. The properties page for the Dojo Toolkit opens.
4. Choose one of the following options to change the Dojo version that is used:
 - From the Dojo Library Project list, select an existing Dojo library project.
 - Click **New Dojo Library** to create a Dojo library project.
5. Click **OK**. A dialog box opens prompting you to confirm whether you want to overwrite the existing Dojo layer files with the new Dojo layer files.

Note: To avoid unpredictable behavior, use Dojo layer files that match the Dojo library. For example, by using Dojo 1.8 layer files with a Dojo 1.9 library, may cause unpredictable behavior. If you choose not to overwrite the Dojo layer files now, you can manually overwrite them later using the pre-built files that are contained within the Dojo library project. In the Project Explorer view, expand *Dojo library project* > **toolkit** > **pre-built**.

Alternate Procedure

6. Follow the **Procedure** steps 1-4. Then continue with the following steps:
 - a. Ensure the resources that are being used by the application are copied into the application. Follow the documentation that is outlined for the **Dojo Library Requests** view or Console (depending on Studio version).
 - b. One suitable method involves building new layers from the new version of Dojo so that the same core and mobile UI layers are created from the updates. Manually copy them into the project's `www` folder.
 - c. The alternative way is to remove the references to the core and mobile UI layers ("`layers/core-web-layer`" and "`layers/mobile-ui-layer`") from the application's JavaScript file, and use the **Dojo Library Requests** view or Console to find out what's used and then start copying them into the project.

Implementing a different version of the Dojo Toolkit:

If you need to use a different Dojo Toolkit version, a special procedure is required.

MobileFirst Studio facilitates the integration of Dojo Toolkit into hybrid mobile applications. However, this Dojo Toolkit and its corresponding optimized resources (called Dojo layers) are tied to a fixed version per release, which is bundled within MobileFirst Studio.

MobileFirst Studio has a set of tools to facilitate the integration of latest available Dojo toolkit into a hybrid application. It also supplies a pre-built set of Dojo files (called Dojo layers) that bundle the Dojo Mobile modules in a few optimized resources. These files are copied by default into your Hybrid Dojo project under the `www` folder.

Note: Having these custom built layers is required for production deployments, not just for performance improvements but for a known limitation in Android environments. For more information, see the Dojo Toolkit website..

Even though MobileFirst Studio provides all the necessary resources to work with the most updated Dojo Toolkit, there is a chance that you might need to move to a different Dojo version or even modify the contents of the pre-defined layers. You also need to optimize your resources for production deployment.

Here is described how those layers are built and the necessary changes that need to be done in order to have a fully working application with a modified or updated Dojo toolkit.

Building standard Dojo layers:

To build standard Dojo layers, you must create a project, and change certain variables.

Procedure

1. Download the latest version of the Dojo-Build-Factory build tool.
 - a. Go to <https://github.com/pruzand/Dojo-Build-Factory>
 - b. Select the branch for the Dojo version you are using in your project.
 - c. Download the compressed repository from the website, which is usually a file with a name similar to `Dojo-Build-Factory-Dojo-Version.zip`
 - d. Extract the file to a known location on your system.

Alternatively, if you Git is installed on your system, you can clone the Dojo-Build-Factory branch for the Dojo version you need, entering the following command from your system's command line: **git clone -b <Dojo-Version-Branch> https://github.com/pruzand/Dojo-Build-Factory.git**
After you have the Dojo-Build-Factory build tool, a directory structure is created that contains the following files and folders:

- build
 - releases
 - LICENSE
 - README
2. Open MobileFirst Studio and create a project:
 - a. **File > New > Other > Project**
 - b. Give project a valid name, such as `DojoBuildFactoryProject`.
 - c. Click **Finish**.
 3. Copy and paste the contents of the `Dojo-Build-Factory/build` folder to your new project root.
 4. Add the Dojo source from which you want to generate your optimized version to the `src` folder of the project. The Dojo source must be a full, decompressed source release of the Dojo Toolkit. Therefore, it must contain the `util` folder, since it is used for the layers generation. The project now has the following structure and files:

5. Open profiles/env-config.js and change the **localeList** to specify the relevant locales you want to include. By default, Dojo Build Factory includes only US English as the default language, so you see the following entry: "localeList": "en-us". If you want to specify additional locales, you can set this variable to something like: "localeList" : "en-us,ar,az,ca,cs,da,de,el,es,fi,fr,he,hr,hu,it,ja,kk,ko,nb,nl,pl,pt,pt-pt,ro,ru,sk,sl,sv,th,tr,zh,zh-tw"

Note: If the language setting for the target mobile phone is expected to not be US English, then you must specify that language in this **localeList**. Otherwise, it is highly possible that your application will not work.

6. Run the Dojo Mobile build.
 - a. From within MobileFirst Studio, select **Run > External Tools > External Tools Configuration**. The External Tools Configurations window is displayed.
 - b. Select **Ant Build** and click **New launch configuration**.

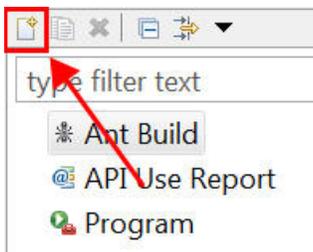

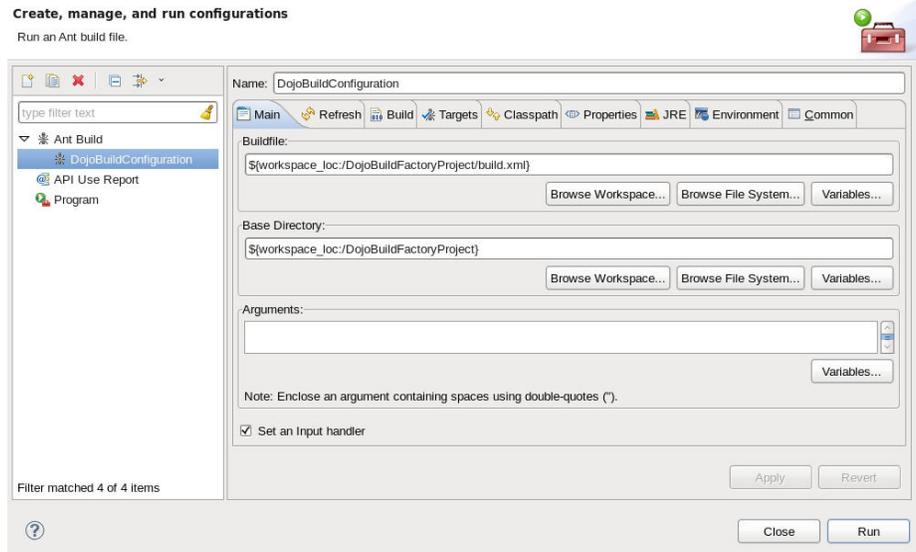

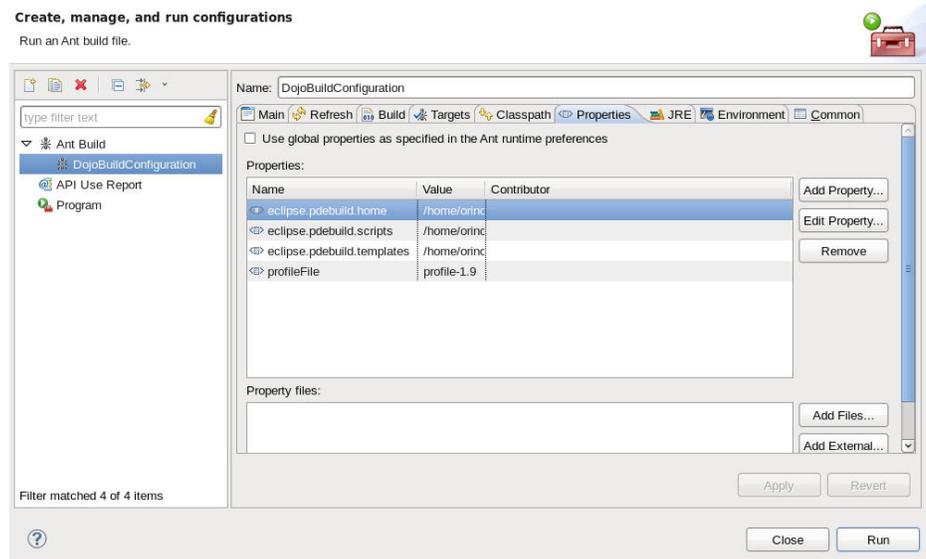

Figure 8-12. New launch configuration

- c. Set the **Buildfile** field to point to the build.xml in the root of your Dojo build factory project.
- d. Set the **Base Directory** to your Dojo build factory project root. Here is an example of what your configuration could look like.:

- e. Go to the Properties tab and confirm that **Use global properties as specified in the Ant runtime preferences** is cleared.
- f. Add a new property with **Name** set to profileFile and value set to the name of the profile file that is located in your project/profiles folder without the .js extension. For example, profile-1.9

- g. After you set up the configuration, click **Run**. The build takes about 6-15 minutes and can be monitored in the console view.

Results

After completion, the generated Dojo layer files are located inside your project in the result/compressed/dojo directory, following the *-layer.js naming convention. If you cannot see those files, do a refresh (F5) on your project root. There are several different layer files available there, which is much more than just the mobile-ui-layer.js. You can find the details about what every layer contains on the Github website.. These instructions can only guide you through the process of replicating the structure that MobileFirst Studio provides. Depending on your

MobileFirst hybrid application requirements, you might want to append extra layers to your project to make additional optimized Dojo resources available.

Note: There can be problems when you produce the Dojo 1.9 custom build. You might see errors such as: error(303) Missing include module for layer. missing: gridx/allModules; layer: dojo/gridx-desktop-layer To resolve these errors, navigate to project/profiles, open theprofile-version.js file, then look for the failing layer(s) (in this case gridx-desktop-layer, but also gridx-mobile-layer fails) and comment out the corresponding layer(s) definition to pull it out from the custom build:

```
149     "dojo/dijit-editor":{
150         include: use("dijit_editor"),
151         exclude: [
152             "dojo/core-web-layer",
153             "dojo/dijit-layer"
154         ]
155     }
156
157 //
158 //
159 //     "dojo/gridx-desktop-layer":{
160 //         include: use("gridx_desktop"),
161 //         exclude: [
162 //             "dojo/core-web-layer",
163 //             "dojo/dijit-layer"
164 //         ]
165 //     },
166 //
167 //     "dojo/gridx-mobile-layer":{
168 //         include: use("gridx_mobile"),
169 //         exclude: [
170 //             "dojo/core-web-layer",
171 //             "dojo/mobile-ui-layer",
172 //             "dojo/dijit-layer"
173 //         ]
174 //     }
175 // }
176 };
177 }();
178
```

What to do next

Repeat build execution until it finishes successfully.

Switching an existing project to a new Dojo library:

If you want to move the resources that you created to a different Dojo library, you must copy them to a new location.

Before you begin

You must already have a Hybrid Dojo Project with a Hybrid app that points to an existing dojoLib project to complete the following steps.

Procedure

1. Switch the current Dojo project to a different Dojo Library.
 - a. In MobileFirst Studio, right-click *<your Dojo project name>*, and select **Properties**.
 - b. Select **Dojo Toolkit**.

- c. Click **New Dojo Library**
- d. Name the library. For example, NewDojoLib
- e. Select **On Disk** and then fill it with the archive file or folder that contains the Dojo source. For example, dojo-release-1.9.2-src.tar.gz Use the same you previously used to create the Dojo Custom build. For the archive file, specify the **Create internal selected folder only** under the **Import options** section if available.

Dojo Library Setup

Choose the Dojo Toolkit to use within the library.

A Dojo library project with this name will be created in the workspace.

Name:

Choose from the provided Dojo Toolkits, or choose a Dojo from your local disk.

Dojo

Provided

On Disk

▼ Select the Dojo components to be included in the project.

Dojo components:

▶

dojo-release-1.9.2-src

Exclude:

Demos and Tests

Experimental Projects

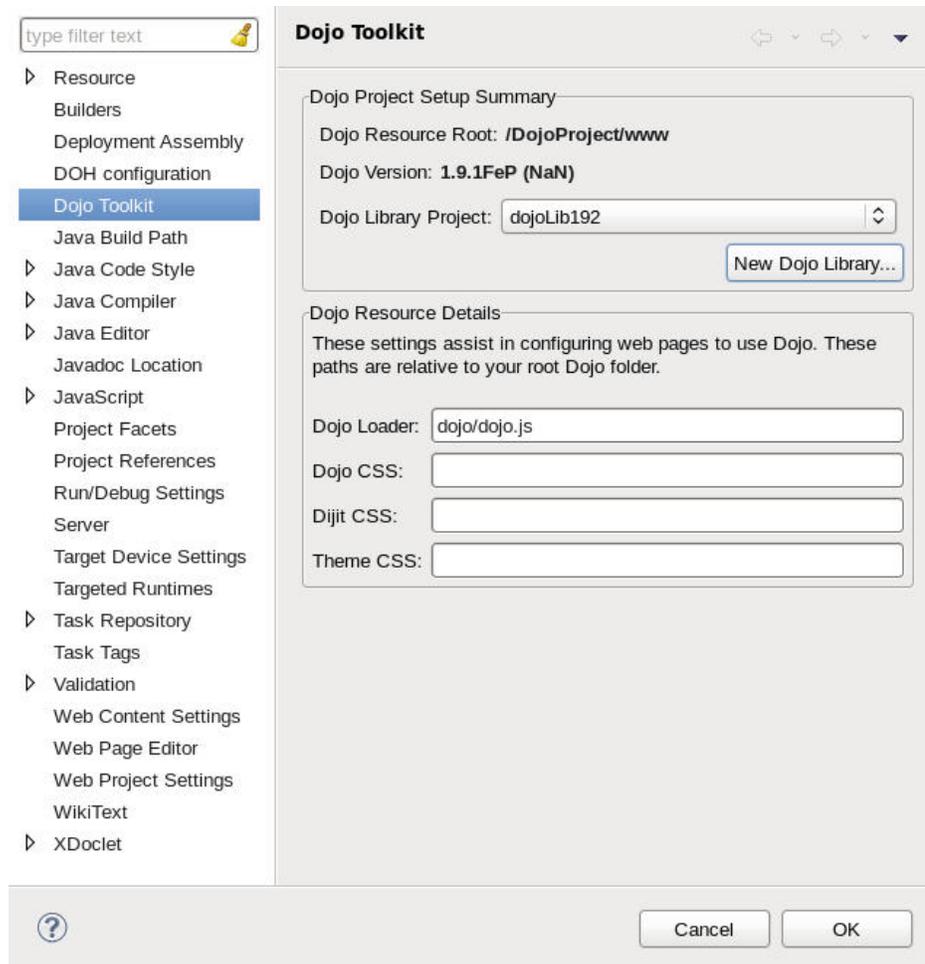

IBM iLog

Import options:

Create complete folder structure

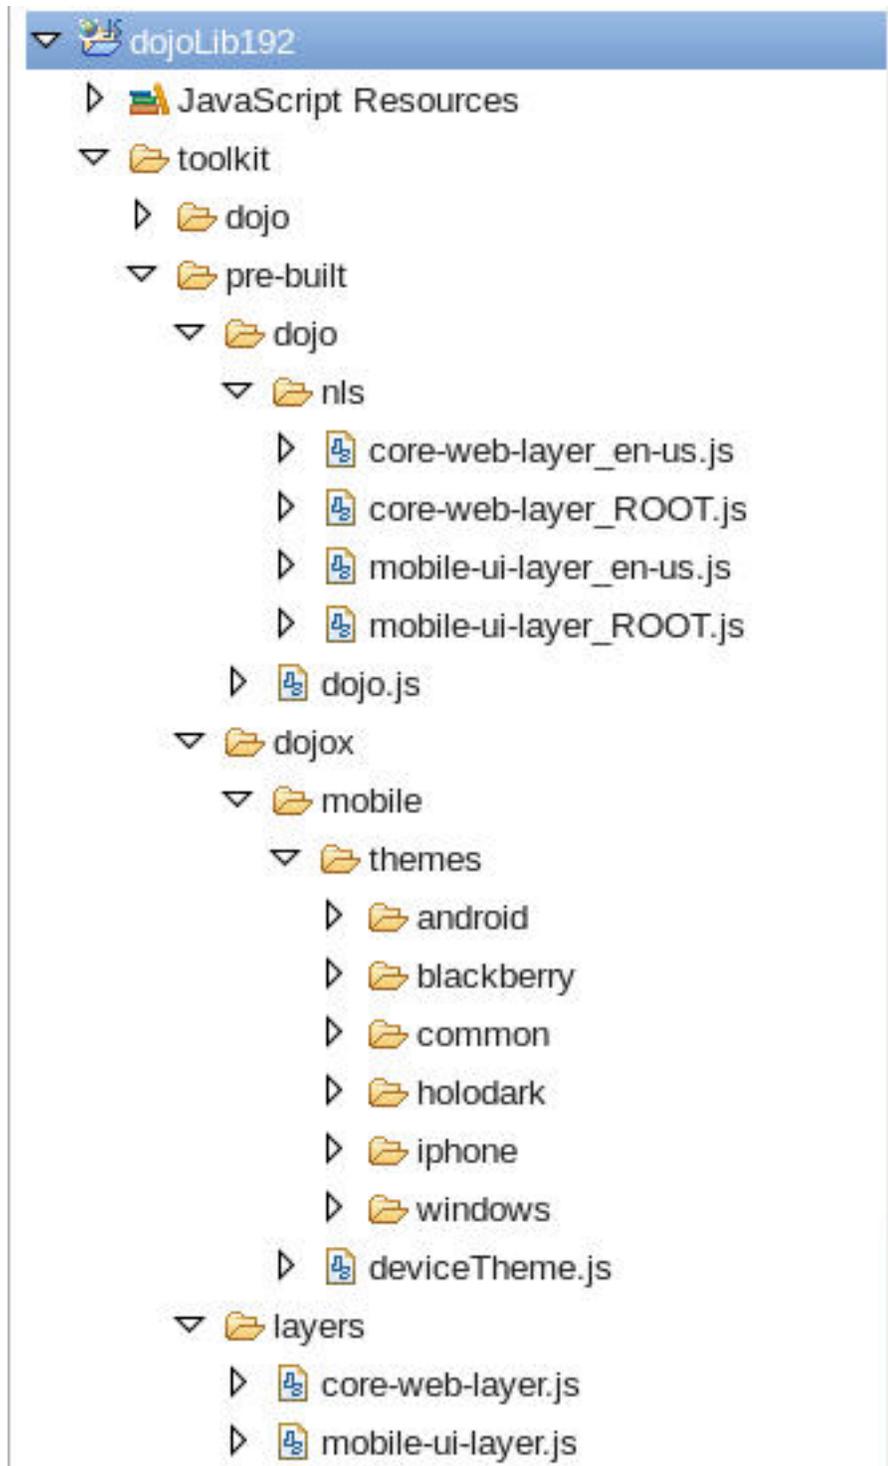

Create internal selected folders only

- f. Click **Finish** to close this dialog. Confirm that the properties page indicates it uses the new Dojo Library, then click **OK**.

A new Dojo Library project must be created, but it is still incomplete because it lacks the optimized layers you created previously, so there are still few steps to complete.

2. Go to the newly created Dojo Library project and create a new folder that is called pre-built under the existing toolkit one.
3. Populate the pre-built folder by creating the following directory structure.

Copy the files from the result/compressed folder in the Dojo Build Factory project.

Updating the optimized resources in the Dojo project:

Follow these steps to update the optimized resources currently hosted in your Dojo Project.

Before you begin

Verify that you switched your project to use the new Dojo Library project to get the MobileFirst Studio tooling from it. However, the project still contains all the old resources that were previously copied from the old Dojo Library into the project, which needs to be updated as well.

Procedure

1. Back up any customization you did to the `www` folder before you start. It is unlikely that you did any customization, but if so you must have a backup to be able to restore it later.
2. Copy the content from the `pre-built` folder of the Dojo Library project into the `www` folder of your current Dojo project.
3. Rebuild the Dojo applications in your Dojo Project to update the resources in the environments to the new ones.
4. Restart MobileFirst Studio to make sure that the entire tooling suite refreshes any session-specific resources.
5. Exercise your application as described in “Working with the Dojo Library Project that serves Dojo resources” on page 8-95.
6. Use the MobileFirst Studio tooling to copy the additional missing Dojo resources into your project
7. Merge the customizations you did in the first step, if applicable.

Changing the jQuery version for MobileFirst applications:

When you develop an application in MobileFirst Studio, the bundled version of jQuery might not be sufficient for development needs. This procedure provides instructions about how to use a different version of jQuery.

About this task

jQuery is bundled as a library within IBM MobileFirst Platform Foundation. By default, every new application includes a main HTML file, which contains the following code that is required to use the embedded jQuery:

```
<script>>window.$ = window.jQuery = WLJQ;</script>
```

To use a different version of the jQuery library, complete the following steps:

Procedure

1. Remove the `<script>window.$ = window.jQuery = WLJQ;</script>` code from the main HTML file of your application.
2. Add jQuery files to your project.
3. Add the `<script>` tag that refers to the files that you added in step 2.

Results

The updated version of jQuery will be used for all environments.

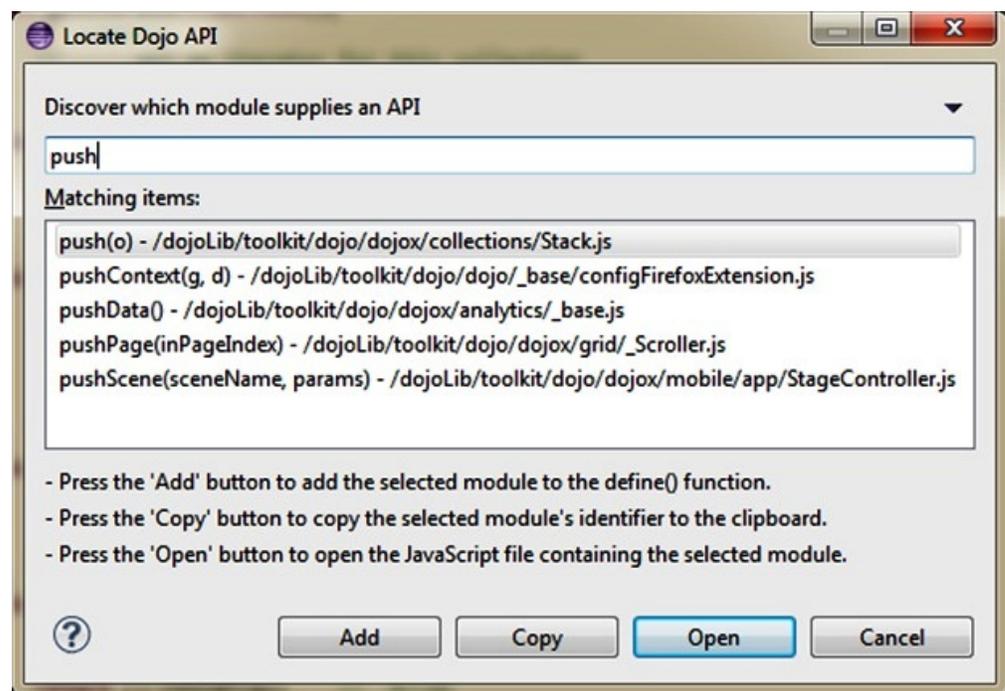

Locate Dojo API:

The Locate Dojo API dialog can be found under the **Navigate** menu and is enabled when a Dojo project resource is open in the active editor. It is enabled if a Dojo project resource is selected in a project explorer view.

The dialog locates the Asynchronous Module Definition (AMD) modules that contain the API that you need. Enter the characters of the API you need, and the locator finds the AMD modules that define that API. For example, if you were to type “push” into the search box it finds all the modules that contain types, methods, and field names that begin with “push”.

Two actions are always provided once a module is selected. The **Open** action opens the JavaScript file that contains the selected module. The **Copy** action computes the selected module’s path and copies it to the clipboard.

A third action that is called **Add** is provided if a JavaScript file that contains either a `require()` or `define()` function is open in the active editor. When **Add** is selected, the module’s path is automatically inserted into the appropriate `require()` or `define()` function.

Application skins:

An application skin is a set of web resources that govern the appearance and behavior of the application. Skins are used to adjust the application to different devices of the same family. You can package multiple skins in your application and decide at run time, on application startup, which skin to apply to the application.

Note: Only the following environments support application skins: Android, iPhone, iPad, BlackBerry 6 and 7 (deprecated; see Table 3-2 on page 3-21) and 10. Cordova applications do not support application skins.

When you use MobileFirst Studio to define a skin, MobileFirst Studio generates a folder for the skin resources and adds a `<skin>` element in the application descriptor file. The `<skin>` element includes the name of the skin and a list of resource folders. When MobileFirst Studio builds the application, it applies the optimization rules on the resource folders in the order in which they occur within the `<skin>` element.

In the following example, two skins are packaged with the Android application: the default skin and another skin called `android.tablet`. Resources for the `android.tablet` skin are in the `android.tablet` folder.

```
<android>
<skins>
<skin name="default">
<folder name="common" />
<folder name="android" />
</skin>
<skin name="android.tablet">
<folder name="common" />
<folder name="android" />
<folder name="android.tablet" />
</skin>
</skins>
</android>
```

You can also create custom skin hierarchies, by creating resource folders under the application folder and manually defining the skin hierarchy in the application descriptor. For example, you can define a `phone` folder to include resources that are related to rendering the app on a phone, and a `tablet` folder to include resources for rendering the app on a tablet. Then you can create four skins by using these resources in the following way:

- `android.phone`: `common > android > phone`
- `android.tablet`: `common > android > tablet`
- `ios.phone`: `common > iphone > phone`
- `ios.tablet`: `common > iphone > tablet`

Applying skins at run time

To set which skin to apply at run time, implement the function `getSkinName()` in the file `skinLoader.js`. This file is located under the `environment/js` folder of the application.

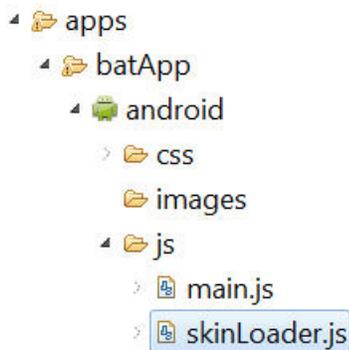

Figure 8-13. The `skinLoader.js` file

Deleting a skin

To delete a skin, remove the element that defines the skin from the app descriptor, delete the skin directory, and delete or modify the `skinLoader.js` file.

Settings page to change the server URL:

With IBM MobileFirst Platform Foundation, you can create a settings page to change the URL of the MobileFirst Server.

With IBM MobileFirst Platform Foundation, you can create a settings page that allows the following changes:

1. Directs the application to connect to a different MobileFirst Server by changing the `<protocol>://<hostname>:<port>/<contextRoot>` values.
2. Loads web resources that belong to a different application or version of the application.

Note: This technique works only if the different MobileFirst Server already exists and these resources or applications are already deployed. This feature is meant only for use in the development environment and not in production.

The settings page is available for the following environments: Android, iPhone, and iPad.

By default, the settings page is disabled with the `include` attribute of `<worklightSettings>` set as `false` in the relevant environment element of the `application-descriptor.xml` file.

To activate the settings page for the supported environments, change the `include` attribute of `<worklightSettings>` to `true`. For example:

```
<iphone version="1.0" bundleId="com.mycompany.myapp">
  <worklightSettings include="true"/>
  <security>
    ...
  </security>
</iphone>
```

Rich Page Editor:

Use Rich Page Editor to easily edit HTML files, add Dojo widgets to HTML pages, and create and edit web pages for mobile devices. Rich Page Editor is a multi-tabbed editor that provides multiple views to show different representations of your page.

Views

You can use the Source, Design, and Split views in Rich Page Editor to view and work with your files or pages. Each view in Rich Page Editor works with several other views and tools that are included in the web perspective, including the following interface elements:

- Mobile Navigation, Outline, and Properties views
- Toolbar buttons
- Menu bar options
- Pop-up (right-click) menus
- Palette components

Note: Since IBM Worklight V6.0, the jQuery Mobile widget of MobileFirst Studio might be not visible in the palette of the Rich Page Editor if you are using jQuery V1.3.2. To resolve this issue, use jQuery Mobile V1.3.1 instead of jQuery Mobile V1.3.2.

Table 8-8. Rich Page Editor views

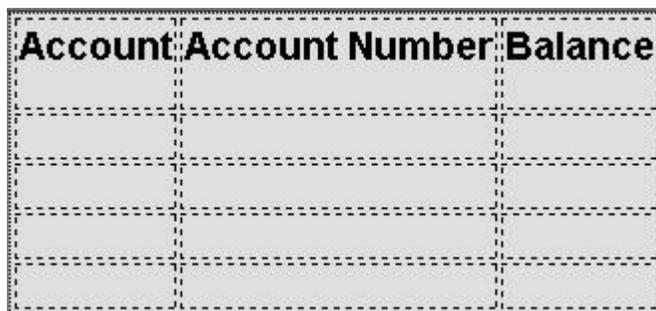

Editor view	Description
Source	The Source view helps you to view and work directly with the source code of a file. The Mobile Navigation, Palette, Outline, Page Data, and Properties views have features that supplement the Source view.
Split	<p>The Split view combines the Source and Design views in a split screen view. Changes that you make in one part of the split screen are automatically updated in the other part. You can split the view horizontally or vertically.</p> 
Design	<p>The Design view is a WYSIWYG environment. This view helps you to create and work with a file while viewing how your web page and dynamic content might look on a mobile device. You can use this view to visually edit files. For example, the Design view includes features that you can use to complete the following tasks:</p> <ul style="list-style-type: none"> • Drag items from the Palette and Enterprise Explorer views. • Rotate the screen orientation when you use a mobile device profile to view your mobile web page in either portrait or landscape mode. • Scale the mobile device to fit the size of the current Design view. Using this feature, you can see the entire visual canvas without the need to scroll. • View how your page is displayed on different devices by selecting a device from the device list. The selected device specifies the size of the mobile device that you want to view and affects the size of the Design view area. • View how your mobile web page is displayed in different styles. For example, Android, iPhone, or BlackBerry. By choosing a particular skin, you can switch to another device-specific style to view the layout and appearance of your page as it would appear on this specific device. <p>Note: The Skin list is available only for MobileFirst application pages.</p>

Design Mode editing

You can use the Design Mode editing features of Rich Page Editor to add and edit widgets in the Design view. To enable the Design Mode editing features, click the **Design Mode** icon.

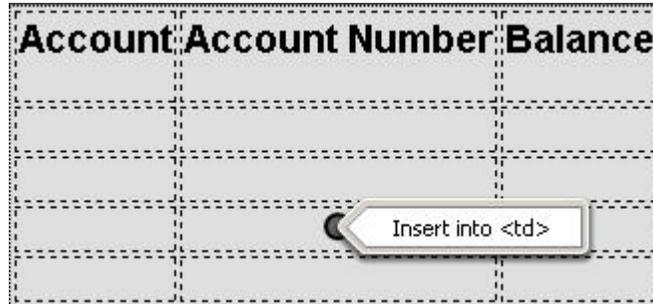

The following screen capture shows what a table looks like in the Design view of Rich Page Editor when Design Mode is enabled.

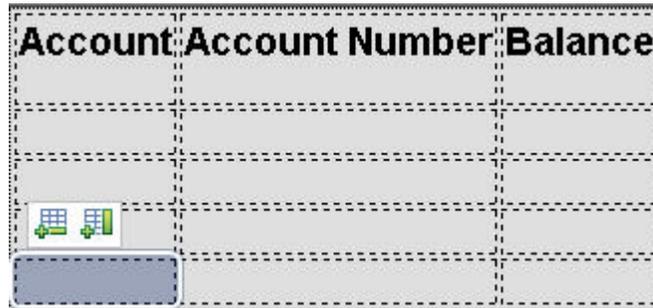

The following screen capture shows what the same table looks like in the Design view of Rich Page Editor when Design Mode is not enabled.

Account Account Number Balance

The Design Mode editing features guide the placement of code when you drop a widget on a container widget. Visual cues highlight the possible drop locations and pop-up cues indicate the editing function that is available for the selected widget. Design Mode also adds dashed borders to empty table cells. For example, dragging a tag from the Palette to a table provides a visual cue for placement:

Selecting a cell in a table opens a pop-up cue that you can use to add a column or row:

Browser requirements for Rich Page Editor:

Rich Page Editor uses embedded browsers to produce a visual representation of a web page in the Design view. The browsers that are available in Rich Page Editor and their installation requirements vary according to the platform.

Procedure

The following table lists and describes the supported browsers in Rich Page Editor, by platform:

Platform	Supported browsers
Windows	<p>Internet Explorer Available for all installations; uses the native browser code in Windows.</p> <p>Firefox Firefox support for Windows is embedded in the product and is functionally equivalent to a Firefox version 3.6 installation. Firefox is available only on 32-bit installations of the product.</p> <p>Safari Safari for Windows can be installed separately. After installation Rich Page Editor can be used in Safari. Safari support is only available on 32-bit installations of the product.</p>
Linux	<p>Firefox or WebKit The product attempts to locate and use browser code:</p> <ul style="list-style-type: none"> • WebKitGTK+libraries • XULRunner installation <p>The editor operates with a compatible XULRunner installation that is in the range of Firefox version 3.0 to version 3.6. You can also use WebKitGTK+ libraries with some additional setup. The Firefox indicators are still used in the editor even if you create a webkit-based browser. For more information about setting up the Linux browser, see “Embedded browsers for Linux.”</p>
Mac	<p>Safari The native Safari browser is automatically used for products that are available on the Mac platform.</p>

The supported browsers are available from the editor toolbar in both the design and split views.

On the toolbar, click the icon for the browser you want to use. For example, in the following screen capture, Firefox, Internet Explorer, and Safari are supported.

Embedded browsers for Linux:

On Linux systems, to ensure that product features, such as the Rich Page Editor use an appropriate embedded web browser, additional steps to configure the browser are necessary.

Product features that use an embedded web browser might not work correctly if an inappropriate browser is used. Using an inappropriate browser can cause

problems such as: scenarios that fail, error messages, or an unexpected output. Product features that use an embedded browser include:

- Rich Page Editor
- Web Browser component
- Welcome page

The Eclipse Standard Widget Toolkit (SWT) supports the following browser types for Linux systems:

- Mozilla (Firefox) through the XULRunner package
- WebKit through WebKitGTK+ shared libraries

The version of Eclipse included in the product determines the default browser type used by SWT. However, you can explicitly configure the default browser type. Only one browser type is available at a time within the product.

- For Eclipse versions 3.7 and later, the WebKit browser is the default browser on Linux. If suitable WebKit libraries are not found, the XULRunner browser is used.

Configuring for the WebKit embedded browser:

A WebKit embedded browser is supplied as a separate installation of the WebKitGTK+ shared libraries, however; these libraries are included in many of the supported Linux distributions.

Procedure

If necessary, install the WebKitGTK+ package onto the system and ensure that it is included on the default library path.

Configuring for the XULRunner embedded browser:

The XULRunner package enables Mozilla as the embedded browser. If several XULRunner packages are installed on the same system, version mismatches can occur even if a specific XULRunner installation is registered as the default version. To clearly define the XULRunner browser and level to be used in your configuration, you must set up an explicit pointer to a XULRunner version.

About this task

The supported XULRunner versions are:

- 1.8.x
- 1.9.2
- 3.6.x

Note: The XULRunner package must match the architecture (32-bit or 64-bit) of the product installation.

To download the XULRunner 1.9.2, click one of the following links:

- [XULRunner 32-bit download](#)
- [XULRunner 64-bit download](#)

Procedure

To set up an explicit pointer to a XULRunner version, complete the following steps.

1. In the `eclipse.ini` file included in the product installation, locate the `-vmargs` section.

Note:

For users of IBM MobileFirst Platform Foundation only:

- If a `Worklight.sh` file is present in the same product directory as the `eclipse.ini` file, add your updates to the `-vmargs` sections of both files.
- Some installations use JRE arguments from the `Worklight.sh` script instead of from the `eclipse.ini` file.

2. In the `-vmargs` section, add the following JVM system variable where `/home/myuser/xulrunner` is the path to the root of an uncompressed XULRunner package.

```
-Dorg.eclipse.swt.browser.XULRunnerPath=/home/myuser/xulrunner
```

Complete the following step to use the XULRunner browser instead of the WebKit browser.

3. Add the following JVM parameter to the `-vmargs` section at the end of the `eclipse.ini` file.

Note:

For users of MobileFirst Studio only: If the `Worklight.sh` file is present, add the same code to the end of this file.

```
-Dorg.eclipse.swt.browser.DefaultType=mozilla
```

Setting the Rich Page Editor preferences:

You can customize the display of Rich Page Editor by setting the preferences for view shortcuts, pane visibility and layout, design mode, and web browser.

Procedure

1. In the main menu, click **Window > Preferences**.
2. Expand **Web > Rich Page Editor**.
3. Specify the default preference settings for Rich Page Editor.

Editor preference	Description
View shortcuts	Specify whether to show or hide the shortcut toolbar buttons in Rich Page Editor for these views: Palette, Properties, Outline, and Mobile Views.
Visible pane	Select which view to show when you open a file with Rich Page Editor. You can choose from these views: Design, Source, and Split.
Pane layout	Set the Split view layout, which is a combination of the Source view and Design view, to split the editor view either horizontally or vertically.

Editor preference	Description
Design mode	<p>Specify whether to enable or disable Design Mode.</p> <p>When Design Mode is available, the editing features help you to add and edit widgets in the Design view of the editor. For example, the editing features guide the placement of code when you drop a widget on a container widget. Visual cues highlight the possible drop locations and pop-up cues indicate the editing function that is available for the selected widget. Design Mode also adds dashed borders to empty table cells.</p> <p>When Design Mode is unavailable, elements in the Design view are displayed exactly as they are shown in the web browser, without any visual aids for editing.</p>
Web browser	<p>Select the web browser in which to show the page that is being edited.</p> <p>Note: The list of available web browsers is dependent on the platform and web browsers that are installed on your computer.</p>

Tip: When you are working with Rich Page Editor, you can change these settings from the editor window. To change the view shortcuts, pane layout, design mode, and web browser settings, use the toolbar in the editor window. To change the visible pane, use the tabs.

- Optional: To specify that you want to remember these preference settings for each resource, select **Remember settings for each individual resource**.
- Specify the Smart Highlight settings for Rich Page Editor.

Smart Highlight preference	Description
jQuery	<p>Specify whether to highlight nodes in the Design and Outline views that are matched by jQuery expression selectors in the Source view or Javascript editors.</p> <p>Tip: By default, matched nodes are highlighted in yellow. To change the highlight color, click Change Highlight Color.</p>

- Click **Apply** and then save your changes by clicking **OK**.

Opening web pages in Rich Page Editor:

You can open web pages in Rich Page Editor to edit HTML files, add Dojo widgets to HTML pages, and edit web pages for mobile devices.

Before you begin

You must complete the following tasks before you can open a web page in Rich Page Editor:

- Create a project.

2. Create a web page.

Procedure

In the Enterprise Explorer view, use one of the following methods to open a web page in Rich Page Editor:

- Double-click your web page.
- Right-click your web page and select **Open**.

Working in the Design and Split views:

You can use the Design and Split views in Rich Page Editor to edit HTML files in WYSIWYG mode.

When you edit in the Design view, your work reflects the layout and style of the web pages that you build. The Design view removes the added complexity of source tag syntax, navigation, and debugging.

Use the Split view to show both the Design view and the Source view in a split screen view. Changes that you make in one part of the split screen are automatically updated in the other part. You can split the view horizontally or vertically.

About this task

The design and split views provide full access to the following features:

- Editor menu options
- Pop-up menu actions
- User interface options, such as those in the Styles view
- Drag-and-drop behavior

The Design and Split views also provide support for absolute positioning. You can see the immediate impact of design decisions more quickly than in a text editor. Using these views, you can efficiently and precisely change the composition and attributes of pages, tags, images, and effects.

Many actions available through the editor menus are also available from design element pop-up menus. To access the design element pop-up menus, select a page object, and then right-click the object.

Working in the Source view:

You can use the Source view in Rich Page Editor to edit HTML and other markup text, such as embedded JavaScript. Any changes you make in the source view are also reflected in the Design and Split views.

About this task

You can also show the Source view by opening the Split view. The Split view shows both the Design and Source views, split vertically or horizontally. If you add or update an attribute value in the Source view while the Properties view is visible, the properties are also refreshed.

Table 8-9. Source view features

Feature	Description
Syntax highlighting	Each tag type uses different highlighting to make it easy to find a specific type of tag for editing. For example, you cannot edit read-only regions of the page which are highlighted in gray.
Unlimited undo and redo	You can incrementally undo and redo every change made to a file for the entire editing session. For text, changes are incremented one character or set of selected characters at a time.
Content assist	Content assist helps you to finish tags or lines of code, and insert macros. The available options in the content assist list are based on the tags that are defined by the tagging standard specified for the file being edited. If content assist does not automatically open, press Ctrl + Space. The content assist text is displayed in a yellow box as you type.
User-defined macros	You can access user-defined templates, which are chunks of predefined code, with content assist to help you add the tagging combinations that are used often.
Element selection	The element selection indicator is located within the vertical border in the Source view. Based on the location of your cursor, the element selection indicator highlights the line numbers that contain the elements being edited.
Pop-up menu options	You can right-click at a specific position in the editor to open the editor pop-up menu. This menu contains many of the same editing options that are available in the workbench Edit menu.
Drag-and-drop	You can drag objects from the Palette view to the position of the cursor in the Source view.
Copy and paste	You can press Ctrl + C and Ctrl + V to copy and paste a selected tag in the Source view.
Validation	You can configure an option on the preferences page to validate your code as you type: <ol style="list-style-type: none"> 1. From the main menu, select Window > Preferences > General > Editors > Structured Text Editor. 2. On the Structured Text Editor preferences page, select Report problems as you type.

Table 8-9. Source view features (continued)

Feature	Description
Customization	<p>You can customize the appearance of the editor on either of the following preferences pages:</p> <ul style="list-style-type: none"> • Window > Preferences > General > Editors > Editors (or Structured Text Editors) • Window > Preferences > Web > HTML Files > Editor

The HTML 5 specification is supported only in the Source view. For example, you can use content assist to insert the <canvas> tag.

You can use any of the following methods to enter, insert, or delete tags and text in the Source view:

- Type the tags directly.
- Use content assist to receive prompts for valid tags.
- Select the menu items.
- Select the toolbar buttons.
- Use the Properties view to change tags.

Procedure

To edit an HTML file in the Source view:

1. Open the HTML file that you want to work with in the editor.
2. In the **Source** tab, use the available features to edit the code, as required.

Tip: You can select attribute values, attribute-value pairs, and entire tag sets by using the double-click feature available in the editor. Use this feature to quickly update, copy, or remove content.

3. At intervals, to see the nesting hierarchies more clearly in the file, format individual elements or the entire document to restore element and attribute indentation. Right-click the editor window and select **Source > Format**.
4. Save the file.

Creating web pages in Rich Page Editor:

You can create interactive web pages in Rich Page Editor.

Before you begin

Before you can create a web page in Rich Page Editor, you must create a project.

Procedure

1. Click **File > New > Web Page** to open the New Web Page wizard.
2. Specify a file name and template for the new web page, and then click **Finish**. Your new web page opens in Rich Page Editor.

Creating web pages for mobile devices:

You can create interactive web pages that are optimized for mobile devices.

Before you begin

Ensure that you complete the following tasks before you create a web page for a mobile device in Rich Page Editor:

1. Create a project.
2. Set the target device for your project.
3. Set Rich Page Editor as the default web page editor.

Procedure

1. Click **File > New > Web Page** to open the New Web Page wizard.
2. Specify a file name and choose one of the following mobile templates for the new web page:

Dojo Mobile HTML template

Sets up the web page for Dojo. Generates content into the web page to prepare the web page for use with Dojo libraries. This content can include:

- JavaScript and CSS includes.
- Basic widgets that are typically required for Dojo Mobile web pages, such as a mobile View widget.

jQuery Mobile HTML template

Sets up the web page for jQuery. Generates content into the web page to prepare the web page for use with its libraries. This content can include:

- JavaScript and CSS includes.
- Basic widgets that are typically required for jQuery Mobile web pages, such as a Page widget.

3. Optional: To open the New Web Page Options page and add more options to your mobile web page, click **Options**.

Option	Description
Set the document type declaration to HTML 5 and cache the page	<ol style="list-style-type: none">1. From the list of options, click Document Markup.2. From the Document Type list, select HTML 5 to show more options.3. Specify the icon that is used by mobile devices when users add bookmarks. To select an icon from your workspace, click Browse next to the File href field.4. Enable browser application caching. In the Manifest Section field, select CACHE and then specify a manifest file. For example, WebContent/META-INF/cache.mf. HTML 5 application caching ensures performance and availability when the mobile device is offline. For more information about cache manifest files, see the latest HTML5 specification at: http://dev.w3.org/html5/spec, and search for "cache manifest".

Option	Description
<p>Set the device detection and stylesheet options</p>	<ol style="list-style-type: none"> From the list of options, click Mobile Web Page. Select one of the following options: <ul style="list-style-type: none"> Detect device The web page detects the device that shows the content and loads the appropriate CSS by including the script <code>dojox/mobile/deviceTheme.js</code>. Select <code>dojox.mobile</code> stylesheet The selected style sheet is loaded by using the <code><link></code> tag. You can select one of the following style sheets: <ul style="list-style-type: none"> <code>blackberry.css</code> <code>android.css</code> <code>ipad.css</code> <code>iphone.css</code> No CSS Use a style sheet other than the ones that are available when you select the <code>dojox.mobile</code> style sheet option. When you specify the No CSS option, you can select Stylesheets from the list of options and add the style sheets that you want to use.

4. Click **Finish**. Your web page opens in Rich Page Editor.

Mobile patterns:

This feature is deprecated in V7.1.0. Mobile patterns provide templates that you can use to develop pages that are associated with a jQuery or Dojo mobile application. Using mobile patterns accelerates development of your mobile application by providing views common to many mobile applications.

You can choose from many mobile patterns available in the Default Mobile Pattern Set, or you can create your own Mobile Pattern Sets. For more information, see “Creating mobile pattern projects” on page 8-129.

All the available Pattern Sets in your workspace and the Default Mobile Pattern Set appear grouped in the Pattern Set combination box. You can select any Mobile Pattern Set and see its content on the Add Mobile Page window.

Each Pattern Set contains categories and each category groups a list of patterns, for example: The Default Mobile Pattern Set are grouped into four categories.

Selecting a category on the Add Mobile Page window displays a list of available patterns that are associated with the category.

Lists Choose from a number of different list formats from simple to complex. You can choose unordered lists patterns or ordered list patterns.

Authentications

Choose the type of login page for your application that contains only a User ID and password fields. Or, select a template that contains more input areas or buttons, such as **forgot password** and **register**.

Navigation and search

Choose from various navigation patterns, which include toolbars, navigation lists, or lists with searchable content.

Configuration

Choose from blank configuration pages to pages that contain predefined configuration items, such as language.

Some mobile patterns are sets where mobile views within the set are appropriately linked. For example, selecting a login page with **Reset password**, the Reset password template page is also created. When you select a mobile pattern that is a set, you see all pages in the preview.

Choosing a mobile pattern adds the appropriate code into your application after which you can alter it as required.

Related tasks:

“Adding a mobile pattern to an application”

Use mobile patterns to accelerate development of mobile applications. Select from a predefined list of mobile patterns to quickly add code to your application.

Adding a mobile pattern to an application:

Use mobile patterns to accelerate development of mobile applications. Select from a predefined list of mobile patterns to quickly add code to your application.

Before you begin

If the Mobile Navigation View is not shown, go to **Window > Show View > Other > Web > Mobile Navigation** to display it.

Procedure

1. In the Mobile Navigation View, click the plus sign icon.
2. In the add window, select a category and click **Create view from UI pattern**. The available patterns that are associated with the category are loaded in the view.
3. Required: Select the mobile pattern and click **Finish** to insert into your application.

Related concepts:

“Mobile patterns” on page 8-128

This feature is deprecated in V7.1.0. Mobile patterns provide templates that you can use to develop pages that are associated with a jQuery or Dojo mobile application. Using mobile patterns accelerates development of your mobile application by providing views common to many mobile applications.

Creating mobile pattern projects:

The UI Pattern is a container for mobile patterns. You can add mobile patterns to either a Dojo or jQuery app. You can also add your own mobile patterns into the tool.

Procedure

1. Use the UI Pattern Project wizard to create your own pattern project.
 - a. Click **File > New > Project**.
 - b. Expand the **Web** folder and select **UI Pattern Project**.
 - c. Click **Next**.
 - d. Give your UI Pattern Project a name.
 - e. Optional: You can click **include jQuery** and **add jQuery Resources** to the project.

Note: Files are **jQuery Mobile** (JS and CSS files) and **jQuery JS Core** so you can properly preview the app by using the Rich Page Editor.

- f. Click **Finish**. A UI Pattern Project is created.
2. Right-click your UI Pattern Project and select **New > UI Pattern**.

Note: Your project must contain either Dojo framework or jQuery framework, or both, for you to be able to continue in the **UI Pattern** wizard. For instructions, see “Adding Dojo framework to a UI Pattern Project” on page 8-131 and “Adding jQuery framework to a UI Pattern Project” on page 8-131.

3. Define the name of your pattern and click **Finish**. A folder with the name of your new pattern is added to the WebContent folder. This folder contains the pattern's resources.
4. Open the pattern.html file that is found in one of the following locations: WebContent/*pattern_name*/Dojo or WebContent/*pattern_name*/jQuery.
 - Adding widgets in the view for Dojo.
 - Adding widgets in the page for jQuery.

Note: If you are creating a Dojo pattern, ensure that the following two script tags are included in the pattern.html file under the Dojo folder.

```
<script type="text/javascript" pattern.discardNode="true">
  require([ "dojox/mobile/parser", "dojox/mobile/compat" ]);
</script>
```

This script tag is required to preview the pattern in the Mobile Pattern Browser. The pattern.discardNode attribute is used by patterns to identify when an element is discarded from pattern insertion.

```
<script type="text/javascript">
  require([ /*START_DEPENDENCIES*/ "dojox/mobile/ScrollableView" /*END_DEPENDENCIES*/ ]);
</script>
```

In the second script tag, when a pattern is added to a mobile page, the require elements between the START_DEPENDENCIES comment and the END_DEPENDENCIES comment are translated to Dojo module requests. Then, they are inserted into the Dojo require section in the final application. The require elements outside the DEPENDENCIES comments are not added to the final application. When you add a Dojo widget to your mobile pattern, add the necessary modules for that widget between the DEPENDENCIES comments

5. Save your UI Pattern project. You can add the mobile pattern to a Dojo or jQuery project by creating or opening a MobileFirst hybrid project with Dojo or jQuery support. Open the index.html file that is found under apps/*app_name*/common in Rich Page Editor.
6. Click (+) from the Mobile Navigation view. Use the following figure for guidance:

Figure 8-14. Mobile Navigation view

If the Mobile Navigation view is not visible, click **Window > Show view > Other**, expand the **Web** folder, select **Mobile Navigation**, and click **OK**.

7. Complete the Add jQuery Mobile Page or Add Dojo Mobile Page wizard.
 - a. Type the name of your UI Pattern in the **ID** field.
 - b. Select the **Create from UI pattern** option.
 - c. From the **Pattern Set** menu, select **UI_Pattern_project_name**. Your mobile pattern is displayed in the Mobile Pattern Browser.
 - d. Select your mobile pattern and click **Finish**.

Your new UI Pattern is displayed in the preview.

8. Save your Dojo or jQuery project where the pattern was added.

Results

The new pattern is available for you to use with other Dojo and jQuery projects in the workspace.

What to do next

To add a mobile pattern to an application, see “Adding a mobile pattern to an application” on page 8-129.

Adding Dojo framework to a UI Pattern Project:

To create UI Patterns in a Pattern Project, Dojo or jQuery framework, or both, must be present in the project.

Before you begin

Before you add Dojo framework to a UI Pattern Project, a UI Pattern Project must already be created.

Procedure

1. In MobileFirst Studio, right-click your UI Pattern Project and select **Properties**.
2. In the **Properties for <Your project name>** window that appears, select **Project Facets** from the list.
3. In the **Project Facet** table, expand **Web 2.0**.
4. Select **Dojo Toolkit** and click **Apply**.
5. Click **OK**.

Adding jQuery framework to a UI Pattern Project:

To create UI Patterns in a Pattern Project, Dojo or jQuery framework, or both, must be present in the project.

Before you begin

Before you add jQuery framework to a UI Pattern Project, a UI Pattern Project must already be created.

Procedure

Copy **jQuery Mobile (JavaScript, CSS, and images)** from jQuery Mobile downloads and **jQuery JS Core** from the jQuery Core - All Versions page into the **WebContent** folder of your MobileFirst Studio UI Pattern Project.

Adding elements to web pages from the palette:

You can populate a web page with content by dragging elements from the Palette view to the web page in Rich Page Editor.

Before you begin

You must complete the following tasks before you can add elements to a web page in Rich Page Editor:

1. Create a project.
2. Create a web page.

Procedure

1. In the Enterprise Explorer view, double-click your web page to open it in Rich Page Editor.
2. Add various elements to your web page by dragging objects from the different drawers in the Palette view, such as radio buttons, check boxes, and submit buttons.

Tip: In the Web perspective, the Palette view is located by default on the right side of the workbench, underneath the Outline and Snippets views.

3. You can select multiple elements by pressing Ctrl and then performing actions on the selected elements from the menu, such as copy, paste, or delete.
4. When you finish adding elements to your web page, save your changes by pressing Ctrl + S.

HTML5 tags in palette:

HTML5 tags are available to use in the Rich Page Editor palette when you are creating an HTML5 web page.

The HTML5 tags can be found in the palette under the **Table** tag. The following tags are HTML5 tags:

- **Canvas**
- **Audio**
- **Embed**
- **Video**
- **Figure**
- **Meter**
- **Progress**
- **Time**

- **Article**
- **Details**
- **Dialog**
- **Figcaption**
- **Footer**
- **Header**
- **Main**
- **Section**

If you drag one of these widgets into the **Design** pane, a new tag is added to the **Source** pane with the correct format.

Note: This function is only visible when you are working on an HTML5 page, where these tags are legal. For example, if you create a new HTML4 web page, these HTML5 tags do not appear in the palette.

Properties view associated with Rich Page Editor:

The Properties view that is associated with Rich Page Editor displays specific information for the currently selected tag in a web page. You can use the Properties view to edit properties that are related to the appearance of tags in a web browser. For example, you can change CSS style information, default attribute values, Dojo properties, and jQuery properties, as required.

You can use the Properties view to edit JavaScript, HTML, or JSP tags when the Design, Source, or Split view is open in Rich Page Editor. Changes in the Properties view are displayed in Rich Page Editor when you change the cursor focus or press Enter. If you update tags in the Source view of Rich Page Editor, your changes take effect immediately in the Properties view.

Breadcrumb navigation

When you select a node in Rich Page Editor, the Properties view uses a breadcrumb trail to provide context for the selected node:

You can scroll through the breadcrumb trail without losing the position of your cursor in Rich Page Editor. Using this feature, you can quickly update the properties of ancestor elements.

Categorized property pages

The Properties view organizes properties into various categories, including:

Styles Use to manipulate basic CSS style information (such as an attribute or the class that is associated with it) or various font, color, and alignment properties.

Layout

Use to configure properties that control the layout of the element within the presentation of the page.

All Use to view all of the attributes for an element, in a tabbed list.

Dojo Use to configure Dojo-specific properties on certain widgets.

Note: This category applies only to Dojo-enabled projects.

jQuery

Use to configure jQuery-specific properties on certain widgets.

Note: This category applies only to jQuery-enabled projects.

Mobile Navigation view:

You can use the Mobile Navigation view to manage Dojo mobile view widgets and jQuery mobile web page widgets.

For example, by using the Mobile Navigation view, you can:

- Add or remove mobile views and pages.
- Switch visibility from one mobile view or page to another.
- Rename mobile views and pages.
- Set the default mobile view or page that is shown the first time that a web page opens.
- Link mobile views or pages.

The Mobile Navigation view is available from both the Web perspective and Rich Page Editor:

- To open the view from the Web perspective, select **Window > Show view > Other > Web > Mobile Navigation**.
- To open the view from Rich Page Editor, on the toolbar click **Show/Hide Mobile Navigation**:

A mobile web page can contain multiple views or pages. You can create these views and pages inline or in external files.

Inline mobile view or page

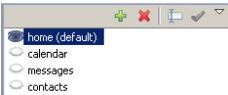

A mobile view or page that is written within the source code of the mobile web page.

External mobile view or page

A mobile view or page that is written in a separate file or fragment. Creating mobile views or pages in separate files or fragments makes source code shorter and easier to manage.

When you open a mobile web page in Rich Page Editor, the mobile views or pages that are contained within that web page are displayed in the Mobile Navigation view. The icon next to each mobile views and pages indicates which one is visible in Rich Page Editor. If the mobile web page references external mobile views or pages, they are displayed in the Mobile Navigation view with a decorated icon. To open a new instance of Rich Page Editor for an external mobile view or page, double-click the mobile view or page.

The following table lists and describes the features available for mobile web pages in the Mobile Navigation view.

What you can do in the Mobile Navigation view	Description
Create mobile views or pages	<p>You can create the following types of Dojo widgets:</p> <p>View A container that represents the entire mobile device screen.</p> <p>ScrollableView A view widget with touch scrolling capability that you can use to provide fixed position header and footer bars.</p> <p>SwapView A view widget that you can swipe horizontally to show adjacent SwapView widgets.</p> <p>You can create the following types of jQuery widgets:</p> <p>Page A container that represents the entire mobile device screen.</p> <p>Dialog page A container that is shown in the form of a dialog box.</p>
Switch between mobile views or pages	<p>You can switch visibility between views or pages to specify which view or page is available in Rich Page Editor. In the following screen capture, the home view is visible in Rich Page Editor; the calendar, messages, and contacts views are not visible.</p> 
Rename mobile views or pages	<p>Right-click the view or page that you want to rename and then click Rename. For example, to rename the calendar view to internet:</p> <ol style="list-style-type: none"> 1. Right-click calendar and then click Rename. 2. In the Mobile View id field, specify internet.
Set the default mobile view or page	<p>Right-click the view or page that you want to set as the default and click Set as default.</p>
Remove mobile views or pages	<p>Right-click the view or page that you want to remove and click Remove.</p>

The following table lists and describes the features available for mobile web pages in the Mobile Navigation view.

What you can do in the Mobile Navigation view	Description
Link mobile views or pages	<p>You can link widgets, such as buttons or list view items, to mobile views or pages. You can drag a widget from the Design view in Rich Page Editor to a mobile view or page in the Mobile Navigation view. You can also drag mobile views or pages from the Mobile Navigation view to widgets in the Design view within Rich Page Editor.</p> <p>Tip: You can link Dojo mobile widgets to mobile views by using the Link to Mobile View action.</p> <ol style="list-style-type: none"> 1. In the Design view within Rich Page Editor, click the Dojo mobile widget that you want to link to a mobile view to open the toolbar. 2. To open the Link to Mobile View dialog, on the toolbar click Link to Mobile View:  3. Select one of the following options. <ul style="list-style-type: none"> • Click Inline Mobile View; from the list, select the mobile view that you want to link to the widget. • Click Page Fragment, and then click Browse to browse to the mobile page file that you want to link to the mobile view. 4. Click Finish.

Web and native code in iPhone, iPad, and Android

Using IBM MobileFirst Platform Foundation, you can include, in your applications, pages that are developed in the native operating system language.

The natively developed pages can be invoked from your web-based pages and can then return control to the web view. You can pass data from the web page to the native page, and return data in the opposite direction. You can also animate the transition between the pages in both directions.

Switching between native and web views:

In iOS and Android applications, natively developed pages can be invoked from your web-based pages and can then return control to the web view and vice versa. You can pass data from the web page to the native page, and return data in the opposite direction. You can also animate the transition between the pages in both directions.

Switching to a native view from a web view

To switch the display from the web view to a native page, use the `WL.NativePage.show` method.

Authenticating in native and retrieving user information in web view

The MobileFirst JavaScript API provides the following methods for retrieving authenticated user information, such as the login name, display name, or any other custom user identity property.

- WL.Client.updateUserInfo()
- WL.Client.getLoginName()
- WL.Client.getUserInfo()
- WL.Client.getUserName()

Note: The preceding methods are available in the JavaScript API only. If your application implements authentication in the native layer and only then moves to the web layer, you must invoke WL.Client.updateUserInfo() methods in order to retrieve authenticated user information from the MobileFirst Server.

Receiving data from the web view in an Objective-C page:

To receive data from the calling web view, follow these instructions.

Before you begin

The native page must be implemented as an Objective-C class that inherits from UIViewController. This UIViewController class must be able to initialize through the `init` method alone. The `initWithNibName:bundle:` method is never called on this class instance.

Procedure

Write a UIViewController class that implements the method `setDataFromWebView:`.

```
-(void) setDataFromWebView:(NSDictionary *)data{
    NSString = (NSString *) [data valueForKey:@"key"];
}
```

Related information:

 http://developer.apple.com/library/ios/#documentation/UIKit/Reference/UIViewController_Class/Reference/Reference.html#/apple_ref/occ/cl/UIViewController

Returning control to the web view from an Objective-C page:

To switch back to the web view, follow these instructions.

Before you begin

The native page must be implemented as an Objective-C class that inherits from UIViewController. This UIViewController class must be able to initialize through the `init` method alone. The `initWithNibName:bundle:` method is never called on this class instance.

Procedure

In the native page, call the `[NativePage showWebView:]` method and pass it an NSDictionary object (the object can be empty). This NSDictionary can be structured with any hierarchy. The MobileFirst runtime framework encodes it in JSON format, and then sends it as the first argument to the JavaScript callback function.

```
// The NSDictionary object will be sent as a JSON object to the JavaScript layer in the webview
[NativePage showWebView:[NSDictionary dictionaryWithObject:@"value" forKey:@"key"]]
```

Related information:

 http://developer.apple.com/library/ios/#documentation/UIKit/Reference/UIViewController_Class/Reference/Reference.html#/apple_ref/occ/cl/UIViewController

Animating the transition from an Objective-C page to a web view:

To implement a transition animation when switching the display from the native page to the web view, follow these instructions.

Procedure

Within your animation code, call the [NativePage showWebView] method.

```
-(IBAction)returnClicked:(id)sender{
NSString *phone = [phoneNumber text];
NSDictionary *returnedData = [NSDictionary dictionaryWithObject:phone forKey:@"phoneNumber"];

// Animate transition with a flip effect
CDVAppDelegate *cordovaAppDelegate = (CDVAppDelegate *)[UIApplication sharedApplication] delegate];

[UIView beginAnimations:nil context:NULL];
[UIView setAnimationDuration:0.5];
[UIView setAnimationTransition:UIViewAnimationTransitionFlipFromRight
forView:[cordovaAppDelegate window] cache:YES];

[UIView commitAnimations];

// Return to WebView
[NativePage showWebView:returnedData];
}
```

Animating the transition from a web view to an Objective-C page:

To implement a transition animation when switching the display from the web view to the native page, follow these instructions.

Procedure

Implement the methods: onBeforeShow and onAfterShow. These methods are called before the display switches from the web view to the native page, and after the transition.

```
-(void)onBeforeShow{
CDVAppDelegate *cordovaAppDelegate = (CDVAppDelegate *)[UIApplication sharedApplication] delegate];
[UIView beginAnimations:nil context:NULL];
[UIView setAnimationDuration:0.5];
[UIView setAnimationTransition:UIViewAnimationTransitionFlipFromRight forView:[cordovaAppDelegate window] cache:YES];
}
-(void)onAfterShow{
[UIView commitAnimations];
}
```

Receiving data from the web view in a Java page:

To receive data from the calling web view, follow these instructions.

Before you begin

The page must be implemented as an Activity object or extend an Activity. As with any other activity, you must declare this activity in the `AndroidManifest.xml` file.

Procedure

To receive data from the calling web view, use the Intent object defined on the native Activity. The MobileFirst client framework makes the data available to the Activity in a Bundle.

Example

Sending data from web view to the native Activity:

```
WL.NativePage.show('com.example.android.tictactoe.library.GameActivity', this.callback, {"gameLevel":1,"playerName":"john",isKeyboardEnable:false});
```

Receiving the data in the native Activity:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    //Read int value, default = 0
    Integer gameLevel = getIntent().getIntExtra("gameLevel", 0);

    //Read String value
    String playerName = getIntent().getStringExtra("playerName");

    //Read boolean value, default = false
    Boolean isKeyboardEnable = getIntent().getBooleanExtra("isKeyboardEnable", false);
}
```

Related information:

 <http://developer.android.com/reference/android/content/Intent.html>

 <http://developer.android.com/reference/android/app/Activity.html>

 <http://developer.android.com/reference/android/os/Bundle.html>

Returning control to the web view from a Java page:

To switch back to the web view, follow these instructions

Before you begin

The page must be implemented as an Activity object or extend an Activity. As with any other activity, you must declare this activity in the `AndroidManifest.xml` file.

Procedure

In the native page, call the `finish()` function of the Activity. You can pass data back to the web view by creating an Intent object.

Example

Passing data and control to the web view:

```
Intent gameInfo = new Intent ();
gameInfo.putExtra("winnerScore", winnerScore);
gameInfo.putExtra("winnerName", winnerName);
setResult(RESULT_OK, gameInfo);
finish();
```

Receiving the data in the web view:

```
this.callback = function(data){$('resultDiv').update('The winner is: ' + data.winnerName + " with score: " + data.winnerScore);}
```

Related information:

<http://developer.android.com/reference/android/app/Activity.html>

Animating the transitions from and to a Java page:

To animate the transitions between a web view and a native page, follow these instructions.

Procedure

To add transition animation, use the `Activity` function `OverridePendingTransition(int, int)`.

Example

```
// Transition animation from the web view to the native page
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    overridePendingTransition(android.R.anim.fade_in, android.R.anim.fade_out);
}

// Transition animation from the native page to the web view
@Override
protected void onActivityResult(int requestCode, int resultCode, Intent data) {
    //your code goes here....
    finish();
    overridePendingTransition(android.R.anim.fade_in, android.R.anim.fade_out);
}
```

Related information:

[http://developer.android.com/reference/android/app/Activity.html#overridePendingTransition\(int, int\)](http://developer.android.com/reference/android/app/Activity.html#overridePendingTransition(int, int))

Guidelines for using native code in hybrid MobileFirst projects:

Follow these guidelines to keep your project's native code intact during a build.

As a rule, MobileFirst builds are non-destructive with respect to files in the native folder. The exception is the target web folder (meaning `/www`, or `assets/www`), which is overwritten during each build with the optimized web resources from common and environment-specific folders. Keep to the following rules to ensure that your native code remains intact during a build:

- If you have edited native code in either Android Studio or Xcode, ensure that your changes are under the app's native folder before the next build in MobileFirst Studio.
- You can safely place and edit non-web assets in the native folder. No duplication or copying of files under native to other locations occurs during a build.

- Additionally, you can place a limited number of assets (for example, icons) under the `nativeResources` folder that is then copied into the `native` folder during a build. However, make this the exception, rather than the rule.
- Never edit web assets directly in the `native` folder. Edit web assets in either the **common** or environment-specific folders, as appropriate. These folders are merged and optimized during a build and placed in the proper web target folder.
- Do not manually delete the `native` folder as it may contain critical custom code that you have implemented. If you must delete the folder, first ensure that you have backed up the code.
- Follow the guidelines for using source control systems with MobileFirst projects: See “Integrating with source control systems” on page 8-337.
- Use the `nativeResources` folder to hold static resources only, such as images.

Development guidelines for desktop and web environments

This collection of topics gives instructions for implementing various functions in desktop and web applications.

Specifying the application taskbar for Adobe AIR applications:

How to display or suppress a **taskbar** button for a widget.

About this task

Adobe AIR applications can be displayed on the system taskbar. Widgets that are opened for a short time (for example, to perform a specific task) and are then closed should normally have a **taskbar** button. Conversely, widgets that remain constantly open on the desktop should not have a **taskbar** button, to save the space required by the button. Instead, such widgets have a tray icon that allows access to the widget.

If the **taskbar** button is not displayed, IBM MobileFirst Platform Foundation adds a tray icon for the widget. You can use the tray icon to minimize the application, restore it, and close it.

Procedure

- To control whether your desktop widget is displayed on the taskbar, specify the `<air>` element in the application descriptor. If the `<air>` element is not specified, the **taskbar** button is displayed.
- To display a **taskbar** button for the widget, specify: `<air showInTaskbar="always" />`.
- To avoid displaying a **taskbar** button for the widget, specify: `<air showInTaskbar="never" />`

Configuring the authentication for web widgets:

Add a realm to the `authenticationConfig.xml` file.

About this task

The `authenticationConfig.xml` file, in the *Worklight Project Name/server/conf* folder, is used to configure how widgets and web applications authenticate users.

For more information about configuring realms, see “MobileFirst security framework” on page 8-527.

Procedure

In the authenticationConfig.xml file, add a realm that uses the login forms, as follows:

```
<realm name="realm-name" loginModule="login-module-name">
<className>com.worklight.core.auth.ext.FormBasedAuthenticator</className>
<parameter name="login-page" value="/apps/services/login-file-name" />
</realm>
```

Writing login form files for web widgets:

Write two files, in HTML or JSP, with the ability to carry out a security check.

Procedure

1. Create two files, one displaying the login form and another one displaying the form after a login error occurred. The files can be HTML or JSP. Both login page and login error page must be able to submit a form with the action `j_security_check` and have `j_username` and `j_password` parameters. This technique is shown in the following code example:

```
<form method="post" action="j_security_check">
<input type="text" name="j_username"/>
<input type="password" name="j_password"/>
</form>
```

2. Save both files in the `Worklight_Project_Name/server/webapps/gadgets-serving` folder.

Setting the size of the login screen for web widgets:

If your login page is displayed in a separate browser window, configure its height and width.

Procedure

If your login page is displayed in a separate browser window, configure its height and width in the application descriptor, by using the `<loginPopupHeight>` and `<loginPopupWidth>` elements.

Signing Adobe AIR applications:

IBM MobileFirst Platform Foundation provides a default certificate for development and test purposes. For production, obtain a certificate from a certificate authority and install it.

About this task

Adobe AIR applications must be digitally signed in order for users to install them. IBM MobileFirst Platform Foundation provides a default certificate for signing AIR applications that can be used for development and test purposes.

To sign an AIR application for production distribution, using your own certificate, follow these instructions:

Procedure

1. Obtain a PKCS12 certificate from a certificate authority, and export it as a PFX file.
2. Place this certificate on your hard disk.

3. Set the <certificate> element under the <air> element in the application descriptor. The structure of the <certificate> element is:

```
<certificate password="password" PFXFilePath="path-to-pfx"/>
```

where *password* is the password for the PFX certificate, and *path-to-pfx* can either be relative to the root of the application, or an absolute path.

Signing Windows 8 Universal apps:

For development and test, you can create a test certificate by using Microsoft Visual Studio. You can use this created certificate to sign the application. For production, obtain a certificate from a certificate authority and install it.

About this task

Windows 8 Universal apps should be digitally signed before users install them. For development and test, you can create a test certificate by using Microsoft Visual Studio. You can use this created certificate to sign the application.

To sign a Windows 8 Universal app for production distribution, using your own certificate, follow these instructions:

Note: You can sign Windows 8 Universal apps only on Windows systems.

Procedure

1. See <http://msdn.microsoft.com/en-us/library/windows/apps/br230260.aspx> for details on obtaining a PKCS12 certificate.
2. Export the PKCS12 certificate as a PFX file.
3. Place this certificate on your hard disk.
4. Set the <certificate> subelement under the <windows8> element in the application descriptor. The structure of the <certificate> subelement is: `<certificate PFXFilePath="Path to certificate file" password="certificate password"/>`, where *Path to certificate file* can either be relative to the root of the application, or an absolute path, and *password* is the password for the PFX certificate.

Embedding widgets in predefined web pages:

Follow these instructions to incorporate widgets into web pages.

Before you begin

If your MobileFirst Studio internal application server does not run on the default port 10080, make sure that you also set this port as the value of the configuration `publicWorkLightPort`. Otherwise, the action **Embed in Web Page** does not provide you with the correct URL. For descriptions of `publicWorkLightPort` and other MobileFirst configuration properties, see “JNDI environment entries for MobileFirst projects in production” on page 12-68. For information about how to specify MobileFirst configuration properties, see “Configuration of MobileFirst applications on the server” on page 12-50.

About this task

MobileFirst widgets can be embedded in predefined web pages, such as corporate websites or intranet portals.

Procedure

To embed a widget in a predefined web page:

1. In the MobileFirst Operations Console, on the Catalog tab page, locate the widget, and then click **Embed in web page**. A window is displayed, which contains the URL of the application to which you point in your website to embed the widget.
2. Paste the URL in an HTML snippet in the web page where you want to embed the widget.

```
<iframe src="URL_to_embed" width="widget_width" height="widget_height" style="border:none;"> </iframe>
```

Developing globalized hybrid applications

To develop globalized hybrid applications, learn about globalization in JavaScript frameworks and IBM MobileFirst Platform Foundation, and about globalizing web services and push notifications.

Applications that are developed and uploaded to application stores must support multiple languages if they are to be used globally. IBM MobileFirst Platform Foundation provides capabilities for you to develop globalized hybrid applications. This series of topics describes how to globalize your applications when using JavaScript frameworks and IBM MobileFirst Platform Foundation and how to globalize web services and push notifications.

Globalization in JavaScript frameworks:

You can use several JavaScript frameworks to globalize your applications: Dojo, jQuery, and Sencha Touch.

You can use the capabilities of different JavaScript frameworks to globalize your applications. Dojo, jQuery, and Sencha Touch (deprecated. See “Deprecated features and API elements” on page 3-20) each provide globalization functions that are based on resource bundles and resource files, and they can switch to different resource bundles based on current locale information. In addition, Dojo also provides string and date format utilities that are based on user locale information.

Dojo globalization framework:

You can use the Dojo globalization framework to globalize your application.

The following example application demonstrates how to use the Dojo Mobile JavaScript API to construct a globalized application with a native look and feel. Dojo Mobile provides globalization functions for detecting locale, loading and accessing resource bundles, and simple formatting utilities for culture-sensitive display. Figure 1 and Figure 2 show pages of the application that display the resource bundles loaded and the string format that is determined by the user preferences on the device.

Figure 8-15. Dojo globalization application

Figure 8-16. Dojo cultural formatting

In the example, the Dojo library is loaded as shown in Listing 1: Including Dojo Mobile. The required modules must be loaded before you can use the Dojo globalization API.

Listing 1: Including Dojo Mobile

```
<script type="text/javascript">
  var dojoConfig = {
    parseOnLoad: false,
    packages: [{
      name: "resource",
      location: "../bundles"
    }]
  };
</script>
<script type="text/javascript" src="libs/dojox/mobile/deviceTheme.js"></script>
<script type="text/javascript" src="libs/dojo/dojo.js"></script>
```

Figure 3 shows how to load Dojo resource bundles by defining a package that maps the location of resource files within your hybrid application to a package name.

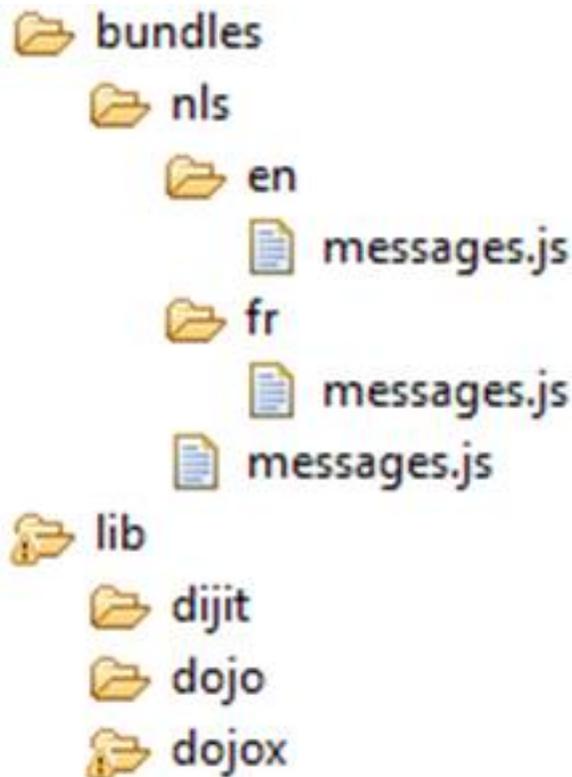

Figure 8-17. Dojo resource bundle structure

In the example, the language resource bundles are part of the application package, and are stored on the client-side instead of being supplied dynamically from the server or inserted directly into the HTML markup. Storing the language resource bundles on the client-side enables the application to be used offline. The resource files are encoded as JSON files.

Listing 2: Globalization application Views

This listing shows the code to generate the pages as simple HTML markup. The following strings are the strings that you globalize in the application.

```

<!-- Main page -->
<div id="globalization" data-dojo-type="dojox.mobile.View" selected="true">
  <h1 id="globalization_heading" data-dojo-type="dojox.mobile.Heading" label="msg_globalization"></h1>
  <ul data-dojo-type="dojox.mobile.RoundRectList">
    <li id="months_choice" data-dojo-type="dojox.mobile.ListItem" moveTo="months" callback="getMonths"
label="msg_months"></li>
    <li id="days_choice" data-dojo-type="dojox.mobile.ListItem" moveTo="days" callback="getDays"
label="msg_days"></li>
    <li id="formats_choice" data-dojo-type="dojox.mobile.ListItem" moveTo="formats" callback="getFormats"
label="msg_formats"></li>
    <li id="icon_choice" data-dojo-type="dojox.mobile.ListItem" label="msg_icon"></li>
  </ul>
  <h1 id="globalization_footer" data-dojo-type="dojox.mobile.Heading" fixed="bottom" label="msg_footer" ></h1>
</div>

<!-- The "Icon" sub-page -->
<div id="icons" data-dojo-type="dojox.mobile.View">
  <h1 id="icon_heading" data-dojo-type="dojox.mobile.Heading" moveTo="globalization" label="msg_icon"
back="msg_previous"></h1>
</div>
  
```

```

<!-- The "Months" sub-page -->
<div id="months" data-dojo-type="dojox.mobile.View">
  <h1 id="months_heading" data-dojo-type="dojox.mobile.Heading" moveTo="globalization" label="msg_months"
back="msg_previous"></h1>
</div>

<!-- The "Days" sub-page -->
<div id="days" data-dojo-type="dojox.mobile.View">
  <h1 id="days_heading" data-dojo-type="dojox.mobile.Heading" moveTo="globalization" label="msg_days"
back="msg_previous"></h1>
</div>

<!-- The "Formats" sub-page -->
<div id="formats" data-dojo-type="dojox.mobile.View">
  <h1 id="formats_heading" data-dojo-type="dojox.mobile.Heading" moveTo="globalization" label="msg_formats"
back="msg_previous"></h1>
</div>

```

Listing 3: Loading modules and resource files with the Dojo Mobile resource bundle API

This listing shows the resources files that are loaded by the `dojo/i18n` plug-in using Asynchronous Module Definition (AMD).

```

require(
  [
    "dojo/domReady",           // Make sure DOM are ready
    "dojo/i18n!resource/nls/messages", // Load our resource bundle
    "dojox/mobile/parser",    // This mobile app uses declarative programming
    "dojox/mobile",          // This is a mobile app
    "dojox/mobile/i18n",     // Load resources bundle declaratively
    "dojox/mobile/compat",   // This mobile app supports running on desktop browsers
  ],
  function(ready, messages, parser, mobile, mi18n) {
    ready( function() {
      // demonstrates how to load resources declaratively
      // dojox.mobile.i18n.load() must be called before dojox.mobile.parser.parse()
      mi18n.load("resource", "messages");
      parser.parse();
    });
  }
);

```

Note: The `dojo.18n.getLocalization` API is deprecated. Use `dojox/mobile/i18n` to load resources declaratively. The `dojox/mobile/i18n load()` method treats text in all mobile widgets as resource keys, and automatically replaces those keys with the actual resources. If you want to explicitly control how these resources are used, they can be loaded programmatically. The following listings show how to load these resources.

Listing 4: Explicitly using the loaded resources

This listing shows how to use an argument such as `resource` to retrieve loaded resources.

```

require(
  [
    "dojo/domReady",           // Make sure DOM are ready
    "dojo/i18n!resource/nls/messages", // Load our resource bundle
    "dijit/registry",         // For registry.byId
    "dojox/mobile/parser",    // This mobile app uses declarative programming
    "dojox/mobile",          // This is a mobile app
    "dojox/mobile/compat",   // This mobile app supports running on desktop browsers
  ],
  function(ready, messages, parser, registry) {

```

```

ready( function() {
    parser.parse();
    registry.byId("globalization_heading").set("label", messages["msg_globalization"]);
    registry.byId("months_choice").set("label", messages["msg_months"]);
    registry.byId("days_choice").set("label", messages["msg_days"]);
    registry.byId("formats_choice").set("label", messages["msg_formats"]);
    // get locale by dojo
    var footer_msg = bundle["msg_footer"] + dojo.locale;
    registry.byId("globalization_footer").set("label", footer_msg);
});
}
);

```

Listing 5: Dojo cultural formatting

This listing shows the Dojo cultural formatting functions.

```

function getFormats(){
    var formatsView = dojo.byId("formats");
    require(
        [
            "dojox/mobile/RoundRectList",
            "dojox/mobile/ListItem",
            "dojo/date/locale",
            "dojo/number",
            "dojo/currency"
        ],
        function(RoundRectList, ListItem, localeDate, localeNumber, localeCurrency){
            var formatsList = new RoundRectList({id: "formats_list"}).placeAt(formatsView);
            // get locale by dojo
            var myLocale = dojo.locale;
            // format locale date by dojo/date/locale
            var date = localeDate.format(new Date(), {locale: myLocale});
            var formattedDate = new ListItem({label: "Date: " + date});
            formatsList.addChild(formattedDate);
            // format with parameter
            date = localeDate.format(new Date(), {selector: 'date', formatLength: 'full'});
            formattedDate = new ListItem({label: "Date: " + date});
            formatsList.addChild(formattedDate);
            // format number
            var number = localeNumber.format(1234567.89);
            var formattedNumber = new ListItem({label: "Number: " + number});
            formatsList.addChild(formattedNumber);
            // format currency
            var currency = localeCurrency.format(1234.567, {currency: "USD"});
            var formattedCurrency = new ListItem({label: "Currency: " + currency});
            formatsList.addChild(formattedCurrency);
        }
    );
};

```

For more information about globalization with Dojo Mobile, see <http://dojotoolkit.org/reference-guide/1.9/dojox/mobile/internationalization.html#dojox-mobile-internationalization>.

jQuery Mobile globalization plug-in:

You can use jQuery globalization functions with the jQuery Mobile globalization plug-in.

There are no official jQuery globalization bundles. Here, the jquery.i18n.properties-1.0.9.js jQuery globalization plug-in is used to

demonstrate jQuery globalization functions. The `jquery.i18n.properties-1.0.9.js` jQuery globalization plug-in can be downloaded from <http://code.google.com/p/jquery-i18n-properties/>.

The example application does not show the jQuery globalization string format feature because there is no official globalization string formatting plug-in for jQuery frameworks.

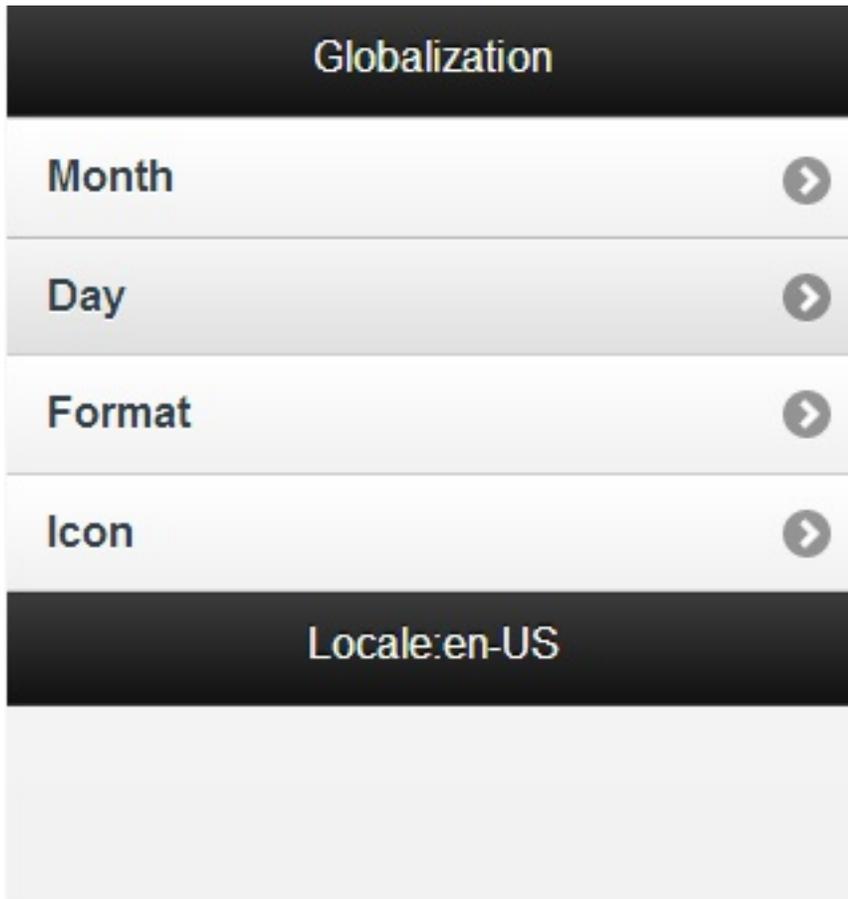

Figure 8-18. jQuery globalization application

Listing 1: Load Cordova, jQuery mobile, and jQuery globalization plug-in

This listing shows the scripts for loading Cordova, jQuery mobile, and the `jquery.i18n.properties-1.0.9.js` jQuery globalization plug-in.

```
<script
  type="text/javascript"
  src="js/CordovaGlobalization.js">
</script>
<script
  type="text/javascript"
  src="js/messages.js">
</script>
<script
  type="text/javascript"
  src="js/jquery.mobile-1.1.1.min.js">
</script>
```

```

<script
  type="text/javascript"
  src="js/jquery.i18n.properties-min-1.0.9.js">
</script>

```

The resource bundle structures in jQuery and Dojo are different. Dojo resource files have the same file name but are in separate folders corresponding to the locale name. jQuery resource files are in one folder but the file names include the locale information. Figure 2 shows the structure of the jQuery resource files.

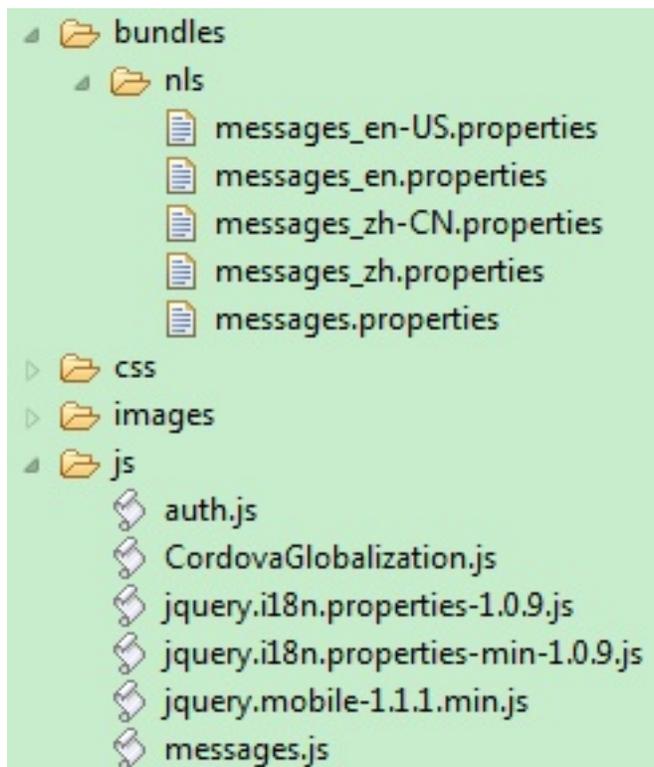

Figure 8-19. jQuery resource bundle structure

Listing 2: Load and use resource by jQuery globalization plug-in

This listing shows the jQuery scripts to initialize the globalization plug-in.

```

function doGlobalization(){
  $.i18n.properties({
    name: 'messages',
    path: 'bundles/nls/',
    mode: 'both',
    // language: 'zh',
    callback: function(){
      // Main page
      $('#globalization_heading').empty().
        append($.i18n.prop('msg_globalization'));
      $('#msg_months').empty().append($.i18n.prop('msg_months'));
      $('#msg_days').empty().append($.i18n.prop('msg_days'));
      $('#msg_formats').empty().append($.i18n.prop('msg_formats'));
      $('#msg_icon').empty().append($.i18n.prop('msg_icon'));
      // Sub page heading
      $('#icon_heading').empty().append($.i18n.prop('msg_icon'));
      $('#months_heading').empty().append($.i18n.prop('msg_months'));
      $('#days_heading').empty().append($.i18n.prop('msg_days'));
      $('#formats_heading').empty().append($.i18n.prop('msg_formats'));
    }
  });
}

```

```

$('#words_heading').empty().append($.i18n.prop('msg_words'));
//Back buttons
var items = $('a[data-rel="back"]');
$.each(items, function(i){
    $(items[i]).empty().append($.i18n.prop('msg_previous'));
});
//Show locale by jQuery i18n plug-in
$('#globalization_footer').empty().
append($.i18n.prop('msg_footer') + $.i18n.browserLang());
    }
});
};

```

Sencha Touch globalization plug-in:

You can use Sencha Touch globalization functions with the Sencha Touch globalization plug-in.

There are no official Sencha Touch globalization bundles. Here, the Ext.i18n.bundle-touch Sencha Touch globalization plug-in is being used to demonstrate globalization functions. The Ext.i18n.bundle-touch globalization plug-in can be downloaded from GitHub.

The example application does not show the Sencha Touch globalization string format feature because there is no official globalization string formatting plug-in for Sencha frameworks.

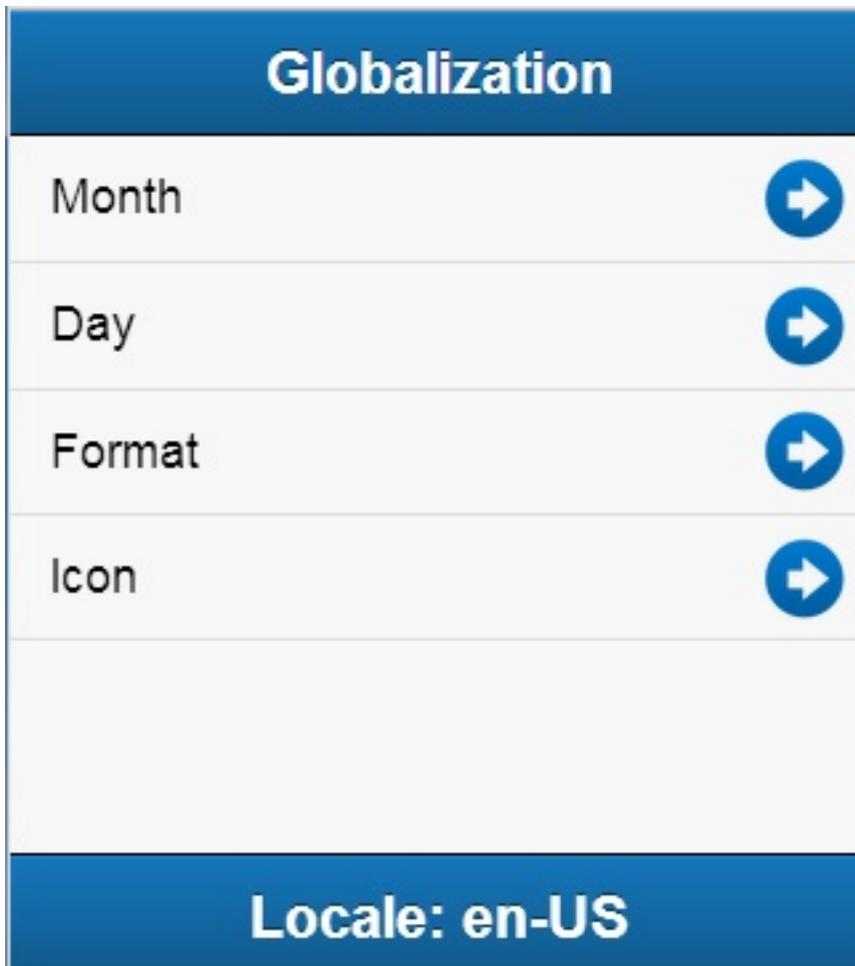

Figure 8-20. Sencha Touch globalization application

Listing 1: Load Sencha Touch and globalization plug-in

This listing shows the scripts for loading Sencha Touch and the Ext.i18n.bundle-touch globalization plug-in.

```
<script src="js/sencha-touch-all.js"></script>
<script>
  Ext.Loader.setConfig({
    enabled: true,
    paths: {
      'Ext.i18n': 'js/i18n',
      'patch': 'js/patch'
    }
  });
</script>
<script src="js/SenchaGlobalization.js"></script>
<script src="js/messages.js"></script>
<script src="js/auth.js"></script>
```

Figure 2 shows the structure of the Sencha Touch resource files.

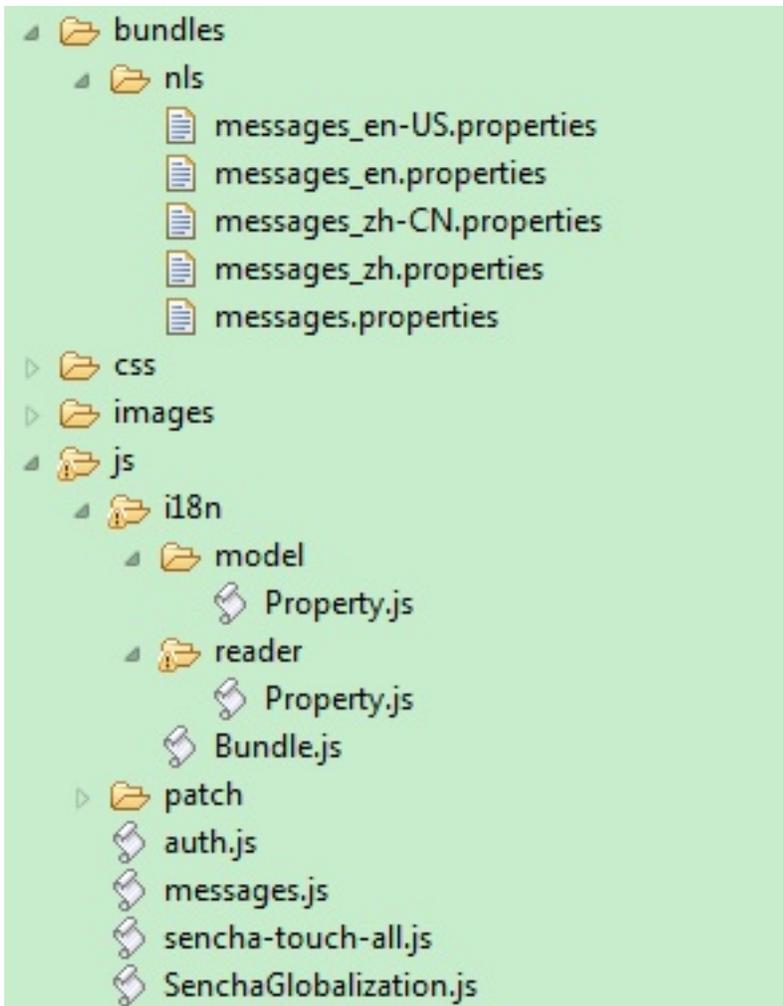

Figure 8-21. Sencha Touch resource bundle structure

Sencha Touch also provides a convenient API to retrieve the message in the resource bundle and set the value to the UI component.

Listing 2: Load and use resource by Sencha Touch globalization plug-in

```
function loadResource(){
    Ext.require('Ext.i18n.Bundle', function(){
        Ext.i18n.appBundle = Ext.create('Ext.i18n.Bundle', {
            bundle: 'messages',
            path: 'bundles/nls',
            noCache: true
        });
    });
    Ext.application({
        name: "Sencha Touch Globalization",
        launch: function(){
            Ext.i18n.appBundle.onReady(function(){doGlobalization();});
        }
    });
};

function doGlobalization(){
    // global header
    var globalHeader = Ext.create('Ext.Toolbar', {
        docked: 'top',
```

```

        xtype: 'toolbar',
        title: '<div width="100px">' +
            Ext.i18n.appBundle.getMsg('msg_globalization') + '</div>'
    });
    // show locale by Ext.i18n.Bundle
    var globalFooter = Ext.create('Ext.Toolbar', {
        docked: 'bottom',
        xtype: 'toolbar',
        title: '<div width="100px">' +
            Ext.i18n.appBundle.getMsg("msg_footer") +
            Ext.i18n.appBundle.language + '</div>'
    });
    // main list data model
    Ext.define('mainListModel', {
        extend: 'Ext.data.Model',
        config: {fields: ['index', 'type']}
    });
    // main list data store
    var mainListStore = Ext.create('Ext.data.Store', {
        model: 'mainListModel',
        sorters: 'index',
        proxy: {
            type: 'localStorage',
            id: 'mainListStore'
        },
        data: [
            {
                index: '1',
                type: Ext.i18n.appBundle.getMsg('msg_months')
            },
            {
                index: '2',
                type: Ext.i18n.appBundle.getMsg('msg_days')
            },
            {
                index: '3',
                type: Ext.i18n.appBundle.getMsg('msg_formats')
            },
            {
                index: '4',
                type: Ext.i18n.appBundle.getMsg('msg_words')
            },
            {
                index: '5',
                type: Ext.i18n.appBundle.getMsg('msg_icon')
            }
        ]
    });
    // main list view
    var mainList = Ext.create('Ext.List', {
        itemTpl: '{type}',
        store: mainListStore,
        onItemDisclosure: function(record, btn, index){
            showSecondContainer(record, btn, index);
        }
    });
}

```

Globalization mechanisms in IBM MobileFirst Platform Foundation:

IBM MobileFirst Platform Foundation automatically translates application strings according to a designated file. Multi-language translation is implemented by using JavaScript.

Cordova globalization API

The Cordova globalization API provides enhanced globalization capabilities that mirror existing JavaScript globalization functions, where possible, without duplicating functions already present in JavaScript. The emphasis of the Cordova globalization API is on parsing and formatting culturally sensitive data. The Cordova API uses native functions in the underlying operating system, where possible, rather than re-creating these functions in JavaScript. Table 1 summarizes the Cordova globalization API functions provided.

Table 8-10. Cordova globalization API summary

Function Name	Purpose
getPreferredLanguage	The current language of the client.
getLocaleName	The client current locale setting on the device.
dateToString	A date that is formatted as a string, according to the locale and timezone of the client.
stringToDate	A string that is parsed as a date, according to the client's user preferences.
getDatePattern	A pattern string for formatting and parsing dates.
getDateNames	The names of the months, or the days of the week.
isDayLightSavingsTime	Whether daylight saving time is in effect for a specified date.
getFirstDayOfWeek	The first day of the week.
numberToString	A number that is formatted as a string, according to the user preferences.
stringToNumber	A string that is parsed as a number, according to the user preferences.
getNumberPattern	A pattern string for formatting and parsing numbers.
getCurrencyPattern	A pattern string for formatting and parsing currencies.

The Cordova globalization API is an independent globalization framework, which can be integrated with any JavaScript libraries to provide globalization functions. The Cordova globalization API is different from other globalization libraries. The Cordova globalization API does not provide a parameter to indicate a locale. The set of supported locales is determined by the device and its SDK and not by Cordova.

The Cordova globalization API uses the client locale setting and any default values that are overridden. This design greatly simplifies the use of the globalization API while still providing robust support. It is important to note that, although the set of interfaces remains constant across the devices that Cordova supports, the results can vary across the devices.

The Cordova framework does not provide access to graphical widgets that are present in device SDKs. The Cordova framework is used in concert with other JavaScript widget libraries, such as Dojo, to build complete mobile applications.

The Cordova globalization API is interoperable with Dojo Mobile, jQuery Mobile, and Sencha Touch. It is an asynchronous implementation to prevent blocking JavaScript execution in user interface code. The following listings and figures show the Cordova globalization API. Dojo is used to demonstrate the user interface.

Table 8-11. Listing 1: Using the Cordova globalization API

```
function onDeviceReady(){
    g11n = window.plugins.globalization;
}
```

The code to generate the names of the months, days of the week, and format the current date is shown in Listing 2, Listing 3, and Listing 4.

Table 8-12. Listing 2: Month names

```
function getMonths(){
    g11n.getDateNames(function(data){
        var items = data.value;
        var monthsView = document.getElementById('monthsView');
        for (var i = 0; i < items.length; i++) {
            monthsView.append('<li>' + items[i] + '</li>');
        }
    },
    function(code){
        alert("Error: " + code);
    });
};
```

Figure 8-22. Using Cordova to show locale-based months

Table 8-13. Listing 3: Days of the week

```
function getDays(){
  gln.getDateNames(
    function(data){
      var items = data.value;
      var daysView = document.getElementById('daysView');
      for (var i = 0; i < items.length; i++) {
        daysView.append('<li>' + items[i] + '</li>');
      }
    },
    function(code){
      alert("Error: " + code);
    },
    {item: "days"}
  );
}
```

Figure 8-23. Using Cordova to show the days of week

Table 8-14. Listing 4: Formatting current date

```
function getFormats(){
  var formatsView = document.getElementById('formatsView');
  g11n.dateToString(
    new Date(),
    function(date){
      formatsView.append('<li>' + date.value + '</li>');
    },
    function(code){
      alert("Error: " + code);
    },
    {selector: "date", formatLength: "full"}
  );
  g11n.getDatePattern(
    function(date){
      formatsView.append('<li>' + date.pattern + '</li>');
      var timeZone = date.timezone;
      formatsView.append('<li>' + timeZone + '</li>');
      var offset = date.utc_offset;
      formatsView.append('<li>' + offset + '</li>');
      var dstoffset = date.dst_offset;
      formatsView.append('<li>' + dstoffset + '</li>');
    },
    function(code){
      alert("Error: " + code);
    },
    {selector: "date", formatLength: "full"}
  );
  g11n.isDayLightSavingsTime(
    new Date(),
    function(date){
      var dst = date.dst;
      formatsView.append('<li>' + dst + '</li>');
    },
    function(code){
      alert("Error: " + code);
    }
  );
  g11n.numberToString(
    1234.56,
    function(number){
      formatsView.append('<li>' + number.value + '</li>');
    },
    function(code){
      alert("Error: " + code);
    },
    {type: "decimal"}
  );
}
```

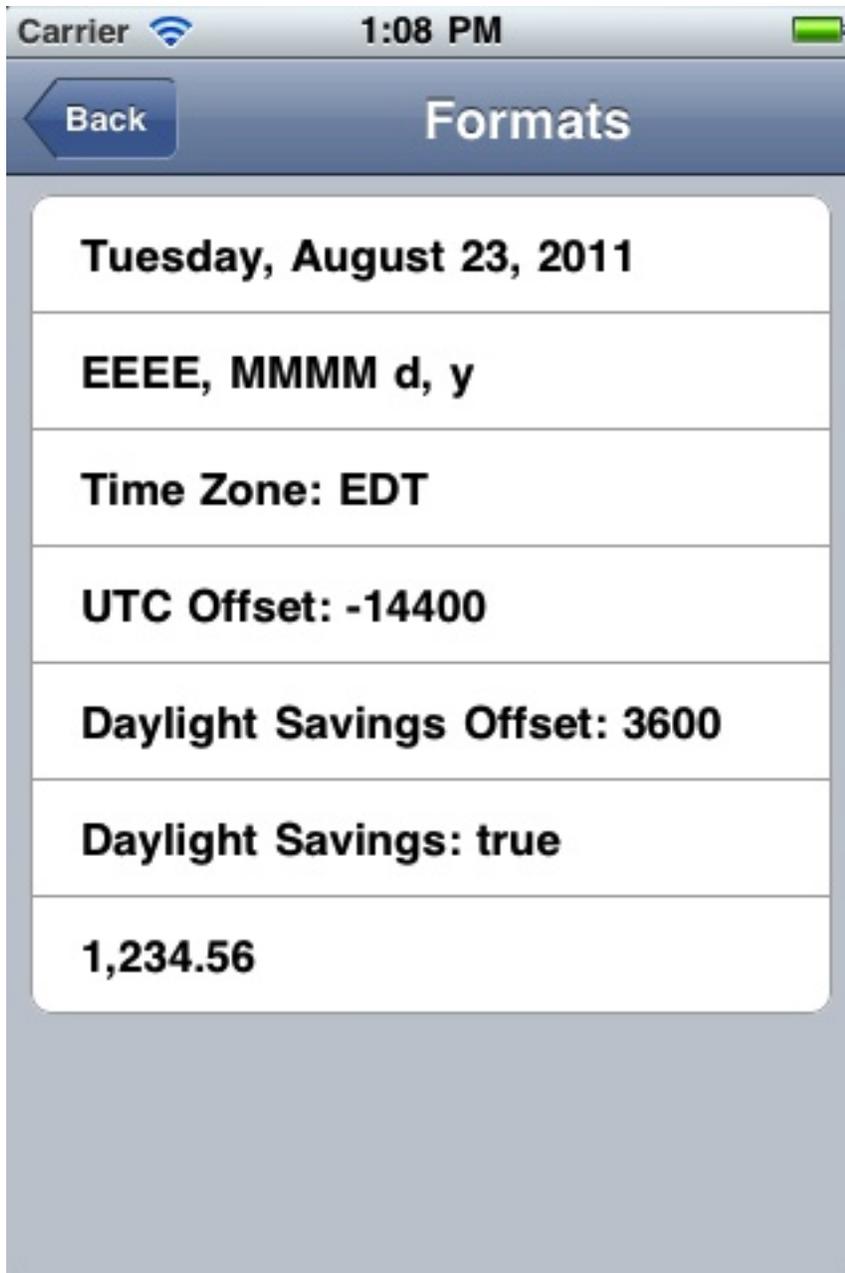

Figure 8-24. Using Cordova for cultural formatting

Enabling translation of application strings

messages.js is the file that is designated for application strings and can be found in the common/js folder. If you use Dojo, jQuery, or Sencha Touch in your application, use the translation resource loading mechanisms and file formats from these JavaScript technologies instead of mechanisms that are provided by IBM MobileFirst Platform Foundation. Use MobileFirst application messages only when the JavaScript graphical toolkit used in your application does not provide these services.

```
Messages = {  
  headerText: "Default header",  
  actionsLabel: "Default action label",  
  sampleText: "Default sample text",  
}
```

```

    englishLanguage: "English",
    frenchLanguage: "French",
    (...)
}

```

Application messages that are stored in `messages.js` can be referenced in two ways:

- As a JavaScript object property; for example, `Messages.header` or `Messages.sampleText`.
- As the ID of an HTML element with `class="translate"`.

```

<div id="header">
  <h1 id="headerText" class="translate"></h1>
</div>

```

Note: A string that is defined in `Messages.headerText` is automatically used here.

Enabling translation of system messages

You can enable the translation of the system messages that the application displays, such as Internet connection is not available, or Invalid user name or password.

You can find the list of the system messages in the `worklight/messages/messages.json` file that is in the environment folder of the projects that you generated with IBM MobileFirst Platform Foundation.

To enable the translation of a system message, you must override its value in the `WL.ClientMessages` object, as indicated in “The `WL.ClientMessages` object” on page 11-5.

Implementing multi-language translation

You can implement multi-language translation for your applications by using JavaScript.

1. Define default application strings in `messages.js` as shown in the following code example:

```

Messages = {
  headerText: "Default header",
  actionsLabel: "Default action label",
  sampleText: "Default sample text",
  englishLanguage: "English",
  frenchLanguage: "French",
  russianLanguage : "Russian",
  hebrewLanguage : "Hebrew"
};

```

2. Override some or all of the default application strings with JavaScript. The following two code examples define JavaScript functions that are used to override the default strings that are defined in `messages.js`:

```

function setFrench(){
  Messages.headerText = "Traduction";
  Messages.actionsLabel = "Sélectionnez langue:";
  Messages.sampleText = "ceci est un exemple de texte en français.";
}
function setRussian(){
  Messages.headerText = "△△△△△△△";
  Messages.actionsLabel = "△△△o△ △△△a:";
  Messages.sampleText = "△△ △△△△△ △△△△△ △△ △△△△△△ △△△△△.";
}

```

```

function languageChanged(lang){
  if (typeof(lang)!="string") lang = $("#languages").val();
  switch (lang){
    case "english":
      setEnglish();
      break;
    case "french":
      setFrench();
      break;
    case "russian":
      setRussian();
      break;
    case "hebrew":
      setHebrew();
      break;
  }
  if ($("#languages").val()=="hebrew")
    $("#AppBody").css({direction: 'rtl'});
  else
    $("#AppBody").css({direction: 'ltr'});
  $("#sampleText").html(Messages.sampleText);
  $("#headerText").html(Messages.headerText);
  $("#actionsLabel").html(Messages.actionsLabel);
}

```

A language parameter is passed to the languageChanged() JavaScript function. The languageChanged() function calls the corresponding function to override the default English language string.

Detecting device-specific information

You can detect the locale and language of your device by using WL.App.getDeviceLocale() and WL.App.getDeviceLanguage().

```

var locale = WL.App.getDeviceLocale();
var lang = WL.App.getDeviceLanguage();
WL.Logger.debug(">> Detected locale: " + locale);
WL.Logger.debug(">> Detected language: " + lang);

```

The following screen capture shows the print output:

```

05-12 12:27:19.685 | D | 26294 | before: app init onSuccess
05-12 12:27:19.735 | D | 26294 | >> Detected locale: en_US
05-12 12:27:19.745 | D | 26294 | >> Detected language: en
05-12 12:27:19.775 | D | 26294 | after: app init onSuccess

```

Globalization of web services:

You can use the Cordova globalization method to get the user locale preference, and check what user locale is used.

In some situations, globalized results are obtained by calling web services. The Cordova globalization method getLocaleName returns the user locale preference, which can be used in client-driven service calls.

The following listing shows how the user locale is used to collate a list of words. The locale of the returned word list can be checked to verify that the user locale was used or a substitute locale was used instead.

Listing: Locale-based service call

```
function getWords(){
    var services;
    require(
        ["dojox/rpc/Service"],
        function(Service){
            services = new Service({
                target: "{Your Web Service URL}",
                transport: "POST",
                envelope: "JSON-RPC-1.0",
                contentType:
                    "application/json",
                services: {
                    "sorter.getWordList": {
                        returns: {"type": "object"},
                        parameters: [{"type": "string"}]
                    }
                }
            });
        }
    );
    g11n.getLocaleName(
        function(locale){
            // invoke the JSON web service to get the list of sorted words
            var deferred = services.sorter.getWordList(locale.value);
            deferred.addCallback(
                function(result){
                    var wordsView = dojo.byId("words");
                    require(
                        [
                            "dojox/mobile/RoundRectList",
                            "dojox/mobile/ListItem",
                            "dojox/mobile/Heading"
                        ],
                        function(RoundRectList, ListItem, Heading){
                            var wordsList = new RoundRectList({
                                id: "words_list").placeAt(wordsView);
                            items = result.words.list;
                            for (var i = 0; i < items.length; ++i) {
                                var word = new ListItem({label: items[i]});
                                wordsList.addChild(word);
                            }
                            var wordsFooter = new Heading({
                                label: result.localeName}).placeAt(wordsView);
                        });
                }
            )
        },
        function(code){
            alert("Error: " + code);
        }
    );
};
```

Globalization of push notifications:

With IBM MobileFirst Platform Foundation, you can globalize push notifications so that push notifications are displayed in the language of the user. You use different methods to globalize push notifications, depending on the way the application runs: in the foreground, in the background, or not at all.

Mobile applications frequently rely on server-side services to provide data to the mobile application. However, sometimes the application is not running or is not connected to the server. Push notifications is a mechanism by which short

messages are sent to let the user of a mobile application know data that can be downloaded or information that can be viewed from a server when the application is either not running or not running in the foreground.

Note: iOS uses Apple Push Notification Service (APNS).

Note: Android uses Google Cloud Messaging (GCM) and Windows Phone uses Microsoft Push Notification Service (MPNS).

Translate push notification messages so that the correct language is displayed to the user. You choose the architectural pattern depending on whether the application runs in the foreground, in the background, or not at all.

- When the application is running in the foreground, it uses the language and cultural settings on the device to determine the appropriate language to display. To support this pattern, messages must be stored in the resource files of the mobile application, and not in the resource files of the server application, even though messages are generated on the server-side.
- When a notification is sent to a mobile application, send the notification resource key and not the actual text of the message.
- When a mobile application receives the notification, or message, use the key that was sent in the notification message to look up the text of the message from its resource file, as shown in Figure 1.

This diagram shows the following data flow:

1. The service that generates the message uses the send resource key and delivers the message data to the messaging mediator.
2. The messaging mediator uses the receive resource key to send the message data to the mobile application.
3. The mobile application uses the resource key to extract the message text and deliver it to the language resource.

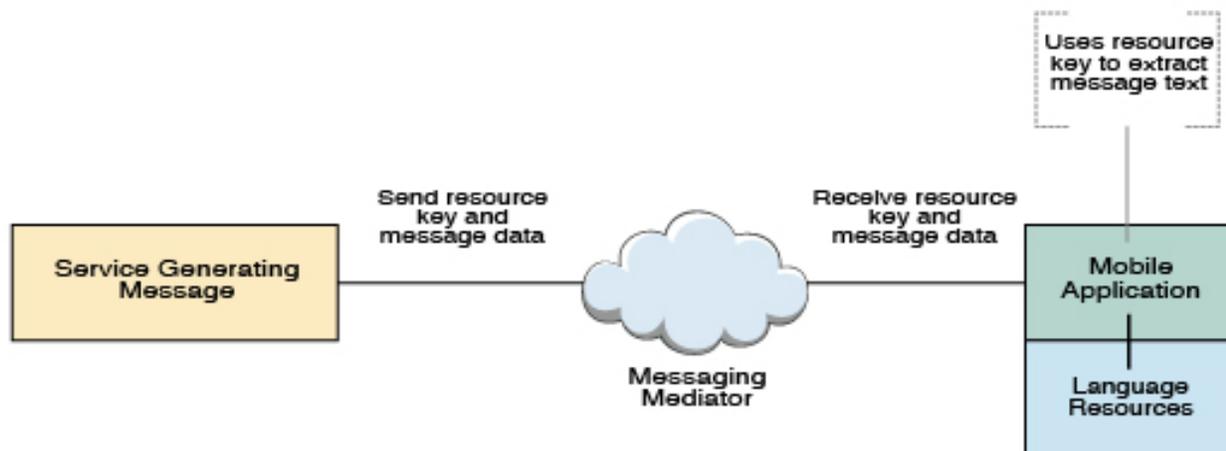

Figure 8-25. Use of resource keys

Listing 1, Listing 2, and Listing 3 show sample code that can be used when the mobile application is running in the foreground.

First, create a MobileFirst adapter to send the notification.

For more information about how to create an adapter, see the tutorials on the Getting Started page.

Listing 1: Send notification using created adapter

This listing shows how to send a notification with the created adapter. The target message, or resource key, to be translated on the client-side, is specified in the payload.

```
function sendNotificationOTA(userId, notificationText) {
    var userSubscription = WL.Server.getUserNotificationSubscription(
        'mysuranceAdapter.mysuranceEventSource', userId);
    WL.Server.notifyAllDevices(
        userSubscription,
        {
            badge : 1,
            sound : "",
            alert : notificationText,
            payload : { globalizeString : 'notificationText' }
        }
    );
}
```

Listing 2: Client-side subscription code

This listing shows the code that is required on the client-side to subscribe to push notification.

```
WL.Client.Push.onReadyToSubscribe = function(){
    WL.Client.Push.registerEventSourceCallback(
        "mysurancePush",
        "mysuranceAdapter",
        "mysuranceEventSource",
        pushNotificationReceived);
};
```

After successful subscription, the callback method is implemented. The callback method is responsible for retrieving the data from the payload, retrieving application locale preferences, retrieving the message by using the resource key, and formatting the message.

Listing 3: Callback method

This listing shows how to retrieve the locale information and load the corresponding translated message with Dojo by using the resource key that is stored in the payload object.

```
function pushNotificationReceived(props, payload){
    if (payload.globalizeString != "undefined"){
        require(
            ["dojox/mobile/i18n", "dojo/number"],
            function(mi18n, number){
                bundle = mi18n.load("resource", "messages");
                // get globalization text by dojo mobile i18n
                var notificationText = bundle[payload.globalizeString];
                // format number by device locale
                var num = number.format(1234567890, {
                    places: 2, locale: WL.App.getDeviceLocale()});
                num = bundle["amount"] + num;
                //display globalization message
                alert(notificationText + "\n" +num);
            }
        );
    }
}
```

```

    }
  );
}

```

- If a notification provides data in addition to the message, send the data in a locale-neutral format. When the application retrieves the message, the data can be formatted based on the user cultural preferences at the time the message is received.
- An application that is running in the background, or not running at all, can elect to use a previously registered user profile to access the appropriate language and cultural settings for push notifications. To support this pattern, the server sends the translated message and data in a format that is determined by the user cultural and language preferences that are stored in the profile, as shown in Figure 2. The push notifications are then processed differently by the mobile application. Processing is based on the native operating system that the application is running on.

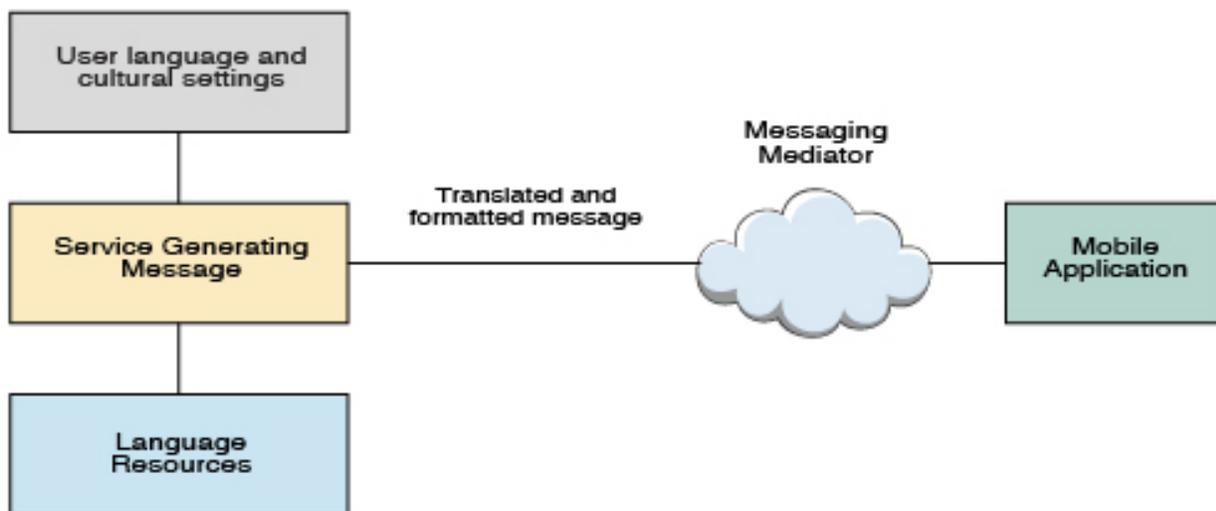

Figure 8-26. Sending push notifications according to the user's settings

- On iOS, notification messages do not wake up iOS applications, therefore the native operating system automatically selects the appropriate language to use for notifications. The iOS operating system automatically attempts to locate and load the correct language resource.
- On Android, notification messages wake up Android applications, and the applications directly access the language and cultural preferences so that the correct translation and formatting can be applied.
- In hybrid applications that are built using IBM MobileFirst Platform Foundation, notifications are not directly processed by the application when the application is not running in the foreground. In this case, the user language and cultural profile that were previously established are used.

Enforce language preference for MobileFirst messages:

IBM MobileFirst Platform Foundation supports several languages, and based on the language of the device, appropriate translations are used to display system messages. However, you can enforce restriction to display messages only in a certain set of languages.

If your application supports only English and French, you can enforce a restriction so that IBM MobileFirst Platform Foundation displays the messages only in these languages.

Enforcing languages in hybrid and mobile web applications

You can provide a preferred list of languages to be used by IBM MobileFirst Platform Foundation for translating system messages in the application-descriptor.xml file. The order of the languages is important and must be separated by comma.

```
<languagePreferences>en, fr, de, es</languagePreferences>
```

Enforcing languages in native applications

You can provide a preferred list of languages in native environments by adding **languagePreferences** property in the appropriate client property file.

Fallback mechanism

The system compares the device locale with the values that are provided in the preference list. Here are the fallback mechanisms on how the system messages are displayed:

1. If the device locale is available, the corresponding translation is used to display system messages.
2. If the device locale (for example, fr-FR) is not in the preference list, or the locale is not supported by IBM MobileFirst Platform Foundation, the device language (for example, fr) is used to compare with the values that are provided in preference list. If the language is available in the preference list, the corresponding translation is used to display system messages.
3. If the device language (fr) is not in the preference list, or the language is not supported by IBM MobileFirst Platform Foundation, the first language available in the list for translation is used.

Note: The order of the languages that are specified in the preference list is important. You must list the order from generic to specific languages so that when the translation is not available, the generic language is loaded.

For the following example of the preference list, if the device language is set to German, IBM MobileFirst Platform Foundation uses English to display the system messages. The reason is that de is not available in the list.

```
<languagePreferences>en, fr, es</languagePreferences>
```

Developing Cordova apps

Develop Cordova apps as detailed here.

Anatomy of a MobileFirst Cordova project

The file structure of a MobileFirst Cordova project helps you organize the code that is necessary for your apps.

Table 8-15. A MobileFirst Cordova project has the following structure:.

Folder name	Description
<project-name>	Root project folder

Table 8-15. A MobileFirst Cordova project has the following structure: (continued).

Folder name		Description
	hooks	For build hooks. Build hooks are tasks that are completed during hook points in a build.
	mobilefirst	Contains the .wlaapp files of your app that you can deploy to the MobileFirst Server.
	platforms	Platforms that your app is meant for. This folder contains subfolders of your platforms.
	plugins	Cordova plug-ins that your app uses. For example, org.apache.cordova.inappbrowser.
	res	Contains resources that are used by your app.
	www	Contains index.html, the main HTML file of your app. This folder also contains the css, img, and js folders.
	.mfp_cli_config.json	This file contains a single configuration setting, which is the default runtime for the application. The mfp push command uses this default runtime if you do not provide it.
	application-descriptor.xml	A metadata file that is used to define various aspects of the application. For more information about this file, see "The Cordova application descriptor."
	config.xml	The global configuration file of the application. For more information, see The config.xml File page of the Apache Cordova Documentation.

The Cordova application descriptor:

The application descriptor is a metadata file that is used to define various aspects of the application. It is in the application root directory.

<application>

The root element of the descriptor.

```
<application id="App_Test" platformVersion="7.1.0"
  xmlns="http://www.worklight.com/application-descriptor"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
```

Attributes

id The identifier of the application. The identifier must be identical to the

application folder name. It must be an alphanumeric string that starts with a letter. It can also contain underscore (" _") characters. It must not be a reserved word in JavaScript.

platformVersion

The product version on which the application was developed.

Elements

<accessTokenExpiration>

Optional

Defines the expiration period (in seconds) of OAuth access tokens. The default is 3600 seconds (one hour).

Client applications can use the token to access protected resources unless the token has expired. When the token expires, the client application must obtain a new access token to access a protected resource. Obtaining a new access token can happen automatically without user intervention if all the realms by which the resource is protected have not expired. However, if one of the realms that is included in the security test of the resource has expired, and the realm requires user input (such as a form-based authenticator), the user must re-authenticate.

```
<accessTokenExpiration>360</accessTokenExpiration>
```

<android>

When an Android platform is added to your Cordova application, the `<android>` XML element is used to contain Android-related configuration. This element has one mandatory attribute: `version`.

<author>

Provides information about the application author. This data is copied to the descriptor files of the web and desktop environments that require it.

<description>

Description of the application. The description is displayed in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

<directUpdateAuthenticityPublicKey>

<displayName>

The name of the application. The name is displayed in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

Note: This element supports English only.

<features>

Note: This element is ignored for Cordova apps. Only JSONStore is supported and it must be enabled by the addition of the plug-in `cordova-plugin-mfp-jsonstore`.

<licenseAppType>

Declares the application type for token licensing. This element is ignored if the MobileFirst Server does not have token licensing activated.

Possible values (values are case-sensitive; must be all uppercase):

- **NON_PRODUCTION:** Use this while you are developing and testing the application on the production server.

Important: Using **NON_PRODUCTION** for a production app is a breach of the license terms.

- **APPLICATION:** Use this for most applications when you are ready to deploy the app on a production server. This is the default. The production server must have token licensing activated, and enough tokens must be available.
- **ADDITIONAL_BRAND_DEPLOYMENT:** Use this when you are ready to deploy an additional brand deployment app on a production server. The app must be an additional brand deployment of an existing app for which an **APPLICATION** token has already been used. Your organization must have purchased an Additional Brand Deployment license for you to use this option. In addition, the code in the similar application must meet specific requirements such as the percentage of code that is different. Refer to your IBM MobileFirst Platform Foundation - Additional Brand Deployment software license for details.

The production server must have token licensing activated, and enough tokens must be available.

If token licensing is activated on the server and this element is not present in the application descriptor, then the default setting **APPLICATION** is used.

For more information, see “Licensing in MobileFirst Server” on page 2-16 and your IBM MobileFirst Platform Foundation software license.

Note: Token licensing, as defined by `<licenseAppType>` is not related to OAuth access tokens, as defined by `<accessTokenExpiration>`.

<iphone>

When an iOS platform is added to your Cordova application, the `<iphone>` XML element is used to contain iPhone-related configuration. This element has one mandatory attribute: `version`.

Note: This `<iphone>` element is used to target both iPhone and iPad target platforms.

<languagePreferences>

Contains a comma-separated list of languages to display system messages. For more information, see “Enforce language preference for MobileFirst messages” on page 8-168.

<mainFile>

Contains the name of the main HTML file of the application. To change this value, use the command `mfp config app_main_file [main-html-file]`. See the “**config**” on page 16-7 CLI command for details.

<smsGateway>

Defines the SMS gateway to be used for SMS push notifications. It has one mandatory attribute, `id`, which contains the identifier of the SMS gateway. The ID must match one of the gateway identifiers that are defined in the `SMSConfig.xml` file.

```
<smsGateway id="kannelgw"/>
```

<targetCategory>

Declares the target category of your application for use with license tracking. If your application is licensed under the ADDRESSABLE DEVICE metric, you must edit this element to specify the relevant target category, to generate more accurate licensing reports. This element is added automatically when the application is created. By default, the target category is set to UNDEFINED. For more information, see “License tracking” on page 14-133.

Possible values:

- UNDEFINED
- B2E: IBM MobileFirst Platform Foundation Enterprise
- B2C: IBM MobileFirst Platform Foundation Consumer

<thumbnailImage>

Contains the path to the thumbnail image for the application, including the image file name. The path is relative to the main application folder.

```
<mainFile>index.html</mainFile>  
<thumbnailImage>common/images/thumbnail.png</thumbnailImage>
```

<userIdentityRealms>

A comma-separated ordered list of user identity realms for OAuth authentication. The realms are normally ordered by preference. The first successfully authenticated realm in this list is selected as the user identity realm. If the list is empty, or no realm in the list was authenticated, the ID token contains no identity information. This element is optional and the default value is an empty list.

```
<userIdentityRealms>WASLTPRealm, CustomAuthenticatorRealm</userIdentityRealms>
```

Note: This attribute is used to set user identity in the OAuth-based flows. For the classic (pre-V7.0) flows, see the documentation for the customSecurityTest security test.

Subattributes

bundleId

Mandatory.

This attribute is copied to the appropriate native configuration file in the Xcode project of the application. Do not modify this value directly in the native configuration file because it is overridden by the builder with the value that you indicate in this attribute.

version

The value of the version attribute is a string of the form *x.y*, where *x* and *y* are digits (0-9).

- For mobile apps, the version is shown to users who download the app from the app store or market.
- For desktop apps, the version determines whether MobileFirst Server automatically downloads a new version of the app to the user's desktop.

Subelements

<pushSender>

- **<iPhone>**: For iOS apps that use the Apple Push Notification Service (APNS). Defines the password to the SSL certificate that encrypts the

communication link with APNS. The password attribute can refer to a property in the `worklight.properties` file and can therefore be encrypted.

- `<android>`: For Android apps that use Google Cloud Messaging (GCM), use the `<pushSender>` element to define the connectivity details to GCM. The **key** is the GCM API key, and the **senderId** is the GCM Project Number. For more information about GCM API key and GCM Project Number, see the Enabling the GCM Service page on the Android website for developers.

<security>

A subelement of the `<iphone>` and `<android>` elements. It is used to configure security mechanisms for protecting your apps against various malware and repackaging attacks. The element has the following structure:

<publicSigningKey>

Valid only in the Android environment, under `<android>/<security>`. This element contains the public key of the developer certificate that is used to sign the Android app. For instructions on how to extract this value, see “Extracting a public signing key” on page 8-69.

For example:

```
<security>
  <!-- publicSigningKey is valid only for Android -->
  <publicSigningKey> value </publicSigningKey>
</security>
```

<simpleDataSharing>

<tags>

Supported by Android and iOS environments. During application deployment, the specified tags are created, updated, or deleted on the management database tables. In the following example, the `<tags>` specifies customer categories. Tags represent topics of interest to the user and provide user with an ability to receive notifications according to the chosen interest. This feature enables ability for sending and receiving messages by tags. A message is targeted to only the devices that are subscribed to a tag. For more information about the setting of tag-based notification, see “Setting up Tag-based notifications” on page 8-513.

<worklightSettings>

Note: This element is ignored for Cordova apps. To change the MobileFirst Server URL, use the “JavaScript client-side API” on page 11-2 `WL.App.setServerUrl`.

Cordova app resources:

When you create a new Cordova app, the following resources are made available to you as a starting point, based on the provided default template.

If you do not use the default template, you must provide these resources, except for the `application.descriptor.xml` file, which is generated automatically.

If you want to change the default file names and paths of any of these resources, you can specify such changes in the Cordova configuration file (`config.xml`).

Application descriptor

The application descriptor is a mandatory XML file which contains application metadata, and is stored in the root directory of the app. The file is automatically generated when you create an application, and can then be manually edited to add custom properties. For more information about this file, see “The Cordova application descriptor” on page 8-170.

index.html

This main file is an HTML5 file that contains the application skeleton. This file loads all the web resources (scripts and stylesheets) that are necessary to define the general components of the application and to hook to required document events. You can find this file in the *<your project name>/www* directory.

Stylesheets

The app code can include CSS files to define the application view. You can find these stylesheets in the *<your project name>/www/css* directory. The stylesheet files are copied to the following platform-specific folders:

- iOS: *<your project name>/platforms/ios/www/css*
- Android: *<your project name>/platforms/android/assets/www/css*

Scripts

The app code can include JavaScript files that implement interactive user interface components, business logic, and back-end query integration, and a message dictionary for globalization purposes. You can find these script files in the *<your project name>/www/js* folder. The script files are copied to the following platform-specific folders:

- iOS: *<your project name>/platforms/ios/www/js*
- Android: *<your project name>/platforms/android/assets/www/js*

Thumbnail image

The thumbnail image provides a graphical identification for the application on the MobileFirst Operations Console. It must be a square image, preferably of size 90 by 90 pixels.

A default thumbnail image is provided. You can override the default image by using the same file name with a replacement image or you can update the application descriptor with the path to a new image. You can find *thumbnail.png* in *<your project name>/www/img*.

Splash image

The splash image is displayed while the application is being initialized.

Splash images are provided for iOS and Android. These default images are stored in:

- iOS: *<your project name>/res/screen/ios/*
- Android: *<your project name>/res/screen/android/*

You can replace the default image with your own image. Your custom splash image must match the size of the default splash image that you are replacing, and

must use the same file name. Various iOS default splash images are provided, appropriate to different iOS displays and operating system versions.

For Android, the file name of the default splash image is `splash.9.png`. The other images in the folder are for use with the Cordova standard splash screen API.

You can override the default images with a splash image that matches your application. Your custom splash image must match the size of the default splash image that you are replacing, and must use the same file name.

Application icons

Application images are provided for iOS and Android. These default images are stored in:

- iOS: `<your project name>/res/icon/ios/`
- Android: `<your project name>/res/icon/android/`

You can replace the default image with your own image. Your custom application image must match the size of the default application image that you are replacing, and must use the same file name. Various default images are provided, appropriate to different displays and operating system versions.

Creating a Cordova project with the CLI

Create a Cordova project by using the `mfp cordova create` command, then configure and preview your app.

Before you begin

Before you can create a Cordova project, you must create an application back-end runtime. For more information, see “Creating an app back-end runtime” on page 8-33.

Note: The **Keychain Sharing** capability is mandatory while running iOS apps in the iOS Simulator when using Xcode 8. You need to enable this capability manually before building the Xcode project.

Procedure

1. Create a Cordova project. Run
`mfp cordova create myCordovaProject`
where `myCordovaProject` is the name of your Cordova project. For more information, see “**cordova create**” on page 16-8.

Important: If you are creating an app for the Android platform, make sure that you set your `ANDROID_HOME` environment variable to your Android SDK.
2. Run `cd myCordovaProject` to change into your Cordova app project directory.
3. Optional: Run `mfp config` to configure the application settings. For more information, see “**config**” on page 16-7.
4. Develop the app in your preferred integrated development environment (IDE) or source code editor.
5. Update the necessary files of your project by using the `mfp cordova prepare` command. For more information, see “**cordova prepare**” on page 16-13.
6. For Android platform only: If you require the Cordova camera plug-in, you must complete the steps in “Preparing a project that uses the Cordova camera plug-in with the Android platform” on page 8-73.

7. Push the app to your server by using the **mfp push** command.
 - For a local development server, run **mfp push local**.
 - For a remote server, run **mfp push *RemoteServerDefinition***, where *RemoteServerDefinition* is the name of the server definition that was given to the server when it was created.

For more information, see “**push**” on page 16-19.

8. Test your application by either previewing it in a browser, running it on a device emulator, or running it on a device.
 - To preview your app in a browser, run **mfp cordova preview**. For more information, see “**cordova preview**” on page 16-13.
 - To run your app on a device emulator, run **mfp cordova emulate**. For more information, see “**cordova emulate**” on page 16-9.
 - To run your app on a device, run **mfp cordova run**. For more information, see “**cordova run**” on page 16-14.

(Android and iOS development only.) If you are developing your app for the Android or iOS platforms or adding the Android or iOS platform to an existing app, the following files are replaced by a version of the file that is provided by IBM MobileFirst Platform Foundation when you add the platform to your app that contains the cordova-plugin-mfp plug-in. These files are:

- Android: The file `MainActivity.java` is replaced. Your original `MainActivity.java` file is backed up and renamed `MainActivity.original`.
- iOS: File `main.m` is replaced. Your original `main.m` file is backed up and renamed `main.m.bak`.

If you made any changes to the original versions of these files, you must merge the changes that you made into the new version of the file that is provided by IBM MobileFirst Platform Foundation.

Managing platforms

With MobileFirst Platform Command Line Interface (CLI), you can build applications for either Android or iOS within your Cordova project. When you add a platform to your application, a new folder for that environment is created.

Procedure

1. Change directories to your Cordova project folder.
2. In your project, run the **mfp cordova platform add** command. For more information, see “**cordova platform add**” on page 16-10.
3. For Android platform only: If you require the Cordova camera plugin, you must complete the steps in “Preparing a project that uses the Cordova camera plug-in with the Android platform” on page 8-73.

Results

A platform folder is added to your Cordova project.

What to do next

You can also list, remove, and update the platforms of your Cordova projects by using the CLI commands. For more information about these commands, see “**cordova platform list**” on page 16-10, “**cordova platform remove**” on page 16-11, and “**cordova platform update**” on page 16-11.

Managing Cordova plug-ins

With MobileFirst Platform Command Line Interface (CLI), you can use any plug-in in the Cordova Plugin Registry. Third-party plug-ins are not supported by IBM, therefore you use them at your own risk.

Procedure

1. Change directories into your Cordova app. Run **cd YourCordovaApp**.
2. Add a plug-in to your app. Run **mfp cordova plugin add**. For more information, see “**cordova plugin add**” on page 16-11.
3. To update the assets for your plug-ins, run **mfp cordova plugin update**. For more information, see “**cordova plugin update**” on page 16-13.
4. For Android platform only: If you require the Cordova camera plug-in, you must complete the steps in “Preparing a project that uses the Cordova camera plug-in with the Android platform” on page 8-73.

Results

Plug-ins are added and updated to your Cordova project.

What to do next

You can also list, remove, and search for plug-ins. For more information, see “**cordova plugin list**” on page 16-12, “**cordova plugin remove**” on page 16-12, and “**cordova plugin search**” on page 16-13.

Enabling a Cordova app to support Android SDK version 23 permissions

You might need to update some items to support permission handling for your IBM MobileFirst Platform Foundation version 7.1 Apache Cordova applications that target Android SDK version 23 and request permissions at runtime.

About this task

The original version of the IBM MobileFirst Platform Foundation version 7.1 did not support permission handling for Android SDK version 23. Enabling this support required some changes to the cordova-android platform and the following Cordova core plug-ins that are included with IBM MobileFirst Platform Foundation:

- Camera
- Contacts
- File
- Media
- Media-capture

To enable this support in your third-party Cordova plug-ins, complete the following steps:

Procedure

1. Update your third-party Cordova plug-ins to a version that supports requesting permissions at runtime.
2. Add the `PermissionHelper.java` file. This file is a dependency for any plug-in that uses the Android SDK version 23 permissions. If you do not have any

third-party Cordova plug-ins that depend on permissions, then you do not need to add the `PermissionHelper.java` file.

- a. Create an `org.apache.cordova` package.
- b. Download the `PermissionHelper.java` file from the Apache cordova-plugin-compat GitHub repository at: <https://github.com/apache/cordova-plugin-compat/blob/master/src/android/PermissionHelper.java>.
- c. Add the `PermissionHelper.java` file into the package directory that you created in step 2a. You only need to add the `PermissionHelper.java` file to your project once, even if you have more than one third-party plug-in.

Connecting to MobileFirst Server

By default, an application starts in offline mode. You can make it start in online mode or connect to MobileFirst Server later.

About this task

You can connect your application to MobileFirst Server either when it starts or at some time during its processing. You are responsible for maintaining the offline or online state within your application, and ensuring that your application can recover from failed attempts to connect to the server. For example, before the application logs in a new user or accesses the server under a new user, the application must ensure that the server received a successful logout.

Procedure

- To make your application begin communicating with MobileFirst Server as soon as it starts, use the `WL.Client.connect` method in `common/js/main.js` inside the `WLCommonInit` method.
- To make your application communicate with the server at a later stage, call the `WL.Client.connect` method, as defined in the `WL.Client` class.

Call this method only once, before any other `WL.Client` methods that communicate with the server. Remember to implement the `onSuccess` and `onFailure` callback functions. For example:

```
WL.Client.connect({
    onSuccess: onConnectSuccess,
    onFailure: onConnectFailure
});
```

Note: `UserPrefs` are updated only after the call to the `WL.Client.connect` method.

Converting existing MobileFirst hybrid app into a Cordova app

You can migrate an existing MobileFirst Hybrid app to a Cordova app by creating a new Cordova project, and migrating your existing code.

Procedure

1. Create a Cordova client app by running the `mfp cordova create` command. Example: `mfp cordova create CordovaApp --id "com.ibm.mfp.CordovaApp" -p ios,android`. For more information about the `mfp cordova create` command, see “`cordova create`” on page 16-8.
2. Move the contents of your hybrid apps `common` directory, to your new Cordova apps `/www` directory. Example: `cp -r MyMFProject/apps/MyMfpApp/common/* CordovaApp/www/`.
3. Move the `application-descriptor.xml` file and, if present, the `.p12` certificate file from the existing hybrid app to the new Cordova app. Example: `cp -r`

~/MyMFPPProject/apps/MyMfpApp/application-descriptor.xml CordovaApp, then run `cp -r ~/MyMFPPProject/apps/MyMfpApp/*.p12 CordovaApp/`.

4. Update the `www/index.html` file.
 - a. Add the following CSS code to the head of your `index.html` file, before your CSS code that is already there.

```
<link rel="stylesheet" href="worklight/worklight.css">
<link rel="stylesheet" href="css/main.css">
```

Note: The `worklight.css` file sets the body attribute to `relative`. If this affects the style of your app, then declare a different value for the position in your own CSS code. For example:

```
body {
  position: absolute;
}
```

- b. Add Cordova JavaScript to the head of the file after the CSS definitions.

```
<script type="text/javascript" src="cordova.js"></script>
```

- c. Remove the following line of code if it is present.

```
<script>window.$ = window.jQuery = WLJQ;</script>
```

You can download your own version of JQuery, and load it as shown in the following code line.

```
<script src="lib/jquery.min.js"></script>
```

You do not have to move the optional JQuery addition to the `lib` folder. You can move this addition anywhere you want to, but you must properly reference it in the `index.html` file.

5. Update the `www/js/InitOptions.js` file to call `WL.Client.init` automatically.
 - a. Remove the following code from `InitOptions.js`.

The function `WL.Client.init` get's call automatically with the global variable `wlInitOptions`.

```
if (window.addEventListener) {
  window.addEventListener('load', function() { WL.Client.init(wlInitOptions); }, false);
} else if (window.attachEvent) {
  window.attachEvent('onload', function() { WL.Client.init(wlInitOptions); });
}
```

6. Optional: Update the `www/InitOptions.js` to call `WLClient.init` manually.

- a. Edit the `config.xml` file and set the preference `mfpManualInit` to `true`.
 - b. If you are using the MobileFirst hybrid default template, replace this code.

```
if (window.addEventListener) {
  window.addEventListener('load', function() { WL.Client.init(wlInitOptions); }, false);
} else if (window.attachEvent) {
  window.attachEvent('onload', function() { WL.Client.init(wlInitOptions); });
}
```

With the following code.

```
if (document.addEventListener) {
  document.addEventListener('mfpready', function() { WL.Client.init(wlInitOptions); }, false);
} else if (window.attachEvent) {
  document.attachEvent('mfpready', function() { WL.Client.init(wlInitOptions); });
}
```

7. Optional: If you have logic specific to a hybrid environment, for example in *Your app/iphone/js/main.js*, copy the function `wlEnvInit()` and append it at the end of `www/main.js`.

```
// This wEnvInit method is invoked automatically by MobileFirst runtime after successful init
function wEnvInit() {
    wCommonInit();
    if (cordova.platformId === "ios") {
        // Environment initialization code goes here for ios
    } else if (cordova.platformId === "android") {
        // Environment initialization code goes here for android
    }
}
```

8. Optional: If your hybrid environment includes the JSONStore feature, add the JSONStore plug-in to your Cordova app.
 - a. Change directories into your Cordova project. Run **cd <CordovaApp>**.
 - b. Run **mfp cordova plugin add cordova-plugin-mfp-jsonstore**.

Note: FIPS 140-2 and the IBM Tealeaf feature are not available in Cordova apps.

Converting a MobileFirst Cordova project to an Android Studio-based project

Follow these instructions if you want to work with a MobileFirst Cordova project in Android Studio, and use Gradle building capabilities.

About this task

This procedure enables you to make changes to your Cordova project, build and deploy to MobileFirst Server, go to Android Studio, and build and deploy your app to an emulator or a device.

Procedure

1. Import the build.gradle file from your project to Android Studio:
 - a. In Android Studio, click **Import project (Eclipse ADT, Gradle, etc.)**.
 - b. Go to your MobileFirst project under **apps > android > native**, and click build.gradle.

Note: Make sure to click build.gradle and not the native folder.

- c. Click **OK** and accept any Gradle configuration that Android Studio prompts for.
2. Accept **Gradle Sync** configuration.
3. Optional: Fix any Gradle sync error by modifying the build.gradle file:
 - a. From the **Project** tab, expand the **Gradle Scripts** drop-down menu, and open the file build.gradle (**Module: android**).
 - b. Configure build.gradle to fix any gradle sync error.

The most common issues that you must resolve are dependencies issues. To know how to fix those problems, see the Gradle documentation:

https://docs.gradle.org/current/userguide/dependency_management.html
and https://docs.gradle.org/current/userguide/java_plugin.html#sec:java_plugin_and_dependenc%20y_management

Note: You must resolve all Gradle sync errors before continuing with this procedure.

4. Run your application in Android Studio. If the application is deployed successfully, continue with this procedure. If you have other build errors, you might have to edit the build.gradle file again to adapt it to your project.
 5. Make a change to any file in the www folder and save it.

6. In the MobileFirst Platform Command Line Interface, run the **mfp cordova prepare** command.
7. Optional: If you need to deploy to MobileFirst Server, run the **mfp push command**.
8. In Android Studio, from the **Android** drop-down menu, go to **assets > www**, open the file that you modified in step 5 on page 8-181, and make sure the changes are present.

Note: If your changes are not there, refresh your project in Android Studio

9. Run the application.

Results

The application is now deployed successfully in Android Studio.

Important: (Android and iOS development only.) When you add the Android or iOS platforms to your app that contains the cordova-plugin-mfp, an existing file in your app is replaced by a version of the file that is provided by MobileFirst Platform Foundation. These files are:

- Android: The file MainActivity.java is replaced. Your original MainActivity.java file is backed up and renamed MainActivity.original.
- iOS: File main.m is replaced. Your original main.m file is backed up and renamed main.m.bak.

If you made any changes to the original versions of these files, you must merge the changes that you made into the new version of the file that is provided by IBM MobileFirst Platform Foundation.

Developing native applications

Whatever the environment, the process for developing native applications shares some common elements.

Each native API application contains the following elements:

- a MobileFirst Native API project
- a project in an IDE that is appropriate to your target environment
- the MobileFirst native library for your target environment
- a client property file
- an application descriptor file

You develop according to the guidelines for your target environment.

When you create a MobileFirst project of type Native API, various files are generated. The names of the files and their content vary, depending on the target environment that you specify. After you create the MobileFirst native API project, you copy some of the generated files to your native development environment (IDE). Which files you need to copy depend on your target development environment and on whether you use a package management tool to obtain the IBM MobileFirst Platform Foundation SDK. If you use a package management tool, you need to copy fewer files.

Application files

Native applications contain the following files:

- The application descriptor file: This file is the `application-descriptor.xml` file in the application root directory.
- The MobileFirst native library and the client property file: Their name and format depend on the environment.

iOS

- The `WorklightAPI` folder defines the MobileFirst native library.
- The `worklight.plist` file is the client property file.

Android

- The `worklight-android.jar` file defines the MobileFirst native library.
- The `wlclient.properties` file is the client property file.

Java ME

- The `worklight-javame.jar` file and the `json4javame.jar` file together define the MobileFirst native library.
- The `wlclient.properties` file is the client property file.

Windows Phone Silverlight 8

- The `worklight-windowsphone8.dll` file defines the MobileFirst native library. The `Newtonsoft.Json.dll` library is required for using JSON objects in C#.
- The `wlclient.properties` file is the client property file.

Windows 8 Universal and Windows Phone 8 Universal

- The `worklight-windows8.dll` file defines the MobileFirst native library. The `Newtonsoft.Json.dll` is a library that is required for using JSON objects in C#.
- The `wlclient.properties` file is the client property file.
- The `worklight-windows8.pri` file. This file contains the static localized strings (user facing and non-user facing).

Using package management tools to obtain the SDK

If you are developing a native iOS application, you can download the IBM MobileFirst Platform Foundation iOS SDK with CocoaPods. For more information, see “Adding the IBM MobileFirst Platform Foundation iOS SDK to a new application with CocoaPods” on page 8-192.

If you are developing a native Android application, you can download the IBM MobileFirst Platform Foundation Android SDK with Gradle. For more information, see “Adding the IBM MobileFirst Platform Foundation SDK to a new or existing application with Android Studio” on page 8-206.

Complementary project for native applications

Native applications need another project, which you create in a different IDE. For example:

- For iOS, a project in the Xcode IDE to develop a native application with Objective-C or Swift.
- For Java ME, a project in the Eclipse IDE to develop a native application with Java.
- For Android, a project in Android Studio or in the Google Android Development Toolkit (ADT) Eclipse plugin to develop a native application with Java..

- For Windows Phone Silverlight 8, a project in Visual Studio Express for Windows Phone or Visual Studio 2012 Professional or higher.
- For Windows 8 Universal, a project in Visual Studio Express for Windows 8 or in Visual Studio 2012 Professional or higher.

Build and deployment

You build and deploy native API applications by creating a `.wlap` file and uploading it to the MobileFirst Operations Console. This is the same process that you use to build hybrid apps. For more information about deployment, see “Deploying applications and adapters to MobileFirst Server” on page 12-87.

Integrating IBM MobileFirst Platform Foundation APIs into native applications

To develop a native application, you must create a MobileFirst project of type Native API. The content of the MobileFirst project varies, depending on the target mobile environment. Then, you transfer files that are generated by the process of creating this project to the IDE for your target environment. You use the API that corresponds to your target environment.

APIs for target environments

Use the MobileFirst API that corresponds to your target environment:

- iOS: the MobileFirst Objective-C client-side API. Specific steps apply if you use Apple Swift, a language that is compatible with Objective-C. For more information, see “Developing native applications for iOS” on page 8-185.
- Android: the MobileFirst Java client-side API.
- Java Platform, Micro Edition (Java ME): the MobileFirst Java client-side API.
- Windows Phone Silverlight 8: the MobileFirst C# client-side API.
- Windows 8 Universal: the MobileFirst C# client-side API.

Creating a native project with the MobileFirst Platform Command Line Interface

The process to integrate IBM MobileFirst Platform Foundation APIs into your application differs depending on whether the MobileFirst project exists or not. If you already have a MobileFirst project, you can create and add your native API application to it.

- If you do not have a MobileFirst project, you can choose from two alternatives: you can use the **mfp push** command, or you can use the **mfp add api** and **mfp create** commands to create a MobileFirst project, then copy some files to a project in your IDE.

Creating the native project in your native IDE with the **mfp push** command

1. Open your native IDE. (For example, Xcode for iOS, or Android Studio for Android, or Visual Studio for Windows environments.)
2. Create your native application project in the native IDE.
3. Navigate, using the command line, to the directory that contains your native project.
4. Run the **mfp push** command. For more information see “push” on page 16-19.

Creating the native project with the **mfp add api** and **mfp create** commands

1. Run the **mfp create** *MyProject* command, where *MyProject* is the name of your project. For more information about the **create** command, see “**create**” on page 16-15.
 2. Change directories to the directory that was created for your project: **cd** *MyProject*.
 3. Run the command **mfp add api***MyProject* **--environment** *environment*, where *environment* is the target environment. For more information about the **add api** command, see “**add api**” on page 16-3.
- If you already have a MobileFirst project, you can create and add your native API application to it. In the directory that contains your project:
 - Run the **add api** command. For more information, see “**add api**” on page 16-3.

Creating a native app with MobileFirst Studio

- If you already have a MobileFirst project, you can create and add your native API application to it. In MobileFirst Studio:
 1. Click **File > New > MobileFirst Native API**.
 2. Select the existing project.
 3. Set the application name.
 4. To specify the environment, select **Android, iOS, Java ME, WindowsPhone8 - Silverlight, Windows8 - Universal, or WindowsPhone8 - Universal**.
 5. Click **Finish**.
- If you do not have a MobileFirst project, you create a MobileFirst project of type native API. Then you create a native API application as its first application. In MobileFirst Studio:
 1. Click **File > New > MobileFirst Project**, and then select the **Native API** template.
 2. Set the application name.
 3. To specify the environment, select **Android, iOS, Java ME, WindowsPhone8 - Silverlight, Windows8 - Universal, or WindowsPhone8 - Universal**.
 4. Click **Finish**.

Developing native applications for iOS

After you create the native API application, you edit the application descriptor and client property files, then set up your Xcode development environment for working with MobileFirst projects. If you want to work with Apple Swift language, you create a Swift project.

Note: The **Keychain Sharing** capability is mandatory while running iOS apps in the iOS Simulator when using Xcode 8. You need to enable this capability manually before building the Xcode project.

Application descriptor of native API applications for iOS

In the application descriptor, you define various aspects of your native API application for iOS.

The application descriptor file is a metadata file in which you define various aspects of the application. It is in the application root directory and its name is `application-descriptor.xml`.

The following example shows the format of the application descriptor file of native API applications for iOS:

```
<?xml version="1.0" encoding="UTF-8"?>
<nativeIOSApp
  id="ios"
  platformVersion="7.1.0"
  version="1.0"
  securityTest="security test name"
  bundleId="com.ios"
  xmlns="http://www.worklight.com/native-ios-descriptor"
  applicationId="ios">
  <displayName>application display name</displayName>
  <description>application description</description>
  <accessTokenExpiration>3600</accessTokenExpiration>
  <userIdentityRealms>Realm1, Realm2</userIdentityRealms>
  <licenseAppType>APPLICATION</licenseAppType>
  <pushSender password="{push.apns.senderpassword}"/>
  <tags>
    <tag>
      <name>tag1</name>
      <description>tag description for tag1</description>
    </tag>
    <tag>
      <name>tag2</name>
      <description>tag description for tag2</description>
    </tag>
  </tags>
  <!--
  Define the target category for generating ADDRESSABLE DEVICE license reports
  Possible values are 'UNDEFINED', 'B2E', 'B2C'
  -->
  <targetCategory>B2E</targetCategory>
</nativeIOSApp>
```

The `<nativeIOSApp>` element is the root element of the descriptor.

id This attribute specifies the ID of the application. The ID must be identical to the application folder name and the value of **applicationId**. It must be an alphanumeric string that starts with a letter. It can contain underscore ("_") characters. It must not be a reserved word in JavaScript.

platformVersion

Contains the version of IBM MobileFirst Platform Foundation on which the app was developed.

version

This attribute specifies the version of the application. This version is a string of the form x.y, where x and y are numbers. It is visible to users who download the app from the app store or market.

securityTest

This optional attribute specifies a security configuration that is defined in the `authenticationConfig.xml` file. When a client attempts to access a protected resource, IBM MobileFirst Platform Foundation checks whether the client is already authenticated according to the security test. If the client is not yet authenticated, IBM MobileFirst Platform Foundation starts the process to obtain the client credentials and to verify them.

bundleId

This optional attribute specifies the bundle ID of the application.

applicationId

This attribute specifies the name of the application, as specified in the `worklight.plist` file. The values in the `application-descriptor.xml` and

worklight.plist must match, and the value of **applicationId** must be the same as the value of **id**. This attribute is required if you use the IBM MobileFirst Platform Foundation classic security model. For more information, see “MobileFirst application authenticity overview” on page 8-564.

<displayName>

This element contains the application name. This name is visible in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

```
<displayName>application display name</displayName>
```

<description>

This element contains the application description. This description is visible in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

```
<description>application description</description>
```

<userIdentityRealms>

This element is a comma-separated ordered list of user identity realms for OAuth authentication. The realms should be ordered by preference. The first successfully authenticated realm in this list is selected as the user identity realm. If the list is empty, or no realm in the list was authenticated, the ID token contains no identity information. This element is optional and the default value is an empty list:

```
<userIdentityRealms>WASLTPRealm, CustomAuthenticatorRealm</userIdentityRealms>
```

Note: This attribute is used to set user identity in the OAuth-based flows. For the classic (pre-V7.0) authentication flows, see the documentation for the customSecurityTest security test.

<accessTokenExpiration>

This element is optional and defines the expiration period (in seconds) of OAuth access tokens. The default is 3600 seconds (one hour). Client applications can use the token to access protected resources as long as the token has not expired. When the token expires, the client application has to obtain a new access token to access a protected resource. Obtaining a new access token may happen automatically without user intervention if all the realms by which the resource is protected have not expired. However, if one of the realms that is included in the security test of the resource has expired, and the realm requires user input (such as a form-based authenticator), the user has to re-authenticate.

```
<accessTokenExpiration>3600</accessTokenExpiration>
```

licenseAppType

Declares the application type for token licensing. This element is ignored if the MobileFirst Server does not have token licensing activated.

Possible values (values are case-sensitive; must be all uppercase):

- **NON_PRODUCTION:** Use this while you are developing and testing the application on the production server.

Important: Using NON_PRODUCTION for a production app is a breach of the license terms.

- **APPLICATION:** Use this for most applications when you are ready to deploy the app on a production server. This is the default. The production server must have token licensing activated, and enough tokens must be available.

- **ADDITIONAL_BRAND_DEPLOYMENT:** Use this when you are ready to deploy an additional brand deployment app on a production server. The app must be an additional brand deployment of an existing app for which an APPLICATION token has already been used. Your organization must have purchased an Additional Brand Deployment license for you to use this option. In addition, the code in the similar application must meet specific requirements such as the percentage of code that is different. Refer to your IBM MobileFirst Platform Foundation - Additional Brand Deployment software license for details.

The production server must have token licensing activated, and enough tokens must be available.

If token licensing is activated on the server and this element is not present in the application descriptor, then the default setting APPLICATION is used.

For more information, see “Licensing in MobileFirst Server” on page 2-16 and your IBM MobileFirst Platform Foundation software license.

```
<licenseAppType>APPLICATION</licenseAppType>
```

<pushSender>

This element defines the password to the SSL certificate that encrypts the communication link with the Apple Push Notification Service (APNS).

```
<pushSender password="{push.apns.senderpassword}"/>
```

<tags>

This element defines the tags that are used for tag-based notifications. For more information, see “Setting up Tag-based notifications” on page 8-513.

```
<tags>
  <tag>
    <name>tag1</name>
    <description>tag description for tag1</description>
  </tag>
  ...
</tags>
```

<targetCategory>

Since IBM MobileFirst Platform Foundation V7.1.0, you can declare the target category of your application. With this capability, you can generate more accurate license reports for the ADDRESSABLE DEVICE license metric. In the application-descriptor.xml file, the <targetCategory> element is added automatically when the application is created. By default, the target category is set to UNDEFINED. If your application is licensed under the ADDRESSABLE DEVICE metric, you must edit the <targetCategory> element to specify the relevant target category. The possible values are B2E for IBM MobileFirst Platform Foundation Enterprise, and B2C for IBM MobileFirst Platform Foundation Consumer.

```
<!--
  Define the target category for generating ADDRESSABLE DEVICE license reports
  Possible values are 'UNDEFINED', 'B2E', 'B2C'
-->
<targetCategory>B2E</targetCategory>
```

</nativeIOSApp>

This tag closes the content of the application descriptor file.

```
</nativeIOSApp>
```

Client property file for iOS

This file defines the client-side properties so that your native app uses the MobileFirst native API for iOS.

The `worklight.plist` client property file contains the necessary information for initializing WLCient instances. Before you use this file in your native application for iOS, you must define the properties as specified in the following table.

Table 8-16. Properties of the `worklight.plist` file

Property	Description	Example values
protocol	The communication protocol with MobileFirst Server.	http or https
host	The host name of MobileFirst Server.	localhost
port	The port of MobileFirst Server. If you leave this value blank, the default port is used. If the protocol property value is https, you must leave this value blank.	10080
wlServerContext	The server URL context.	/ Note: If you use IBM MobileFirst Platform Foundation Developer Edition, you must set the value of this property to the name of your MobileFirst project.
application id	The application ID, as defined in the <code>application-descriptor.xml</code> file.	myApp
application version	The application version, as defined in the <code>application-descriptor.xml</code> file.	1.0
environment	This property defines the MobileFirst environment. The value of this property must be <code>iOSnative</code> . Important: You must not modify the value of this property value.	iOSnative
languagePreferences	This property defines a comma-separated list of preferred languages to be used by IBM MobileFirst Platform Foundation to display system messages. This property is optional.	en, fr, de, es
platformVersion	This property defines the version number of the IBM MobileFirst Platform Foundation.	6.3.0.00.20140813-0730

Table 8-16. Properties of the `worklight.plist` file (continued)

Property	Description	Example values
<code>TRUSTEER_AUTO_INIT</code>	When set to false, this property disables the default initialization of the Trusteer Mobile SDK for MobileFirst projects with Trusteer integration. For more information, see “Integrating IBM Trusteer for iOS” on page 15-11.	false
<code>wlUId</code>	This property is for internal usage. You must not modify the value.	wY/mbnwKTDDYQUvuQCdSgg==

Methods of setting up your environment

You can prepare your environment for developing MobileFirst applications in either of two ways: by copying several files or by obtaining the files from CocoaPods.

You can get the IBM MobileFirst Platform Foundation for iOS SDK framework and library files by copying them from your MobileFirst project that you created in MobileFirst Studio or with the MobileFirst Platform Command Line Interface. Or, you can get the framework and library files by installing the MobileFirst iOS SDK from the CocoaPods dependency manager.

Copying SDK and configuration files from the project:

You can get framework and library files that are required for MobileFirst development by creating a MobileFirst project and copying certain generated files into your Xcode project. Then, in Xcode, you configure what frameworks, libraries, and build settings to include.

Before you begin

You must have already created a MobileFirst native API project with MobileFirst Studio or the MobileFirst Platform Command Line Interface. For more information, see “Creating MobileFirst projects with MobileFirst Studio” on page 8-6 or the “**create**” on page 16-15 command.

About this task

You need to copy and reference the files generated from MobileFirst Studio or the MobileFirst Platform Command Line Interface to your native iOS project in the Xcode development environment in order for Xcode to find the frameworks and libraries for linking. There are additional settings that need to be configured.

Procedure

Setting up the Xcode project to include the MobileFirst API.

1. In your Xcode project add the MobileFirst files to your project:
 - a. Select the project root icon in the project explorer.
 - b. From the **File** menu choose the **AddFiles** option and add the `WorklightAPI` folder and the `worklight.plist` file from your MobileFirst project.

- c. Select **Copy items if needed** and **Create groups for any added folders** options.
- d. Click **Add**.

Note: These steps add the MobileFirst frameworks to the **Link Binary with Libraries** list in the **Build Phases** tab.

2. Make sure the following resources are linked to your project in the **Link Binary With Libraries** section of the **Build Phases** tab.
 - IBMMobileFirstPlatformFoundation.framework
 - SystemConfiguration.framework
 - MobileCoreServices.framework
 - CoreData.framework
 - CoreLocation.framework
 - Security.framework
 - sqlcipher.framework

Note: Some frameworks may already be linked.

- libstdc++.6.dylib
- libz.dylib
- libc++.dylib

Important: If you are using Xcode 7, link libstdc++.6.tbd, libz.tbd, and libc++.tbd, instead of the corresponding .dylib files. Using Xcode 7 and iOS9 require the latest interim fix.

Important: If you are using the latest interim fix link these framework:

- openssl.framework
- If you want to enable the JSONStore feature (which is optional in the latest interim fix) link the following frameworks:
 - IBMMobileFirstPlatformFoundationJSONStore.framework
 - SQLCipher.framework

3. If you are using the JSONStore feature, import the IBMMobileFirstPlatformFoundationJSONStore framework.

For Objective C

```
#import <IBMMobileFirstPlatformFoundationJSONStore/IBMMobileFirstPlatformFoundationJSONStore.h>
```

For Swift

```
import IBMMobileFirstPlatformFoundationJSONStore
```

4. Optional: If the required frameworks do not appear in the **Build Phases** tab:.
 - a. Open the **Build Settings** page.
 - b. Find the **Search Paths** section.
 - c. Add the following entry to the **Framework Search Paths**:
\$(PROJECT_DIR)/WorklightAPI/Frameworks. If you did not copy the folder into the Xcode project, enter the full path of the WorklightAPI folder.
5. in the **Other Linker Flags** field, enter the following value: -ObjC
6. If you are using Swift see “Configuring a Swift application” on page 8-194
7. In the **Deployment** section, select a value for the **iOS Deployment Target** field that is greater than or equal to 6.0.
8. Optional: Set the build options.

Important: If you are using Xcode 7, in the **Build Settings** tab:

- a. Open the **Build Options** section.
- b. Set **Enable Bitcode** to No.

For more information, see “Disabling bitcode in Xcode builds” on page 8-199.

Adding the IBM MobileFirst Platform Foundation iOS SDK to a new application with CocoaPods:

You can prepare your environment for developing a IBM MobileFirst Platform Foundation native application for iOS by installing the MobileFirst iOS SDK from the CocoaPods dependency manager, then copying one file from your MobileFirst project to your Xcode project.

Before you begin

- You must have CocoaPods installed in your development environment. For more information, see the "Getting Started" guide for CocoaPods installation.
- You must have already created a MobileFirst native API project with MobileFirst Studio or the MobileFirst Platform Command Line Interface so that you have a client properties (`worklight.plist`) file. For more information, see “Creating MobileFirst projects with MobileFirst Studio” on page 8-6 or the “**create**” on page 16-15 command.

About this task

The IBM MobileFirst Platform Foundation iOS SDK consists of a collection of pods, available through CocoaPods, that you can add to your project. The pods correspond to core and other functions that are exposed by IBM MobileFirst Platform Foundation. The SDK contains the following pods for development of new applications:

- `IBMMobileFirstPlatformFoundation`: The core of the system. It implements client/server connections, and handles security, calling adapters, and other required functions.
- If you are using the latest interim fix for IBM MobileFirst Platform Foundation, `IBMMobileFirstPlatformFoundationJSONStore`: Contains the JSONStore feature. Specify this pod in your podfile if you intend to use the JSONStore feature in your app.
- `CloudantToolkitLocal`: Enables interaction with Cloudant data stores. Specify this pod in your podfile if you intend to use Cloudant in your app for local or remote database storage.

Note:

The following pods are also part of IBM MobileFirst Platform Foundation iOS SDK, but are for use in migrating existing client applications that were developed for IBM MobileFirst Platform for iOS on IBM Bluemix to IBM MobileFirst Platform Foundation.

- `IMFCompatibility`: Simplifies the migration process by providing a compatibility API.
- `IMFDataLocal`: Provides security integration between IBM MobileFirst Platform Foundation and the Cloudant Toolkit.

For more information about migrating apps from Bluemix Mobile Services see “Migrating applications created on IBM Bluemix to IBM MobileFirst Platform Foundation” on page 9-1.

The `IMFCompatibility`, `IMFDataLocal`, and `CloudantToolkitLocal` pods all depend on the `IBMMobileFirstPlatformFoundation` pod, so specifying any one of them causes `IBMMobileFirstPlatformFoundation` to be included. `IMFDataLocal` depends on `CloudantToolkitLocal`, so specifying `IMFDataLocal` also causes `CloudantToolkitLocal` to be included. If you are using the latest interim fix for IBM MobileFirst Platform Foundation, the `IBMMobileFirstPlatformFoundationJSONStore` pod depends on the `IBMMobileFirstPlatformFoundation` pod, so specifying `IBMMobileFirstPlatformFoundationJSONStore` also causes `IBMMobileFirstPlatformFoundation` to be included.

Procedure

1. Create an Xcode project.
2. Close Xcode.
3. Open **Terminal** at the location of your new Xcode project.
4. Run the **pod init** command to create a Podfile file.
5. Open the Podfile file that is in the root of the project with a text editor.
6. Comment out or remove the existing content.
7. Add the following lines, including the iOS version, and save the changes:

```
source 'https://github.com/CocoaPods/Specs.git'  
use_frameworks!  
target :name-of-the-target-in-xcode-project do  
  platform :ios, 9.0  
  pod 'IBMMobileFirstPlatformFoundation'
```

Note:

The pod examples assume you are upgrading to the latest version of the MobileFirst pod. If you are not using the latest version of MobileFirst, you need to indicate the version. For example, for importing the latest pod for 7.1.0 `IBMMobileFirstPlatformFoundation` the line would look like this:

```
pod 'IBMMobileFirstPlatformFoundation', '~> 7.1.0'
```

8. Optional: Specify additional pods in the file, if your app needs to use the additional functionality that they provide. For example, if your app uses Cloudant for data storage, the podfile might look like:

```
source 'https://github.com/CocoaPods/Specs.git'  
use_frameworks!  
platform :ios, 9.0  
pod 'IBMMobileFirstPlatformFoundation'  
pod 'CloudantToolkitLocal'
```

Note: If the podfile in this example specified only the `CloudantToolkitLocal` pod and not the `IBMMobileFirstPlatformFoundation` pod, the results would be the same due to the built-in dependencies.

9. Verify that the Xcode project is closed.
10. Run the **pod install** command. This command installs the MobileFirst SDK `IBMMobileFirstPlatformFoundation.framework` and any other frameworks that are specified in the Podfile and their dependencies. It then generates the pods project, and integrates the client project with the MobileFirst SDK.
11. Open your `ProjectName.xcworkspace` file in Xcode by typing `open ProjectName.xcworkspace` from a command line. This file is in the same directory as the `ProjectName.xcodeproj` file.
12. Add a `worklight.plist` client property file to the Xcode project. This file is generated when you create a new IBM MobileFirst Platform Foundation

project with MobileFirst Studio or the IBM MobileFirst Platform Command Line Interface. For more information, see “Client property file for iOS” on page 8-188.

- a. Locate the `worklight.plist` in the directory where you ran MobileFirst Studio or the IBM MobileFirst Platform Command Line Interface to create the project.
- b. Copy the `worklight.plist` file to a location under the root folder of your Xcode project.

Results

You can now start developing your native iOS application with the IBM MobileFirst Platform Foundation iOS SDK.

Configuring a Swift application

Because Apple Swift is compatible with Objective-C, you can use the MobileFirst API from within an iOS Swift project.

Procedure

1. Create a Swift project and install the MobileFirst SDK into an iOS native application as explained in “Installing required components” on page 9-12.
2. Use the `import IBMMobileFirstPlatformFoundation` statement in any class that needs to use the MobileFirst SDK.

Results

All the MobileFirst classes are now available from any of your Swift files. The Xcode IDE provides code autocompletion, converted to the Swift style.

What to do next

A tutorial is available on the Developer Center. See [Configuring a native iOS application with the MobileFirst Platform SDK](#).

Using Logger in Swift Projects

In order to use `OCLogger` in Swift projects, you can configure your Swift application by following the steps described in this section.

Procedure

1. Create a native MobileFirst application for iOS that uses Swift. For more information, see “Developing native applications for iOS” on page 8-185.
2. In the Xcode IDE, create a Swift file and name it `OCLoggerSwiftExtension.swift`.

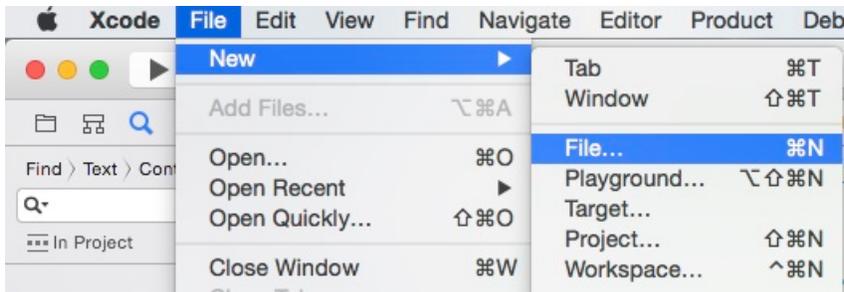

Figure 8-27. New Xcode File

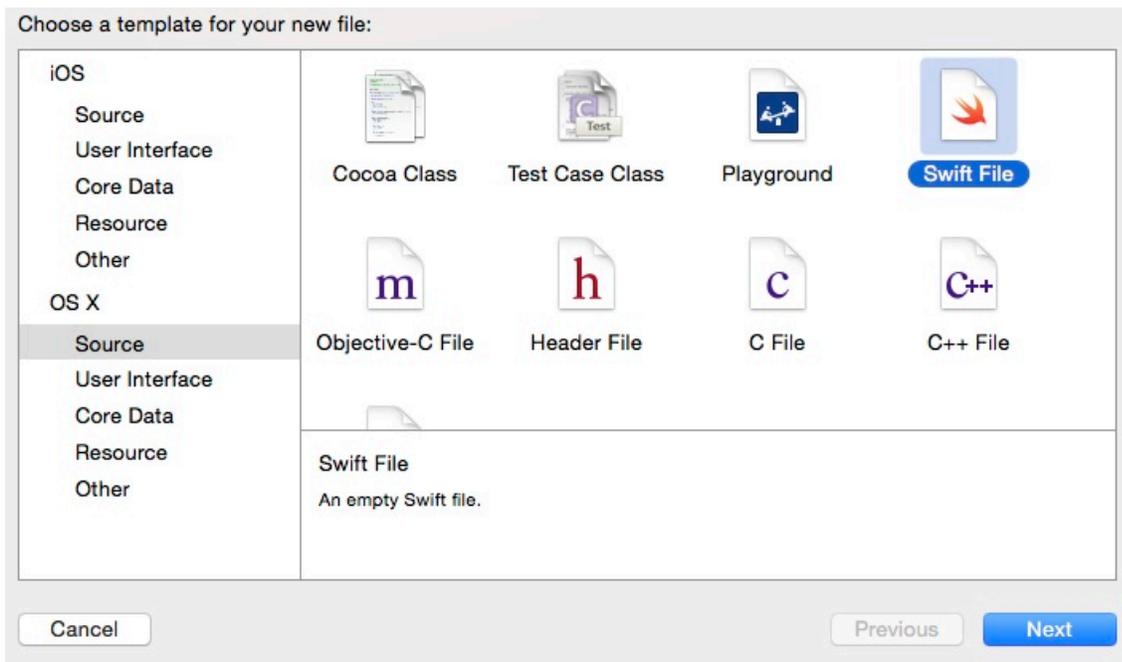

Figure 8-28. Swift File Type

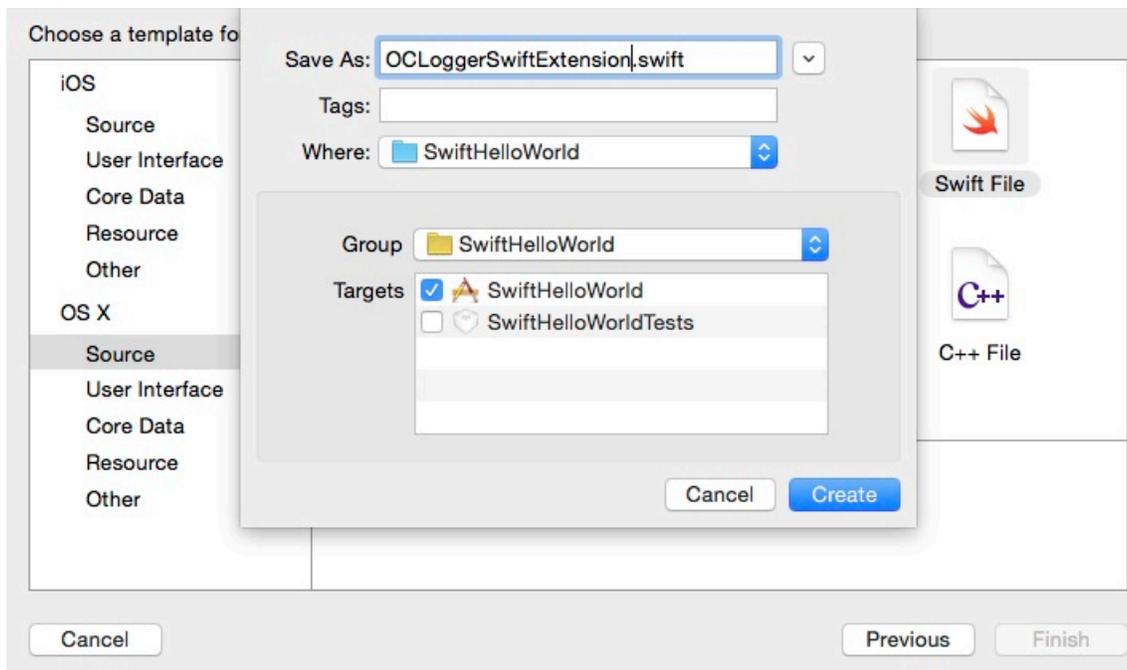

Figure 8-29. Name a Swift File

3. Add the following code to the file:

```
import Foundation

extension OCLogger {
    //Log methods with no metadata

    func logTraceWithMessages(message:String, _ args: CVarArgType...) {
        logWithLevel(OCLogger_TRACE, message: message, args:getValList(args), userInfo:Dictionary<String, String>())
    }

    func logDebugWithMessages(message:String, _ args: CVarArgType...) {
        logWithLevel(OCLogger_DEBUG, message: message, args:getValList(args), userInfo:Dictionary<String, String>())
    }

    func logInfoWithMessages(message:String, _ args: CVarArgType...) {
        logWithLevel(OCLogger_INFO, message: message, args:getValList(args), userInfo:Dictionary<String, String>())
    }

    func logWarnWithMessages(message:String, _ args: CVarArgType...) {
        logWithLevel(OCLogger_WARN, message: message, args:getValList(args), userInfo:Dictionary<String, String>())
    }

    func logErrorWithMessages(message:String, _ args: CVarArgType...) {
        logWithLevel(OCLogger_ERROR, message: message, args:getValList(args), userInfo:Dictionary<String, String>())
    }

    func logFatalWithMessages(message:String, _ args: CVarArgType...) {
        logWithLevel(OCLogger_FATAL, message: message, args:getValList(args), userInfo:Dictionary<String, String>())
    }

    func logAnalyticsWithMessages(message:String, _ args: CVarArgType...) {
        logWithLevel(OCLogger_ANALYTICS, message: message, args:getValList(args), userInfo:Dictionary<String, String>())
    }

    //Log methods with metadata

    func logTraceWithUserInfo(userInfo:Dictionary<String, String>, message:String, _ args: CVarArgType...) {
        logWithLevel(OCLogger_TRACE, message: message, args:getValList(args), userInfo:userInfo)
    }
}
```

```

}

func logDebugWithUserInfo(userInfo:Dictionary<String, String>, message:String, _ args: CVarArgType...) {
    logWithLevel(OCLogger_DEBUG, message: message, args:getVaList(args), userInfo:userInfo)
}

func logInfoWithUserInfo(userInfo:Dictionary<String, String>, message:String, _ args: CVarArgType...) {
    logWithLevel(OCLogger_INFO, message: message, args:getVaList(args), userInfo:userInfo)
}

func logWarnWithUserInfo(userInfo:Dictionary<String, String>, message:String, _ args: CVarArgType...) {
    logWithLevel(OCLogger_WARN, message: message, args:getVaList(args), userInfo:userInfo)
}

func logErrorWithUserInfo(userInfo:Dictionary<String, String>, message:String, _ args: CVarArgType...) {
    logWithLevel(OCLogger_ERROR, message: message, args:getVaList(args), userInfo:userInfo)
}

func logFatalWithUserInfo(userInfo:Dictionary<String, String>, message:String, _ args: CVarArgType...) {
    logWithLevel(OCLogger_FATAL, message: message, args:getVaList(args), userInfo:userInfo)
}

func logAnalyticsWithUserInfo(userInfo:Dictionary<String, String>, message:String, _ args: CVarArgType...) {
    logWithLevel(OCLogger_ANALYTICS, message: message, args:getVaList(args), userInfo:userInfo)
}
}

//Alternatives for macros

private func _metadataDictionary(file:String, fn:String, line:Int) -> Dictionary<String, String> {
return [
    "$method" : fn,
    "$file" : file.lastPathComponent,
    "$line" : String(line),
    "$src": "swift"
];
}

public func OCLoggerTrace(message:String, package:String =
"IMF", file: String = __FILE__, fn: String = __FUNCTION__, line: Int = __LINE__, #args: CVarArgType...) {
    OCLogger.getInstanceWithPackage(package).logWithLevel(OCLogger_TRACE, message: message, args:getVaList(args),
userInfo: _metadataDictionary(file, fn, line));
}

public func OCLoggerDebug(message:String, package:String =
"IMF", file: String = __FILE__, fn: String = __FUNCTION__, line: Int = __LINE__, #args: CVarArgType...) {
    OCLogger.getInstanceWithPackage(package).logWithLevel(OCLogger_DEBUG, message: message, args:getVaList(args),
userInfo: _metadataDictionary(file, fn, line));
}

public func OCLoggerInfo(message:String, package:String =
"IMF", file: String = __FILE__, fn: String = __FUNCTION__, line: Int = __LINE__, #args: CVarArgType...) {
    OCLogger.getInstanceWithPackage(package).logWithLevel(OCLogger_INFO, message: message, args:getVaList(args),
userInfo: _metadataDictionary(file, fn, line));
}

public func OCLoggerWarn(message:String, package:String =
"IMF", file: String = __FILE__, fn: String = __FUNCTION__, line: Int = __LINE__, #args: CVarArgType...) {
    OCLogger.getInstanceWithPackage(package).logWithLevel(OCLogger_WARN, message: message, args:getVaList(args),
userInfo: _metadataDictionary(file, fn, line));
}

public func OCLoggerError(message:String, package:String =
"IMF", file: String = __FILE__, fn: String = __FUNCTION__, line: Int = __LINE__, #args: CVarArgType...) {
    OCLogger.getInstanceWithPackage(package).logWithLevel(OCLogger_ERROR, message: message, args:getVaList(args),
userInfo: _metadataDictionary(file, fn, line));
}

```

```

public func OCLoggerFatal(message:String, package:String =
"IMF", file: String = __FILE__, fn: String = __FUNCTION__, line: Int = __LINE__, #args: CVarArgType...) {
    OCLogger.getInstanceWithPackage(package).logWithLevel(OCLogger_FATAL, message: message, args:getVaList(args),
userInfo: _metadataDictionary(file, fn, line));
}

public func OCLoggerAnalytics(message:String, package:String =
"IMF", file: String = __FILE__, fn: String = __FUNCTION__, line: Int = __LINE__, #args: CVarArgType...) {
    OCLogger.getInstanceWithPackage(package).logWithLevel(OCLogger_ANALYTICS, message: message, args:getVaList(args),
userInfo: _metadataDictionary(file, fn, line));
}

```

4. Test that the Swift extension is working by using the Logger in Swift with the following code:

```

OCLogger.setLevel(OCLogger_TRACE)
OCLogger.setCapture(true);

let logger : OCLogger = OCLogger.getInstanceWithPackage("MyTestLoggerPackage")

logger.logTraceWithMessages("Hello %@", "Trace");
logger.logTraceWithMessages("Hello Trace");

OCLoggerDebug("Hello Debug!");
OCLoggerDebug("Hello %@", package: "SomePackageName", args: "Debug!");

```

Results

Verify the output is similar to the following output:

```

SwiftHelloWorld[7591:4265124] [TRACE] [MyTestLoggerPackage] Hello Trace
SwiftHelloWorld[7591:4265124] [TRACE] [MyTestLoggerPackage] Hello Trace
SwiftHelloWorld[7591:4265124] [DEBUG] [IMF] viewDidLoad() in ViewController.swift:26 :: Hello Debug!
SwiftHelloWorld[7591:4265124] [DEBUG] [SomePackageName] viewDidLoad() in ViewController.swift:27 :: Hello Debug!

```

Note: The project name used in this example is SwiftHelloWorld. Your project name will show in the output in place of SwiftHelloWorld. The code was added to the viewDidLoad() function in the ViewController.swift file. Your output depends on where you added the code in your project. The timestamps were removed from this example for clarity.

Enforcing TLS-secure connections in iOS apps

From iOS 9 Transport Layer Security (TLS) protocol version 1.2 must be enforced in all apps. You can disable this and bypass the iOS 9 requirement for development purposes.

About this task

Apple's App Transport Security (ATS) is a new feature of iOS 9 that enforces best practices for connections between the app and the server. By default, this feature enforces some connection requirements that improve security. These include client-side HTTPS requests and server-side certificates and connection ciphers that conform to Transport Layer Security (TLS) version 1.2 using forward secrecy.

For **development purposes**, you can override the default behavior by specifying an exception in the Info.plist file in your app, as described in App Transport Security Technote. However, in a full **production environment**, all iOS apps must enforce TLS-secure connections for them to work properly.

Starting from the latest interim fix of IBM MobileFirst Platform Foundation V7.1.0, the apps that you develop in IBM MobileFirst Platform Foundation V6.0.0 and later automatically turn off transport security to allow all non-secure connections to the MobileFirst Development Server.

To enable non-TLS connections, the following exception must appear in the `<projectname>info.plist` file in the `<project>\Resources` folder:

```
<key>NSExceptionDomains</key>
<dict>
  <key>yourserver.com</key>
  <dict>
    <!--Include to allow subdomains-->
    <key>NSIncludesSubdomains</key>
    <true/>

    <!--Include to allow insecure HTTP requests-->
    <key>NSTemporaryExceptionAllowsInsecureHTTPLoads</key>
    <true/>
  </dict>
</dict>
```

Note: If you are creating a hybrid iOS application, your IBM MobileFirst Platform Server host name is added automatically to the `NSException` dictionary.

Procedure

1. To prepare for production, remove or comment out the code that appears earlier in this page.
2. Set up the client to send HTTPS requests by using the following entry to the dictionary:

```
<key>protocol</key>
<string>https</string>

<key>port</key>
<string>10443</string>
```

The SSL port number is defined on the server in `server.xml` in the `httpEndpoint` definition.

3. Configure a server that is enabled for the TLS 1.2 protocol. For more information, see [Configuring MobileFirst Server to enable TLS V1.2](#).
4. Make settings for ciphers and certificates, as they apply to your setup. For more information, see [App Transport Security Technote, Secure communications using Secure Sockets Layer \(SSL\) for WebSphere Application Server Network Deployment](#), and [Enabling SSL communication for the Liberty profile](#).

Disabling bitcode in Xcode builds

You must disable the new bitcode option in Xcode builds for IBM MobileFirst Platform Foundation projects.

About this task

Starting with Xcode 7, bitcode is a default, but optional option for iOS apps. The bitcode option is not currently supported in IBM MobileFirst Platform Foundation. To use the MobileFirst SDK in your Xcode projects, you must disable bitcode.

Note: Applications that are based on Apple watchOS 2 require the bitcode to be enabled and are currently not supported in IBM MobileFirst Platform Foundation.

Procedure

On the **Xcode Build Settings** tab, in the **Build Options** group, set **Enable Bitcode** to **No**.

Developing native applications for Android

After you create the native API application, you edit the application descriptor and client property files, then set up your development environment for working with MobileFirst projects.

Note: The MobileFirst APIs cannot be activated from within an Android Service.

Application Descriptor of Native API application for Android

The application descriptor is a metadata file that is used to define various aspects of the Native API application for Android.

The application descriptor is a metadata file that is used to define various aspects of the application. It is in the application root directory, and its name is `application-descriptor.xml`.

The following example shows the format of the application descriptor file of Native API applications for Android:

```
<?xml version="1.0" encoding="UTF-8"?>
<nativeAndroidApp
  id="android"
  platformVersion="7.1.0"
  securityTest="security test name"
  version="1.0"
  <security>
    <encryptWebResources enabled="false"/>
    <testWebResourcesChecksum enabled="false" ignoreFileExtensions="png, jpg, jpeg,
      gif, mp4, mp3"/>
    <publicSigningKey>my-very-long-public-key</publicSigningKey>
    <packageName>com.myPackageName</packageName>
  </security>
  xmlns="http://www.worklight.com/native-android-descriptor">
  <displayName>application display name</displayName>
  <description>application description</description>
  <accessTokenExpiration>3600</accessTokenExpiration>
  <userIdentityRealms>Realm1, Realm2</userIdentityRealms>
  <licenseAppType>APPLICATION</licenseAppType>
  <pushSender key="gcm api key" senderId="gcm project number"/>
  <publicSigningKey>application public signing key</publicSigningKey>
  <tags>
    <tag>
      <name>tag1</name>
      <description>tag description for tag1</description>
    </tag>
    <tag>
      <name>tag2</name>
      <description>tag description for tag2</description>
    </tag>
  </tags>
  <!--
  Define the target category for generating ADDRESSABLE DEVICE license reports
  Possible values are 'UNDEFINED', 'B2E', 'B2C'
  -->
  <targetCategory>B2E</targetCategory>
</nativeAndroidApp>
```

The `<nativeAndroidApp>` element is the root element of the descriptor. It has three mandatory attributes and one optional attribute:

id (Mandatory.) This attribute specifies the ID of the application. The ID must be identical to the application folder name. It must be an alphanumeric string that starts with a letter. It can contain underscore ("_") characters. It must not be a reserved word in JavaScript.

platformVersion

(Mandatory.) Contains the version of IBM MobileFirst Platform Foundation on which the app was developed.

version

(Mandatory.) This attribute specifies the version of the application. This version is a string of the form `x.y`, where `x` and `y` are numbers. It is visible to users who download the app from the app store or market.

securityTest

This attribute specifies a security configuration that is defined in the `authenticationConfig.xml` file. When a client attempts to access a protected resource, IBM MobileFirst Platform Foundation checks whether the client is already authenticated according to the security test. If the client is not yet authenticated, IBM MobileFirst Platform Foundation starts the process to obtain the client credentials and to verify them.

This attribute is **optional**.

<packageName>

The package name. This value of this parameter must be the same as the value of the package attribute of the manifest element in the `AndroidManifest.xml` file. This parameter is required if you use the IBM MobileFirst Platform Foundation classic security model. For more information, see "MobileFirst application authenticity overview" on page 8-564.

```
<displayName>application display name</displayName>
```

<displayName>

This element contains the application name. This name is visible in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

```
<description>application description</description>
```

<description>

This element contains the application description. This description is visible in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

```
<accessTokenExpiration>3600</accessTokenExpiration>
```

<accessTokenExpiration>

This element is optional and defines the expiration period (in seconds) of OAuth access tokens. The default is 3600 seconds (one hour). Client applications can use the token to access protected resources as long as the token has not expired. When the token expires, the client application has to obtain a new access token to access a protected resource. Obtaining a new access token may happen automatically without user intervention if all the realms by which the resource is protected have not expired. However, if one of the realms that is included in the security test of the resource has expired, and the realm requires user input (such as a form-based authenticator), the user has to re-authenticate.

```
<userIdentityRealms>WASLTPRealm, CustomAuthenticatorRealm</userIdentityRealms>
```

<userIdentityRealms>

This element is a comma-separated ordered list of user identity realms for OAuth authentication. The realms should be ordered by preference. The first successfully authenticated realm in this list is selected as the user identity realm. If the list is empty, or no realm in the list was authenticated, the ID token contains no identity information. This element is optional and the default value is an empty list:

Note: This attribute is used to set user identity in the OAuth-based flows. For the classic (pre-V7.0) authentication flows, see the documentation for the customSecurityTest security test.

```
<licenseAppType>APPLICATION</licenseAppType>
```

<licenseAppType>

Declares the application type for token licensing. This element is ignored if the MobileFirst Server does not have token licensing activated.

Possible values (values are case-sensitive; must be all uppercase):

- NON_PRODUCTION: Use this while you are developing and testing the application on the production server.

Important: Using NON_PRODUCTION for a production app is a breach of the license terms.

- APPLICATION: Use this for most applications when you are ready to deploy the app on a production server. This is the default. The production server must have token licensing activated, and enough tokens must be available.
- ADDITIONAL_BRAND_DEPLOYMENT: Use this when you are ready to deploy an additional brand deployment app on a production server. The app must be an additional brand deployment of an existing app for which an APPLICATION token has already been used. Your organization must have purchased an Additional Brand Deployment license for you to use this option. In addition, the code in the similar application must meet specific requirements such as the percentage of code that is different. Refer to your IBM MobileFirst Platform Foundation - Additional Brand Deployment software license for details.

The production server must have token licensing activated, and enough tokens must be available.

If token licensing is activated on the server and this element is not present in the application descriptor, then the default setting APPLICATION is used.

For more information, see “Licensing in MobileFirst Server” on page 2-16 and your IBM MobileFirst Platform Foundation software license.

Note: Token licensing, as defined by <licenseAppType> is not related to OAuth access tokens, as defined by <accessTokenExpiration>.

```
<pushSender key="gcm api key" senderId="gcm project number"/>
```

<pushSender>

This element contains the connectivity details to Google GCM (Android push notification service). The key is the GCM API key, and the senderId is the GCM Project Number.

```
<publicSigningKey>application public signing key</publicSigningKey>
```

<publicSigningKey>

This element contains the public key of the developer certificate that is

used to sign the Android app. To extract this value, see “Extracting a public signing key from native apps” on page 8-208.

```
<tags>
  <tag>
    <name>tag1</name>
    <description>tag description for tag1</description>
  </tag>
  ...
</tags>
```

<tags> This element defines the tags that are used for tag-based notifications. For more information, see “Setting up Tag-based notifications” on page 8-513.

```
<!--
Define the target category for generating ADDRESSABLE DEVICE license reports
Possible values are 'UNDEFINED', 'B2E', 'B2C'
-->
<targetCategory>B2E</targetCategory>
```

<targetCategory>

Since IBM MobileFirst Platform Foundation V7.1.0, you can declare the target category of your application. With this capability, you can generate more accurate license reports for the ADDRESSABLE DEVICE license metric. In the application-descriptor.xml file, the <targetCategory> element is added automatically when the application is created. By default, the target category is set to UNDEFINED. If your application is licensed under the ADDRESSABLE DEVICE metric, you must edit the <targetCategory> element to specify the relevant target category. The possible values are B2E for IBM MobileFirst Platform Foundation Enterprise, and B2C for IBM MobileFirst Platform Foundation Consumer.

```
</nativeAndroidApp>
```

</nativeAndroidApp>

This tag closes the content of the application descriptor file.

Client property file for Android

The w\client.properties file defines the properties that your native app for Android requires to use the MobileFirst native API for Android.

You must define these properties before you use the file in your native app for Android.

The following table lists the properties of the w\client.properties file, their descriptions, and possible examples for their values.

Table 8-17. Properties and values of the w\client.properties file

Property	Description	Example values
w\ServerProtocol	The communication protocol with the MobileFirst Server.	http or https
w\ServerHost	The host name of the MobileFirst Server.	localhost
w\ServerPort	The port of the MobileFirst Server. If you leave this value blank, the default port is used. If the w\ServerProtocol property value is https, you must leave this value blank.	10080

Table 8-17. Properties and values of the `wlclient.properties` file (continued)

Property	Description	Example values
<code>wlServerContext</code>	The server context.	/ Note: If you use IBM MobileFirst Platform Foundation Developer Edition, you must set the value of this property to the name of your MobileFirst project.
<code>wlAppId</code>	The application identifier, as defined in the <code>application-descriptor.xml</code> file.	myApp
<code>wlAppVersion</code>	The application version, as defined in the <code>application-descriptor.xml</code> file.	1.0
<code>wlEnvironment</code>	This property defines the MobileFirst environment. Its value must be <code>Androidnative</code> . Important: You must not modify the value of this property value.	Androidnative
<code>GCMsenderID</code>	This property defines the GCM sender identifier that you must use for push notifications. By default, this property is commented out.	
<code>languagePreferences</code>	This property defines a list of preferred languages, separated by comma, to be used by IBM MobileFirst Platform Foundation to display system messages.	en, fr, de, es
<code>TRUSTEER_AUTO_INIT</code>	When set to <code>false</code> , this property disables the default initialization of the Trusteer Mobile SDK for MobileFirst projects with Trusteer integration. For more information, see “Integrating IBM Trusteer for Android” on page 15-12.	false
<code>wlUId</code>	This property is for internal usage. You must not modify the value.	wY/mbnwKTDDYQVvuQCdSgg==

Methods of setting up your environment

You can prepare your environment for developing MobileFirst applications in either of two ways: by copying several files or by using Gradle with Android Studio.

You can get the IBM MobileFirst Platform Foundation for Android SDK framework and library files by copying them from your MobileFirst project that you created in MobileFirst Studio or with the MobileFirst Platform Command Line Interface. Or, you can get the framework and library files by installing the IBM MobileFirst Platform Foundation for Android SDK from Gradle.

Copying SDK and configuration files from the MobileFirst project:

To copy the files in the Native API application for Android into the project that defines the native app for Android

About this task

To use the MobileFirst Native API for Android in your native app, you must copy the library and the client property file of your Native API application into your native app for Android project.

Procedure

In your project for the native app for Android:

1. Copy the `worklight-android.jar` file, the `android-async-http.jar` file, the `bcprov.jar` file, and the `uicandroid.jar` file from the Native API application, and paste them into the `app/libs` folder of your native app for Android.
2. Copy the `wlclient.properties` client property file from the Native API application into the `assets` folder of your native app for Android. The `assets` folder is not created by default. To create the `assets` folder, right-click the app folder, and select **New > Folder > Asset Folder**.
3. If the push notification support is required:
 - a. Copy the `push.png` file from the Native API application.
 - b. In the `res` folder of your native app for Android, identify the folders with a name that starts with `drawable` (such as `res/drawable` or `res/drawable-ldpi`), and then paste the `push.png` file into each of these folders.
 - c. To set up Google Play Services in your Android project, see “Adding Google Play services to your Android project” on page 8-500.
4. Add the following lines to the `AndroidManifest.xml` file of your native app for Android:
 - a. `<activity android:name="com.worklight.wlclient.ui.UIActivity"/>` With this line, a designated MobileFirst UI activity can run in the user application.
 - b. `<uses-permission android:name="android.permission.INTERNET"/>` This line adds Internet access permissions to the user application.
 - c. `<uses-permission android:name="android.permission.GET_TASKS"/>` This line adds the permission to get a list of running tasks that are required for the heartbeat functionality. This permission is required if you are targeting your apps for Android API level 13 and earlier levels.
 - d. `<uses-permission android:name="android.permission.ACCESS_WIFI_STATE"/>`
5. If push notification support is required, add the following permissions to the `AndroidManifest.xml` file of your native app for Android:
 - a. `<uses-permission android:name="com.worklight.androidnativepush.permission.C2D_MESSAGE"/>`
 - b. `<uses-permission android:name="com.google.android.c2dm.permission.RECEIVE"/>`
 - c. `<uses-permission android:name="android.permission.WAKE_LOCK"/>`
 - d. `<uses-permission android:name="android.permission.GET_ACCOUNTS"/>`
 - e. `<uses-permission android:name="android.permission.USE_CREDENTIALS"/>`
 - f. `<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE"/>`
6. Optional: If `JSONStore` is required, copy the contents of the `jsonstore/assets/` and `jsonstore/libs/` folders into your application's `assets/` and `libs/` folders, respectively.

7. Manage your splash screens: In the res folder of your native app for Android, identify the folders with a name that starts with drawable (such as res/drawable or res/drawable-ldpi), and then:
 - a. If you want to use a splash screen in your app, you must create a splash.png file or splash.9.png file and place it in each of these folders.
 - b. If you do not want to use a splash screen in your app, ensure that no splash.png file or splash.9.png file is present in these folders.

Note: If you create a hybrid Android app, the splash.9.png file is automatically created. If you do not want to use the splash screen in your app, you must delete it from these drawable folders.

8. Optional: If app authenticity is required:
 - a. Create a new folder jniLibs inside the <project>/src/main/ folder.
 - b. Copy the armeabi, armeabi-v7a, mips, and x86 folders (subfolders of the Native API application folder) into the new jniLibs folder. These folders each contain a version of the libauthjni.so file.

Adding the IBM MobileFirst Platform Foundation SDK to a new or existing application with Android Studio:

Before you begin

Ensure that you set up Android Studio and the Android SDK properly. For more information about how to set up your system, see Android Studio Overview.

About this task

The official development environment for Android applications is now Android Studio. To develop a new IBM MobileFirst Platform Foundation native Android application with Android Studio, follow these steps to prepare your application to use the IBM MobileFirst Platform Foundation SDK.

Procedure

1. If you do not already have one, create an Android application in Android Studio.
2. Ensure that you have JCenter as one of the repositories that your application uses to look for dependencies. Edit the build.gradle file, usually at the root of the Android project, by adding jcenter() to the list of repositories in the allprojects{} closure.

```
allprojects {
  repositories {
    jcenter()
    // other repositories
  }
}
```

The following example shows a sample build.gradle file:

```
// Top-level build file where you can add configuration options common to all sub-projects/modules
buildscript {
  repositories {
    jcenter()
  }
  dependencies {
    classpath 'com.android.tools.build:gradle:1.1.3'
  }
}
```

```

allprojects {
    repositories {
        jcenter()
    }
}

```

The actual contents of your file can vary, depending on if you add other repositories or dependencies.

3. Edit the `build.gradle` file under your `app/module` to add the IBM MobileFirst Platform Foundation SDK to your compile scope dependencies. Add the following lines under your dependencies:

```

compile group: 'com.ibm.mobile.foundation',
        name: 'ibmmobilefirstplatformfoundation',
        version: '7.1.0.0',
        ext: 'aar',
        transitive: true

```

4. Add the following packaging options under your `android{}` closure in the `build.gradle` file:

```

packagingOptions {
    pickFirst 'META-INF/ASL2.0'
    pickFirst 'META-INF/LICENSE'
    pickFirst 'META-INF/NOTICE'
}

```

The following example shows the final `app/build.gradle` file:

```

apply plugin: 'com.android.application'
android {
    compileSdkVersion 22
    buildToolsVersion "21.1.2"

    defaultConfig {
        applicationId "com.ibm.test"
        minSdkVersion 10
        targetSdkVersion 22
        versionCode 1
        versionName "1.0"
    }

    buildTypes {
        release {
            minifyEnabled false
            proguardFiles getDefaultProguardFile('proguard-android.txt'), 'proguard-rules.pro'
        }
    }

    packagingOptions {
        pickFirst 'META-INF/ASL2.0'
        pickFirst 'META-INF/LICENSE'
        pickFirst 'META-INF/NOTICE'
    }

    dependencies {
        compile group: 'com.ibm.mobile.foundation',
                name: 'ibmmobilefirstplatformfoundation',
                version: '7.1.0.0',
                ext: 'aar',
                transitive: true

        // other dependencies
    }
}

```

5. Add a `wlclient.properties` file under the `app/src/main/assets` folder. Create the `assets` folder if it does not exist. This file is created when you deploy your native Android application to the MobileFirst Server and is in the same folder as the native Android application descriptor. For more information about the `wlclient.properties` file, see “Client property file for Android” on page 8-203.
6. Optional: If push notification is used, follow these steps.
 - a. Copy the `push.png` file from the Native API application.
 - b. In the `res` folder of your native app for Android, identify the folders with a name that starts with `drawable`, such as `res/drawable` or `res/drawable-ldpi`. Paste the `push.png` file into each of these folders.
 - c. For more information about how to set up Google Play Services in your Android project, see “Adding Google Play services to your Android project” on page 8-500.
7. Add the following lines to the `AndroidManifest.xml` file of your native app for Android:
 - `<activity android:name="com.worklight.wlclient.ui.UIActivity" />`
This line adds the ability for a designated MobileFirst UI activity to run in the user application.
 - `<uses-permission android:name="android.permission.INTERNET" />`
This line adds internet access permissions to the user application.
 - `<uses-permission android:name="android.permission.GET_TASKS" />`
This line adds the permission to get a list of running tasks that are used for the heartbeat functions.
 - `<uses-permission android:name="android.permission.ACCESS_WIFI_STATE" />`
This permission is required if you are targeting your apps for Android API level 13 and earlier.
8. Optional: If push notification support is used, add the following permissions to the `AndroidManifest.xml` file of your native app for Android.

```
<uses-permission android:name="com.worklight.androidnativepush.permission.C2D_MESSAGE" />
<uses-permission android:name="com.google.android.c2dm.permission.RECEIVE" />
<uses-permission android:name="android.permission.WAKE_LOCK" />
<uses-permission android:name="android.permission.GET_ACCOUNTS" />
<uses-permission android:name="android.permission.USE_CREDENTIALS" />
<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />
```
9. Optional: If app authenticity is required follow the following steps.
 - a. Copy the `armeabi`, `armeabi-v7a`, `mips`, and `x86` folders (subfolders of the Native API application folder) into the `app/libs` folder. These folders each contain a version of the `libauthjni.so` file.
 - b. Find the `build.gradle` file in the main project folder and add this to the `android` section: `sourceSets { main { jniLibs.srcDirs = ['libs'] } }`.
10. Rebuild your application.

Results

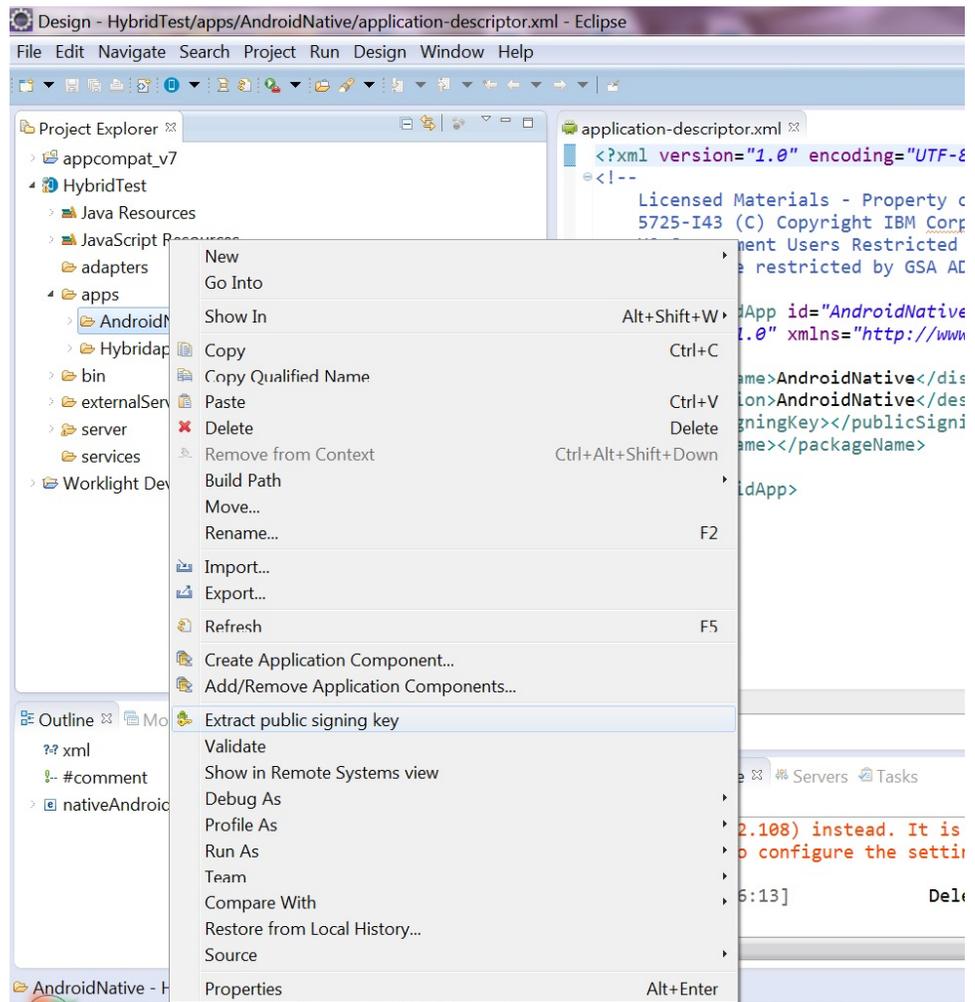

You can now start developing your native Android application with the IBM MobileFirst Platform Foundation SDK.

Extracting a public signing key from native apps

Copy the public signing key from the keystore to the application descriptor.

Procedure

1. In the Eclipse project explorer, right-click your Native API folder created for the Android environment and click **Extract public signing key**.

A wizard window opens.

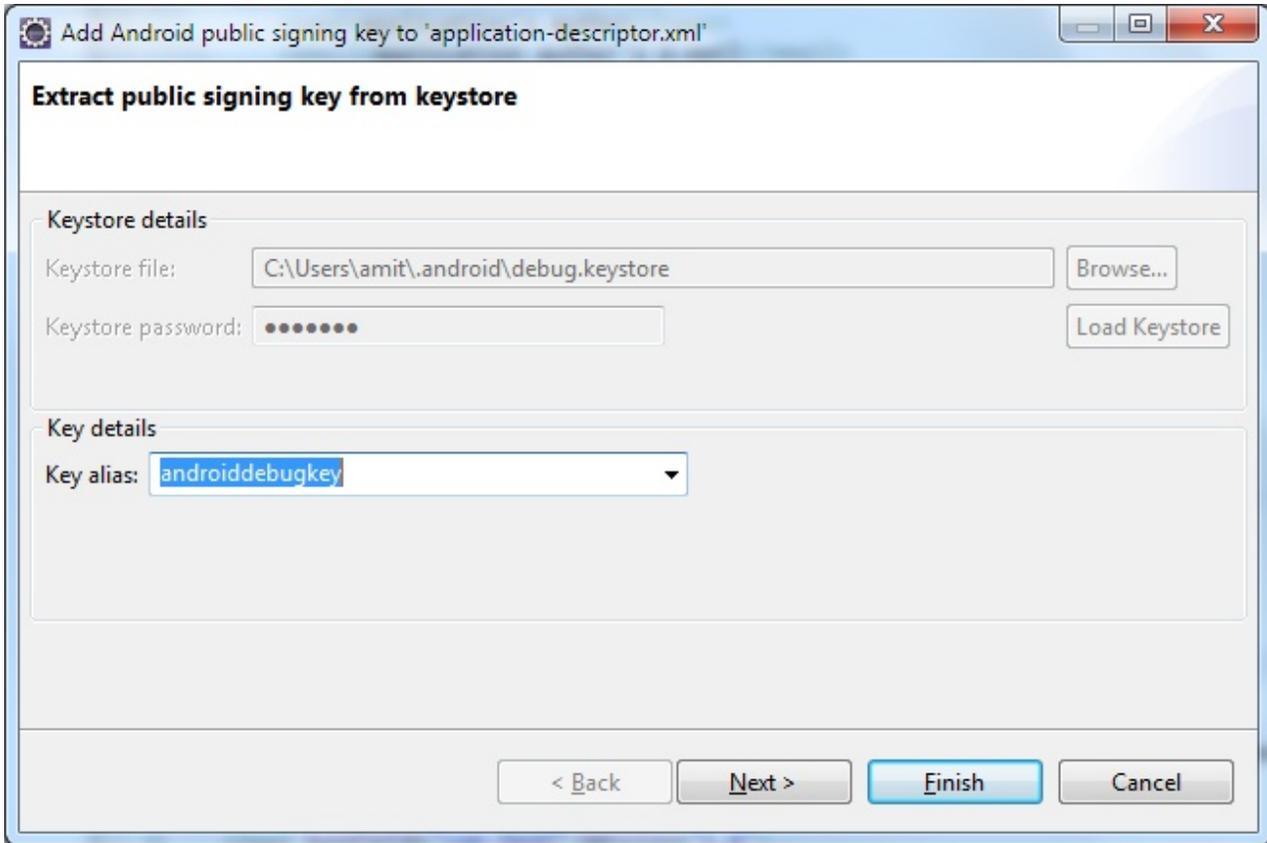

Figure 8-30. Adding the Android public signing key

- In this window, enter the path to your keystore. The keystore is usually in one of the following directories, according to operating system:

Option	Description
Windows	C:\Documents and Settings\user_name\ .android\
OS X and Linux	~/.android/

- Enter the password to your keystore and click **Load Keystore**.
The password is usually android.
- When the keystore is loaded, select an alias from the **Key alias** menu and click **Next**.
For more information about the Android keystore, see <http://developer.android.com/guide/publishing/app-signing.html>.
- In the window, click **Finish** to copy the public signing key directly into the application descriptor.

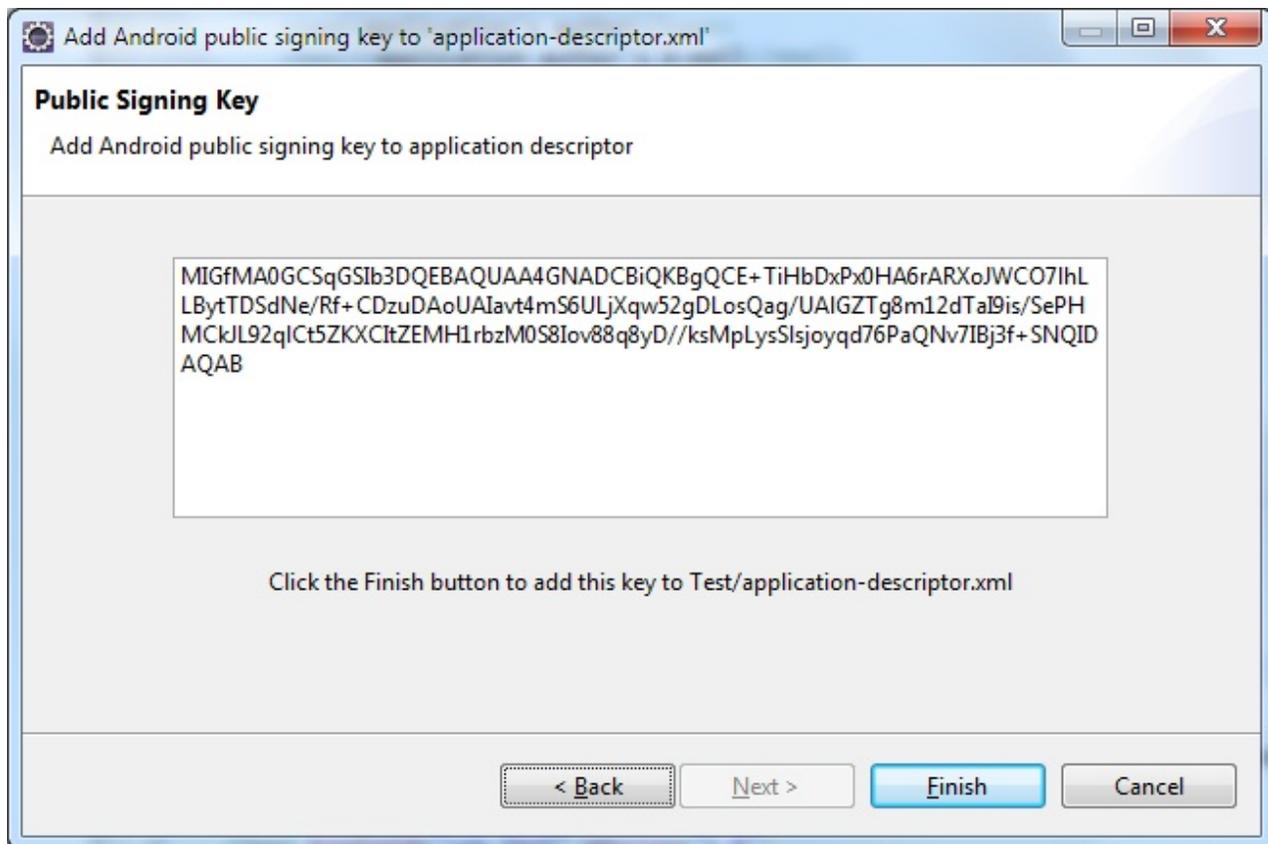

Figure 8-31. Android public signing key

Results

The public key is copied to the application descriptor. See the following code example:

```
<android version="1.0">
  <worklightSettings include="false"/>
  <security>
    <testAppAuthenticity enabled="false"/>
    <encryptWebResources enabled="false"/>
    <testWebResourcesChecksum enabled="false" ignoreFileExtensions="png, jpg, jpeg, gif, mp4, mp3"/>
    <publicSigningKey>MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQCE+TiHbDxPx0HA6rARXoJWC071hLLBytTDSdNe/>
  </security>
</android>
```

Developing native applications for Java Platform, Micro Edition

After you have created the native API application in MobileFirst Studio and added the complementary project from Eclipse IDE, you edit the application descriptor and client property files, and then copy the files to the appropriate project.

Application descriptor of native API applications for Java Platform, Micro Edition (Java ME)

The application descriptor is a metadata file that is used to define various aspects of the native API application for Java ME.

The application-descriptor.xml file, in the application root directory, is a metadata file that is used to define various aspects of the application.

The following example shows the format of the application descriptor file of native API applications for Java ME:

```
<?xml version="1.0" encoding="UTF-8"?>
<nativeJavaMEApp
  id="JavaME"
  platformVersion="6.0.0"
  version="1.0"
  securityTest="security test name"
  xmlns="http://www.worklight.com/native-javame-descriptor">
  <displayName>application display name</displayName>
  <description>application description</description>
  <licenseAppType>APPLICATION</licenseAppType> </nativeJavaMEApp>
```

The `<nativeJavaMEApp>` element is the root element of the descriptor. It takes three mandatory attributes and one optional attribute:

id This attribute specifies the identifier of the application. This identifier must be identical to the application folder name. It must be an alphanumeric string that starts with a letter. It can contain underscore (" _ ") characters. It must not be a reserved word in JavaScript.

platformVersion

Contains the version of IBM MobileFirst Platform Foundation on which the app was developed.

version

This attribute specifies the version of the application. This version is a string of the form `x.y`, where `x` and `y` are numbers. It is visible to users who download the app from the app store or market.

securityTest

This **optional** attribute specifies a security configuration that is defined in the `authenticationConfig.xml` file. When a client attempts to access a protected resource, IBM MobileFirst Platform Foundation checks whether the client is already authenticated according to the security test. If the client is not yet authenticated, IBM MobileFirst Platform Foundation starts the process to obtain the client credentials and to verify them.

<displayName>

This element contains the application name. This name is visible in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

```
<displayName>application display name</displayName>
```

<description>

This element contains the application description. This description is visible in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

```
<description>application description</description>
```

licenseAppType

Declares the application type for token licensing. This element is ignored if the MobileFirst Server does not have token licensing activated.

Possible values (values are case-sensitive; must be all uppercase):

- `NON_PRODUCTION`: Use this while you are developing and testing the application on the production server.

Important: Using `NON_PRODUCTION` for a production app is a breach of the license terms.

- **APPLICATION:** Use this for most applications when you are ready to deploy the app on a production server. This is the default. The production server must have token licensing activated, and enough tokens must be available.
- **ADDITIONAL_BRAND_DEPLOYMENT:** Use this when you are ready to deploy an additional brand deployment app on a production server. The app must be an additional brand deployment of an existing app for which an APPLICATION token has already been used. Your organization must have purchased an Additional Brand Deployment license for you to use this option. In addition, the code in the similar application must meet specific requirements such as the percentage of code that is different. Refer to your IBM MobileFirst Platform Foundation - Additional Brand Deployment software license for details.

The production server must have token licensing activated, and enough tokens must be available.

If token licensing is activated on the server and this element is not present in the application descriptor, then the default setting APPLICATION is used.

For more information, see “Licensing in MobileFirst Server” on page 2-16 and your IBM MobileFirst Platform Foundation software license.

```
<licenseAppType>APPLICATION</licenseAppType>
```

</nativeJavaMEApp>

This tag closes the content of the application descriptor file

```
</nativeJavaMEApp>
```

Client property file for Java Platform, Micro Edition (Java ME)

This file defines the properties that your native app for Java Platform, Micro Edition (Java ME) requires to use the MobileFirst native API for Java ME.

The `wlclient.properties` client property file contains the necessary data to use the MobileFirst API for Java ME.

You must define the properties of this client property file before using it in your native app for Java ME.

The following table lists the properties of the `wlclient.properties` file, their descriptions, and possible examples for their values.

Table 8-18. Properties and values of the `wlclient.properties` file

Property	Description	Example values
wlServerProtocol	The communication protocol with the MobileFirst Server.	http or https
wlServerHost	The host name of the MobileFirst Server.	localhost
wlServerPort	The port of the MobileFirst Server.	10080
wlServerContext	The server context.	/ Note: If you use IBM MobileFirst Platform Foundation Developer Edition, you must set the value of this property to the name of your MobileFirst project.
wlAppId	The application ID, as defined in the <code>application-descriptor.xml</code> file.	myApp

Table 8-18. Properties and values of the `wlclient.properties` file (continued)

Property	Description	Example values
<code>wlAppVersion</code>	The application version, as defined in the <code>application-descriptor.xml</code> file.	1.0
<code>wlEnvironment</code>	This property defines the MobileFirst environment. The value of this property must be <code>JavaMEnative</code> . You must not modify the value of this property value.	<code>JavaMEnative</code>
<code>languagePreference</code>	This property defines a list of preferred languages separated by comma, to be used by IBM MobileFirst Platform Foundation to display system messages.	en, fr, de, es

Copying files of Native API applications for Java Platform, Micro Edition (Java ME)

To copy the files in the Native API application for Java ME into the project that defines the app for Java ME.

About this task

To use the MobileFirst Native API for Java ME in your native app, you must copy the library and the client property file of your Native API application into your native app for Java ME project.

Procedure

1. Create a `lib` folder in your native Java ME application.

Note: You can name this folder differently. If you select a folder name other than `lib`, ensure that you use this folder name instead of `lib` in the following steps.

2. Make sure that the build path of your native Java ME application includes this `lib` folder.
3. Copy the `worklight-javame.jar` file of your Native API application into this `lib` folder of your native Java ME application.
4. Copy the `json4javame.jar` file of your Native API application into this `lib` folder of your native Java ME application.
5. Copy the `wlclient.properties` file of your Native API application into the `res` folder of your native Java ME application.

Developing native C# applications for Windows Phone Silverlight 8

After you have created the native API application in MobileFirst Studio and added the complementary Visual Studio Express project, you edit the application descriptor and client property files, and then copy the files to the appropriate project.

Application descriptor of native C# API application for Windows Phone Silverlight 8

The application descriptor is a metadata file that is used to define various aspects of the native C# API application for Windows Phone Silverlight 8.

The application-descriptor.xml file, in the application root directory, is a metadata file that is used to define various aspects of the application.

The following example shows the format of the application descriptor file of native C# API applications for Windows Phone Silverlight 8:

```
<?xml version="1.0" encoding="UTF-8"?>
<nativeWindowsPhone8App
  xmlns="http://www.worklight.com/native-windowsphone8-descriptor">
  id="WP8"
  platformVersion="6.2.0"
  version="1.0"
  <displayName>application display name</displayName>
  <description>application description</description>
  <licenseAppType>APPLICATION</licenseAppType>
  <pushSender>
    <authenticatedPush serviceName="MPNS Service name" keyAlias="certificate alias"
    keyAliasPassword="certificate password"/>
  </pushSender>
  <tags>
    <tag>
      <name>tag1</name>
      <description>tag description for tag1</description>
    </tag>
    <tag>
      <name>tag2</name>
      <description>tag description for tag2</description>
    </tag>
  </tags>
  <!--
  Define the target category for generating ADDRESSABLE DEVICE license reports
  Possible values are 'UNDEFINED', 'B2E', 'B2C'
  -->
  <targetCategory>B2E</targetCategory>
</nativeWindowsPhone8App>
```

The <nativeWindowsPhone8App> element is the root element of the descriptor. This element has three mandatory attributes:

id This attribute specifies the identifier of the application. The identifier must be identical to the application folder name. It must be an alphanumeric string that starts with a letter. It can contain underscore ("_") characters. It must not be a reserved word in C# or JavaScript.

platformVersion

This attribute contains the version of IBM MobileFirst Platform Foundation on which the app was developed.

version

This attribute specifies the version of the application. This version is a string of the form x.y, where x and y are numbers. It is visible to users who download the app from the app store or market.

<displayName>

This element contains the application name. This name is visible in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

```
<displayName>application display name</displayName>
```

<description>

This element contains the application description. This description is visible in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

```
<description>application description</description>
```

licenseAppType

Declares the application type for token licensing. This element is ignored if the MobileFirst Server does not have token licensing activated.

Possible values (values are case-sensitive; must be all uppercase):

- **NON_PRODUCTION**: Use this while you are developing and testing the application on the production server.

Important: Using **NON_PRODUCTION** for a production app is a breach of the license terms.

- **APPLICATION**: Use this for most applications when you are ready to deploy the app on a production server. This is the default. The production server must have token licensing activated, and enough tokens must be available.
- **ADDITIONAL_BRAND_DEPLOYMENT**: Use this when you are ready to deploy an additional brand deployment app on a production server. The app must be an additional brand deployment of an existing app for which an **APPLICATION** token has already been used. Your organization must have purchased an Additional Brand Deployment license for you to use this option. In addition, the code in the similar application must meet specific requirements such as the percentage of code that is different. Refer to your IBM MobileFirst Platform Foundation - Additional Brand Deployment software license for details.

The production server must have token licensing activated, and enough tokens must be available.

If token licensing is activated on the server and this element is not present in the application descriptor, then the default setting **APPLICATION** is used.

For more information, see “Licensing in MobileFirst Server” on page 2-16 and your IBM MobileFirst Platform Foundation software license.

```
<licenseAppType>APPLICATION</licenseAppType>
```

<pushSender>

This element indicates to the MobileFirst Server that the app is designed to receive push notifications. It also contains information necessary to provide to MPNS for sending authenticated push notifications.

```
<pushSender>
```

<authenticatedPush>

```
<authenticatedPush serviceName="MPNS Service name" keyAlias="certificate alias" keyAliasPassword="certificate password"/>
```

This element has three attributes:

serviceName

The common name (CN) found in the subject value of the MPNS certificate.

keyAlias

The alias that is used to access the keystore as specified by the following properties in the `worklight.properties` file:

- **ssl.keystore.path**
- **ssl.keystore.type**
- **ssl.keystore.password**

keyAliasPassword

The password for your key alias.

<tags>

This element defines the tags that are used for tag-based notifications. For more information, see “Setting up Tag-based notifications” on page 8-513.

```
<tags>
  <tag>
    <name>tag1</name>
    <description>tag description for tag1</description>
  </tag>
  ...
</tags>
```

<targetCategory>

Since IBM MobileFirst Platform Foundation V7.1.0, you can declare the target category of your application. With this capability, you can generate more accurate license reports for the ADDRESSABLE DEVICE license metric. In the application-descriptor.xml file, the <targetCategory> element is added automatically when the application is created. By default, the target category is set to UNDEFINED. If your application is licensed under the ADDRESSABLE DEVICE metric, you must edit the <targetCategory> element to specify the relevant target category. The possible values are B2E for IBM MobileFirst Platform Foundation Enterprise, and B2C for IBM MobileFirst Platform Foundation Consumer.

```
<!--
Define the target category for generating ADDRESSABLE DEVICE license reports
Possible values are 'UNDEFINED', 'B2E', 'B2C'
-->
<targetCategory>B2E</targetCategory>
```

</nativeWindowsPhone8App>

This tag closes the content of the application descriptor file.

```
</nativeWindowsPhone8App>
```

Client property file for Windows Phone Silverlight 8

This file defines the properties that your native C# app for Windows Phone Silverlight 8 requires to use the MobileFirst native C# API for Windows Phone Silverlight 8.

The `wlclient.properties` client property file contains the necessary data to use the MobileFirst API for Windows Phone Silverlight 8.

You must define the properties of this client property file before you use it in your native C# app for Windows Phone Silverlight 8.

The following table lists the properties of the `wlclient.properties` file, their descriptions, and possible examples for their values.

Table 8-19. Properties and values of the `wlclient.properties` file

Property	Description	Example values
<code>wlServerProtocol</code>	The communication protocol with the MobileFirst Server.	http or https
<code>wlServerHost</code>	The host name of the MobileFirst Server.	localhost
<code>wlServerPort</code>	The port of the MobileFirst Server. If you leave this value blank, the default port is used. If the <code>wlServerProtocol</code> property value is https, you must leave this value blank.	10080

Table 8-19. Properties and values of the `wlclient.properties` file (continued)

Property	Description	Example values
<code>wlServerContext</code>	The server context.	/ Note: If you use IBM MobileFirst Platform Foundation Developer Edition, you must set the value of this property to the name of your MobileFirst project.
<code>wlAppId</code>	The application id, as defined in the <code>application-descriptor.xml</code> file.	myApp
<code>wlAppVersion</code>	The application version, as defined in the <code>application-descriptor.xml</code> file.	1.0
<code>wlEnvironment</code>	This property defines the MobileFirst environment. The value of this property must be <code>WindowsPhone8native</code> . You must not modify the value of this property.	WindowsPhone8native
<code>wlMPNSServiceName</code>	The service name to be used for authenticated push as specified in the application descriptor. For more information, see “Application descriptor of native C# API application for Windows Phone Silverlight 8” on page 8-214.	MyServiceName
<code>languagePreferences</code>	This property defines a list of preferred languages separated by comma, to be used by IBM MobileFirst Platform Foundation to display system messages.	en, fr, de, es

Copying files of Native API applications for Windows Phone Silverlight 8

To copy the files in the Native C# API application for Windows Phone Silverlight 8 into the project that defines the native C# app for Windows Phone Silverlight 8.

About this task

To use the MobileFirst Native C# API for Windows Phone Silverlight 8 in your native C# app, you must copy the library and the client property file of your Native C# API application into your native C# app for Windows Phone Silverlight 8 project.

Procedure

In your Microsoft Visual Studio project for the native C# app for Windows Phone Silverlight 8:

1. Add the Arm or x86 based `worklight-windowsphone8.dll` file as a reference to your Visual Studio project. The `worklight-windowsphone8.dll` file defines the MobileFirst native library.

Note: You can edit `<appName>.csproj` file to add the reference. For example:

```
<ItemGroup>
  <Reference Include="worklight-windowsphone8">
    <HintPath>.\buildtarget\$(Platform)\worklight-windowsphone8.dll</HintPath>
  </Reference>
</ItemGroup>
```

2. Add the `Newtonsoft.Json.dll` file as a reference to your Visual Studio Project. The `Newtonsoft.Json.dll` library is required for using JSON objects in C#.
3. Copy the `wlclient.properties` client property file from the Native C# API application, and paste it into your Visual Studio project.
4. Right-click the `wlclient.properties` file and select **Properties**.
5. In the **Properties** window, set the **Copy to Output Directory** option to **Copy always**.
6. Add the following capabilities to the `WMAppManifest.xml` file of your Windows Phone Silverlight 8 Visual Studio project:
 - a. `ID_CAP_NETWORKING`
 - b. `ID_CAP_IDENTITY_DEVICE`
 - c. `ID_CAP_PUSH_NOTIFICATION`, if the native app is used for push notifications.

Developing native C# applications for Windows 8 Universal and Windows Phone 8 Universal

After you have created the native API application in MobileFirst Studio and added the complementary Visual Studio Express project, you edit the application descriptor and client property files, and then copy the files to the appropriate project.

When you create native API applications, you can choose to create a Windows 8 Universal environment that supports either desktops and tablets or phones. The contents of the associated application descriptor file reflect your choice.

Application Descriptor of native C# API application for Windows 8 Universal and Windows Phone 8 Universal

The application descriptor is a metadata file that is used to define various aspects of the native API application for Windows 8 Universal and Windows Phone 8 Universal.

The application descriptor is a metadata file that is used to define various aspects of the application. It is in the application root directory, and its name is `application-descriptor.xml`.

The following example shows the format of the application descriptor file of native API applications for Windows 8 Universal:

```
<?xml version="1.0" encoding="UTF-8"?>
<nativeWindows8App
  xmlns="http://www.worklight.com/native-windows8-descriptor"
  id="name of the app"
  platformVersion="6.2.0"
  version="1.0">
  <displayName>application display name</displayName>
  <description>application descriptor</description>
  <licenseAppType>APPLICATION</licenseAppType>
  <packageName>e01bb27d-dade-4e87-a197-e3b7846c1b86_zvqh5c8ea4de8</packageName>
  <pushSender clientSecret="wms secret key" packageSID="wms unique identifier"/>
  <tags>
    <tag>
      <name>tag1</name>
      <description>tag description for tag1</description>
    </tag>
    <tag>
      <name>tag2</name>
      <description>tag description for tag2</description>
    </tag>
  </tags>
</nativeWindows8App>
```

```

<!--
Define the target category for generating ADDRESSABLE DEVICE license reports
Possible values are 'UNDEFINED', 'B2E', 'B2C'
-->
<targetCategory>B2E</targetCategory>
</nativeWindows8App>

```

The `<nativeWindows8App>` element is the root element of the descriptor for desktop and tablet Universal applications. The `<nativeWindowsPhoneUniversalApp>` element is the root element of the descriptor for phone Universal applications. The root element has three mandatory attributes:

id This attribute specifies the ID of the application. The ID must be identical to the application folder name. It must be an alphanumeric string that starts with a letter. It can contain underscore ("_") characters. It must not be a reserved word in JavaScript.

platformVersion

This attribute contains the version of IBM MobileFirst Platform Foundation on which the app was developed.

version

This attribute specifies the version of the application. This version is a string of the form x.y, where x and y are numbers. It is visible to users who download the app from the app store or market.

```
<displayName>application display name</displayName>
```

<displayName>

This element contains the application name. This name is visible in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

```
<description>application description</description>
```

<description>

This element contains the application description. This description is visible in the MobileFirst Operations Console and is copied to the descriptor files of various web and desktop environments.

```
<packageName>e01bb27d-dade-4e87-a197-e3b7846c1b86_zvqh5c8ea4de8</packageName>
```

```
<licenseAppType>APPLICATION</licenseAppType>
```

<licenseAppType>

Declares the application type for token licensing. This element is ignored if the MobileFirst Server does not have token licensing activated.

Possible values (values are case-sensitive; must be all uppercase):

- NON_PRODUCTION: Use this while you are developing and testing the application on the production server.

Important: Using NON_PRODUCTION for a production app is a breach of the license terms.

- APPLICATION: Use this for most applications when you are ready to deploy the app on a production server. This is the default. The production server must have token licensing activated, and enough tokens must be available.
- ADDITIONAL_BRAND_DEPLOYMENT: Use this when you are ready to deploy an additional brand deployment app on a production server. The app must be an additional brand deployment of an existing app for which an APPLICATION token has already been used. Your organization must have

purchased an Additional Brand Deployment license for you to use this option. In addition, the code in the similar application must meet specific requirements such as the percentage of code that is different. Refer to your IBM MobileFirst Platform Foundation - Additional Brand Deployment software license for details.

The production server must have token licensing activated, and enough tokens must be available.

If token licensing is activated on the server and this element is not present in the application descriptor, then the default setting APPLICATION is used.

For more information, see “Licensing in MobileFirst Server” on page 2-16 and your IBM MobileFirst Platform Foundation software license.

Note: Token licensing, as defined by <licenseAppType> is not related to Oauth access tokens, as defined by <accessTokenExpiration>.

<packageName>

This element contains the package family name as it is available in the packaging tab of the Package.appxmanifest file of your Visual Studio Windows Universal project. In addition to the security test that have the <testAppAuthenticity> tag, this tag should be present in the application-descriptor.xml.

```
<pushSender clientSecret="wms secret key" packageSID="wms unique identifier"/>
```

<pushSender>

This element contains the connectivity details to Windows Push Notification Service (WNS). The **packageSID** is the unique identifier of the Windows Store app, and the **clientSecret** is the secret key.

```
<tags>
  <tag>
    <name>tag1</name>
    <description>tag description for tag1</description>
  </tag>
  ...
</tags>
```

<tags>

This element defines the tags that are used for tag-based notifications. For more information, see “Setting up Tag-based notifications” on page 8-513.

```
<!--
Define the target category for generating ADDRESSABLE DEVICE license reports
Possible values are 'UNDEFINED', 'B2E', 'B2C'
-->
<targetCategory>B2E</targetCategory>
```

<targetCategory>

Since IBM MobileFirst Platform Foundation V7.1.0, you can declare the target category of your application. With this capability, you can generate more accurate license reports for the ADDRESSABLE DEVICE license metric. In the application-descriptor.xml file, the <targetCategory> element is added automatically when the application is created. By default, the target category is set to UNDEFINED. If your application is licensed under the ADDRESSABLE DEVICE metric, you must edit the <targetCategory> element to specify the relevant target category. The possible values are B2E for IBM MobileFirst Platform Foundation Enterprise, and B2C for IBM MobileFirst Platform Foundation Consumer.

```
</nativeWindows8App>
```

</nativeWindows8App>

This tag closes the content of the application descriptor file for desktop and tablet Universal applications.

</nativeWindowsPhoneUniversalApp>

This tag closes the content of the application descriptor file for phone Universal applications.

Client property file for Windows 8 Universal and Windows Phone 8 Universal

This file defines the properties that your native app for Windows 8 Universal requires to use the MobileFirst native API for Windows 8 Universal.

The `wlclient.properties` client property file contains the necessary data to use the MobileFirst API for Windows 8 Universal.

You must define the properties of this client property file before you use it in your native app for Windows 8 Universal.

The following table lists the properties of the `wlclient.properties` file, their descriptions, and possible examples for their values.

Table 8-20. Properties and values of the `wlclient.properties` file

Property	Description	Example values
wlServerProtocol	The communication protocol with the MobileFirst Server.	http or https
wlServerHost	The host name of the MobileFirst Server.	localhost
wlServerPort	The port of the MobileFirst Server. If you leave this value blank, the default port is used. If the wlServerProtocol property value is https, you must leave this value blank.	8080
wlServerContext	The server context, which is automatically generated.	/
wlAppId	The application id, as defined in the <code>application-descriptor.xml</code> file.	myApp
wlAppVersion	The application version, as defined in the <code>application-descriptor.xml</code> file.	1.0
wlEnvironment	This property defines the MobileFirst environment. You must not modify the value of this property.	Windows8native
wlPlatformVersion	This property defines the version number of the IBM MobileFirst Platform Foundation.	7.1.0.00.20150613-0730

Copying files of native API applications for Windows 8 Universal and Windows Phone 8 Universal

To copy the files in the native API application for Windows 8 Universal into the project that defines the native app for Windows 8 Universal.

About this task

To use the MobileFirst native API for Windows 8 Universal in your native app, you must copy the library and the client property file of your native API

application into your native app for Windows 8 Universal project.

Procedure

In your Microsoft Visual Studio project for the native C# app for Windows 8 Universal:

1. In the native API project, locate the `worklight-windows8.dll` file appropriate to the architecture (ARM, x86 or x64) of your device. The `worklight-windows8.dll` file defines the MobileFirst native library. You can find the `worklight-windows8.dll` file in the `buildtarget/<platform>` folder. Add it as a reference to your Visual Studio project.
2. Similarly, add the `Newtonsoft.Json.dll`, `AuthWinRT.dll`, and `sharpcompress.dll` files as a reference to the Visual Studio Project. If you are copying these files from another folder or computer, ensure that you copy the `worklight-windows8.pri` file and place it in the same folder as `worklight-windows8.dll`.
 - The `Newtonsoft.Json.dll` is a library that is required for using JSON objects in C# .
 - The `AuthWinRT.dll` is a library that is used by the Windows 8 Universal native API when application authenticity is enabled on the MobileFirst Server.
 - The `sharpcompress.dll` library is used to decompress the response that is received from the server in compressed form.
 - The `worklight-windows8.pri` file contains the static localized strings (user facing and non-user facing).
3. Copy the `wlclient.properties` client property file from the native API application into your Visual Studio project. Right-click the `wlclient.properties` file and click **Properties**. In the **Properties** window, set the **Copy to Output Directory** option to Copy always.
4. In your Visual Studio IDE, open the `Package.appxmanifest` file of your Windows 8 Universal project. Navigate to the **Capabilities** tab and select the following capabilities:
 - a. **Internet (Client & Server)**
 - b. **Private Networks (Client & Server)**
5. Optional: To enable push notification support, follow these steps.
 - a. The **Name** attribute and **Publisher** attribute of the `<Identity>` element must be set manually in the package manifest. You can also associate your Windows 8 Universal project with the application in the Windows Store by right-clicking on the project and selecting **Store > Associate App** with the store. For more information, see “Setting up push notifications for Windows 8 Universal and Windows Phone 8 Universal” on page 8-506.
 - b. To support toast notification for your app, add the attribute **ToastCapable="true"** to the `<VisualElements>` element in the package manifest.

```
<Applications>
  <Application Id="App" StartPage="www\default\index.html">
    <VisualElements .. ... ToastCapable="true">
      ....
    </VisualElements>
  </Application>
</Applications>
```
6. Optional: If your app uses the application authenticity or extended authenticity feature, you must add either Microsoft Visual C++ 2013 Runtime Package for

Windows or Microsoft Visual C++ 2013 Runtime Package for Windows Phone as a reference to your app. To do so, in Visual Studio, right-click on the references of your native project and complete one of the following choices depending on which environment you added to your native API app:

- (Desktops and tablets): Click **Add reference > Windows 8.1 > Extensions > Microsoft Visual C++ 2013 Runtime Package for Windows**, and then click **OK**.
 - (Phones): Click **Add reference > Windows 8.1 > Extensions > Microsoft Visual C++ 2013 Runtime Package for Windows Phone**, and then click **OK**.
7. Optional: For enabling or disabling adapter response compression, add the optional boolean parameter **compressresponse** when you call an adapter. For example,

```
WLProcedureInvocationData invocationData = new WLProcedureInvocationData("myAdapterName", "myProc
```

or

```
//To enable data compression  
WLProcedureInvocationData invocationData = new WLProcedureInvocationData("myAdapterName", "myProc
```

For more information about `WLProcedureInvocationData` class, see “C# client-side API for Windows 8 Universal and Windows Phone 8 Universal apps” on page 11-7.

Adding MobileFirst web capabilities to an existing native app

You can add a MobileFirst web view into an existing native Android, iOS, or Windows Phone Silverlight 8 application. For example, you can transform the application from pure native to hybrid. With such a change, you can add MobileFirst web capabilities to an existing native application.

About this task

To add MobileFirst web capabilities to an existing native app:

1. Export the corresponding resources from an existing MobileFirst project.
2. Integrate those resources into your native app and update your code to show a MobileFirst web view.

Procedure

1. Using either the Eclipse plug-in or the command-line interface, export the corresponding resources from an existing MobileFirst hybrid project.

Note: When first adding the web view to a native app, you must select the option to export the native libraries. Subsequent exports do not need to include these libraries and will result in much smaller archives.

- **With MobileFirst Studio:**
 - a. Ensure that the latest resources are built.
 - b. Right-click **Run As: Build Environment**.
 - c. Right-click the environment directory. For example, right-click **iphone**, **android**, or **windowsphone8**.
 - d. Select **Export MobileFirst Hybrid Resources**.
 - e. Specify the location in which to create the `.zip` file archive. For example, `hybrid_resources.zip`.
- **With MobileFirst Platform Command Line Interface:**

- a. Change the directory to the environment directory. For example: `cd apps/myhybridapp/android`
 - b. Make sure that the latest resources are built. For example: `mfp build`
 - c. Run the `mfp export` command.
 - d. Specify the name and location where to create the `.zip` archive. For example: `hybrid_resources.zip`
2. Integrate the hybrid resources into the native application to show a MobileFirst web view. Here are the steps for Android, iOS, and Windows Phone Silverlight 8 devices.
- **For Android devices:**
 - a. For Android devices, extract the archive, for example `hybrid_resources.zip` file, to the native Android project.
 - b. If you are using the Android Native API, some files might need to be replaced, such as the libraries (`lib/*.jar`) and the client properties (`assets/wlclient.properties`).
 - c. When you are extracting the file, if your application contains a file with the same path name as provided by the MobileFirst hybrid archive, merge the contents of the two files such as `res/` and `values/strings.xml`.
 - d. Update the `AndroidManifest.xml` file for your native Android application with the contents of the `AndroidManifest-WL.xml` file, which is provided in the MobileFirst hybrid archive.
 - e. If you are using Android Studio, take into account that the project directory might differ from the Eclipse ADT. Extract the MobileFirst hybrid archive content to the `app/libs` directory for libraries and the `app/src/main/` directory for assets and resources.
 - f. Update your code to initialize the MobileFirst Web Framework and show a Cordova web view. See the sample in “Implementing a custom startup process in Android-based hybrid applications” on page 8-68.
 - **For iOS devices:**
 - a. If the `WorklightAPI` and `worklight.plist` files are in your iOS native project, delete them.
 - b. Extract the MobileFirst hybrid resources contents from the archive, for example the `hybrid_resources.zip` file, into the directory that contains your iOS native project where the `.xcodeproj` file is located.
 - c. Add the Cordova subproject to the native application:
 - 1) Right-click **Project Navigator - Add Files to Xcode_project_name**.
 - 2) Select **CordovaLib/CordovaLib.xcodeproj**.
 - 3) Select **Copy items into destination group's folder (if needed)**.
 - 4) Select **Create groups for any added folders**.
 - d. Add the MobileFirst files to the native application:
 - 1) Right-click **Project Navigator - Add Files to Xcode_project_name**.
 - 2) Select the following files and directories:

```

buildtime.sh
config.xml
FipsHttp
Frameworks/
Resources/
Tealeaf/
worklight.plist
WorklightSDK

```
 - 3) Select **Copy items into destination group's folder (if needed)**.

- 4) Select **Create groups for any added folders**.
- e. Add the web assets to the native application:
 - 1) Right-click **Project Navigator - Add Files to Xcode_project_name**.
 - 2) Select **www/**.
 - 3) Select **Copy items into destination group's folder (if needed)**.
 - 4) Select **Create groups for any added folders**.
- f. Add the Cordova library as a build dependency:
 - 1) Select **Target**.
 - 2) Select **Build Phases**.
 - 3) Under **Target Dependencies**, add **CordovaLib**.
- g. Add the Cordova library dependency, which is **libCordova.a**.
- h. Add **Run Script Before Copy Bundle Resources**.
- i. Add **Run Script as last Phase**.
- j. Select **Editor > Add Build Phase > Add Run Script Build Phase**.
- k. Open a shell. At the command prompt, type:

```

/bin/sh
touch -cm ${PROJECT_DIR}/www
      
```
- l. Add **Run Script After Copy Bundle Resources**.
- m. Select **Editor > Add Build Phase > Add Run Script Build Phase**.
- n. Open a shell. At the command prompt, type:

```

/bin/sh
script_file="builddtime.sh"
echo "Running a custom build phase script: $script_file"
unsecure_project_path=${PROJECT_DIR}
secure_project_path="${unsecure_project_path// /\ }"
eval "${secure_project_path}/${script_file}"
scriptExitStatus=$?
echo "DONE with script: ${script_file} (exitStatus=${scriptExitStatus})\n\n"
exit "${scriptExitStatus}"
      
```
- o. Add Linker flag to link the external dependencies:
 - 1) Select **Target**.
 - 2) Click **Build Settings**.
 - 3) Expand **Linking** and select **All**.
 - 4) Double-click the value for **Other Linker Flags**.

Tip: Use the search box to filter the list.
 - 5) Copy and paste the following code:

```

-force_load
"${BUILT_PRODUCTS_DIR}/libCordova.a"
-ObjC
          
```
- p. Check the **armv7** architecture.
 - 1) Select **Project**.
 - 2) Click **Build Settings**.
 - 3) Expand the **Architectures** section.
 - 4) Click a value for **Architectures**.
 - 5) Select **Other**.
 - 6) Remove **Standard architectures (including 64-bit)** or **\$ARCHS_STANDARD_INCLUDING_64_BIT**.
 - 7) Add **armv7**.

- q. Verify that the following libraries and frameworks are referenced:

```
AddressBook.framework
AddressBookUI.framework
AssetsLibrary.framework
AudioToolbox.framework
AVFoundation.framework
CFNetwork.framework
CoreData.framework
CoreGraphics.framework
CoreLocation.framework
CoreMedia.framework
CoreMotion.framework
CoreTelephony.framework
Foundation.framework
ImageIO.framework
MediaPlayer.framework
MobileCoreServices.framework
Security.framework
SystemConfiguration.framework
QuartzCore.framework
UIKit.framework
libz.dylib
libstdc++.6.dylib
```

- r. Update your code to initialize the MobileFirst web framework and show a Cordova web view. See the sample in “Implementing a custom startup process for iOS-based hybrid applications” on page 8-62.

• **For Windows Phone Silverlight 8 devices:**

- a. Extract the hybrid resources, for example the hybrid_resources.zip file, into a directory, such as WP8HybridResources.
- b. Add the hybrid resources to the native application by completing the following steps:
- 1) Open the native application in Visual Studio.
 - 2) Add the www directory to the native application.
 - 3) Add the config.xml file to the native application.
 - 4) Add the worklight.xml file to the native application properties.
 - 5) Add the wlclient.properties file to the native application.
 - 6) Copy the WP8Hybridresources/buildtarget directory to the native application root directory.
 - 7) Add the WLCordovaClassLib.dll file to the native application.
 - 8) Add the NewtonSoft.Json.dll file to the native application.
 - 9) Open the *native_application.csproj* file, which is the Visual Studio project file for the native application.

```
<ItemGroup>
  <Reference Include="WLWPNativeLib.dll">
    <HintPath>buildtarget\$(Platform)\WLWPNativeLib.dll</HintPath>
  </Reference>
  <Reference Include="WLCordovaClassLib.dll">
    <HintPath>.\WLCordovaClassLib.dll</HintPath>
  </Reference>
  <Reference Include="NewtonSoft.Json.dll">
    <HintPath>.\NewtonSoft.Json.dll</HintPath>
  </Reference>
</ItemGroup>
```

Note: This step adds the DLL references to the project.

- c. Update the capabilities from the hybrid application:

- 1) From the native application in Visual Studio, open **Native App > Properties > WMAAppManifest.xml**.
 - 2) Add the missing capabilities, which are part of the WP8HybridResources/Properties/WMAAppManifest.xml file.
- d. Create a page and copy the contents from the hybrid application:
- 1) Add a page from native project in Visual Studio.
 - 2) Right-click the native project and select **Add > New Item > Windows phone portrait page**.
 - 3) Provide a name for the page. For the sake of this procedure, consider that the page name is: HybridPage.xaml
- e. Open the new HybridPage.xaml page, and remove the existing Grid XML content.
- f. Open the WP8HybridResources/MainPage.xaml page in a text editor.
- g. Copy the Grid XML section and paste it into the new HybridPage.xaml page. The following code shows the new grid XML section:
- ```
<Grid x:Name="LayoutRoot" Background="Transparent">
 <Grid.RowDefinitions>
 <RowDefinition Height="*" />
 </Grid.RowDefinitions>
 <my:CordovaViewHorizontalAlignment="Stretch"
 Margin="0,0,0,0"
 x:Name="CordovaView"
 VerticalAlignment="Stretch"
 StartPageUri="/www/skinLoader.html" />
</Grid>
```
- h. Copy the xmlns:mytag from the WP8HybridResources/Mainpage.xaml file to the HybridPage.xaml page for the phone tag. For example:
- ```
xmlns:my="clr-namespace:WPCordovaClassLib;
assembly=WPCordovaClassLib"
```
- i. Open the App.xaml.cs file of the native application in Visual Studio.
- j. In the App constructor method, after the line InitializePhoneApplication method, add the following code to initialize the native library:
- ```
new WPNativeLib.Initializer();
new HybridPluginInitializer.Initializer();
```
- k. Open the HybridPage.xaml.cs file of the native application in Visual Studio.
- l. After the constructor, add the following method:
- ```
voidCordovaView_Loaded(object sender, RoutedEventArgs e){
}
```
- m. Open the hybrid page from the native application.
- n. Add a button in the native application.
- o. For the Click method, write the following code to open the hybrid page:
- ```
NavigationService.Navigate(new Uri("/HybridPage.xaml", UriKind.Relative));
```
- p. Open the HybridPage.xaml.cs file inside the default construction and add the following entry:
- ```
WL.CreateInstance(); //create the instance of the ActionSender API
```

Note: Select your target architecture, such as “x86” or “ARM”, but not “Any CPU”.

- q. If you use the JSONStore feature from the JavaScript API on Windows Phone Silverlight 8, follow the next steps:

- 1) Open the *native_application.csproj* file, which is the Visual Studio project file for the native application.
- 2) Copy the following XML code into this project file:

```
<ItemGroup>
  <Content Include="buildtarget\$(Platform)\sqlite3.dll">
    <Link>sqlite3.dll</Link>
    <CopyToOutputDirectory>Always</CopyToOutputDirectory>
  </Content>
  <Reference Include="JSONStoreWP8Lib">
    <HintPath>buildtarget\$(Platform)\JSONStoreWP8Lib.dll</HintPath>
  </Reference>
</ItemGroup>
```

- 3) In Visual Studio, open the *App.xaml.cs* file of the native application.
- 4) In the *App* constructor method, after the *new WPNativeLib.Initializer()* line, add the following code to initialize the *JSONStore* library:

```
new JSONStoreWP8Lib.Initializer();
```

Token licensing: setting the license app type

Set the license application type for your app if your MobileFirst Server uses token licensing.

About this task

If the server on which you are deploying your MobileFirst app has or will have token licensing activated, you must set the license application type so that the correct number of license tokens are used.

You can set the license app type by using the command line, by using MobileFirst Studio, or by manually editing the *application-descriptor.xml* file. The license application type must be one of the following values:

- **NON_PRODUCTION:** Use this value while you are developing and testing the application on the production server.

Important: Using **NON_PRODUCTION** for a production app is a breach of the license terms.

- **APPLICATION:** Use this value for most applications when you are ready to deploy the app on a production server. This is the default value. The production server must have token licensing activated, and enough tokens must be available.
- **ADDITIONAL_BRAND_DEPLOYMENT:** Use this value when you are ready to deploy an additional brand deployment app on a production server. The app must be an additional brand deployment of an existing app for which an **APPLICATION** token has already been used. Your organization must have purchased an Additional Brand Deployment license for you to use this option. In addition, the code in the similar application must meet specific requirements such as the percentage of code that is different. Refer to your IBM MobileFirst Platform Foundation - Additional Brand Deployment software license for details.

The production server must have token licensing activated, and enough tokens must be available.

If token licensing is activated on the server and this element is not present in the application descriptor, then the default setting **APPLICATION** is used.

For more information, see “Licensing in MobileFirst Server” on page 2-16 and your IBM MobileFirst Platform Foundation software license.

Set the license app type in one of the following ways:

Procedure

- Use the **mfp config** command in the MobileFirst Platform Command Line Interface.
From a command prompt, run the **mfp config** command in either interactive mode or direct mode.
 - Interactive mode:
 1. Type `mfp config`.
 2. Select Client App Type.
 3. Select `app_license_type`.
 4. Specify the appropriate license type: `APPLICATION`, `ADDITIONAL_BRAND_DEPLOYMENT`, or `NON_PRODUCTION`.
 - Direct mode:
 1. Type `mfp config app_license_type value`.
The *value* placeholder takes one of the following values: `APPLICATION`, `ADDITIONAL_BRAND_DEPLOYMENT`, or `NON_PRODUCTION`.
- Use MobileFirst Studio.
 1. Open MobileFirst Studio in your Eclipse workspace.
 2. Double-click the `application-descriptor.xml` file. The application descriptor opens in the Application Descriptor Editor.
 3. In the **Licensing** section of the application descriptor, select the appropriate value for the **License App Type**.
- Manually edit the application descriptor.
 1. Open the `application-descriptor.xml` file for your app in a text editor.
 2. Specify one of the following values for the `licenseAppType` element, as appropriate: `APPLICATION`, `ADDITIONAL_BRAND_DEPLOYMENT`, or `NON_PRODUCTION`.

Important: If the `licenseAppType` element does not yet exist in the `application-descriptor.xml` file, you must add the `licenseAppType` element as a child of the root element in the file to use token licensing. For more information, see the documentation for the application descriptor for your application type.

Artifacts produced during development cycle

When you use IBM MobileFirst Platform Foundation to develop a mobile application, you produce client and server artifacts.

Client artifacts

A mobile binary file ready for deployment on a mobile device. For example, an Android `.apk` file, or an iPhone `.ipa` file. These are usually uploaded to an “App Store” such as the Apple Store or Google Play.

Application metadata and resources (`.wlap`)

A `.wlap` file. Metadata and web resources of a MobileFirst application deployed on the MobileFirst Server. Used by the MobileFirst Server to identify and service mobile applications. For hybrid Windows 8 Universal apps, two `.wlap` files are produced: one for desktop devices, the other for phones and tablets.

Adapter files (`.adapter`)

An adapter file (`.adapter`) contains server-side code written by the

MobileFirst developer (for example, retrieve data from a remote database). Adapter code is accessed by MobileFirst applications via a simple invocation API.

.wlapp and .adapter files are referred to in this topic as *content*. These are typically identical between the organization's development, testing, and production environments.

A project web archive (WAR) file to be deployed on your application server

This file contains the default server-specific configurations such as security profiles, server properties, and more. .wlapp and .adapter files use these properties at various stages. Typically, the project WAR file is adapted to the test and production environment, when you deploy the file to your application server. For more information, see "Deploying the project WAR file" on page 12-5.

Developing the server side of a MobileFirst application

This collection of topics relates to various aspects of developing the server-side components of a MobileFirst application.

Overview of MobileFirst adapters

Adapters are the server-side code of applications that are deployed on and serviced by IBM MobileFirst Platform Foundation.

Adapters run on the IBM MobileFirst Platform Server as middleware between mobile apps and enterprise (back-end) systems.

Adapters are the server-side code of applications that are deployed on and serviced by IBM MobileFirst Platform Foundation. Adapters connect to enterprise applications (also referred to as back-end systems), deliver data to and from mobile applications, and perform any necessary server-side logic on this data.

You can "hot deploy" adapters, meaning deploy, undeploy, and redeploy them at run time. This capability lends great flexibility to the MobileFirst server-side development process. Here are the benefits of using a Java adapter:

- Ability to fully control the URLs structure, the content types, the request and response headers, content and encoding.
- Easy and fast development and testing by using MobileFirst Studio and CLI.
- Easy and fast deployment to a running MobileFirst Server without compromising on performance and without any downtime.
- Ready-to-use security integration with MobileFirst security that uses simple annotations in the source code.

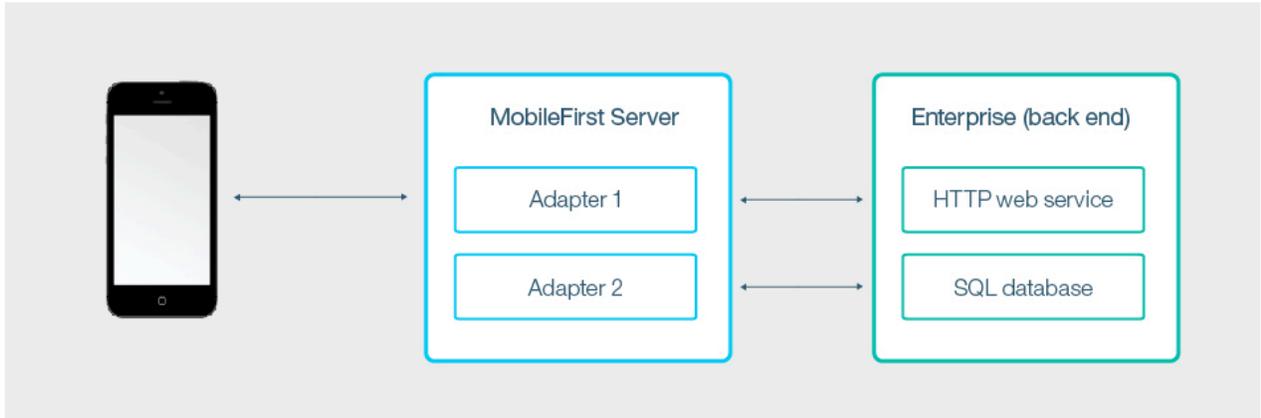

Figure 8-32. MobileFirst adapters

Development Language

Adapters can be developed in either in JavaScript or in Java. The source code of the adapter in both cases has access to a rich server API, which enables it to perform operations on the server side such as sending push notifications, calling other adapters, getting the user identity and more. For more information, see “MobileFirst Java adapters” on page 8-233 and “MobileFirst JavaScript adapters” on page 8-245.

Lifecycle

The adapter lifecycle comprises three stages:

Develop

The adapters are developed in IBM MobileFirst Platform Studio or from the command-line interface (CLI) as a part of the MobileFirst project development.

Test IBM MobileFirst Platform Studio and CLI tools make it easy to test adapter code. It is also possible to use external tools such as Postman or cURL to test the adapter. The Java adapters tutorials on the Getting Started page of the Developer Center show an implementation of HTTP connectivity in a Java adapter.

Deploy to staging, test, and production environments

After development and testing have been completed, you deploy the adapter to a running MobileFirst runtime of the various runtime environments (beta, test, pre-production, production). You can use the IBM MobileFirst Platform Operations Console to deploy the adapter from its web-based GUI. It is also possible to automate the build and deploy process of MobileFirst adapters by using MobileFirst Apache Ant tasks. For more information, see “Administering MobileFirst applications through Ant” on page 13-12.

Third-party dependencies

MobileFirst Server comes packaged with third-party dependencies. Ensure that you do not package different versions of those dependencies in your project. For a full list of the third-party JAR files in MobileFirst Server, see Third-party adapter dependencies.

MobileFirst Java adapters

With IBM MobileFirst Platform Foundation, you can create, test, and deploy adapters that are written in Java.

Java adapters were introduced to IBM MobileFirst Platform Foundation, starting with V7.0. Java adapters, which are written in Java, are based on the JAX-RS specification and make a full REST API available to the client. In other words, a Java adapter is a JAX-RS service that can be deployed to MobileFirst Server and that by default, has access to MobileFirst Server APIs.

Here are the benefits of using a Java adapter:

- Ability to fully control the URLs structure, the content types, the request and response headers, content and encoding.
- Rapid development and testing by using MobileFirst Studio and CLI.
- Rapid deployment to a running MobileFirst Server without compromising on performance and without any downtime.
- Ready-to-use security integration with MobileFirst security that uses simple annotations in the source code.

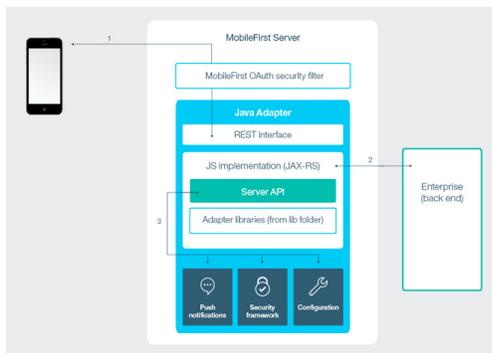

Figure 8-33. The Java adapter framework

Figure 1 illustrates how a mobile device (1) can access any Java adapter from its REST endpoint. The REST interface is protected by the MobileFirst OAuth security filter, meaning that the client needs to obtain an access token to access the adapter

resources. Because any of the resources of the adapter can have its own URL, it is possible to use a third-party (that is, non-MobileFirst) URL-based security framework. The REST interface invokes the Java code (JAX-RS service) to handle incoming requests. The Java code can perform operations on the server by using the Java MobileFirst Server API (3). In addition, the Java code can connect to the enterprise system to fetch data, update data, or perform any other operation that the enterprise system exposes (2).

For more information about MobileFirst adapters, see “Overview of MobileFirst adapters” on page 8-231.

Adapter sandboxing

Every Java adapter has its own isolated sandbox, in which all its classes are running without knowing about or interrupting the sandboxes of other adapters. It is possible to include third-party libraries that are required by the adapter code in the `adapter/lib` folder. Libraries that are included in that folder override any libraries that are provided by the application server or included in the `server/lib` folder.

Setting up the connectivity to back-end configuration

Unlike JavaScript adapters, Java adapters do not provide back-end connectivity, by default. It is the responsibility of the adapter developer to write code that connects to the back-end system. Examples of open source libraries are Apache HttpClient for connecting over HTTP and java.sql APIs for connecting directly to databases.

For more information about connectivity and samples of implementations of back-end connectivity inside a Java adapter, see Java Adapter.

Structure of Java adapters

Learn about the make-up of the adapter in IBM MobileFirst Platform Studio and about the adapter configuration in the XML adapter file.

In Studio

Java adapter structure is shown in IBM MobileFirst Platform Studio, as follows:

There are two folders under each Java adapter:

- **src:** This folder must contain the Java sources of the JAX-RS service. JAX-RS services are made up of an application class, which extends `javax.ws.rs.core.Application` and resource classes.

- **lib:** This folder can be used for JAR library files that are available to the adapter during runtime, for example, if you are using a third-party library that is specific to the current adapter.

Note: These JARs are loaded according to a "parent-last" policy, meaning that they override any libraries that were provided by the application server.

The Adapter XML configuration file

The Java adapter has an XML configuration file, as in all types of MobileFirst adapters.

```
<?xml version="1.0" encoding="UTF-8"?>
<!--
    Licensed Materials - Property of IBM
    5725-I43 (C) Copyright IBM Corp. 2011, 2013. All Rights Reserved.
    US Government Users Restricted Rights - Use, duplication or
    disclosure restricted by GSA ADP Schedule Contract with IBM Corp.
-->
<wl:adapter name="JavaAdapter1"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:wl="http://www.ibm.com/mfp/integration"
  xmlns:http="http://www.ibm.com/mfp/integration/http">

  <displayName>JavaAdapter1</displayName>
  <description>JavaAdapter1</description>
  <connectivity>
    <connectionPolicy xsi:type="wl:NullConnectionPolicy"></connectionPolicy>
  </connectivity>

  <JAXRSApplicationClass>com.acme.JavaAdapter1Application</JAXRSApplicationClass>
</wl:adapter>
```

Note the following points:

- The new `<JAXRSApplicationClass>` element defines the class name of the JAX-RS application of this adapter. In the previous example, it is `com.acme.JavaAdapter1Application`. For more information, see “Implementing the JAX-RS service of the adapter” on page 8-236.
- Java adapters have been designed to give maximum flexibility to the developer, but connection policies that are provided in JavaScript adapters are not available for Java adapters. For this reason, the `NullConnectionPolicy` definition for the `<connectivity>` element must remain as-is. It is the responsibility of the developer to implement the connection to the back end, as required. The Java Adapter tutorial in Getting Started shows an implementation of HTTP connectivity in a Java adapter.

Developing Java adapters

Learn about creating a new Java adapter and developing Java adapter code.

Creating a Java adapter using MobileFirst Studio:

Follow these instructions to create a new Java adapter in MobileFirst Studio.

About this task

You can create a Java adapter in MobileFirst Studio.

Procedure

1. In MobileFirst Studio, right-click a MobileFirst project, then select **New > MobileFirst Adapter**.
2. In the dialog, select **Java Adapter**.
3. Enter the adapter name and package name.
4. Click **Finish**.

Creating a Java adapter using MobileFirst CLI commands:

Follow these instructions to create a Java adapter using MobileFirst CLI commands.

About this task

You can create a Java adapter from the command line.

Procedure

1. Open a terminal.
2. Change directory to the MobileFirst project directory.
3. Type: **mfp add adapter <name> -type java -package <package name>**.

Developing Java adapter code:

Learn about implementing the adapter's JAX-RS service, the Java server side API, and debugging Java adapter code.

Implementing the JAX-RS service of the adapter:

To implement the JAX-RS service of the adapter, you must first implement the JAX-RS application class, then implement the JAX-RS resources classes.

Overview:

- “Implementing the JAX-RS application class”
- “Implementing a JAX-RS resource” on page 8-237
- “Security configuration of a JAX-RS resource” on page 8-239

Implementing the JAX-RS application class:

About this task

The JAX-RS application class tells the JAX-RS framework which resources are included in the application. Any resource can have a separate set of URLs. Traditionally the application class should extend `javax.ws.rs.core.Application` and implement the method `getClasses` or `getSingletons` that will be called by the JAX-RS framework to get information about this application. In the following example, a JAX-RS application defines three resources: `Resource1`, `UsersResource`, and `MyResourceSingleton`. The first two are provided by the `getClasses` method, while the last is provided by `getSingletons`:

```
import java.util.HashSet;
import java.util.Set;
import javax.ws.rs.core.Application;

public class MyApplication extends Application{

    @Override
    public Set<Class<?>> getClasses() {
        HashSet<Class<?>> classes = new HashSet<Class<?>>();
```

```

        classes.add(Resource1.class);
        classes.add(UsersResource.class);
        return classes;
    }

    @Override
    public Set<Object> getSingletons() {
        Set<Object> singletons = new HashSet<Object>();
        singletons.add(MyResourceSingleton.getInstance());
        return singletons;
    }
}

```

An alternative to using the `javax.ws.rs.core.Application` is to use `com.worklight.wink.extensions.MFPJAXRSApplication`. In the following example, it is not necessary to put all the resources classes (or singletons) in a list, because `MFPJAXRSApplication` scans the package that is returned by the `getPackageToScan` method for JAX-RS resources and creates the list automatically. Additionally, its `init` method is called by IBM MobileFirst Platform Server as soon as the adapter is deployed (before serving has begun) and when the MobileFirst runtime starts up:

```

import com.worklight.wink.extensions.MFPJAXRSApplication;
public class MyApplication2 extends MFPJAXRSApplication{
    @Override
    protected void init() throws Exception {
        //Perform initialization
    }

    @Override
    protected String getPackageToScan() {
        return getClass().getPackage().getName();
    }
}

```

Implementing a JAX-RS resource:

About this task

A JAX-RS resource is a POJO (plain old Java object) which is mapped to a root URL and has Java methods for serving requests to this root URL and its sub-URLs. For example:

```

import java.util.ArrayList;
import javax.ws.rs.Consumes;
import javax.ws.rs.DELETE;
import javax.ws.rs.GET;
import javax.ws.rs.POST;
import javax.ws.rs.PUT;
import javax.ws.rs.Path;
import javax.ws.rs.PathParam;
import javax.ws.rs.Produces;
import javax.ws.rs.core.MediaType;
import javax.ws.rs.core.Response;
import javax.ws.rs.core.Response.Status;

@Path("/users")
//This is the root URL of the resource ("/users")
public class UsersResource {
    //Instead of this static field, it could be a users DAO that works with Database or cloud storage
    static ArrayList<User> users = new ArrayList<User>();

    @GET
    @Produces(MediaType.APPLICATION_JSON)
    //This will serve: GET /users
    public ArrayList<User> getUsers(){
        return users;
    }
}

```

```

}

@Path("/{userId}")
@Produces(MediaType.APPLICATION_JSON)
//This will serve: GET /users/{userId}
public User getUser(@PathParam("userId") String userId){
    return findUserById(userId);
}

@POST
@Consumes(MediaType.APPLICATION_JSON)
//This will serve: POST /users
public void addUser(User u) {
    users.add(u);
}

@PUT
@Consumes(MediaType.APPLICATION_JSON)
//This will serve: PUT /users
public Response updateUser(User u) {
    User user = findUserById(u.getId());
    if (user == null){
        return Response.status(Status.NOT_FOUND)
            .entity("User with ID: "+u.getId()+" not found")
            .build();
    }
    users.remove(user);
    users.add(u);
    return Response.ok().build();
}

@DELETE
@Path("/{userId}")
//This will serve: DELETE /users/{userId}
public void deleteUser(@PathParam("userId") String userId){
    User user = findUserById(userId);
    users.remove(user);
}

private User findUserById(String userId) {
    //TODO implement...
    return null;
}
}

```

The resource just shown is mapped to the URL /users and serves the following requests:

Table 8-21. Resource requests.

Request	Description
GET /users	Gets all users list
POST /user	Adds a new user
GET /users/{id}	Gets a specific user with id id
PUT /users	Updates an existing user
DELETE /users/{id}	Deletes a user with id id

The JAX-RS framework does the mapping from the simple Java object User to a JSON object and conversely, making it easier for the service developer to use without taking care of repeating conversion-related code. The implementation also helps in extracting parameter values from the URL and from the query string without having to parse it manually.

Security configuration of a JAX-RS resource:

About this task

A JAX-RS adapter resource is protected by default by the MobileFirst security framework, meaning that access to the resource requires a valid OAuth access token. You can configure the resource protection by using the `@OAuthSecurity` annotation of the MobileFirst Java server-side `com.worklight.core.auth` package to assign a custom security scope, or to disable resource protection. The annotation can be applied either to a specific resource method or to an entire resource class. For detailed usage instructions, see the annotation's API reference.

Examples

Using `@OAuthSecurity` at the resource class level

To disable the default protection of the `UsersResource` class that was used in the previous examples, and make all resource procedures in this class unprotected, add the `OAuthSecurity` annotation to the class definition, and set the annotation's `enabled` element to `false`:

```
@OAuthSecurity(enabled=false)
```

The annotation should be added above the class definition, as shown in the following example:

```
@Path("/users")
@OAuthSecurity(enabled=false)
//This is the root URL of the resource ("/users")
public class UsersResource {
    ...
}
```

Using `@OAuthSecurity` at the method level

Suppose that you want to disable protection of the user's resource for read operations, but protect the add, edit, and delete user operations. To do so, add the `@OAuthSecurity` annotation with the `enabled` element set to `false` at the class level, and then add the annotation to the methods that you want to protect to override the class annotation. In the following example, the `addUser`, `updateUser`, and `deleteUser` methods are protected by an `adminRealm` scope:

```
@Path("/users")
@OAuthSecurity(enabled=false)
//This is the root URL of the resource ("/users")
public class UsersResource {

    @GET
    @Produces(MediaType.APPLICATION_JSON)
    //This will serve: GET /users
    public ArrayList<User> getUsers(){
        ...
    }

    @Path("/{userId}")
    @Produces(MediaType.APPLICATION_JSON)
    //This will serve: GET /users/{userId}
    public User getUser(@PathParam("userId") String userId){
        ...
    }

    @POST
    @Consumes(MediaType.APPLICATION_JSON)
    @OAuthSecurity(scope="adminRealm")
    //This will serve: POST /users
}
```

```

        public void addUser(User u) {
            ...
        }

        @PUT
        @Consumes(MediaType.APPLICATION_JSON)
        @OAuthSecurity(scope="adminRealm")
        //This will serve: PUT /users
        public Response updateUser(User u) {
            ...
        }

        @DELETE
        @Path("/{userId}")
        @OAuthSecurity(scope="adminRealm")
        //This will serve: DELETE /users/{userId}
        public void deleteUser(@PathParam("userId") String userId){
            ...
        }
    }
}

```

Java server side API:

Java adapters can use the IBM MobileFirst Platform Server Java API to perform server-related operations such as: calling other adapters, submitting push notifications, logging on to the server log, getting values of configuration properties, reporting activities to analytics, and getting the identity of the request issuer.

To get the server API interface use the following code:

```
WLServerAPI serverApi = WLServerAPIProvider.getWLServerAPI();
```

The WLServerAPI interface is the parent of all the API categories: analytics, configuration, push, adapters, authentication. If you want to use the push API, you can write:

```
PushAPI pushApi = serverApi.getPushAPI();
```

For more information on the Java API, see the `com.worklight.adapters.rest.api` package. Examples of the use of the API are provided in the following sections.

Logger

Adding a logger to the JAX-RS resource of your adapter is essential for logging debug information, information, warnings, and errors to the MobileFirst Server log. In the Java adapters, you can use the standard `java.util.logging` logger. To add logger declare the following static field:

```
static Logger logger = Logger.getLogger(UsersResource.class.getName());
```

Note: The logger is part of the new adapter template, so in most cases, there is no need to add it.

Push API

You can extend the UsersResource described in “Implementing the JAX-RS service of the adapter” on page 8-236 to notify all the devices of a user when the user record is updated:

```
WLServerAPI serverAPI = WLServerAPIProvider.getWLServerAPI();
```

```

@PUT
@Consumes(MediaType.APPLICATION_JSON)
public Response updateUser(User u) {

```

```

//TODO Really update the user...

//Notify all devices that the user has been updated
PushAPI push = serverAPI.getPushAPI();
INotification notification = push.buildNotification();
notification.getTarget().setUserIds(u.getId()); //Targeted only for the updated user

JSONObject payload = new JSONObject();
payload.put("user", u.getId());
notification.getSettings().getAPNS().setPayload(payload);

try {
    push.sendMessage(notification, "myApp");
} catch (MFPSendMessageFailedException e) {
    e.printStackTrace(); //Ignore failure in this case, since the update succeeded.
}
return Response.ok().build();
}

```

Security API

The security API provides the security context object that contains information about the identity of the request issuer. In the following example, a new validation is added to the user's resource: User records can be updated only by users themselves:

```

WLServerAPI serverAPI = WLServerAPIProvider.getWLServerAPI();

@PUT
@Consumes(MediaType.APPLICATION_JSON)
public Response updateUser(User u) {

    SecurityAPI security = serverAPI.getSecurityAPI();
    String requestIssuerUserId = security.getSecurityContext().getUserIdentity().getId();
    if (!u.getId().equals(requestIssuerUserId)) {
        return Response.status(Status.FORBIDDEN)
            .entity("The user: "+requestIssuerUserId+
                " is not allowed to modify the user record of another user").build();
    }

    //TODO Really update the user...
}

```

Adapters API

The adapters API makes it easy to perform requests to other adapters in the same server.

The following example shows how to use the adapters API to call a JavaScript adapter:

```

@Path("/")
public class JavaAdapter1Resource {
    static Logger logger = Logger.getLogger(JavaAdapter1Resource.class.getName());

    @GET
    @Path("/calljs")
    @Produces("application/json")
    public JSONObject callJSAdapterExample() throws Exception {
        AdaptersAPI adaptersAPI = WLServerAPIProvider.getWLServerAPI().getAdaptersAPI();
        //Using helper method to create a request to the JS adapter
        HttpRequest req = adaptersAPI.createJavascriptAdapterRequest("JSAdapter", "getStories");
        //Execute the request and get the response
        HttpResponse resp = adaptersAPI.executeAdapterRequest(req);
        //Convert the response to JSON since we know that JS adapters always return JSON
        JSONObject json = adaptersAPI.getResponseAsJSON(resp);
        //Return the json response as the response of the current request that is being taking care of
        return json;
    }
}

```

Configuration API

The configuration API enables the adapter to read server-side configuration properties defined in the `worklight.properties` file or as JNDI entries. For more information about MobileFirst configuration properties, see “CLI Commands” on page 16-1.

For example, to get the value of the `serverSessionTimeout` property, write the following code:

```
String serverSessionTimeout = serverAPI.getConfigurationAPI().getMFPCConfigurationProperty("serverSessionTimeout");
```

Saving applicative state between requests in Java RESTful adapters

In versions earlier than V7.1.0, developers were able to store the applicative state in the HTTP session, by using the session object, namely `request.getSession()` (see `WL.Server`).

If you are working in session-independent mode that became available starting with IBM MobileFirst Platform Foundation V7.1.0, the applicative state of the adapter must be persisted outside the session, for example, by using a database such as Cloudant. For more information on session-independent mode, including steps for upgrading projects that were created in earlier versions of IBM MobileFirst Platform Foundation, see “Session-independent mode” on page 8-324.

The following code snippets provide examples for migrating code from an earlier version of IBM MobileFirst Platform Foundation so that it support the changes for session-independent mode in V7.1.0.

Consider a shopping-cart app, in which users can add items to a cart, see the list of items that are already in the cart, and submit an order when satisfied with the items in it. Before V7.1.0, this functionality might have been implemented in the following code:

```
//Define the server API to be able to perform server operations
WLServerAPI api = WLServerAPIProvider.getWLServerAPI();

@GET
@Path("/addItemToCart")
public void addItemToCart(@Context HttpServletRequest request, @HeaderParam("item") String item) {

    String oldItems = getItemsFromCart(request);

    HttpSession session = request.getSession();
    session.setAttribute("items", oldItems + " " + item);
}

@GET
@Path("/getItemsFromCart")
public String getItemsFromCart(@Context HttpServletRequest request) {
    HttpSession session = request.getSession();
    return (String) session.getAttribute("items");
}
```

Assume you are using Cloudant as the persist store over the Cloudant Java Client API and that you are implementing a Java RESTful HTTP adapter called `ShoppingCartAdapter`. See Figure 1: using `OAuthSecurityContext.getClientId()`, the adapter requests the ID that is associated with the current client from MobileFirst Server and uses it when reading or writing applicative data to or from Cloudant.

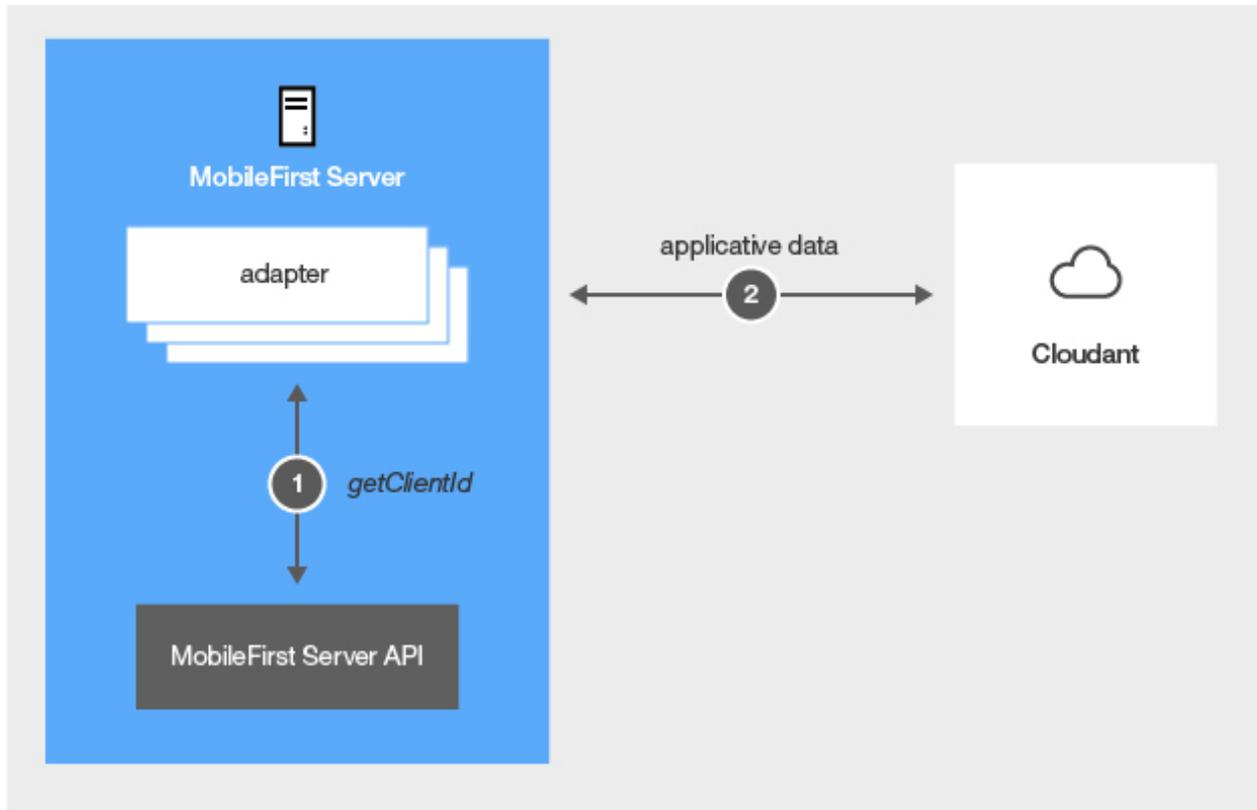

Figure 8-34. Retrieving applicative data using the server-side `OAuthSecurityContext.getClientId` API.

If you adapt the code to work in session-independent mode under V7.1.0, the code for MobileFirst V7.1.0 might look as follows:

```
//Define the server API to be able to perform server operations
WLServerAPI api = WLServerAPIProvider.getWLServerAPI();

CloudantClient client = new CloudantClient("cloudantId", "username", "password");
@GET
@Path("/addItemToCart")
public void addItemToCart(@HeaderParam("item") String item) {
    // Get the clientID from the MFP API (new in 7.1.0)
    String userId = api.getSecurityAPI().getSecurityContext().getClientId();
    saveItemToCloudant("shoppingcartdb", userId, item);
}

@GET
@Path("/getItemsFromCart")
public String getItemsFromCart() {
    // Get the clientID from the MFP API (new in 7.1.0)
    String userId = api.getSecurityAPI().getSecurityContext().getClientId();
    return (String) readItemFromCloudant("shoppingcartdb", userId).get("items");
}

/**
 * Reads a JSONObject shopping cart item from Cloudant and returns the document
 * that corresponds to this _id
 * @param db
 * @param key
 * @return a JSONObject
 */
public JSONObject readItemFromCloudant(String db, String key){
    Database cloudantDb = client.database(db, false);
```

```

    // Search for the document
    return cloudantDb.find(JSONObject.class, key);
}

/**
 * Saves a JSONObject shopping cart item to Cloudant
 * @param db - the DB to save to
 * @param key - the _id
 * @param value
 */
public void saveItemToCloudant(String db, String key, String value){
    Database cloudantDb = client.database(db, false);

    // Search for the document
    try{
        JSONObject document = cloudantDb.find(JSONObject.class, key);
        String listOfItems = (String) document.get("items");
        // Add new shopping cart item to list
        listOfItems += " " + value;
        document.put("items", listOfItems);

        // Update the document
        cloudantDb.update(document);
    }catch(NoDocumentException e){
        // New Document
        JSONObject obj = new JSONObject();
        obj.put("_id", key);
        obj.put("items", value);

        // Save the object to cloudant db
        cloudantDb.save(obj);
    }
}

```

Debugging Java adapter code:

Use IBM MobileFirst Platform Studio's debug mode to debug Java adapter code.

Starting debug mode:

Before you begin

After you enter debug mode, you can debug the Java code exactly as you debug a standard Java application. You might need to issue a request to the adapter to make its code run and hit the breakpoints.

Note: While in debug mode, you can debug the code of all deployed Java adapters and the code in the **server/java** folder as well.

Procedure

1. Right-click a Java adapter and select **Debug As > Debug MobileFirst Java Adapters**.
2. Optional: Open the **Debug** perspective in MobileFirst Studio to see threads, breakpoints, and values.

Stopping debug mode:

Procedure

1. Open the **Debug** perspective in MobileFirst Studio.
2. Right-click the **Debug** tab and select **remote debug [Remote Java Application] > Terminate**.

MobileFirst JavaScript adapters

With IBM MobileFirst Platform Foundation, you can create, test, and deploy adapters that are written in JavaScript.

You can create and configure all JavaScript adapters manually. In addition, you can automatically generate SAP Netweaver Gateway or SOAP adapters with the services discovery wizard. For more information about how to automatically generate adapters, see “Generating adapters with the services discovery wizard” on page 8-266.

Starting with IBM MobileFirst Platform Foundation V6.3, changes were made to the XML definition and behavior of JavaScript adapter timeout and concurrency. For more information, see “Adapter timeout and concurrency” on page 8-275.

For more general information about IBM MobileFirst Platform Foundation adapters, see “Overview of MobileFirst adapters” on page 8-231.

Benefits of MobileFirst JavaScript adapters

JavaScript adapters provide various benefits, as follows:

- **Fast Development:** Adapters are developed in JavaScript and XSL. Developers employ flexible and powerful server-side JavaScript to produce succinct and readable code for integrating with back-end applications and processing data. Developers can also use XSL to transform hierarchical back-end data to JSON.
- **Read-only and Transactional Capabilities:** MobileFirst adapters support read-only and transactional access modes to back-end systems.
- **Security:** MobileFirst adapters use flexible authentication facilities to create connections with back-end systems. Adapters offer control over the identity of the user with whom the connection is made. The user can be a *system* user, or a user on whose behalf the transaction is made.
- **Transparency:** Data that is retrieved from back-end applications is available in a uniform manner, so that application developers can access data uniformly, regardless of its source, format, and protocol.
- **REST Interface:** With the new REST interface, you can benefit from the OAuth 2.0 security framework, even when you use your existing JavaScript adapters. For more information, see “Accessing adapters from the /adapters endpoint” on page 8-334.

The adapter framework

The adapter framework mediates between the mobile apps and the back-end services. A typical flow is depicted in the following diagram. The app, the back-end application, and the JavaScript code and XSLT components in the MobileFirst Server are supplied by the adapter or app developer. The procedure and auto-conversions are part of IBM MobileFirst Platform Foundation.

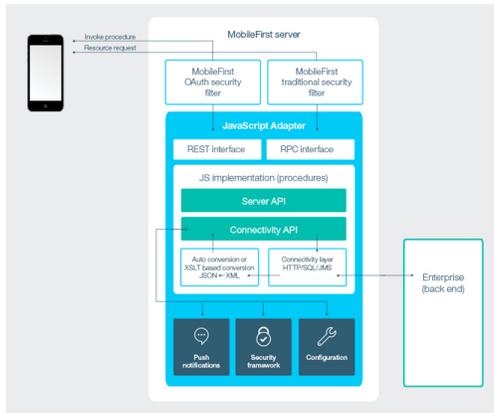

Figure 8-35. The JavaScript adapter framework

1. An adapter provides a set of services, called procedures. Mobile apps invoke procedures by issuing Ajax requests.
2. The procedure retrieves information from the back-end application.
3. The back-end application then returns data in some format.
 - If this format is JSON, the MobileFirst Server keeps the data intact.
 - If this format is not JSON, the MobileFirst Server automatically converts it to JSON. Alternatively, you can provide an XSL transformation to convert the data to JSON. In this case, the returned content type from the back end must be XML. Then, you can use an XSLT to filter the data.
4. The JavaScript implementation of the procedure receives the JSON data, performs any additional processing, and returns it to the calling app.
 - Take note of the following points:
 - Writing an adapter that pulls large amounts of data and transfers it to the client application is discouraged because the data must be processed twice: once at the adapter and once again at the client application.
 - HTTP POST requests are used for client-server communications between the MobileFirst application and the MobileFirst Server. Parameters must be

supplied in a plain text or numeric format. To transfer images (or any other type of file data), they must be converted to base64 first.

Anatomy of JavaScript adapters

MobileFirst adapters are developed by using XML, JavaScript, and XSL. Each adapter must have the following elements:

- Exactly one XML file, describing the connectivity to the back-end system to which the adapter connects, and listing the procedures that are provided by the adapter to other adapters and to applications.
- Exactly one JavaScript file, containing the implementation of the procedures declared in the XML file.
- Zero or more XSL files, each containing a transformation from the raw XML data that is retrieved by the adapter to JSON returned by adapter procedures.

The files are packaged in a compressed file with a `.adapter` suffix (such as `myadapter.adapter`).

The root element of the XML configuration files is `<adapter>`. The main subelements of the `<adapter>` element are as follows:

- `<connectivity>`: Defines the connection properties and load constraints of the back-end system. When the back end requires user authentication, this element defines how the credentials are obtained from the user. For more information, see “Structure of the adapter XML file.”
- `<procedure>`: Declares a procedure that is provided by the adapter. For more information, see “Implementing adapter procedures” on page 8-305.

The structure of the `<adapter>` element is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<wl:adapter>
  <description>
    <connectivity>
      <connectionPolicy>
        <loadConstraints>
      </connectivity>

  <procedure /> <!-- One or more such elements -->
</wl:adapter>
```

Structure of the adapter XML file

The adapter XML file is used to configure connectivity to the back-end system and to declare the procedures that are exposed by the adapters to applications and to other adapters.

The adapter element

The adapter element is the root element of the adapter configuration file. It has the following structure, which consists of both attributes and subelements:

```
<wl:adapter name="Java_adap"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:wl="http://www.ibm.com/mfp/integration"
  xmlns:http="http://www.ibm.com/mfp/integration/http">

  <displayName>Java_adap</displayName>
  <description>Java_adap</description>
  <connectivity>
    <connectionPolicy xsi:type="wl:NullConnectionPolicyType"></connectionPolicy>
```

```
</connectivity>
<JAXRSApplicationClass>java_package.Java_adapApplication</JAXRSApplicationClass>
</wl:adapter>
```

The adapter element attributes

IBM MobileFirst Platform Foundation provides two schemas that are used by all adapters. Additionally, this product provides a specific schema for each type of adapter. Each schema must be associated with a different namespace. Namespaces are declared by using the `xmlns` attribute, and are linked to their schemas by using the `xsi:schemaLocation` attribute. The `<adapter>` element contains the following attributes.

name

Mandatory.

The name of the adapter. This name must be unique within the MobileFirst Server. It can contain alphanumeric characters and underscores, and must start with a letter. After you define and deploy an adapter, you cannot modify its name.

xmlns:namespace

Mandatory.

Defines schema *namespaces*.

This attribute must appear three times.

- `xmlns:xsi`: Defines the namespace associated with the `http://www.w3.org/2001/XMLSchema-instance` schema.
- `xmlns:wl`: Defines the namespace that is associated with the `http://www.ibm.com/mfp/integration` schema.
- `xmlns:namespace`: Defines the namespace that is associated with the schema related to the back-end application. For example, `xmlns:sap` or `xmlns:sql`.

xsi:schemaLocation

Optional.

Identifies the schema locations.

```
xsi:schemaLocation="http://www.ibm.com/mfp/integration location-of-integration-schema-file
URI-of-specific-adapter-schema location-of-schema"
```

If this attribute is missing, auto-complete for XML elements and attributes that are defined in the schema is not available in MobileFirst Studio.

At run time, this attribute has no effect.

The adapter element subelements

The adapter element has the following subelements.

displayName

Optional.

This element is deprecated. The name of the adapter that is displayed in the MobileFirst Operations Console. If this element is not specified, the value of the name attribute is used instead.

description

Optional.

Additional information about the adapter. Displayed in the MobileFirst Operations Console.

connectivity

Mandatory.

Defines the mechanism by which the adapter connects to the back-end application. It contains the `connectionPolicy` subelement. The `connectionPolicy` subelement is mandatory, and it defines connection properties. The structure of this subelement depends on the integration technology of the back-end application.

procedure

Mandatory.

Defines a process for accessing a service that is exposed by a back-end application. Occurs once for each procedure that is exposed by the adapter.

The procedure element has the following structure.

```
<procedure
  name="unique-name"
  connectAs="value"
  audit="value"
  securityTest="value"
/>
```

The procedure element has the following attributes.

name

Mandatory.

The name of the procedure. This name must be unique within the adapter. It can contain alphanumeric characters and underscores, and must start with a letter.

connectAs

Optional.

Defines how to create a connection to the back end for invoking the retrieve procedure. The following values are valid.

- `server`: Default. The connection to the back-end is created according to the connection policy defined for the adapter.
- `endUser`: The connection to the back-end is created with the user's identity. Only valid if you identify a user realm in the security tests for this procedure.

audit

Optional.

Defines whether calls to the procedure are logged in the audit log. The log file is *Project Name/server/log/audit/audit.log*.

The following values are valid.

- `true`: Calls to the procedure are logged in the audit log.
- `false`: Default. Calls to the procedure are not logged in the audit log.

securityTest

Optional.

The name of the security test that you want to use to protect the adapter procedure, as defined in the authenticationConfig.xml file.

Cast Iron adapter connectionPolicy element:

You can access various enterprise data sources, such as databases, web services, and JMS, and provides validation, aggregation, and formatting capabilities by using Cast Iron.

Structure

The connectionPolicy element has the following structure.

```
<connectionPolicy xsi:type="http:HTTPConnectionPolicyType">
  <protocol>http</protocol>
  <domain>your.CastIron.com</domain>
  <port>80</port>
  <connectionTimeoutInMilliseconds>30000</connectionTimeoutInMilliseconds>
  <socketTimeoutInMilliseconds>30000</socketTimeoutInMilliseconds>
  <maxConcurrentConnectionsPerNode>50</maxConcurrentConnectionsPerNode>
</connectionPolicy>
```

Attributes

The connectionPolicy element has the following attributes.

xsi:type

Mandatory.

The value of this attribute must be set to http:HTTPConnectionPolicyType.

Subelements

The connectionPolicy element has the following subelements.

protocol

Optional.

The URL protocol to use. The following values are valid.

- http: default
- https

domain

Mandatory.

The host address.

port

Optional.

The port address.

connectionTimeoutInMilliseconds

Optional

The time until a connection to the back-end can be established. This timeout does not ensure that a timeout exception occurs after a time elapses after the invocation of the HTTP request.

If you pass a different value for this parameter in the `invokeHTTP()` JavaScript function, you can override the value that is defined here. For more information, see the `WL.Server` class.

socketTimeoutInMilliseconds

Optional.

The timeout between two consecutive packets, starting from the connection packet. This timeout does not ensure that a timeout exception occurs after a time elapses after the invocation of the HTTP request.

If you pass a different value for this parameter in the `invokeHttp()` JavaScript function, you can override the value that is defined here. For more information, see the `WL.Server` class.

maxConcurrentConnectionsPerNode

Optional.

Defines the maximum number of concurrent connections, which the MobileFirst Server can open to the back end.

IBM MobileFirst Platform Foundation does not limit the incoming service requests from applications. This subelement can be configured at the application server level. This product limits only the number of concurrent HTTP connections to the back-end service.

The default number of concurrent HTTP connections is 50. You can modify this number based on the expected concurrent requests to the adapter and the maximum requests allowed on the back-end service. You can also configure the back-end service to limit the number of concurrent incoming requests.

Consider a two-node system, where the expected load on the system is 100 concurrent requests and the back-end service can support up to 80 concurrent requests. You can set `maxConcurrentConnectionsPerNode` to 40. This setting ensures that no more than 80 concurrent requests are made to the back-end service.

If you increase the value, the back-end application needs more memory. To avoid memory issues, do not set this value too high. Instead, estimate the average and peak number of transactions per second, and evaluate their average duration. Then, calculate the number of required concurrent connections as indicated in this example, and add a 5-10% margin. Then, monitor your back end, and adjust this value as required, to ensure that your back-end application can process all incoming requests.

When you deploy adapters to a cluster, set the value of this attribute to the maximum required load divided by the number of cluster members.

For more information about how to size your back-end application, see the **Scalability and Hardware Sizing** document and the hardware calculator spreadsheet at Developer Center website for IBM MobileFirst Platform Foundation.

HTTP adapter **connectionPolicy** element:

You can use the HTTP adapter to start RESTful services and SOAP-based services. You can also complete HTML scraping.

Structure

The `connectionPolicy` element has the following structure.

```
<connectionPolicy xsi:type="http:HTTPConnectionPolicyType"; cookiePolicy="cookie-policy" maxRedirects="int">
  <protocol>protocol</protocol>
  <domain>host-name</domain>
  <port>host-port</port>
  <connectionTimeoutInMilliseconds>connection_timeout</connectionTimeoutInMilliseconds>
  <socketTimeoutInMilliseconds>socket_timeout</socketTimeoutInMilliseconds>
  <authentication> ... </authentication>
  <proxy> ... </proxy>
  <sslCertificateAlias>ssl-certificate-alias</sslCertificateAlias>
  <sslCertificatePassword>ssl-certificate-password</sslCertificatePassword>
  <maxConcurrentConnectionsPerNode>max_concurrent_connections</maxConcurrentConnectionsPerNode>
</connectionPolicy>
```

Attributes

The `connectionPolicy` element has the following attributes.

xsi:type

Mandatory.

The value of this attribute must be set to `http:HTTPConnectionPolicyType`.

cookiePolicy

Optional.

This attribute sets how the HTTP adapter handles cookies that arrive from the back-end application. The following values are valid.

- RFC_2109: default value
- RFC_2965
- NETSCAPE
- IGNORE_COOKIES

For more information about these values, see HTTP components.

maxRedirects

Optional.

The maximum number of redirects that the HTTP adapter can follow. This attribute is useful when the back-end application sends circular redirects as a result of some error, such as authentication failures. If this attribute is set to 0, the adapter does not attempt to follow redirects at all, and the HTTP 302 response is returned to the user. The default value is 10.

Subelements

The `connectionPolicy` element has the following subelements.

protocol

Optional.

The URL protocol to use. The following values are valid.

- http: default
- https

domain

Mandatory.
The host address.

port

Optional.
The port address.

sslCertificateAlias

Optional for regular HTTP authentication and simple SSL authentication.
Mandatory for mutual SSL authentication.

The alias of the adapter private SSL key, which is used by the HTTP adapter key manager to access the correct SSL certificate in the keystore. For more information about the keystore setup process, see “SSL certificate keystore setup” on page 12-60.

sslCertificatePassword

Optional for regular HTTP authentication and simple SSL authentication.
Mandatory for mutual SSL authentication.

The password of the adapter private SSL key, which is used by the HTTP adapter key manager to access the correct SSL certificate in the keystore. For more information about the keystore setup process, see “SSL certificate keystore setup” on page 12-60.

authentication

Optional.

Authentication configuration of the HTTP adapter. The HTTP adapter can use one of four protocols, and can also contain a server identity. You can configure the HTTP adapter to use one of four authentication protocols by defining the <authentication> element. You can define the <authentication> element in one of the following ways.

- Basic Authentication

```
<authentication>
  <basic/>
</authentication>
```
- Digest Authentication

```
<authentication>
  <digest/>
</authentication>
```
- NTLM Authentication

```
<authentication>
  <ntlm workstation="value"/>
</authentication>
```

The workstation attribute is optional. This attribute denotes the name of the computer on which the MobileFirst Server runs.

- SPNEGO/Kerberos Authentication

```
<authentication>
  <spnego stripPortOffServiceName="true"/>
</authentication>
```

The attribute `stripPortOffServiceName` is optional. This attribute specifies whether the Kerberos client uses the service name without the port number.

When you use this option, you must also place the `krb5.conf` file under *Project Name/server/conf*. This file must contain Kerberos configuration such as the location of the Kerberos server, and domain names. Its structure is described in the Kerberos V5 System Administrator's Guide in the mit.edu website.

If the adapter exposes procedures with the attribute `connectAs="server"`, the connection policy can contain `<serverIdentity>` element. This feature applies to all authentication schemes. For example:

```
<authentication>
  <basic/>
  <serverIdentity>
    <username> ${DOMAIN\user} </username>
    <password> ${password} </password>
  </serverIdentity>
</authentication>
```

proxy

Optional.

Access the back-end application. Add a `<proxy>` element inside the `<connectionPolicy>` element. If the proxy requires authentication, add a nested `<authentication>` element inside `<proxy>`. This element has the same structure as the one used to describe the authentication protocol of the adapter, described in The HTTP adapter's `<authentication>` element.

The following example shows a proxy that requires basic authentication and uses a server identity.

```
<connectionPolicy xsi:type="http:HTTPConnectionPolicyType">
  <protocol>http</protocol>
  <domain>www.bbc.co.uk</domain>
  <proxy>
    <protocol>http</protocol>
    <domain>wl-proxy</domain>
    <port>8167</port>
    <authentication>
      <basic/>
      <serverIdentity>
        <username>${proxy.user}</username>
        <password>${proxy.password}</password>
      </serverIdentity>
    </authentication>
  </proxy>
</connectionPolicy>
```

maxConcurrentConnectionsPerNode

Optional.

Defines the maximum number of concurrent connections, which the MobileFirst Server can open to the back end.

IBM MobileFirst Platform Foundation does not limit the incoming service requests from applications. This subelement can be configured at the application server level. This product limits only the number of concurrent HTTP connections to the back-end service.

The default number of concurrent HTTP connections is 50. You can modify this number based on the expected concurrent requests to the adapter and the maximum requests allowed on the back-end service. You can also configure the back-end service to limit the number of concurrent incoming requests.

Consider a two-node system, where the expected load on the system is 100 concurrent requests and the back-end service can support up to 80 concurrent requests. You can set `maxConcurrentConnectionsPerNode` to 40. This setting ensures that no more than 80 concurrent requests are made to the back-end service.

If you increase the value, the back-end application needs more memory. To avoid memory issues, do not set this value too high. Instead, estimate the average and peak number of transactions per second, and evaluate their average duration. Then, calculate the number of required concurrent connections as indicated in this example, and add a 5-10% margin. Then, monitor your back end, and adjust this value as required, to ensure that your back-end application can process all incoming requests.

When you deploy adapters to a cluster, set the value of this attribute to the maximum required load divided by the number of cluster members.

For more information about how to size your back-end application, see the Scalability and Hardware Sizing document and the hardware calculator spreadsheet at Developer Center website for IBM MobileFirst Platform Foundation.

connectionTimeoutInMilliseconds

Optional.

The timeout in milliseconds until a connection to the back-end can be established. Setting this timeout does not ensure that a timeout exception occurs after a specific time elapses after the invocation of the HTTP request.

If you pass a different value for this parameter in the `invokeHTTP()` JavaScript function, you can override the value that is defined here. For more information, see the `WL.Server` class.

socketTimeoutInMilliseconds

Optional.

The timeout in milliseconds between two consecutive packets, starting from the connection packet. Setting this timeout does not ensure that a timeout exception occurs after a specific time elapses after the invocation of the HTTP request.

If you pass a different value for the **socketTimeoutInMilliseconds** parameter in the `invokeHttp()` JavaScript function, you can override the value that is defined here. For more information, see the `WL.Server` class.

JMS adapter connectionPolicy element:

You can use Java™ Messaging Service (JMS) is the standard messaging Java API to send messages between two or more clients. The MobileFirst JMS adapter provides reading and writing capabilities to messaging providers that implement the JMS API.

Structure

The `connectionPolicy` element has the following structure.

```
<connectionPolicy xsi:type="jms:JMSConnectionPolicyType">
  <!-- uncomment this if you want to use an external JNDI repository -->
  <!-- <namingConnection url="MY_JNDI_URL"
    initialContextFactory="providers_initial_context_factory_class_name"
    user="JNDIUserName"
    password="JNDIPassword"/>
  -->

  <jmsConnection
    connectionFactory="java:comp/env/MYConnectionFactory"
    user="MessagingSystemUserName"
    password="MessagingSystemPassword"
  />
</connectionPolicy>
```

Attributes

The `connectionPolicy` element has the following attributes.

xsi:type

Mandatory.

The value of this attribute must be set to `jms:JMSConnectionPolicyType`.

Subelements

The `connectionPolicy` element has the following subelements.

namingConnection

Optional.

Describes how to connect to an external JNDI repository. Only used if the JNDI objects are not stored in the Java Platform, Enterprise Edition server that the adapter is deployed in. This element has the following attributes.

url

Mandatory.

The URL of the external JNDI repository. For example: `iiop://localhost`. The URL syntax is dependent upon the JNDI provider.

initialContextFactory

Mandatory.

The `initialContextFactory` class name of the JNDI provider. For example: `com.ibm.Websphere.naming.WsnInitialContextFactory`. The driver, and any associated files, must be placed in the `/server/lib` directory. If you develop in the Eclipse environment, the driver and associated files must be placed in the `/lib` directory.

Note: If you develop for WebSphere Application Server with WebSphere MQ, do not add the WebSphere MQ Java™ archive (JAR) files to the `/lib` directory. If the WebSphere MQ JAR files are added, class loading problems occur because the files already exist in the WebSphere Application Server environment.

user

Optional.

User name of a user with authority to connect to the JNDI repository. If user is not specified, the default user name is guest.

password

Optional.

User name of a user with authority to connect to the JNDI repository. If user is not specified, the default password is guest.

jmsConnection

Mandatory.

Describes the connection factory and optional security details that are used to connect to the messaging system.

connectionFactory

Mandatory.

The name of the connection factory that is used when you connect to the messaging system.

If you are deploying in WebSphere Application Server, the connection factory must be a global JNDI object. The object must be addressed without the `java:comp/env` context. For example: `jms/MyConnFactory` and not `java:comp/env/jms/MyConnFactory`. However, if you are deploying in Tomcat, the connection factory must be addressed including the `java:/comp/env` context. For example: `java:comp/env/jms/MyConnFactory`.

user

Optional.

User name of a user with authority to connect to the messaging system.

password

Optional.

Password for the user who is specified in the user attribute.

SAP Gateway adapter connectionPolicy element:

You can use SAP adapters to communicate with SAP Netweaver Gateway back-end services.

Structure

Note: Service Discovery now generates HTTP adapters for SAP Gateway connections instead of a specific SAP-type adapter.

The connectionPolicy element has the following structure.

```
<connectionPolicy xsi:type="nwgateway:NWGatewayHTTPConnectionPolicyType">
  <protocol>HTTP</protocol>
  <domain>host</domain>
  <port>8320</port>
  <connectionTimeoutInMilliseconds>30000</connectionTimeoutInMilliseconds>
  <socketTimeoutInMilliseconds>30000</socketTimeoutInMilliseconds>
```

```

<serviceRootUrl>/sap/opu/odata/IWBEP/RMTSAMPLEFLIGHT_2/</serviceRootUrl>
<authentication>
  <basic/>
  <serverIdentity>
    <client>001</client>
    <username>mygatewayuser</username>
    <password>mygatewaypassword</password>
  </serverIdentity>
</authentication>
<!-- Following properties used by adapter's key manager for choosing specific certificate from key store
<sslCertificateAlias></sslCertificateAlias>
<sslCertificatePassword></sslCertificatePassword>-->
<maxConcurrentConnectionsPerNode>50</maxConcurrentConnectionsPerNode>
</connectionPolicy>

```

Attributes

The connectionPolicy element has the following attributes.

xsi:type

Mandatory.

The value of this attribute must be set to `nwgateway:NWGatewayHTTPConnectionPolicyType`.

Subelements

The connectionPolicy element has the following subelements.

protocol

Mandatory.

The URL protocol to use. The following values are valid.

- http: default
- https

domain

Mandatory.

The host address.

port

Mandatory.

The port address.

connectionTimeoutInMilliseconds

Optional.

The time until a connection to the back-end can be established. Setting this timeout does not ensure that a timeout exception occurs after a time elapses after the invocation of the HTTP request.

If you pass a different value for this parameter in the `invokeHTTP()` JavaScript function, you can override this value. For more information, see the `WL.Server` class.

socketTimeoutInMilliseconds

Optional.

The time between two consecutive packets, starting from the connection packet. Setting this timeout does not ensure that a timeout exception occurs after a time elapses after the invocation of the HTTP request.

If you pass a different value for this parameter in the `invokeHttp()` JavaScript function, you can override the value that is defined here. For more information, see the `WL.Server` class.

serviceRootUrl

Mandatory.

The root URL for the SAP Netweaver gateway service that you are trying to access.

authentication

Mandatory.

Authentication configuration of the SAP Netweaver Gateway adapter. Your adapter can use one of four protocols, and a server identity, which you can configure if you define this element. You can define the authentication in one of the following ways.

- Basic Authentication

```
<authentication>
  <basic/>
</authentication>
```
- Digest Authentication

```
<authentication>
  <digest/>
</authentication>
```
- NTLM Authentication

```
<authentication>
  <ntlm workstation="value"/>
</authentication>
```

The `workstation` attribute is optional. This attribute denotes the name of the computer on which the MobileFirst Server runs.

- SPNEGO/Kerberos Authentication

```
<authentication>
  <spnego stripPortOffServiceName="true"/>
</authentication>
```

The attribute `stripPortOffServiceName` is optional. This attribute specifies whether the Kerberos client uses the service name without the port number.

When you use this option, you must also place the `krb5.conf` file under *Project Name/server/conf*. This file must contain Kerberos configuration such as the location of the Kerberos server, and domain names. Its structure is described in the Kerberos V5 System Administrator's Guide in the `mit.edu` website.

If the adapter exposes procedures with the attribute `connectAs="server"`, the connection policy can contain the `serverIdentity` element. This feature applies to all authentication schemes. For example:

```
<authentication>
  <basic/>
  <serverIdentity>
    <client>001</client>
```

```

    <username> ${DOMAIN\user} </username>
    <password> ${password} </password>
  </serverIdentity>
</authentication>

```

The `serverIdentity` element has the following 3 subelements.

client

Mandatory.

The SAP-Client to be used to contact the Netweaver Gateway.

username

Mandatory.

The user name for contacting the Netweaver Gateway.

password

Mandatory.

The password for contacting the Netweaver Gateway.

sslCertificateAlias

Optional for regular HTTP authentication and simple SSL authentication.

Mandatory for mutual SSL authentication.

The alias of the adapter private SSL key, which is used by the HTTP adapter key manager to access the correct SSL certificate in the keystore. For more information about the keystore setup process, see “SSL certificate keystore setup” on page 12-60.

sslCertificatePassword

Optional for regular HTTP authentication and simple SSL authentication.

Mandatory for mutual SSL authentication.

The password of the adapter private SSL key, which is used by the HTTP adapter key manager to access the correct SSL certificate in the keystore. For more information about the keystore setup process, see “SSL certificate keystore setup” on page 12-60.

SAP JCo adapter connectionPolicy element:

You can use the SAP Java Connector (SAP JCo) adapters to develop SAP-compatible components and applications in Java.

Structure

The `connectionPolicy` element has the following structure.

```

<connectionPolicy xsi:type="sapjco:JCOConnectionPolicy"
  jcoClientClient="001"
  jcoClientUser="userName"
  jcoClientPasswd="password"
  jcoClientLang="EN"
  jcoClientAsHost="mysapserver.ibm.com"
  jcoClientSysnr="01"
  maxConnections="10"
/>

```

Attributes

The `connectionPolicy` element has the following attributes.

xsi:type

Mandatory.

The value of this attribute must be set to `sapjco:JC0ConnectionPolicy`.

jcoClientClient

Mandatory.

The SAP client.

jcoClientUser

Mandatory.

The logon user.

jcoClientPasswd

Mandatory.

The logon password.

jcoClientLang

Mandatory.

The logon language.

jcoClientAsHost

Mandatory.

The application server.

jcoClientSysnr

Mandatory.

The SAP system number.

maxConnections

Mandatory.

The maximum number of connections that are allowed for the pool.

SQL adapter `connectionPolicy` element:

You can use the MobileFirst SQL adapter to run SQL queries with parameters and stored procedures that retrieve or update data in the database.

Structure

The `connectionPolicy` element has two options for connection:

- The `dataSourceDefinition` subelement: for development mode.
- The `dataSourceJNDIName` subelement: for production mode.

Connecting by using the `dataSourceDefinition` subelement:

```
<connectionPolicy xsi:type="sql:SQLConnectionPolicy">
  <dataSourceDefinition>
    <driverClass>com.mysql.jdbc.Driver</driverClass>
    <url>jdbc:mysql://localhost:3306/mydb</url>
```

```

    <user>myUsername</user>
    <password>myPassword</password>
  </dataSourceDefinition>
</connectionPolicy>

```

Connecting by using the `dataSourceJNDIName` subelement:

```

<connectionPolicy xsi:type="sql:SQLConnectionPolicy">
  <dataSourceJNDIName>jdbc/myAdapterDS</dataSourceJNDIName>
</connectionPolicy>

```

Attributes

The `connectionPolicy` element has the following attributes.

xsi:type

Mandatory.

The value of this attribute must be set to `sql:SQLConnectionPolicy`.

Subelements

The `connectionPolicy` element contains either of the following subelements.

dataSourceDefinition

Mandatory

Contains the parameters that are needed to connect to a data source. The `url`, `user`, `password`, and `driverClass` parameters can be externalized as custom properties. Then, they can then be overridden by environment entries.

The following example illustrates this process.

`adapter.xml`:

```

<connectionPolicy xsi:type="sql:SQLConnectionPolicy">
  <dataSourceDefinition>
    <driverClass>com.mysql.jdbc.Driver</driverClass>
    <url>${my-mysql-url}</url>
    <user>${my-mysql-user}</user>
    <password>${my-mysql-password}</password>
  </dataSourceDefinition>
</connectionPolicy>

```

`worklight.properties`:

```

my-mysql-url=jdbc:mysql://localhost:3306/mysql dbname
my-mysql-user=user_name
my-mysql-password=password

```

dataSourceJNDIName

Mandatory.

Connect to the data source by using the JNDI name of a data source that is provided by the application server. Application servers provide a way to configure data sources. For more information, see “Creating and configuring the databases manually” on page 12-20.

You can also externalize the data source JNDI name and make it configurable from the server configuration. For example:

`adapter.xml`

```
<connectionPolicy xsi:type="sql:SQLConnectionPolicy">
  <dataSourceJNDIName>${my-adapter-ds}</dataSourceJNDIName>
</connectionPolicy>

worklight.properties
my - adapter - ds = jdbc / myAdapterDS
```

For more information, see “JNDI environment entries for MobileFirst projects in production” on page 12-68.

Developing JavaScript adapters

Learn to configure a new IBM MobileFirst Platform Foundation JavaScript adapter, and set up connectivity to back-end configuration.

Creating a JavaScript MobileFirst adapter:

Follow these instructions to create a MobileFirst project and configure a new MobileFirst adapter.

About this task

On initial creation of a new adapter, MobileFirst automatically generates the default skeleton for the adapter with all the required properties, based on the type (HTTP, SQL, or JMS). You need only to modify the default skeleton to configure an adapter.

Procedure

1. Optional: Perform this step only if you do not already have an existing MobileFirst project. If you set up MobileFirst shortcuts, right-click anywhere within the Eclipse Project Explorer view and click **New > MobileFirst Project**. Otherwise, click **New > Other**, then select **MobileFirst > MobileFirst Project** from the list of wizards and click **Next**.

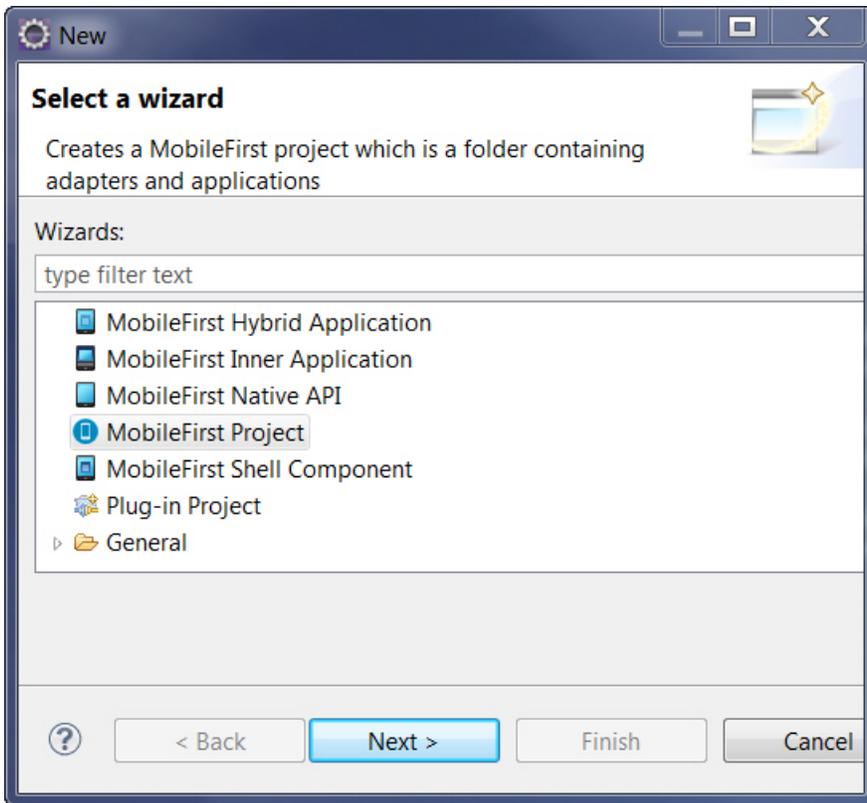

Figure 8-36. Creating a MobileFirst project from the wizard.

2. In the **New MobileFirst Project** wizard, specify a name for the project and click **Finish**.
3. If you set up MobileFirst shortcuts, right-click the MobileFirst Project to which you want to add the adapter, and select **New > Adapter**. Otherwise, select **New > Other**, then select **MobileFirst > MobileFirst Adapter** from the list of wizards and click **Next**.

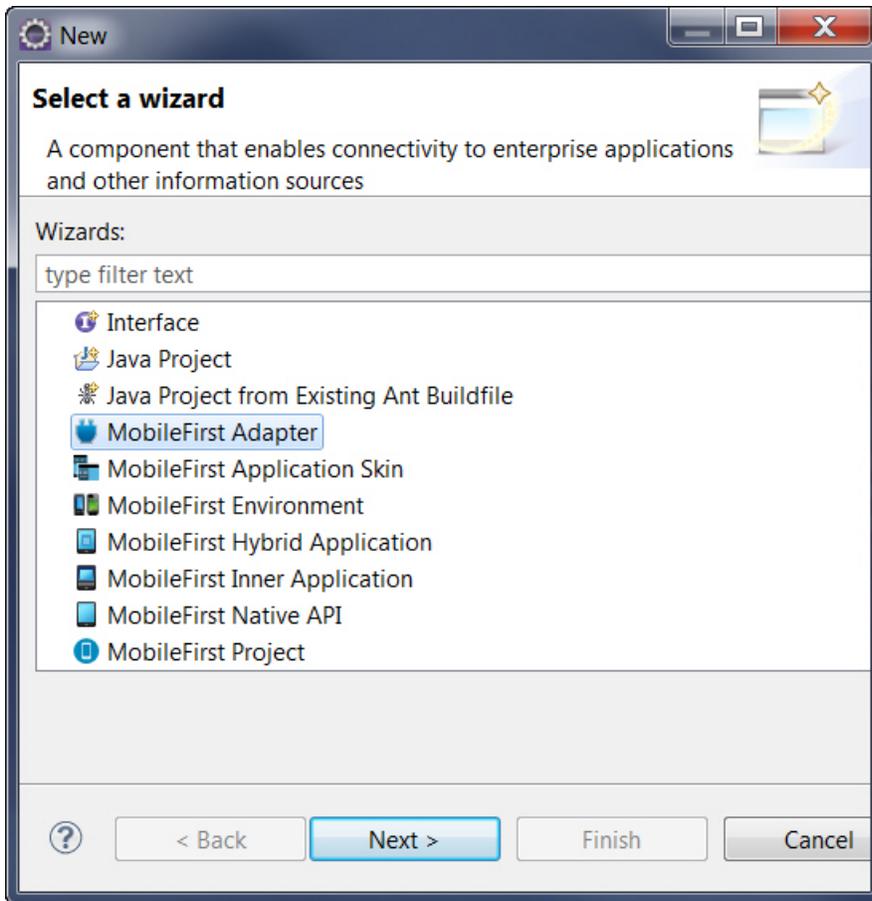

Figure 8-37. Configuring a new MobileFirst adapter.

The **New Adapter** wizard opens.

4. Select the required adapter type from the **Adapter type** list and enter a name for the adapter in the **Adapter name** field.

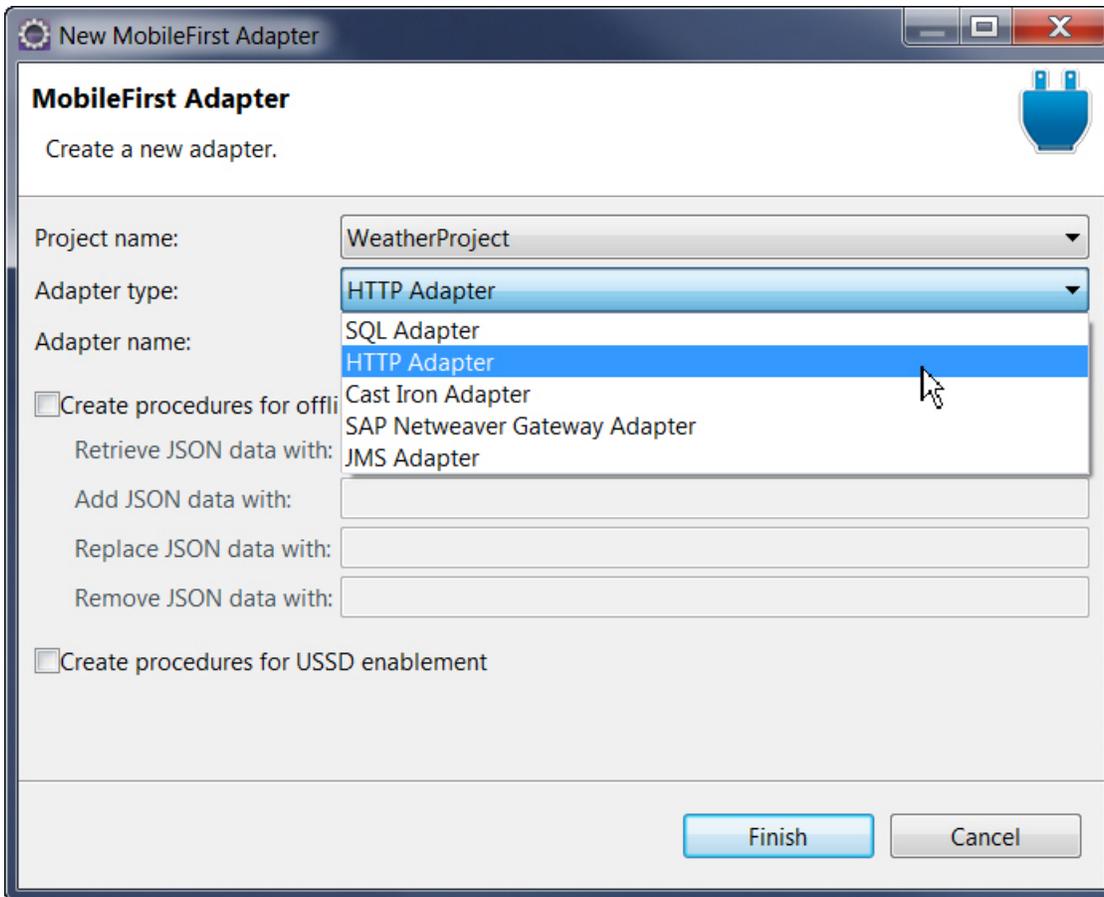

Figure 8-38. Selecting an adapter type.

5. Optional:

- Select **Create procedures for offline JSONStore** to include four place holder procedures in the adapter template: a procedure that gets data, a procedure that adds data, a procedure that replaces data, and a procedure that removes data. These procedures are designed to help you develop a JSONStore-enabled application that communicates with a back end.
- Select **Create procedures for USSD enablement** to generate sample procedures for USSD in the adapter js file.

6. Click **Finish**.

Generating adapters with the services discovery wizard:

With the services discovery wizard, you specify the back-end services that you want to invoke from your MobileFirst project, and generate the adapters that connect to those services.

The services discovery wizard supports the following types of back-end services:

- IBM Business Process Manager (IBM BPM) process applications. Discover IBM BPM process applications and generate the generic and application-specific adapters.
- Microsoft Azure Marketplace DataMarket.
- OData RESTful APIs.

- RESTful resources. Describe a RESTful resource by accessing your back-end service.
- Services that are exposed by an SAP Netweaver Gateway. These services are resource-based, which means that they expose a collection of resources that you can manipulate. Like web services, they can also have custom procedural operations, and generate inputs and outputs.
- Web Services, as described by Web Services Description Language (WSDL) files. These services are procedural in nature, with inputs and outputs that are explicit. For example, when a web service calls a remote procedure, it gets a result.

The adapters that communicate with the chosen back-end service are automatically generated, and placed in the **adapters** folder of your project.

Note: If you manually modify an adapter file, first create a copy of this file, and make sure to modify only the copied file. The services discovery wizard might regenerate the original file each time you add a service. The exact adapter that is regenerated depends on the type of service that is involved.

Generating adapters with IBM BPM:

You can use the Add Service Wizard to select an active snapshot and generate an adapter that provides access to the IBM Business Process Manager (IBM BPM) REST APIs.

Procedure

1. Right-click the **services** folder of your project in the Project Explorer tab, and click **Discover Back-end Services**. The Add Service Wizard window opens.

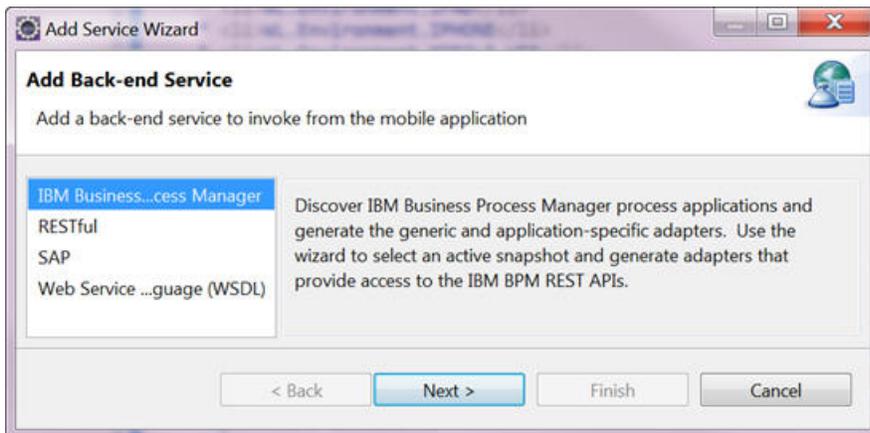

Figure 8-39. The Add Service Wizard

2. Select **IBM Business Process Manager** and click **Next**. The IBM BPM process applications page is displayed.
3. You can set up a connection to an IBM BPM server if you complete one of the following choices.
 - Click **Add** next to the **Connections** field.
 - Click **Manage IBM BPM Connections** to edit existing connections.
 - a. Click **Add**.

- Select an existing IBM BPM connection from the drop-down list in the **Connections** field.
4. Enter your server URL, user, and password credentials and click **OK**. The IBM BPM process applications and their available active snapshots are visible in the **Select Snapshot** field.
 5. Expand the process application that you want to create an adapter for, select a snapshot, and click **Next**.
 6. Name your adapter and click **Finish**.

Results

A generic adapter and an application-specific adapter are generated under the **adapters** folder of your project. You can use this adapter to access IBM BPM REST APIs on the IBM BPM server.

The project's `/server/conf/worklight.properties` file is also updated to include the necessary IBM BPM server properties.

Generating adapters by using Microsoft Azure:

You can use the Add Service Wizard to generate adapters that discover your subscribed data services from Microsoft Azure Marketplace DataMarket.

Procedure

1. Right-click the **services** folder of your project in the Project Explorer tab, and click **Discover Back-end Services**. The Add Service Wizard window opens.
2. Select **Microsoft Azure Marketplace DataMarket** and click **Next**.
3. Set up a connection to a server by either:
 - Clicking **Add** to create an Azure connection.
 - Clicking the **Manage Azure Connections** link to edit existing connections.
 - Selecting an existing Azure connection from the **Connection** list.
4. Click **Finish**.

Results

- An adapter is generated under the **adapters** folder of your project. You can use this adapter to invoke services with JavaScript calls.

- An `.xml` service description file is also generated under the **services** folder of your project. You can refer to the `.xml` files under the **services** folder of your project to have a summary view of the target adapters.

Generating adapters with OData:

You can use the Add Service Wizard to generate adapters that access the OData RESTful APIs, and explore the OData metadata for a service URL.

Procedure

1. Right-click the **services** folder of your project in the Project Explorer tab, and click **Discover Back-end Services**. The Add Service Wizard window opens.
2. Select **OData** and click **Next**.
3. Set up a connection to a server by either:

- Clicking **Add** to create an OData connection.
 - Clicking the **Manage OData Connections** link to edit existing connections.
 - Selecting an existing OData connection from the **Connection** list.
4. Click **Finish**.

Results

- An adapter is generated under the **adapters** folder of your project. You can use this adapter to invoke services with JavaScript calls.
- An **.xml** service description file is also generated under the **services** folder of your project. You can refer to the **.xml** files under the **services** folder of your project to have a summary view of the target adapters.

Generating adapters by describing RESTful resources:

You can use the Add Service wizard to describe a RESTful resource to access your back-end service. Use the wizard to describe URL segments that are dynamic parameters to generate MobileFirst adapters.

Procedure

1. Right-click the **services** folder of your project in the Project Explorer tab, and click **Discover Back-end Services**. The Add Service Wizard window opens.
2. Select **RESTful** and click **Next**.
The **Resource Structure** page is visible.

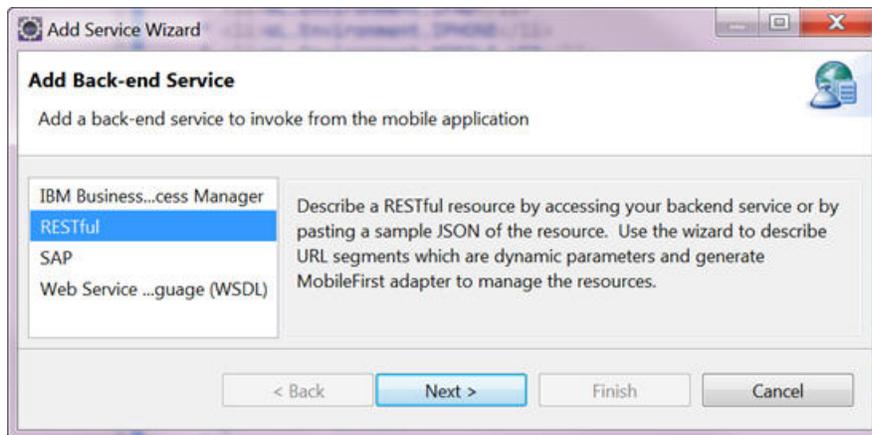

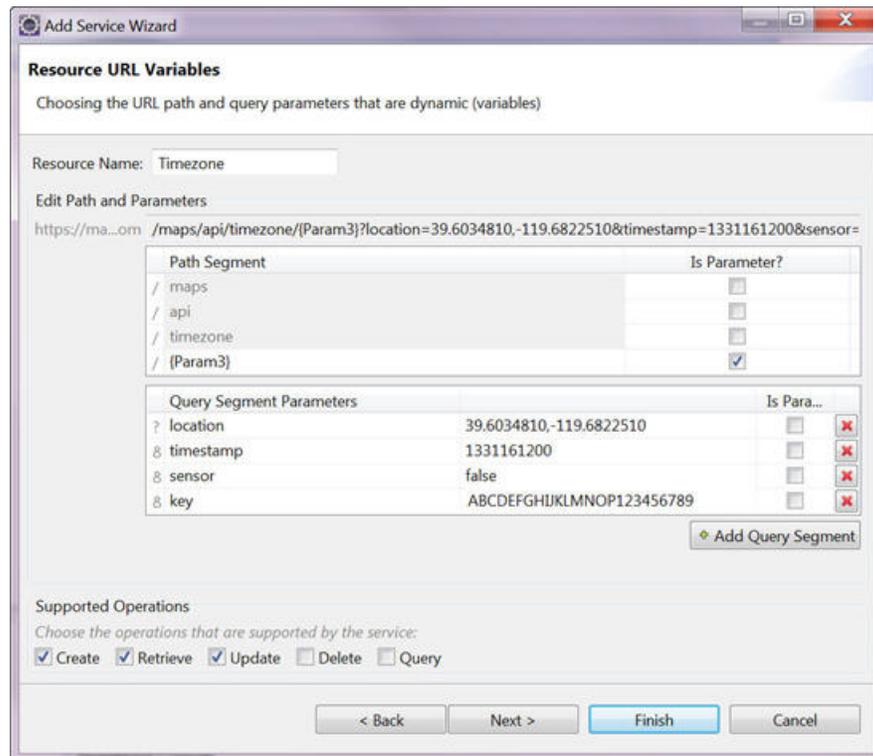

Figure 8-40. The Add Service Wizard

3. Complete the **Resource Structure** page.
 - a. Type the URL to the resource into the **Resource URL** field and complete one of the following choices.
 - Click **Fetch URL** to retrieve a JSON payload from the URL entered and display it in the **Sample Resource (as JSON)** field.
You might need to set up authentication and custom headers before you click **Fetch URL**.
 - Manually enter a sample JSON payload in the **Sample Resource (as JSON)** field.

The **Sample Resource (as JSON)** field is completed with the JSON code that results from the provided URL. That JSON code is parsed into build structures that are visible in the **Resource Structure** field.

- b. From the **Resource Structure** field, select which parameter is the **Key**.
 - c. Select the level of authentication from the **Authentication** field.
 - **None:** Authentication is not needed.
 - **Basic Authentication:** Authentication is needed. The user ID and password are sent in clear text, according to HTTP Basic Authentication guidelines.
 - **Digest:** Authentication is needed. The user ID and password are sent by using HTTP Digest authentication (as a hash).
 - d. If you need specific HTTP headers to communicate with the back-end service, complete the **Request Custom HTTP Header** fields. The left column is the header name, and the right column is the value. The drop-down list on the left includes a set of HTTP header names. Or, you can type any header name.
 - e. Click **Next**.
4. From the Resource URL Variables page, select the settings for your adapter.

5. To customize resource operations, click **Next**. Otherwise, click **Finish**.
6. If you clicked **Next**, customize your resource operations.
 - a. Choose the **HTTP Method** for each operation.

Table 8-22. HTTP methods

Method	Safe	Idempotent	Cacheable	Description
GET	Yes	Yes	Yes	Retrieves information from the input server by using the input URI
PUT	No	Yes	No	Puts or updates a resource on the server
POST	No	No	No	Sends data to the server
DELETE	No	Yes	No	Deletes the requested resource

- b. Complete the **Edit path and parameters** field.
- c. If you need specific HTTP headers to communicate with the back-end service, complete the **Request Custom HTTP Header** fields. The left column is the header name, and the right column is the value. The drop-down list on the left includes a set of HTTP header names. Or, you can type any header name.
- d. Click **Finish**.

Results

- An adapter is generated under the **adapters** folder of your project. You can use this adapter to invoke services with JavaScript calls.
- A **.xml** service description file is also generated under the **services** folder of your project. You can refer to the **.xml** files under the **services** folder of your project to have a summary view of the target adapters.

Generating adapters with SAP Gateway:

You can use the Add Service Wizard to discover services that are exposed by an SAP Gateway and generate MobileFirst adapter for invoking the services.

Procedure

1. Right-click the **services** folder of your project in the Project Explorer tab, and click **Discover Back-end Services**. The Add Service Wizard window opens.

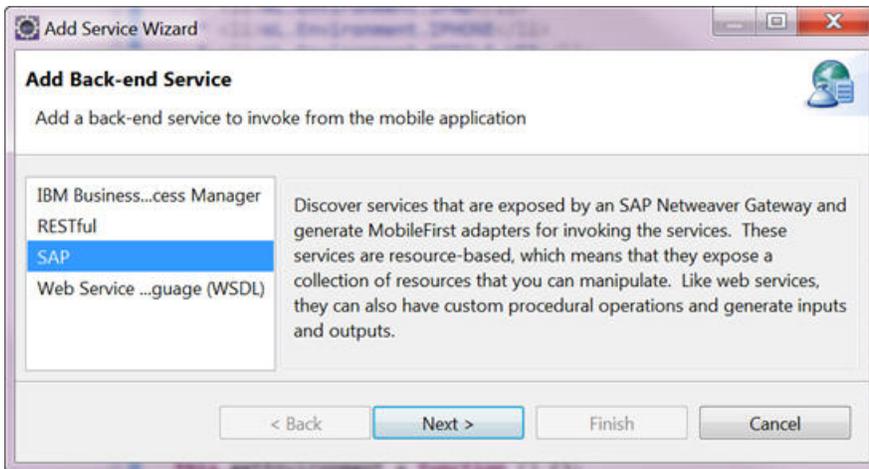

Figure 8-41. The Add Service Wizard

2. Select **SAP** and click **Next**.
3. Set up a connection to an SAP Netweaver Gateway server by either:
 - Clicking **Add** to create an SAP connection.
 - Clicking the **Manage SAP Connections** link to edit existing connections.
 - Selecting an existing SAP connection from the **Connection** list.
4. Proceed with the connection configuration by entering your server URL, client ID, user name, and password. In the **Select Service** pane, you can now see the list of SAP services that are available on the server you specified.
5. Click **Finish**.

Results

- An adapter is generated under the **adapters** folder of your project. You can use this adapter to invoke services with JavaScript calls.
- An **.xml** service description file is also generated under the **services** folder of your project. You can refer to the **.xml** files under the **services** folder of your project to have a summary view of the target adapters.

Generating adapters with WSDL:

You can use the Add Service Wizard to discover and generate MobileFirst adapters for invoking a SOAP-based Web Service. You can import a Web Service Definition Language (WSDL) of the service from your file system, workspace, or remotely by typing its URL in the wizard.

Procedure

1. Right-click the **services** folder of your project in the Project Explorer tab, and click **Discover Back-end Services**. The Add Service Wizard window opens.

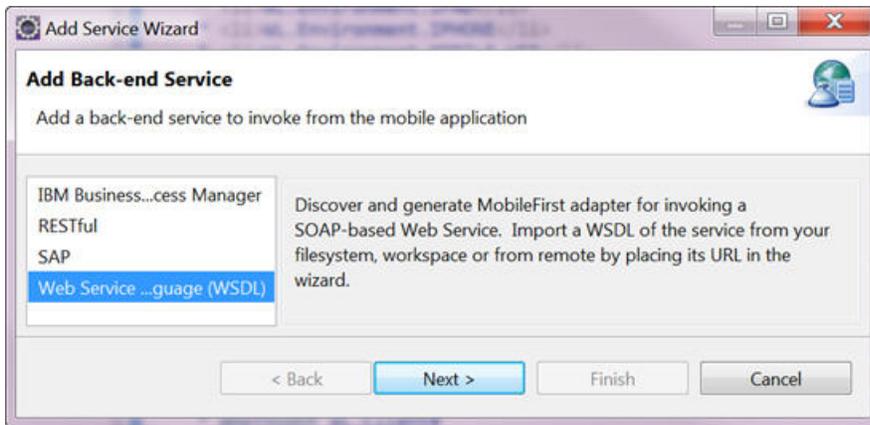

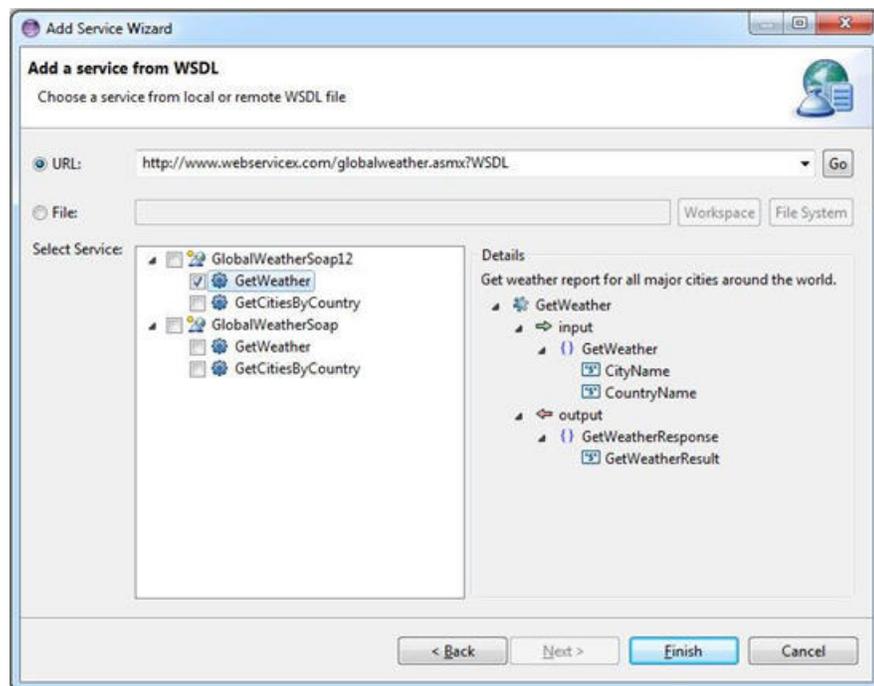

Figure 8-42. The Add Service Wizard

2. Select **Web Service Definition Language (WSDL)** and click **Next**.
3. Complete the Add a Service from WSDL page. Enter a URL or select one from the **URL** drop-down list, and click **Go**. Or browse to a file in your workspace or in your system.

- a. Enter a URL or select one from the **URL** drop-down list, and click **Go**.

Note: If you enter a secure URL (https), the system fetches the certificate from the specified server, and stores it into a private key storage area that is created in your workspace.

- b. Optional. If you are prompted to, enter your credentials. You can now see the list of available services. Different types of information are displayed in the **Details** pane, depending on the level you select:
 - The first level corresponds to the binding configuration details. When this level is selected, the **Details** pane shows the SOAP version.

- The second level corresponds to the data operation details. When this level is selected, the **Details** pane shows the input and the output of the remote invoked procedure.
- c. Select one or more services that you want to invoke from your application.
4. Click **Finish**.

Results

- An adapter is generated under the **adapters** folder of your project. You can use this adapter to invoke services with JavaScript calls.
- An .xml service description file is also generated under the **services** folder of your project. You can refer to the .xml files under the **services** folder of your project to have a summary view of the target adapters.
A sample payload of each service is available from the Properties dialog box of the service. You can reuse this sample payload in other adapters. To use the sample payload of a service:
 1. Right-click the service name in the services folder of your project in the Eclipse Project Explorer view, and click **Properties**.
 2. Copy the text from the **Sample Procedure Parameter** field.

Invocation of generated SOAP adapters:

The generated SOAP adapters have a procedure that calls the back-end service operation. You can invoke this procedure from your MobileFirst application in the same way as you invoke other MobileFirst adapter procedures, by providing the necessary parameters for the invocation.

The generated procedure accepts two parameters: the message to the service, and custom HTTP headers.

The message to send to the service (required)

This mandatory parameter is the message to send to the service in JSON format.

The message parameter is a JSON representation of the XML message to include in the SOAP body that is sent to the service.

The following examples show JSON representations for sample XML messages.

1. Simple XML message: the adapter converts the provided JSON parameter into XML body by creating a matching element for each JSON attribute.

The following JSON parameter in the procedure:

```
{"GetTechnicianVisits": {"TechnicianId": "1"}}
```

is transformed by the adapter into the following XML fragment in the SOAP body:

```
<GetTechnicianVisits>
  <TechnicianId>1</TechnicianId>
</GetTechnicianVisits>
```

2. XML messages with namespaces

The generated adapter implementation (SoapAdapterX-impl.js) has a set of namespace prefixes imported from the provided WSDL service. To specify elements with specific namespaces, those prefixes must be used to name the relevant JSON attributes.

The following JSON parameter in the procedure:

```
{"tns1:GetTechnicianVisits": {"tns1:TechnicianId": "1"}}
```

is transformed by the adapter into the following XML fragment in the SOAP body:

```
<GetTechnicianVisits xmlns:tns1="http://namespace/sample">  
  <TechnicianId>1</TechnicianId>  
</GetTechnicianVisits>
```

Note: Since IBM MobileFirst Platform Foundation V6.2.0, if the names of the elements are unique, the generated SOAP adapters no longer require the use of namespace prefixes on all the fields in the payload.

3. XML messages with attributes

Adding the @ prefix to a JSON attribute name instructs the adapter to create an attribute instead of creating an element.

The following JSON parameter in the procedure:

```
{"GetTechnicianVisits": {"@technicianId": "1"}}
```

is transformed by the adapter into the following XML fragment in the SOAP body:

```
<GetTechnicianVisits technicianId="1"/>
```

A JSON object that holds custom HTTP headers for the invocation (optional)

This optional parameter is a JSON object that lists custom HTTP headers (key values). These custom HTTP headers are added to the service call when the POST request is invoked with the generated SOAP message.

```
{ 'custom-header-1': 'value1', 'custom-header-2': 'value2' }
```

Setting up connectivity to back-end configuration:

Learn about adapter timeout and concurrency, connectivity for non-Java adapters, and developing JavaScript adapter code.

Adapter timeout and concurrency:

Changes in the behavior of adapter timeout and concurrency starting in IBM MobileFirst Platform Foundation V6.3 have impact on the adapter XML schema. Adapter failures can occur if the JSON data exceeds available memory.

Timeout and concurrency in IBM MobileFirst Platform Foundation V6.3

Starting in IBM MobileFirst Platform Foundation V6.3, the behavior of timeout and concurrency was modified for HTTP-based, JMS, and SQL adapters.

HTTP-based adapters

In earlier versions of IBM MobileFirst Platform Foundation, timeout and concurrency were handled by thread pools. They are now enforced by the underlying HTTP framework.

- Timeout:

Previously, you were able to define a timeout for a single procedure. Starting from V6.3, you can use the standard socket timeout and connection timeout that are provided by HTTP frameworks. A socket timeout defines the time between two consecutive packets, starting from the connection packet. A connection timeout defines the time within which a connection to the back-end must be established.

You can set the socket and connection timeouts in two places:

- To set the default value for an adapter, set it in the adapter XML file. For more details on timeout in the XML file, see “Structure of the adapter XML file” on page 8-247.
 - To set the timeouts for a specific back-end invocation, use the **options** struct in the `invokeHttp()` JavaScript function. For more information, see the `WL.Server` class.
- **Concurrency:**
You use the **<maxConcurrentConnectionsPerNode>** subelement of the **<connectionPolicy>** element in the adapter XML file to set concurrency limits. For more information, see “Structure of the adapter XML file” on page 8-247.

JMS adapters

- **Timeout:** JMS adapter provides several timeout specifications based on the action that is attempted. There has been no change in functionality in that sense but the per-procedure timeout has been removed.
- **Concurrency:** Starting from IBM MobileFirst Platform Foundation V6.3, concurrency is no longer supported for JMS adapters.

SQL adapters

Previously, concurrency and timeout were handled by thread pools. Starting from V6.3, the only method to define concurrency and timeout, is to use the SQL Connection Pool obtained using a JNDI reference.

XML schema changes in IBM MobileFirst Platform Foundation V6.3

IBM MobileFirst Platform Foundation V6.3 uses a new adapter XML schema. Adapters using earlier schemas cannot be used in Studio V6.3 and CLI V6.3. The following changes are made to the adapter schema during upgrade:

- The **requestTimeoutInSeconds** attribute of the **<procedure>** element is no longer supported. During project upgrades to IBM MobileFirst Platform Foundation V6.3, the attribute is commented out in all **<procedure>** elements.
- The **<loadConstraints>** element and its attributes are no longer supported. During project upgrades to IBM MobileFirst Platform Foundation V6.3, this element is removed.
- In HTTP-based adapters, there are three new elements: **<connectionTimeoutInMilliseconds>**, **<socketTimeoutInMilliseconds>**, and **<maxConcurrentConnectionsPerNode>** under **<connectionPolicy>**. During project upgrades to IBM MobileFirst Platform Foundation V6.3, these new elements are added. For more information, see “Structure of the adapter XML file” on page 8-247.

Compatibility with earlier versions

Adapters from previous versions work and can be deployed on the MobileFirst Server V6.3. However, they behave differently.

HTTP-based adapters

- **Timeout:**
The value of the **requestTimeoutInSeconds** attribute of **<procedure>** elements is now used to set the value of the HTTP socket timeout and connection timeout per procedure.
- **Concurrency:**
The concurrency limits are enforced by the underlying HTTP framework, instead of by a thread pool.

JMS adapters

The **requestTimeoutInSeconds** attribute of **<procedure>** and **<loadConstraints>** elements is ignored.

SQL adapters

The **requestTimeoutInSeconds** attribute of **<procedure>** and **<loadConstraints>** elements is ignored. Use JNDI configuration instead.

Adapter invocation failures due to large data

Adapter calls are not intended for returning very large JSON data. The adapter response is stored in memory and string parsed. Data that exceeds the amount of available memory might cause adapter invocation to fail. To reduce the possibility that such a failure occurs, limit the amount of data to less than 10 MB.

Connectivity for non-Java adapters:

With IBM MobileFirst Platform Studio, you can configure back-end connectivity for non-Java adapters.

HTTP adapters:

The MobileFirst HTTP adapter can be used to invoke RESTful services and SOAP-based services. It can also be used to perform HTML scraping.

You can use the HTTP adapter to send GET, POST, PUT, and DELETE HTTP requests and retrieve data from the response body. Data in the response can arrive in XML, HTML, or JSON formats.

You can use SSL in an HTTP adapter with simple and mutual authentication to connect to back-end services. Configure the MobileFirst Server to use SSL in an HTTP adapter by implementing the following steps:

- Set the URL protocol of the HTTP adapter to `https`.
- Store SSL certificates in a keystore that is defined by using JNDI environment entries. The keystore setup process is described in “SSL certificate keystore setup” on page 12-60.
- If you use SSL with mutual authentication, the following extra steps must also be implemented:
 - Generate your own private key for the HTTP adapter or use one provided by a trusted authority.
 - If you generated your own private key, export the public certificate of the generated private key and import it into the back-end truststore.
 - Save the private key of the keystore that is defined by using JNDI environment entries.
 - Define an alias and password for the private key in the **<connectionPolicy>** element of the HTTP adapter XML file, *adaptername.xml*. The

<sslCertificateAlias> and <sslCertificatePassword> subelements are described in “HTTP adapter connectionPolicy element” on page 8-252.

- If you use WebSphere Application Server, you can benefit from the WebSphere SSL configuration as described in WebSphere Application Server SSL configuration and HTTP adapters.

Note, however that SSL represents transport level security, which is independent of basic authentication. It is possible to do basic authentication either over HTTP or HTTPS.

Encoding a SOAP XML envelope:

Encode a SOAP XML envelope within a request body when you need to invoke a SOAP-based service in an HTTP adapter.

About this task

Important: This workaround is only for WebSphere Application Server.

Procedure

1. Encode XML within JavaScript by using E4X.

E4X is officially part of JavaScript 1.6. This technology can be used to encode any XML document, not necessarily SOAP envelopes. You can use the `WL.Server.signSoapMessage()` method only inside a procedure declared within an HTTP adapter. It signs a fragment of the specified envelope with ID `wsId` by using the key in the specified **keystoreAlias**, and inserting the digital signature into the input document.

To use `WL.Server.signSoapMessage()` API when running IBM MobileFirst Platform Foundation on IBM WebSphere Application Server, you might need to add a JVM argument that instructs the application server to use a specific **SOAPMessageFactory** implementation instead of a default one.

2. To do this, go to **Application servers > {server_name} > Process definition > Java Virtual Machine** and provide the following argument under **Generic JVM arguments**.

Type in the code phrase exactly as it is presented here:

```
-Djavax.xml.soap.MessageFactory=com.sun.xml.internal.messaging
.saaj.soap.ver1_1.SOAPMessageFactory1_1Impl
```

3. Restart the JVM.

Example

```
var request =
<S:Envelope xmlns:S="http://schemas.xmlsoap.org/soap/envelope/">
<S:Body>
<requestMessageObject xmlns="http://acme.com/ws/">
<messageHeader>
<version>1.0</version>
<originatingDevice>{originatingDevice}</originatingDevice>
<originatingIP>
{WL.Server.configuration["local.IPAddress"]}
</originatingIP>
<requestTimestamp>
{new Date().toLocaleString()}
</requestTimestamp>
</messageHeader>
<messageData>
<context>
<userkey>{userKey}</userkey>
```

```
<sessionid>{sessionid}</sessionid>  
</context>  
</messageData>  
</requestMessageObject>  
</S:Body>  
</S:Envelope>;
```

NTLM configuration for HTTP adapters:

NTLM uses a challenge-response mechanism for authentication. Learn how to use a MobileFirst adapter when connecting to a back end or resource that is protected by NTLM protocol.

Back-end connection types

MobileFirst Server can connect with a back-end system or resource that is protected by NTLM protocol, either as a server or as an end-user.

Connect as server

In this connection type, all sessions use the same connection context to the back end. This is the default MobileFirst Server behavior. See Figure 1.

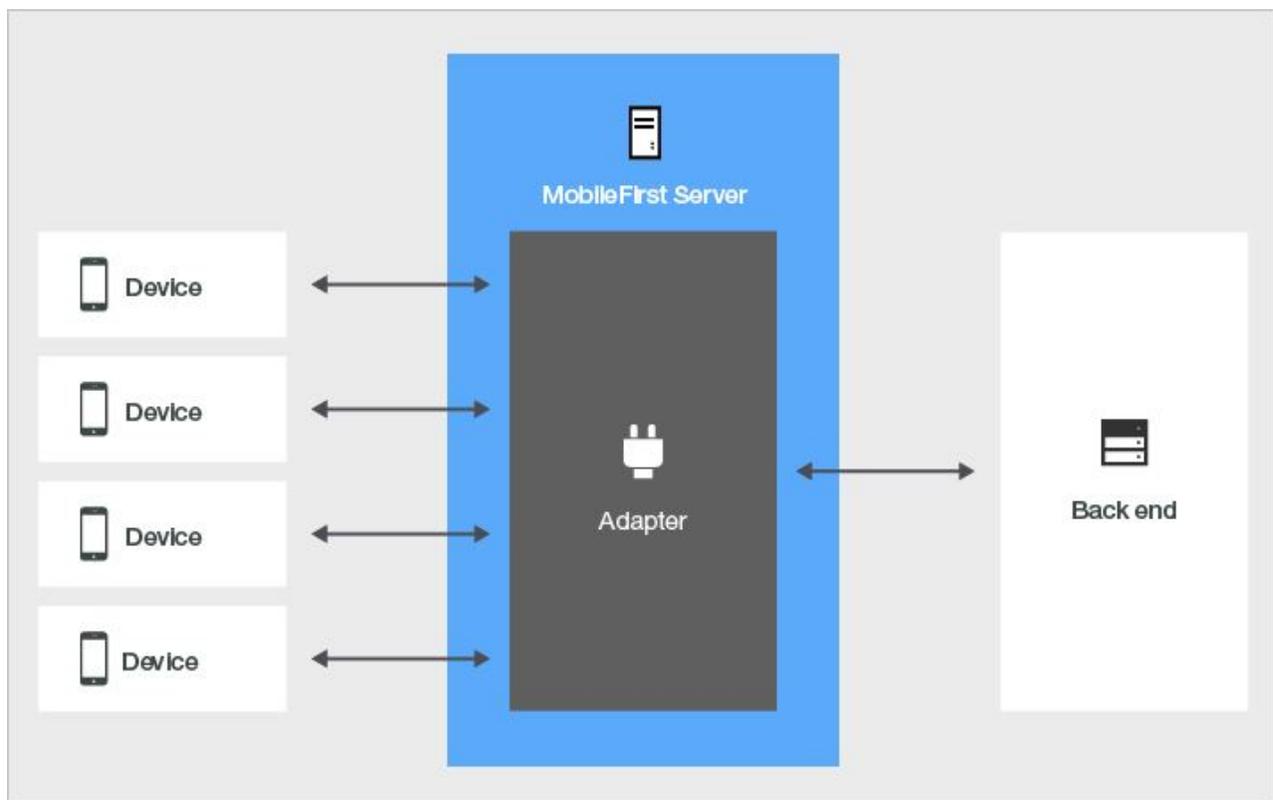

Figure 8-43. Connecting to the back end as server

Connect as end user

In this connection type, each session is authenticated separately and has a unique connection context against the back end. See Figure 2.

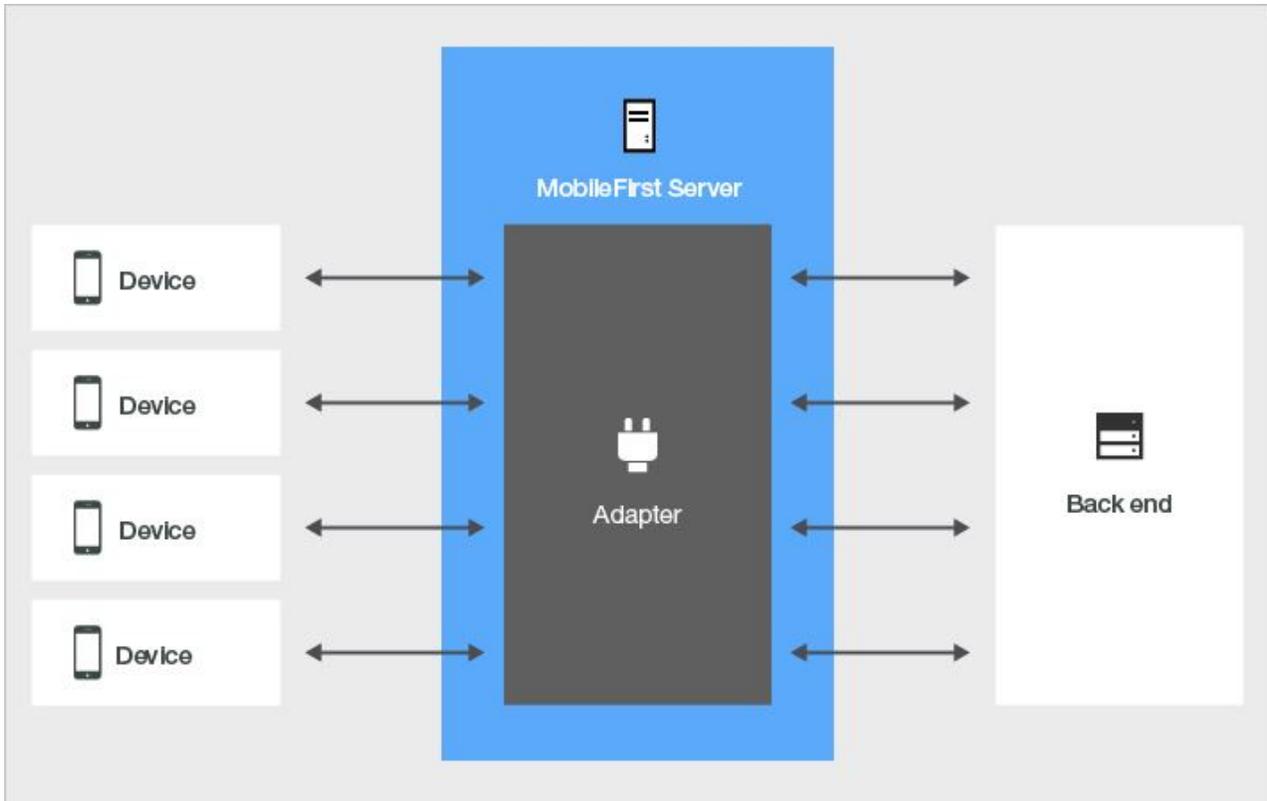

Figure 8-44. Connecting to the back end as end user

Back-end connection settings

The connection types that are described in the previous section correspond to the server and endUser options of the connectAs attribute in the adapter XML file.

- To connect as server (the default), there is no need to make any configuration change to the adapter.xml file.
- To connect as an end-user, add a procedure element to the adapter XML file, as follows:

```
<procedure name= "MyProcedure" connectAs= "endUser" />
```

For more information about the connectAs attribute, see “Structure of the adapter XML file” on page 8-247.

Implementing NTLM authentication for server requests:

Implement NTLM authentication where a single, shared instance of HTTP client is used per adapter for all mobile application instances.

About this task

By default, procedures that connect to a back-end server that uses NTLM protocol are handled on a server-to-server basis, as the connectAs attribute is defined as =“server”. You need only configure serverIdentity of the adapter XML file as a subelement of the authentication. You also add the ntlm workstation attribute, so that MobileFirst Server knows which authentication method to use when connecting to the back end.

Procedure

1. Open the adapter.xml file of the project.
2. Add an authentication element as follows:

```
<connectivity>
  <connectionPolicy xsi:type="http:HTTPConnectionPolicyType">
    <protocol>http</protocol>
    <domain>your-domain-here</domain>
    <port>80</port>
    <connectionTimeoutInMilliseconds>30000</connectionTimeoutInMilliseconds>
    <socketTimeoutInMilliseconds>30000</socketTimeoutInMilliseconds>
    <authentication>
      <ntlm workstation="ServerName"/>
      <serverIdentity>
        <username>your-server-name-here/your-username-here</username>
        <password>your-password-here</password>
      </serverIdentity>
    </authentication>
    <maxConcurrentConnectionsPerNode>50</maxConcurrentConnectionsPerNode>
  </connectionPolicy>
</connectivity>
```

Note: When the NTLM protocol is used, the user name must always be specified in the format: server-name/user-name. Ensure that in the adapter.xml file, you pass the server and user names to the back-end server in that pattern. For more information, see “HTTP adapter connectionPolicy element” on page 8-252.

Implementing NTLM authentication for end-user requests:

Implement NTLM authentication where a separate instance of HTTP session is opened for each client session.

About this task

To enable NTLM authentication with connectAs="endUser", you configure the server and add handling functions in the adapter.

Configure MobileFirst Server authentication:

Procedure

1. In the authenticationConfig.xml file for your project, make the following edits:

- a. Create a security test to protect the procedure:

```
<customSecurityTest name="NTLMSecurityTest">
  <test isInternalUserID="true" realm="NTLMAuthRealm"/>
</customSecurityTest>
```

- b. Use BasicAuthenticator, AdapterBasedAuthenticator, or any other authenticator that handles userIdentity, as the class for the realm to be used by the security test:

```
<realm name="NTLMAuthRealm" loginModule="AuthLoginModule">
  <className>com.worklight.integration.auth.AdapterAuthenticator</className>
  <parameter name="login-function" value="MyAdapter.onAuthRequired"/>
  <parameter name="logout-function" value="MyAdapter.onLogout"/>
</realm>
```

- c. Add a login module to create and store user identities to be used by this realm:

```
<loginModule name="AuthLoginModule">
  <className>com.worklight.core.auth.ext.NonValidatingLoginModule</className>
</loginModule>
```

2. In the adapter.xml file, make the following edits:
 - a. Add the authentication element and its ntlm workstation subelement to the adapter XML file, so that MobileFirst Server knows which authentication method to use when connecting to the back end:

```
<connectivity>
  <connectionPolicy xsi:type="http:HTTPConnectionPolicyType">
    <protocol>http</protocol>
    <domain>Put.Your.Domain.Here</domain>
    <port>80</port>
    <connectionTimeoutInMilliseconds>30000</connectionTimeoutInMilliseconds>
    <socketTimeoutInMilliseconds>30000</socketTimeoutInMilliseconds>
    <authentication>
      <ntlm workstation="wl-ntlm"/>
    </authentication>
    <maxConcurrentConnectionsPerNode>50</maxConcurrentConnectionsPerNode>
  </connectionPolicy>
</connectivity>
```

- b. Assign this security test to the procedure that is used to connect to the back end protected by the NTLM protocol, and add connectAs="endUser" to the procedure declaration in the adapter XML file:

```
<procedure name= "getNTLMData" securityTest= "NTLMSecurityTest" connectAs= "endUser"/>
```

Create adapter functions:

Procedure

1. Define the submitAuthentication function. Create a userIdentity that contains a user identifier and credentials properties. Format the userId in the pattern servername/username:

```
function submitAuthentication(username, password){
  var userIdentity = {
    userId: "MyServerName\"/" + username,
    credentials: password
  };
  WL.Server.setActiveUser("NTLMAuthRealm", null);
  WL.Server.setActiveUser("NTLMAuthRealm", userIdentity);
  ...
}
```

For more information, see “Implementing adapter-based authenticators” on page 8-638.

2. Create an HTTP request to the NTLM-protected back end:

```
function getSecretData(){
  var input = {
    method : 'get',
    returnedContentType : 'html',
    path : "index.html"
  };
  return WL.Server.invokeHttp(input);
}
```

For more information, see the invokehttp() function in the WL.Server class.

Back-end responses in adapters:

Understanding the logic of invocation results both on the client side and inside adapters helps you handle different failure scenarios.

HTTP adapter flow

For a general description of an adapter flow, see “MobileFirst JavaScript adapters” on page 8-245. The following sections explain how to handle back-end responses in the case of an HTTP adapter. A typical HTTP adapter flow might involve the following sequence of events:

1. The client (that is, the mobile app) uses the `invokeProcedure` method of the `WL.Client` class to invoke one of the adapter's procedures from the MobileFirst Server.
2. The adapter then uses the `invokeHttp` method of the `WL.Server` class to call the back-end service.
3. The adapter procedure processes the data from the back end and returns a JSON object to the client.
4. The client calls its `onSuccess` handler to process the data received by the adapter.

Responses from the invoke procedure

The adapter flow starts with a `WL.Client` class `invokeProcedure` call, which supports `onSuccess` and `onFailure` handlers. Both handlers receive an object, which is a standard JSON object. The following table describes some of its properties:

Table 8-23. Properties of the object received following the invoke procedure

Property	Description
<code>isSuccessful</code>	Whether the procedure call is successful. Note: The text following the table explains the circumstances when a request is considered to be successful.
<code>status</code>	HTTP status code from the procedure call. This is not the HTTP code from the back-end service, only from the connection with the MobileFirst Server.
<code>errorCode</code>	A possible error code if the call is not successful.
<code>errorMsg</code>	A possible error message if the call is not successful.
<code>invocationContext</code>	An optional object that is sent in the procedure call and is returned as-is.
<code>invocationResult</code>	JSON object that is returned by your procedure call. This object may be augmented with additional data such as session information.

Which handler is called depends on the value of the `isSuccessful` property in the invocation result:

- If `isSuccessful` is set to `true`, `onSuccess` is called.
- If `isSuccessful` is set to `false`, `onFailure` is called.

As long as your adapter returns something, the procedure invocation is considered successful and so the `isSuccessful` property is set to `true`. The `isSuccessful` property is set to `false` under the following circumstances:

- When calling a procedure that does not exist.

- When calling an adapter that does not exist.
- When the MobileFirst Server is unresponsive (for example, due to a bad host name or because the MobileFirst Server is currently unavailable).
- When the invocation times out (you can set a timeout value as one of the `invokeProcedure` options).
- When the adapter throws an exception.
- When the code in the procedure specifically overwrites the `onSuccess` property.

The `isSuccessful` property is set to `false` if there is a connection issue between the client and the adapter; not if there is an error in the back-end service. This means, for example, that if your procedure calls a back-end service which returns an error (such as a "404" error) but your procedure still returns a valid JSON object, your procedure invocation is still considered to be successful from the perspective of the client. If you simply return the result of `invokeHttp` straight to the client, since you are returning something, `isSuccessful` is `true` by default and `onSuccess` is called. This may or may not be what you want to happen. You need to make sure that your procedure code is capable of handling cases when a back-end service returns an error.

Invocations from the adapter to the back end

From your procedure, you call a remote back-end service by using the `invokeHttp` method of the `WL.Server` class. The returned object from this call is a JSON object that represents the result of the HTTP request. If the response is an XHTML or XML tree, it is converted to JSON. For example, if the response is an HTML page, you see a property called "html" (the root HTML tag) with the content tree inside.

The following table describes some of the other properties. Additional arbitrary properties might also be returned by the back-end service.

Table 8-24. Properties of the object received following the invocation from the adapter to the back end

Property	Description
<code>errors</code>	Array of errors during the request.
<code>isSuccessful</code>	Boolean value summarizing whether the request is successful. Note: The text following the table explains the circumstances when a request is considered to be successful.
<code>responseHeaders</code>	JSON object representing the different HTTP headers of the response.
<code>responseTime</code>	HTTP response time.
<code>statusCode</code>	HTTP status code of the remote invocation.
<code>statusReason</code>	Short text description that explains the status code.
<code>totalTime</code>	Response time plus any additional time for IBM MobileFirst Platform Foundation to complete processing or convert formats.

Similar to the client side, if `isSuccessful` is set to `true`, the data that you receive is not necessarily exactly what you expect. It merely indicates that something was returned. You can therefore assume that `isSuccessful` is `true` by default. This includes the following cases:

- The remote HTTP server returns an OK status code such as 200.
- The remote HTTP server returns **any valid status code** such as 2XX, 3XX, 4XX, 5XX, and other codes.

The `isSuccessful` property is set to `false` under the following circumstances:

- The HTTP host cannot be reached or is invalid.
- The HTTP request has timed out.

Because `isSuccessful` is set to `true` by default, you might not receive the data that you want or expect. For example, you might want a “404” error to be treated as a failure whereas IBM MobileFirst Platform Foundation considers it a success. You can use properties such as the `statusCode` property that is returned in the result of a `WL.Server.invokeHttp` call (or any other interesting data from the response) to decide if the procedure should be considered successful or not. You can then handle situations that should be considered unsuccessful in one of the following ways:

- Overwrite the `isSuccessful` property by setting its value to `false` in your JSON response.
- Consider the request as successful, set some custom flags in your JSON response, and handle the situation in your client's `onSuccess` handler. You might also want to place a `try/catch` block around your procedure code and handle any exceptions accordingly. If an exception is thrown, the client will receive an `isSuccessful` response that is set to `false`.

In a production environment, returning the result of the `invokeHttp` call back to the client might not be the ideal value to return at the end of the procedure for the following reasons:

- The meaning of a “successful” request might vary in different cases.
- The back-end response might include additional data that should not be forwarded to the client; such as certain response headers, architecture of the back end, or any data that is not relevant to the logic of the app. Instead, consider building a new JSON object with your own data, which might possibly include parts of the original response.

Example

Here is an example of an adapter that receives a “404” error as a result of trying to get data from an invalid URL: `www.ibm.com/no-such-place`.

adapt.xml

This file can be generated from the Design view in MobileFirst Studio. The back end host name is set to `www.ibm.com`.

```
<?xml version="1.0" encoding="UTF-8"?>
<wl:adapter name="adapt"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:wl="http://www.ibm.com/mfp/integration"
  xmlns:http="http://www.ibm.com/mfp/integration/http"

  <displayName>adapt</displayName>
  <description>adapt</description>
  <connectivity>
```

```

        <connectionPolicy xsi:type="http:HTTPConnectionPolicyType">
        <protocol>http</protocol>
        <domain>www.ibm.com</domain>
        <port>80</port>
        </connectionPolicy>
    </connectivity>
    <procedure name="test"/>
</wl:adapter>

```

adapt-impl.js

This is the implementation of the procedure. It calls a remote URL and generates a response. If the HTTP status code is anything other than 200, the `isSuccessful` property is set to false.

```

function test(){

    var input = {
        method : 'get',
        path : 'no-such-place' //Replace this with a valid path to see success
    };
    var backendResponse = WL.Server.invokeHttp(input);
    var procedureResponse = {};

    if(backendResponse.isSuccessful && backendResponse.statusCode == 200){
        //For simplicity, considering only 200 as valid
        //Do something interesting with the data
        procedureResponse.interestingData = backendResponse.html.head.title;
    }
    else{
        procedureResponse.isSuccessful = false; //Overwrite to failure
    }

    return procedureResponse;
}

```

main.js

The client app invokes the procedure. If the request is successful, the app logic continues. If the request is not successful, an error message is displayed.

```

WL.Client.invokeProcedure({
    adapter : 'adapt',
    procedure : 'test'
}, {
    onSuccess : function(result) {
        //Do something interesting with resulting JSON
        $('#someDiv').html(result.invocationResult.interestingData);
    },
    onFailure: function(result){
        WL.SimpleDialog.show("Error","The service is temporarily not available.
Please try again later.",[{text: "OK"}]);
    }
});

```

SQL adapters:

You can use the IBM MobileFirst Platform Foundation SQL adapter to execute parameterized SQL queries and stored procedures that retrieve or update data in an SQL database.

You can use plain SQL queries or stored procedures. As a developer, you must download the JDBC connector driver for the specific database type separately and add it to the `server\lib\` folder of a MobileFirst project. You can download the JDBC connector driver from the appropriate vendor website.

For more information about SQL adapters, see the JavaScript SQL Adapter tutorial on the Getting Started of the Developer Center.

JMS adapters:

Java messaging service (JMS) is the standard messaging Java API for sending messages between two or more clients. The MobileFirst JMS adapter provides reading and writing capabilities to messaging providers that implement the JMS API.

You can configure a JMS adapter to work with such messaging providers as a Liberty profile server or a WebSphere MQ message broker.

Connecting a JMS adapter to the WebSphere Application Server messaging provider:

You can develop and test MobileFirst adapters that use Java Message Service (JMS) on a WebSphere Application Server messaging provider. The WebSphere Application Server messaging provider can be the default messaging provider, a WebSphere MQ messaging provider, or a third-party provider.

Before you begin

You must have configured the WebSphere Application Server messaging provider and JMS resources such as the queue connection factories and the queues or topics.

About this task

The following procedure shows how to connect a JMS adapter to a WebSphere Application Server messaging provider.

Procedure

1. Create a MobileFirst JMS adapter.
2. Because the adapter runs on a JMS-enabled server, the naming connection section of the adapter.xml file is not necessary. It can remain commented out.
3. Enter the JNDI name for the queue connection factory that was created in the server.xml file.

```
<connectivity>
  <connectionPolicy xsi:type="jms:JMSConnectionPolicyType">

    <!-- <namingConnection url="MY_JNDI_URL"
      initialContextFactory="providers_initial_context_factory_class_name"
      user="JNDIUserName"
      password="JNDIPassword"/> -->

    <jmsConnection
      connectionFactory="jms/WASQCF"
      user="admin"
      password="admin"
    />
  </connectionPolicy>

  <loadConstraints maxConcurrentConnectionsPerNode="10"/>
</connectivity>
```

4. In the JMS adapter implementation file, enter the JNDI name for the queue as the destination for both the read and write methods:

```
function readMessage() {
  var result = WL.Server.readSingleJMSMessage({
    destination: "jms/WASQueue",
    timeout: 60
```

```

});
if (!result.message) {
    WL.Logger.debug(">> JMS adapter >> readNextMessage >> no message in queue");
    return {};
} else {
    WL.Logger.debug(">> JMS adapter >> readNextMessage >> message received ::");
    return result.message;
}
}

```

5. Change the MobileFirst target server in MobileFirst Studio to point to your WebSphere Application Server environment. For more information, see “Working with multiple MobileFirst Server instances in MobileFirst Studio” on page 8-23.
6. Build and deploy the MobileFirst adapter to the WebSphere Application Server environment. You can test the JMS adapter in your browser by using the following URL syntax:

```

http://<was-hostname>:<port>/<context-root>/invoke?adapterName=
<adapterName>&procedure=<procedureName>&parameters=["<parameters>"]

```

An example of a URL pointing to an external WebSphere Application Server server:

```

http://localhost:9080/worklight/invoke?adapter=JMSAdapter&procedure=
writeMessage&parameters=["Hello World"]

```

Connecting a JMS adapter to a Liberty profile server:

You can develop and test MobileFirst adapters that use Java Message Service (JMS) on a WebSphere Application Server Liberty profile ND server.

Before you begin

If you want to create adapters that use the JMS API, you must understand that the WebSphere Application Server Liberty profile included with IBM MobileFirst Platform Foundation does not contain the built-in Liberty JMS features. Therefore, an embedded MobileFirst Development Server or a local external instance of this bundled WebSphere Application Server Liberty profile server cannot act as a JMS provider.

About this task

JMS is supported by the WebSphere Application Server Liberty profile V8.5 ND (Network Deployment) server. If you have a local copy of this application server that is installed on the same workstation as your MobileFirst tools, you can use it to develop and test your JMS applications.

Because WebSphere Application Server Liberty profile does not support remote JNDI lookups, it is not possible to make remote connections to the JMS server. The MobileFirst adapter must be running on the same local Liberty profile server that has JMS enabled.

The following procedure shows how to connect to an external Liberty profile server that supports JMS.

Procedure

1. Enable JMS on your Liberty profile ND server by using the procedures in the WebSphere Application Server user documentation at Configuring

point-to-point messaging for a single Liberty profile server. Make a note of the JNDI connection factory and queue name, as shown in the following code example:

```
<!-- Enable features -->
<featureManager>
  <feature>jsp-2.2</feature>
  <feature>wasJmsServer-1.0</feature>
  <feature>wasJmsClient-1.1</feature>
  <feature>jndi-1.0</feature>
</featureManager>

<messagingEngine id="defaultME">
  <queue
    id="libertyQ"
    forceReliability="ReliablePersistent"
    maxQueueDepth="5000">
  </queue>
</messagingEngine>

<jmsQueueConnectionFactory jndiName="jms/libertyQCF" connectionManagerRef="ConMgr2">
  <properties.wasJms
    nonPersistentMapping="ExpressNonPersistent"
    persistentMapping="ReliablePersistent"/>
</jmsQueueConnectionFactory>

<connectionManager id="ConMgr2" maxPoolSize="2"/>

<jmsQueue jndiName="jms/libertyQue">
  <properties.wasJms
    queueName="libertyQ"
    deliveryMode="Application"
    timeToLive="500000"
    priority="1"
    readAhead="AsConnection" />
</jmsQueue>
```

2. Create a MobileFirst JMS adapter.
3. Because the adapter runs on a JMS-enabled Liberty profile server, the naming connection section of the adapter.xml file is not necessary. It can remain commented out.
4. Enter the JNDI name for the connection factory that was created in the server.xml file.

```
<connectivity>
  <connectionPolicy xsi:type="jms:JMSConnectionPolicyType">

    <!-- <namingConnection url="MY_JNDI_URL"
      initialContextFactory="providers_initial_context_factory_class_name"
      user="JNDIUserName"
      password="JNDIPassword"/> -->
    <jmsConnection
      connectionFactory="jms/libertyQCF"
      user="admin"
      password="admin"
    />
  </connectionPolicy>
</connectivity>
```

5. In the JMS adapter implementation file, enter the JNDI name for the queue as the destination for both the read and write methods:

```
function readMessage() {
  var result = WL.Server.readSingleJMSMessage({
    destination: "jms/libertyQue",
    timeout: 60
  });
  if (!result.message) {
```

```

        WL.Logger.debug(">> JMS adapter >> readNextMessage >> no message in queue");
        return {};
    } else {
        WL.Logger.debug(">> JMS adapter >> readNextMessage >> message received ::");
        return result.message;
    }
}

```

6. Change the MobileFirst target server in MobileFirst Studio to point to your Liberty ND server. For more information, see “Working with multiple MobileFirst Server instances in MobileFirst Studio” on page 8-23.
7. Build and deploy the MobileFirst adapter to the Liberty profile ND server. You can test the JMS adapter in your browser by using the following URL syntax:

```

http://<liberty-hostname>:<port>/<context-root>/invoke?adapterName=
<adapterName>&procedure=<procedureName>&parameters=["<parameters>"]

```

An example of a URL pointing to an external Liberty profile ND server:

```

http://localhost:9080/worklight/invoke?adapter=JMSAdapter&procedure=
writeMessage&parameters=["Hello World"]

```

Connecting a JMS adapter to WebSphere MQ:

You can connect a MobileFirst Java Message Service (JMS) adapter to WebSphere MQ.

Before you begin

If you are running the adapter on WebSphere Application Server, use the WebSphere Application Server messaging provider. For more information, see “Connecting a JMS adapter to the WebSphere Application Server messaging provider” on page 8-287.

Ensure that you have prior knowledge of WebSphere MQ and have a WebSphere MQ Message Broker setup with the appropriate JMS administered objects. For more information about setting up WebSphere MQ for JMS, see the IBM WebSphere MQ user documentation.

About this task

The MobileFirst JMS adapter does not support connecting to WebSphere MQ through bindings mode, only in client mode. A TCP connection is created for each JMS request, even if the JMS broker and MobileFirst adapter are running on the same computer.

To connect a MobileFirst JMS adapter to WebSphere MQ, you create a project, copy some JAR files to the project directory, and modify the adapter file.

Procedure

Include the required WebSphere MQ Java libraries

1. Create a MobileFirst project.
2. Locate the java/lib directory in your WebSphere MQ directory.
Example: /opt/mqm/java/lib
3. Copy the following JAR files from the java/lib directory into the server/lib directory of your MobileFirst project:
 - CL3Export.jar
 - CL3Nonexport.jar

- com.ibm.mq.axis2.jar
- com.ibm.mq.commonservices.jar
- com.ibm.mq.defaultconfig.jar
- com.ibm.mq.headers.jar
- com.ibm.mq.jar
- com.ibm.mq.jmqi.jar
- com.ibm.mq.jms.Nojndi.jar
- com.ibm.mq.pcf.jar
- com.ibm.mq.postcard.jar
- com.ibm.mq.soap.jar
- com.ibm.mq.tools.ras.jar
- com.ibm.mqjms.jar
- connector.jar
- dhbcore.jar
- fscontext.jar
- jta.jar
- providerutil.jar
- rmm.jar

Modify the adapter XML file

4. Create a MobileFirst JMS adapter.
5. Open the adapter.xml file.
6. In the namingConnection element of the xml file, set the URL to the location of your bindings file that was generated by WebSphere MQ.

Example:

```
url="file:/home/user/JMS"
```

7. In the namingConnection element of the XML file, set the **initialContextFactory** attribute to com.sun.jndi.fscontext.ReffSContextFactory.
8. In the jmsConnection element, set the **connectionFactory** attribute to the name of the connection factory that was set up in WebSphere MQ.
9. Optional: If security is enabled in WebSphere MQ, include the credentials as shown in the following code example.

```
<connectivity>
  <connectionPolicy xsi:type="jms:JMSConnectionPolicyType">
    <namingConnection
      url="file:/home/user/JMS"
      initialContextFactory="com.sun.jndi.fscontext.ReffSContextFactory"
      user="admin"
      password="password"/>
    <jmsConnection
      connectionFactory="myConnFactory"
      user="admin"
      password="password"/>
  </connectionPolicy>
</connectivity>
```

Modify the adapter implementation file

10. Open the adapter's implementation file.
11. In the autogenerated read and write methods, replace the **destination** property with the name that was configured in your JMS administered object in WebSphere MQ.

Example:

```
function readMessage() {
  var result = WL.Server.readSingleJMSMessage({
    destination: "JMS1",
    timeout: 60
  });
  WL.Logger.debug(result);
  if (result.errors) {
    WL.Logger.debug(">> JMS adapter >> readNextMessage >> errors occurred");
    return result;
  } else if (!result.message) {
    WL.Logger.debug(">> JMS adapter >> readNextMessage >> no messages in queue");
    return result;
  } else {
    WL.Logger.debug(">> JMS adapter >> readNextMessage >> message received ::");
  }
}
```

Results

The MobileFirst JMS adapter is now properly configured to connect to WebSphere MQ. You can test the JMS adapter in your browser by using the following URL:

`http://<hostname>:<port>/<context-root>/invoke?adapterName=<adapterName>&procedure=<procedureName>¶meters=['<parameters>']`

Example

`http://localhost:10080/worklight/invoke?adapter=JMSAdapter&procedure=writeMessage¶meters=['Hello World']`

Microsoft Azure OData adapters:

Your IBM MobileFirst Platform Foundation applications can communicate with back-end services by using Microsoft Azure OData adapters. Using HTTP rest calls and the OData protocol, applications can remotely retrieve and query entities through the adapter.

You can use Microsoft Azure Odata adapters to retrieve and query entities that exist on a back-end system. For more information, see “Retrieving an entity” on page 8-299 and “Querying an existing entity” on page 8-302.

For information about using the Service Discovery wizard, see “Generating adapters with the services discovery wizard” on page 8-266.

OData adapters:

Your IBM MobileFirst Platform Foundation applications can communicate with back-end services by using OData adapters. Using HTTP rest calls and the OData protocol, applications can remotely create, retrieve, update, and delete entities through the adapter.

You can use OData adapters to create, retrieve, update, delete, and analyze Entities that exist on a back-end system. For more information about invoking an adapter, see “Starting an adapter” on page 8-297.

For information about using the Service Discovery wizard, see “Generating adapters with the services discovery wizard” on page 8-266.

SAP Gateway adapters:

Your IBM MobileFirst Platform Foundation applications can communicate with back-end services by using an SAP Gateway adapter. Using HTTP rest calls and the OData protocol, applications can remotely create, retrieve, update, and delete entities through the adapter.

Note: Starting with V7.1.0, communication to an SAP Gateway is done by using regular HTTP adapters.

For information about invoking an adapter, see “Starting an adapter” on page 8-297.

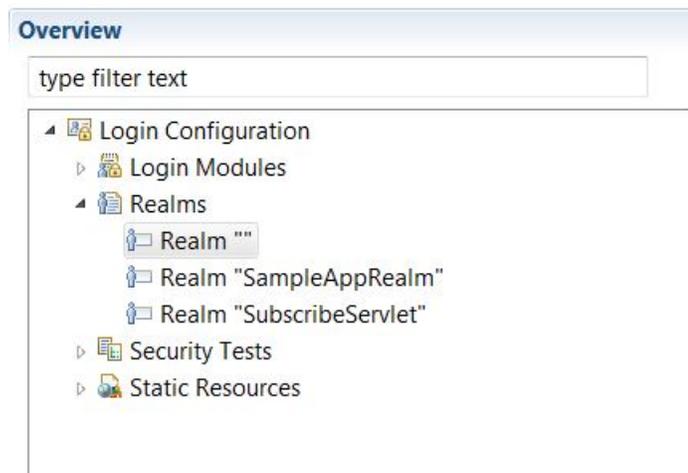

For information about using the Service Discovery wizard, see “Generating adapters with the services discovery wizard” on page 8-266.

Configuring an SAP Gateway adapter for user-based authentication:

To configure an SAP Gateway adapter for user-based authentication, you edit the authenticationConfig.xml configuration file.

Procedure

1. Expand the **server** folder of your MobileFirst project and right-click **authenticationConfig.xml**.
2. Select **Open With > Authentication Configuration Editor** and ensure that you are using the **Design** view.
3. In the Authentication Configuration Editor view, select **Realms** and click **Add**.
 - a. In the Add Item window, select **Realm** and click **OK**.
4. Expand **Realms**. Your view looks similar to the following example.

5. Select the newly created realm and proceed as follows.
 - a. Name the realm. This example uses **SAPAuthRealm**.
 - b. Type `com.worklight.integration.auth.AdapterAuthenticator` into the **Class name** field.
 - c. Type `StrongDummy` into the **Login Module** field. For more information on login modules, see “Configuring login modules” on page 8-617.
6. Save your MobileFirst project.
7. Create a login parameter.

- a. Select your Realm from the **Realms** folder. Click **Add**.
 - b. In the Add Item window that appears, select **Parameter** and click **OK**.
 - c. Type login-function in the **Name** field.
 - d. Type `<SAP Adapter name>.onLogin` in the **Value** field.
 - e. Save the file.
8. Create a log out parameter.
 - a. Select your Realm from the **Realms** folder. Click **Add**.
 - b. In the Add Item window that appears, select **Parameter** and click **OK**.
 - c. Type logout-function in the **Name** field.
 - d. Type `<SAP Adapter name>.onLogout` in the **Value** field.
 - e. Save the file.
 9. Select **Security Tests** from the list and click **Add**.
 - a. In the Add Item window, select **Custom Security Test**. Click **OK**.
 10. Select your **Custom Security Test** to view its details and Type `SAPAuthAdapter-securityTest` into the **Name** field.
 11. With the **Custom Security Test** still selected, click **Add**. In the Add Item window, select **Test**. Click **OK**.
 12. Select your **Test** to complete the following fields.
 - a. In the **Is internal user id** field, select **true** from the drop-down menu.
 - b. Type the name of the realm that you created in step 5a.
 13. Save the changes that you made in the `authenticationConfig.xml` file.
 14. In the project explorer, right-click `adapters > <SAP Adapter name>.xml` and select **Open With > Adapter Editor**.
 15. In the **Adapter Editor** view, click **Add**.
 - a. In the Add Item window that appears, select **Procedure** and click **OK**.
 16. Select your new procedure to view its details and type `submitAuthentication` in the **Name** field.
 17. Select a procedure that requires user-based authentication and proceed as follows.
 - a. From the **Connect as** drop-down menu, select **endUser**.
 - b. Type `SAPAuthAdapter-securityTest` in the **Security test** field.
 18. Repeat step 17 for any other procedures that require user-based authentication.
 19. Save the changes that you made in the adapter.
 20. Define three functions at the end of the JavaScript file that is associated with your SAP adapter.
 - a. Expand the **adapters** folder.
 - b. Expand the *Your SAP Adapter name* folder and open *Your SAP Adapter name-impl.js*.
 - c. Copy and paste the following three functions at the end of your JavaScript file.

```
function onLogin(headers, errorMessage) {
    errorMessage = errorMessage ? errorMessage : null;

    return {
        authRequired : true,
        errorMessage : errorMessage
    };
}
```

```

function submitAuthentication(username, password) {

    var userIdentity = {
        userId : username,
        displayName : username,
        credentials : password,
        attributes : {
            foo : "bar"
        }
    };

    WL.Server.setActiveUser("SAPAuthRealm", userIdentity);

    return {
        authRequired : false
    };
}

function onLogout() {
    WL.Server.setActiveUser("SAPAuthRealm", null);
    WL.Logger.debug("Logged out");
}

```

21. Save the JavaScript file.

Results

Your SAP Gateway adapter is now configured to start procedures on a user-based authentication basis.

What to do next

Now you must pass your SAP Netweaver credentials to MobileFirst Server. You can use the `submitAuthentication` function to pass your credentials. For more information about how to start an SAP procedure, see “Testing adapters” on page 8-322. For more information about adapter authentication, see the tutorials on the Getting Started web site.

Configuring an SAP Gateway adapter with a system user:

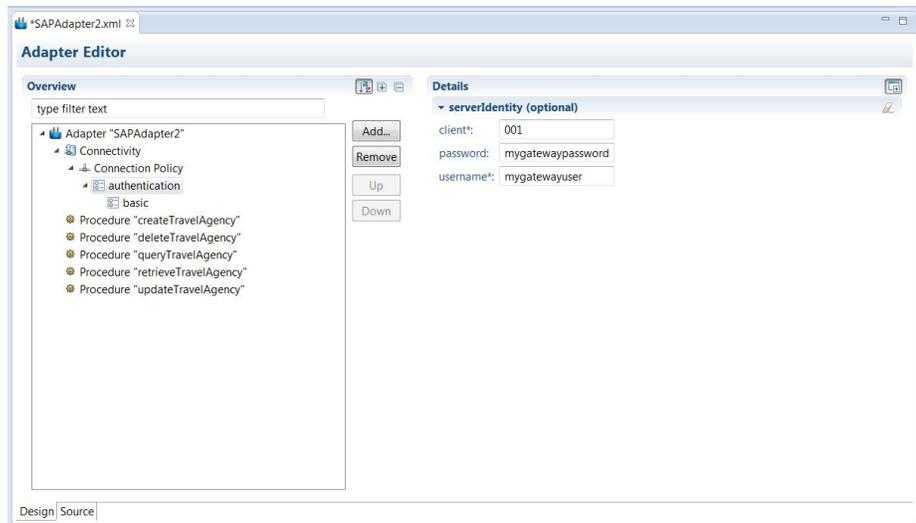

You can connect to an SAP back end with a system user. However, you should use user-based authentication for most scenarios. Check your SAP license terms.

Before you begin

Make sure that SAP Gateway adapters exist in your MobileFirst project.

Procedure

1. Expand the **adapters** folder of your MobileFirst project, right-click **<SAP Adapter name>.xml**, and select **Open With > Adapter Editor**.
2. In the **Adapter Editor** view, expand **Connectivity** and select **Connection Policy**.
3. Click **Add**, select **authentication** from the Add Item window, and click **OK**.
4. Under Connection Policy, select **authentication** and click **Add**.
 - a. Select the appropriate authentication mechanism of your SAP server. This example uses **basic**. The results look something like the following image.

- To see the changes in the source code, select the **Source** tab at the bottom of the **Adapter Editor** view.

Results

Your SAP Gateway adapter is configured to start procedures on a server-identity authentication basis.

SAP JCo adapters:

You can use the SAP Java Connector (SAP JCo) adapters to develop SAP-compatible components and applications in Java.

Invoking an SAP JCo adapter:

If you invoke the SAP Java Connector (SAP JCo) adapter, you can communicate with the SAP Server both inbound and outbound.

About this task

Table 8-25. Parameters

Parameter	Mandatory or Optional	Description
FunctionName	Mandatory	The name of the function to be run on the SAP system
Imports	Mandatory	The input parameters

Procedure

- Call the invokeSAPFunction procedure and pass in the following parameters.

```

{"FunctionName" : "BAPI_USER_GET_DETAIL", "Imports" : {"USERNAME" : "DEVELOPER"}}

```
- Save your *adapter_name-impls.js* file.

Results

The following message is displayed in the Console: Adapter build and deploy finished.

The Cast Iron adapter:

The MobileFirst Cast Iron[®] adapter initiates orchestrations in Cast Iron to retrieve and return data to mobile clients.

Cast Iron accesses various enterprise data sources, such as databases, web services, and JMS, and provides validation, aggregation, and formatting capabilities.

The Cast Iron adapter supports two patterns of connectivity:

Outbound pattern.

The invocation of Cast Iron orchestrations from IBM MobileFirst Platform Foundation.

Inbound pattern.

Cast Iron sends notifications to devices through IBM MobileFirst Platform Foundation.

The Cast Iron adapter supports the invocation of a Cast Iron orchestration over HTTP only. Cast Iron Template Integration Projects (TIPs) are provided in Cast Iron as examples of this technique, and for you to use as a basis for your own orchestrations. For more information, see the Cast Iron documentation.

Cast Iron uses the standard MobileFirst notification adapter and event sources to publish notification messages to be delivered to devices by using one of the many notification providers.

For information about defining event sources, see the `createEventSource` method in the `WL.Server` class.

Cast Iron Template Integration Projects (TIPs) are provided in Cast Iron as examples of this technique, and for you to use as a basis for your own notification scenarios. For more information, see the Cast Iron documentation.

To protect the notification adapter, use basic authentication.

Troubleshooting a Cast Iron adapter – connectivity issues

Symptom: The MobileFirst adapter cannot communicate with the Cast Iron server.

Causes:

- Cast Iron provides two network interfaces, one for administration and one for data. Ensure that you are using the correct host name or IP address of the Cast Iron data interface. You can find this information under the Network menu item in the Cast Iron administrative interface. This information is stored in the `adapter-name.xml` file for your adapter.
- The invocation fails with a message Failed to parse the payload from backend. This failure is typically caused by a mismatch between the data returned by the Cast Iron orchestration and the `returnedContentType` parameter in the `adapter-name.js` implementation. For example, the Cast Iron orchestration returns JSON but the adapter is configured to expect XML.

Starting an adapter:

You can create, retrieve, update, delete, and analyze Entities that exist on an back-end system by using a MobileFirst adapter.

Creating an entity:

You can create entity remotely through the back-end system.

About this task

Table 8-26. Attributes

Attribute	Mandatory or Optional	Description
content	Mandatory	Defines the properties of the entity. Supports JSON and Atom/XML formatting.

Procedure

- To create an entity in JSON format, write the input parameters as shown in the following example.

```
"City": "Midland",
"Country": "USA",
"LanguageCode": "3",
"LocalCurrencyCode": "324",
"MimeType": "",
"Name": "Destination Paradise",
"POBox": "322",
"PostalCode": "48642",
"Region": "B",
"Street": "100 Electric Ave",
"TelephoneNumber": "5558675309",
"TravelAgencyID": "0000099",
"URL": "www.foo.com"
```

- To create an entity in XML format, write the input parameters as shown in the following example.

```
<?xml version="1.0" encoding="utf-8"?>

Retrieving an entity:

You can retrieve an entity through a back-end system.

About this task

Table 8-27. Attributes

Attribute	Mandatory or Optional	Description
expand	Optional	Indicates that the response from the back-end represents navigation properties inline, rather than referenced. Formatted as a JSON array.
keys	Mandatory	Identifies which entity is to be retrieved based on its key property or properties. Formatted as a JSON object.

Table 8-27. Attributes (continued)

Attribute	Mandatory or Optional	Description
select	Optional	Indicates that a response from the back-end is formatted with a subset of specified properties. Formatted as a JSON array.

Procedure

To retrieve an entity in JSON format, write the input parameters as shown in the following example.

```
{
  "keys":{
    "carrid":"LH"
  },
  "select":["carrid", "carrierFlights"],
  "expand":["carrierFlights"]
}
```

Results

If you use the previous example, you receive the following response from MobileFirst Server.

```
{
  "_metadata": {
    "content_type": "image/gif",
    "edit_media": "https://sap4.sapdevelopcenter.com:444/sap/opu/odata/iwfn/RMTSAMPLEFLIGHT/CarrierCollection('LH')/$value",

  }
}
...

```

Updating an entity:

You can update an entity from a back-end system.

About this task

Table 8-28. Attributes

Attribute	Mandatory or Optional	Description
updateContent	Mandatory	This attribute is the new set of properties for the specified entity. Any properties that are not defined in updateContent are set to an empty string when the update is complete. Supports JSON and Atom/XML formatting.

Procedure

To update an entity in XML format, write the input parameters as shown in the following example.

```

{
  "keys":{
    "TravelAgencyID"
  }
}

```

Results

If you use the previous example, you receive the following response from MobileFirst Server.

```

"City": "Midland",
"Country": "USA",
"LanguageCode": "3",
"LocalCurrencyCode": "324",
"MimeType": "",
"Name": "Destination Paradise",
"POBox": "322",
"PostalCode": "48642",
"Region": "B",
"Street": "100 Electric Ave",
"TelephoneNumber": "5558675309",
"TravelAgencyID": "00000099",
"URL": "www.foo.com"

```

Deleting an entity:

You can delete an existing entity through the back-end system.

About this task

Table 8-29. Attributes

Attribute	Mandatory or Optional	Description
keys	Mandatory	Identifies which entity must be deleted, based on its key properties. Formatted as a JSON object.

Procedure

To delete an entity in JSON format, write the input parameters as shown in the following example.

```
{
  "keys": {
    "TravelAgencyID": "99"
  }
}
```

If you use the previous example, you receive the following response from MobileFirst Server.

```
{
  "isSuccessful": true,
  "responseHeaders": {
    "content-length": "0",
    "dataserviceversion": "2.0",
    "server": "SAP NetWeaver Application Server \/ ABAP 731"
  },
  "statusCode": 204,
  "statusReason": "No Content"
}
```

Results

A successful deletion results in a 204 No Content response from the server.

Querying an existing entity:

You can search for existing Collections within a back-end system.

About this task

Table 8-30. Attributes

Attribute	Mandatory or Optional	Description
expand	Optional	Indicates that the response from the back-end represents navigation properties inline, rather than referenced. Formatted as a JSON array.
filter	Optional	Uses logic operators to indicate that only the matching criteria are returned in the response. Formatted as a String. For examples, see: Filter System Query Option.

Table 8-30. Attributes (continued)

Attribute	Mandatory or Optional	Description
custom	Optional	Overrides all other input parameters and directly appends this query to your resource path. You can use this parameter to generate more complex queries. For example: <code>\$expand=Products(\$filter=Date eq null)</code> .
select	Optional	Indicates that a response from the Gateway is formatted with a subset of specified properties. Formatted as a JSON array.
skip	Optional	Identifies that the first input number of items of a Collection are skipped in the response.
top	Optional	Identifies how many items of a Collection are returned in a response. Formatted as a non-negative integer, which is enclosed in quotation marks.

Procedure

- To use the **select** parameter for querying an existing entity in JSON format, write the input parameter as shown in the following example.

```
{
  "select": ["TravelAgencyID"]
}
```
- To use the **filter** parameter for querying an existing entity in JSON format, write the input parameter as shown in the following example.

```
{
  "filter": "TelephoneNumber eq '5558675309'"
}
```
- To use the **expand** parameter for querying an existing entity in JSON format, write the input parameter as shown in the following example.

```
{
  "expand": ["carrierFlights"]
}
```
- To use the **skip** parameter for querying an existing entity in JSON format, write the input parameter as shown in the following example.

```
{
  "skip": "2"
}
```
- To use the **top** parameter for querying an existing entity in JSON format, write the input parameter as shown in the following example.

```
{
  "top": "2"
}
```

Retrieving a property of an entity:

You can retrieve a specific property from an entity through a back-end system.

About this task

Table 8-31. Attributes

Attribute	Mandatory or Optional	Description
keys	Mandatory	Identifies the entity to be retrieved based on its key properties. Formatted as a JSON Object.
property	Optional	Defines the Property to be retrieved. Formatted as a String.

Procedure

- To retrieve a property from an entity in JSON format, write the input parameters as shown in the following example.

```
{
  "keys":{
    "carrid":"'IBM Air',
    "connid":"'0017',
    "fldate":"'2013-12-18T00:00:00"
  },
  "property":"carrierFlights"
}
```

If you use the previous example, you receive the following response from MobileFirst Server.

```
{
  "isSuccessful": true,
  "results": [
    {
      "CURRENCY": "USD",
      "FlightCarrier": {
        "_deferred": {
          "uri": "https://serv101.tampa.ibm.com:1234/sap/opu/odata/iwfnd/RMTSAMPLEFLIGHT\
/FlightCollection(carrid='IBM Air',connid='0017',fldate=datetime'2013-12-18T00%3A00%3A00')\
/FlightCarrier"
        }
      },
      "PAYMENTSUM": "192281.41",
      "PLANETYPE": "747-400",
      "PRICE": "422.94",
      "SEATSMAX": 385,
      "SEATSMAX_B": 31,
      "SEATSMAX_F": 21,
      "SEATSOCC": 374,
      "SEATSOCC_B": 28,
      "SEATSOCC_F": 21,
      "_metadata": {
        "type": "RMTSAMPLEFLIGHT.Flight",
        "uri": "https://serv101.tampa.ibm.com:1234/sap/opu/odata/iwfnd/RMTSAMPLEFLIGHT\
/FlightCollection(carrid='IBM Air',connid='0017',fldate=datetime'2013-12-18T00%3A00%3A00')"
      },
      "carrid": "IBM Air",
      "connid": "0017",
      "fldate": "\/Date(1387324800000)\/",
      "flightBookings": {
        "_deferred": {

```

```

    "uri": "https://serv101.tampa.ibm.com:1234/sap/opu/odata/iwfnf/RMTSAMPLEFLIGHT\
/FlightCollection(carrid='IBM Air',connid='0017',fldate=datetime'2013-12-18T00%3A00%3A00')\flightBookings"
  },
  "flightDetails": {
    "_metadata": {
      "type": "RMTSAMPLEFLIGHT.FlightDetails"
    },
    "airportFrom": "JFK",
    "airportTo": "SFO",
    ...
  }
}

```

- To retrieve a property from an entity in JSON format, write the input parameters as shown in the following example.

```

{
  "keys":{
    "carrid":'AA',
    "connid":'0017',
    "fldate":'2013-12-18T00:00:00'
  },
  "property":'CARRNAME/$value'
}

```

If you use the previous example, you receive the following response from MobileFirst Server.

```

{
  "RETURN": "American Airlines",
  "isSuccessful": true,
  "responseHeaders": {
    "content-length": "17",
    "content-type": "text/plain; charset=utf-8",
    "dataserviceversion": "2.0",
    "server": "SAP NetWeaver Application Server \/ Tampa 1234",
    "x-csrf-token": "9PfsXHsbriIR4PNwfLKBAG=="
  },
  "statusCode": 200,
  "statusReason": "OK"
}

```

Developing JavaScript adapter code:

Learn about implementing a procedure in the adapter XML file, calling Java code from a JavaScript adapter, and invoking a back-end service.

Implementing adapter procedures:

Implement a procedure in the adapter XML file, using an appropriate signature and any return value.

Ensure that you have declared a procedure in the adapter XML file, using a `<procedure>` tag. The signature of the JavaScript function that implements the procedure has the following format:

```
function funcName (param1, param2, ...),
```

Where:

- *funcName* is the name of function which the procedure implements. This name must be the same as the value specified in the name attribute of the `<procedure>` element in the adapter XML file.
- *param1* and *param2* are the function parameters. The parameters can be scalars (strings, integers, and so on) or objects.

In your JavaScript code, you can use the MobileFirst server-side JavaScript API to access back-end applications, invoke other procedures, access user properties, and write log and debug lines.

You can return any value from your function, scalar or object.

Example

This example demonstrates how to use JavaScript on the server side. Note the following when performing procedures on the server side:

- Procedures are implemented in the adapter JavaScript file.
- The service URL is used for procedure invocations.
- Some parts of the URL are constant; for example, `http://example.com/`. They are declared in the XML file. Other parts of the URL can be parameterized; that is, substituted at run time by parameter values that are provided to the MobileFirst procedure. The following URL parts can be parameterized:
 - Path elements
 - Query string parameters
 - Fragments

For advanced options for adapters, such as cookies, headers, and encoding, see “HTTP adapter `connectionPolicy` element” on page 8-252.

In the JavaScript file, use the same procedure name as in the XML file. The mandatory parameters to call the procedure are `method`, `path`, and `returnedContentType`. The procedure can be parameterized at run time, for example:

```
function getFeeds() {
  var input = {
    method : 'get',
    returnedContentType : 'xml',
    path : "rss.xml"
  };

  return WL.Server.invokeHttp(input);
}
```

To call an HTTP request, use the `WL.Server.invokeHttp` method. Provide an input parameter object, which must specify the following options:

- The HTTP method: GET, POST, PUT, or DELETE
- The returned content type: XML, JSON, HTML, or plain
- The service path
- The query parameters (optional)
- The request body (optional)
- The transformation type (optional)

For a complete list of options, see `WL.Server` class.

Implementing JavaScript adapters to support session-independent mode

In versions earlier than V7.1.0, developers were able to store the applicative state in the HTTP session, either directly by using the session object, namely `WL.Server.getClientRequest().getSession()` (see `WL.Server`) or by using a global JavaScript variable.

If you are working in session-independent mode that became available starting with IBM MobileFirst Platform Foundation V7.1.0, you may not

use HTTP sessions to save the applicative state of the adapter. It must be persisted outside the session, for example, by using a database such as Cloudant. For more information on session-independent mode, including steps for upgrading projects that were created in earlier versions of IBM MobileFirst Platform Foundation, see “Session-independent mode” on page 8-324.

Example: Upgrading application code from pre-V7.1.0 to V7.1.0

The following code snippets provide an example for upgrading an app, ShoppingCartAdapter, from an earlier version of IBM MobileFirst Platform Foundation so that it support the changes for session-independent mode in V7.1.0

Consider a shopping-cart app in which users can add items to a cart, see the list of items that are already in the cart, and submit an order when satisfied with the items in it. Before V7.1.0, this functionality might have been implemented by the following code:

```
//ShoppingCartAdapter-impl.js

var itemsArray = new Array();

function addItemToCart(item) {
    itemsArray.push(item);
}

function getItemsFromCart() {
    return itemsArray;
}
```

If you adapt the code to work in session-independent mode under V7.1.0 and persist to an external database, such as Cloudant, the code might look as follows:

```
//ShoppingCartAdapter.xml

//Insert cloudant credentials in the domain tag of the adapter.xml
<domain>username.cloudant.com</domain>

//ShoppingCartAdapter-impl.js

function addItemToCart(item) {
    var db = 'shoppingcartdb';

    // Get the clientID from the MFP API (new in 7.1.0)
    var userId = WL.Server.getClientId();

    var response = readFromCloudant(db, userId);

    // See if we found the document
    if(response.cloudantSuccess){
        var doc = response.document;

        // Update the document
        doc.items.push(item);

        // Save the updated document
        return saveOnCloudant(db, doc);
    }else{
        // New Document - save to DB
        var items = new Array();
        items.push(item);
        return saveOnCloudant(db, {_id:userId, 'items':items});
    }
}
```

```

}

function getItemsFromCart() {
    // Get the clientID from the MFP API (new in 7.1.0)
    var userId = WL.Server.getClientId();
    // This will return all documents by this user ID in the shoppingCartsDB
    var response = readFromCloudant('shoppingcartdb', userId);

    return response;
}

/**
 * Saves this document on the cloudant DB
 * @param db - the cloudant DB to store the document to
 * @param document - the document to insert
 * @returns
 */
function saveOnCloudant(db, document){
    var input = {
        method : 'post',
        returnedContentType : 'plain',
        path : db,
        headers: {
            "Authorization":"<your authorization information>"
        },
        body:{
            contentType:'application/json; charset=UTF-8',
            content:JSON.stringify(document)
        }
    };

    return WL.Server.invokeHttp(input);
}

/**
 * Gets the document (If exists) that corresponds to this _id
 * @param db - the cloudant DB to get the document from
 * @param key - the _id to search by
 * @returns
 */
function readFromCloudant(db, key){
    var input = {
        method : 'get',
        returnedContentType : 'plain',
        path : db + "/" + key,
        headers: {
            "Authorization":"<your authorization information>"
        }
    };

    var response = WL.Server.invokeHttp(input);

    // Document was found - Note this is not enough to only check for 200
    if(response.statusCode == 200){
        return {cloudantSuccess:true, document:JSON.parse(response.text)};
    }
    else{
        return {cloudantSuccess:false};
    }
}
}

```

Adapting custom security code to support session-independent mode

In versions earlier than V7.1.0, developers were able to store custom security state in the HTTP session.

In session-independent mode that became available starting with IBM MobileFirst Platform Foundation V7.1.0, you may not use the HTTP session to save state. Custom security context must therefore be stored elsewhere.

For more information on session-independent mode, see “Session-independent mode” on page 8-324.

This section describes the three main forms of customized security features: adapter-based authentication, custom Java authenticator or login module, and event source (push and geolocation) flows.

Adapter-based authentication

This example shows how to create a double-step authentication flow with adapter-based authentication to support session-independent mode. The example uses a third-party database, in this case, Cloudant and the MobileFirst `WL.Server.getClientId()` API.

See Figure 1: the adapter requests the ID that is associated with the current client from MobileFirst Server and uses it when reading or writing the custom security context to or from Cloudant.

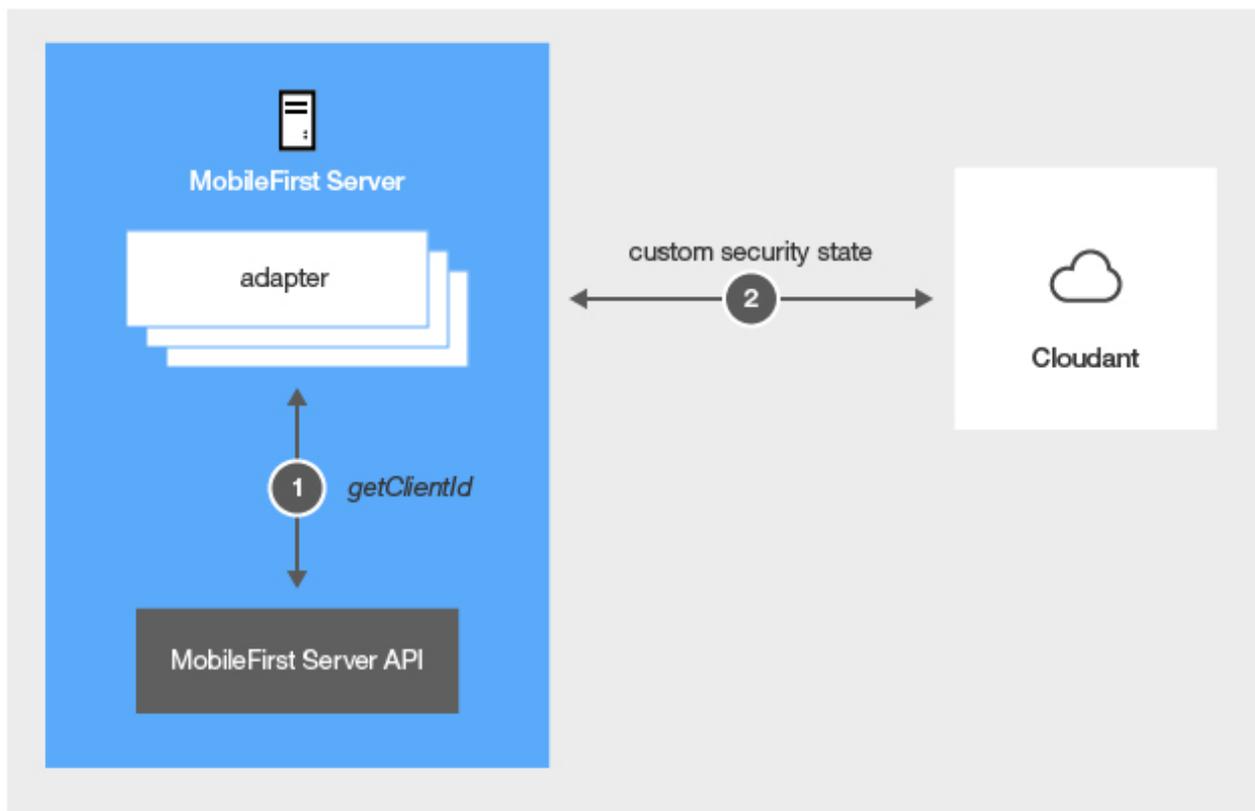

Figure 8-45. Double-step authentication flow with `WL.Server.getClientId()`

Here's the code:

```
var dbName = "REPLACE_ME_WITH_THE_DATABASE_NAME";
var auth = "Basic REPLACE_ME_WITH_THE_BASE-64_ENCODED_STRING";

function onAuthRequired(headers, errorMessage){
    errorMessage = errorMessage ? errorMessage : null;
```

```

    return {
        authRequired: true,
        authStep: 1,
        errorMessage: errorMessage
    };
}

function submitAuthenticationStep1(username, password){
    if (username === "user" && password === "password"){
        WL.Logger.debug("Step 1 :: SUCCESS");
        // Get the internal MFP Unique ClientID (New in 7.1.0)
        var clientId = WL.Server.getClientId();
        var userIdentity = {
            userId: username,
            displayName: username,
            attributes: {}
        };

        //Validate that the DB doesn't already contains the ClientId
        var response = deleteUserIdentityFromDB(dbName, null);

        //Write ClientId to DB
        var response = writeUserIdentityToDB(dbName, {_id:clientId, "userIdentity":userIdentity});
        if (response){
            return {
                authRequired: true,
                authStep: 2,
                question: "What is your pet's name?",
                errorMessage : ""
            };
        } else {
            return onAuthRequired(null, "Database ERROR");
        }
    } else{
        WL.Logger.debug("Step 1 :: FAILURE");
        return onAuthRequired(null, "Invalid login credentials");
    }
}

function submitAuthenticationStep2(answer){
    // Get the internal MFP Unique ClientID (New in 7.1.0)
    var clientId = WL.Server.getClientId();
    var response = readUserIdentityFromDB(dbName, clientId);
    if (response){
        if (answer === "Lassie"){
            var doc = JSON.parse(response.text);
            var userIdentity = doc.userIdentity;
            WL.Logger.debug("Step 2 :: SUCCESS");
            WL.Server.setActiveUser("DoubleStepAuthRealm", userIdentity);
            WL.Logger.debug("Authorized access granted");

            var response = deleteUserIdentityFromDB(dbName, doc);

            return {
                authRequired: false
            };
        } else{
            WL.Logger.debug("Step 2 :: FAILURE");
            return onAuthRequired(null, "Wrong security question answer");
        }
    } else {
        WL.Logger.debug("Step 1 :: FAILURE");
        return onAuthRequired(null, "Database ERROR");
    }
}
}

```

```

function getSecretData(){
    return {
        secretData: "Very very very very secret data"
    };
}

function onLogout(){
    WL.Logger.debug("Logged out");
}

function writeUserIdentityToDB(db, document){
    var input = {
        method : 'post',
        returnedContentType : 'plain',
        path : db,
        headers: {
            "Authorization":auth
        },
        body:{
            contentType:'application/json; charset=UTF-8',
            content:JSON.stringify(document)
        }
    };

    var response = WL.Server.invokeHttp(input);
    var responseString = "" + response.statusCode;

    //Checking if the invocation was successful - status code = 2xx
    if (responseString.indexOf('2') === 0){
        return response;
    }
    return null;
}

function deleteUserIdentityFromDB(db, document){
    var doc = document;
    if (!doc){
        var clientId = WL.Server.getClientId();
        var response = readUserIdentityFromDB(dbName, clientId);
        if(!response){
            return;
        } else {
            doc = JSON.parse(response.text);
        }
    }
    var id = doc._id; // The id of the doc to remove
    var rev = doc._rev; // The rev of the doc to remove
    var input = {
        method : 'delete',
        returnedContentType : 'plain',
        path : db + "/" + id + "?rev=" + rev,
        headers: {
            "Authorization":auth
        }
    };
    return WL.Server.invokeHttp(input);
}

function readUserIdentityFromDB(db, key){
    var input = {
        method : 'get',
        returnedContentType : 'plain',
        path : db + "/" + key,
        headers: {

```

```

        "Authorization":auth
    };
    var response = WL.Server.invokeHttp(input);
    var responseString = "" + response.statusCode;

    //Checking if the invocation was successful - status code = 2xx
    if (responseString.indexOf('2') === 0){
        return response;
    }
    return null;
}

```

Custom Java authenticator/login module

For more information, see “Implementing Java-based custom authenticators” on page 8-632.

Event sources

Event sources are adapters that are called indirectly, as a result of a push event, or a geolocation trigger. Keep in mind that event sources in a session-independent configuration cannot store information in an HTTP session, as described in “Session-independent mode” on page 8-324.

isSuccessful is a reserved JSON object key

isSuccessful is a reserved key name in the JSON object that is used by the MobileFirst server-client protocol. You cannot use isSuccessful as a key name in the JSON object that is returned in any of your adapter procedures.

The Rhino container:

IBM MobileFirst Platform Foundation uses Rhino as the engine for running the JavaScript script used to implement adapter procedures.

Rhino is an open source JavaScript container developed by Mozilla. In addition to being part of Java 6, Rhino has two other advantages:

- It compiles the JavaScript code into byte code, which runs faster than interpreted code.
- It provides access to Java code directly from JavaScript. For example:

```

var date = new java.util.Date();
var millisec = date.getTime()

```

Note: Global variables are handled according to the following rules:

- In the same user session (for example, an application loaded in a browser), the values of global variables persist from one method call of an adapter to another method call of the same adapter (that is, they are not reset).
- If you create two different user sessions that connect to the same adapter (for example, by opening the same app in different browsers or devices), every user session holds its own global variable state.
- If a user session expires, the Rhino session expires, and variables are no longer defined.

Calling Java code from a JavaScript adapter:

Follow these instructions to instantiate Java objects and call their methods from JavaScript code in your adapter.

Before you begin

Attention: The name of any Java package to which you refer from within an adapter must start with the domains com, org, or net.

Procedure

1. Instantiate a Java object by using the new keyword and apply the method on the newly instantiated object.
2. Optional: Assign a JavaScript variable to be used as a reference to the newly instantiated object.
3. Include the Java classes that are called from the JavaScript adapter in your MobileFirst project under *Worklight Project Folder/server/java*. They are automatically built and deployed to the MobileFirst Server, and the result of the build is placed under *Worklight Project Folder/bin*

Example

```
var x = new MyJavaClass();  
var y = x.myMethod(1, "a");
```

Invoking a back-end service:

You can use MobileFirst Studio to invoke a back-end service and receive the data retrieved by the service.

About this task

Note: This feature is only available when running within MobileFirst Studio. It is not available when running an adapter on a stand-alone server based on WebSphere Application Server or Tomcat.

In MobileFirst Studio, you can invoke a back-end service and immediately receive the data retrieved by the service in XML and JSON formats. You can also define and test a custom XSL transformation that converts the resulting XML into JSON.

Procedure

To run a back-end service:

1. Right-click an adapter file, and select **Run As > Invoke MobileFirst Back-end Service**.

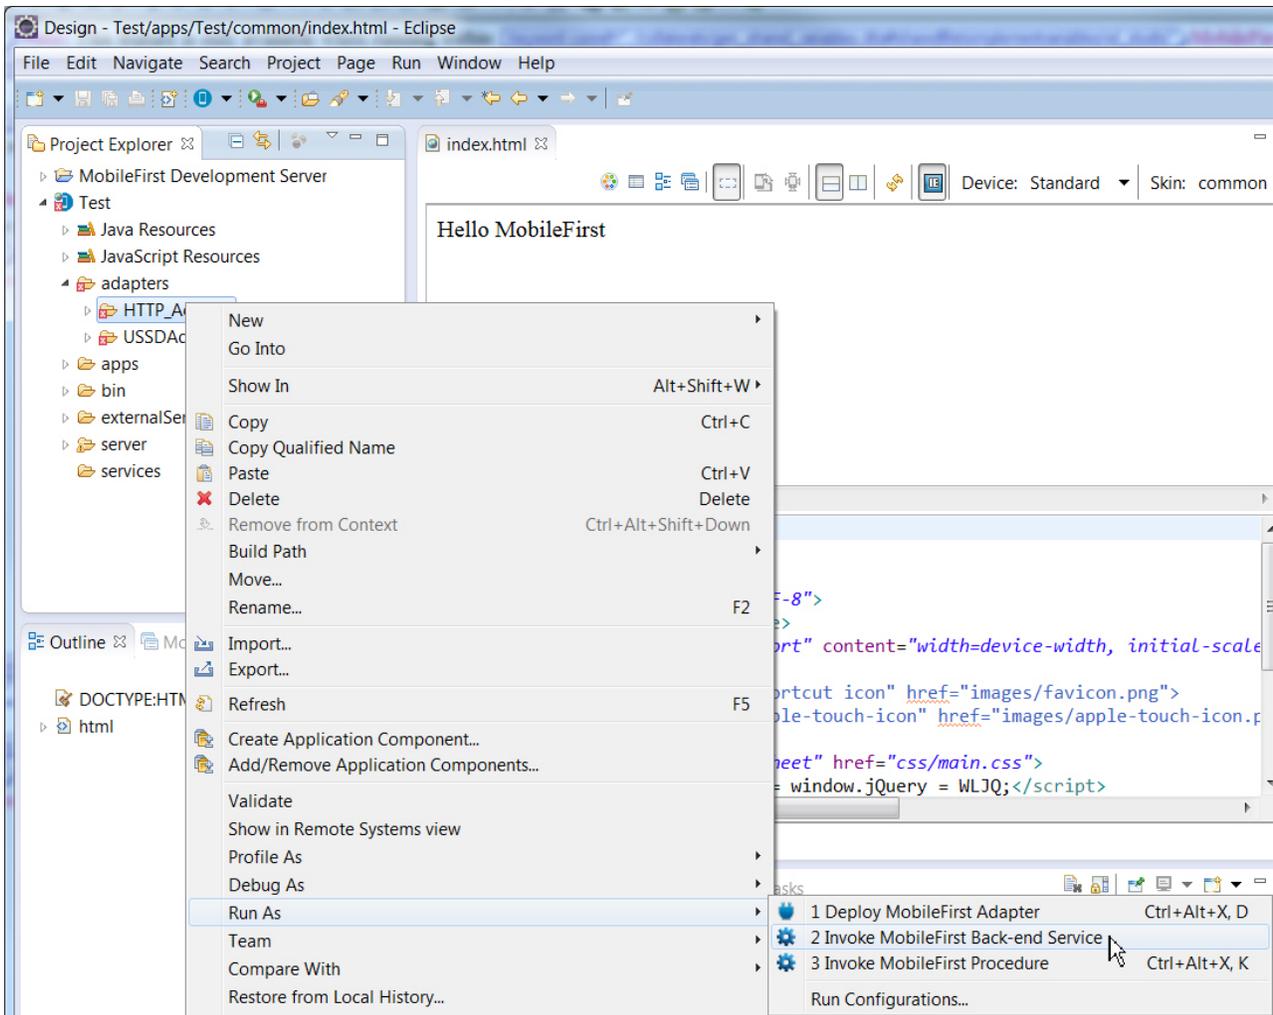

Figure 8-46. Invoking a MobileFirst back-end service

2. In the dialog box, provide the invocation service parameters. You can copy them from your code and paste them directly into the dialog box.

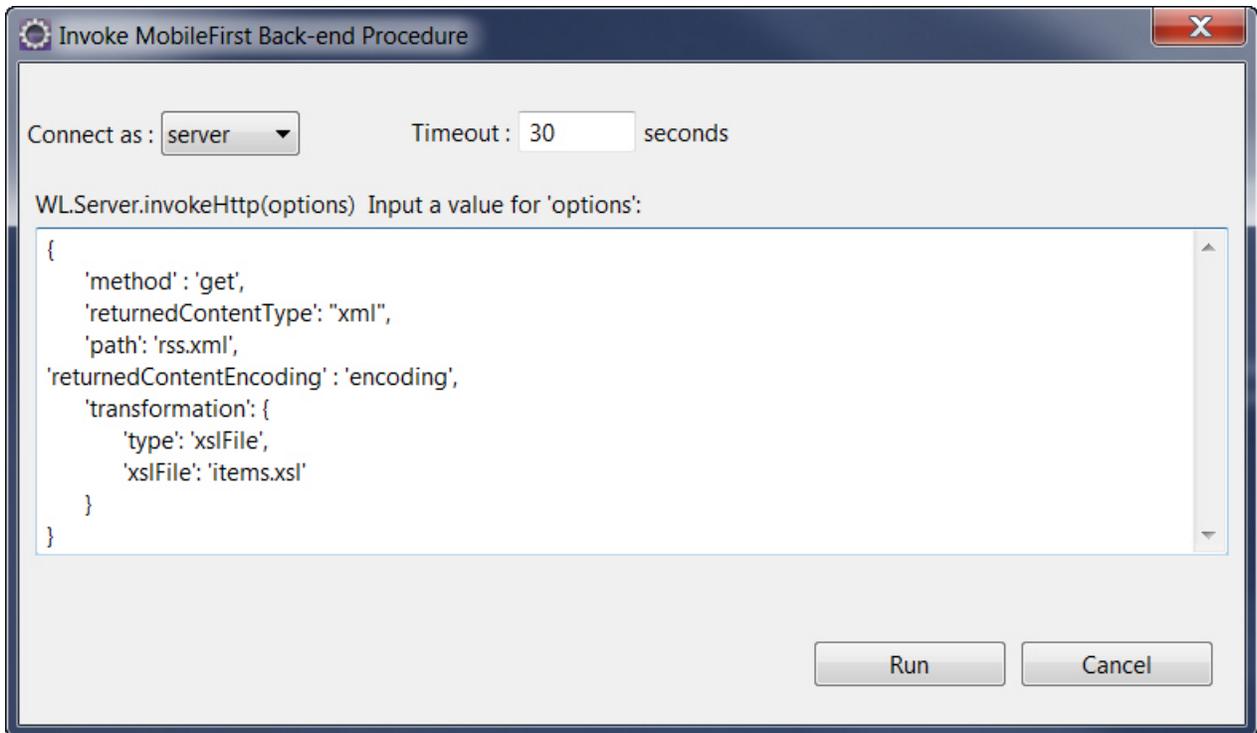

Figure 8-47. Invocation parameters.

A browser window opens, displaying the retrieved data in XML and JSON format, and the XSL transformation (if defined) that was used to convert the XML to JSON.

3. Optional: Change the XSL transformation by editing it in the edit box, then click **Apply XSL** to regenerate the JSON format.

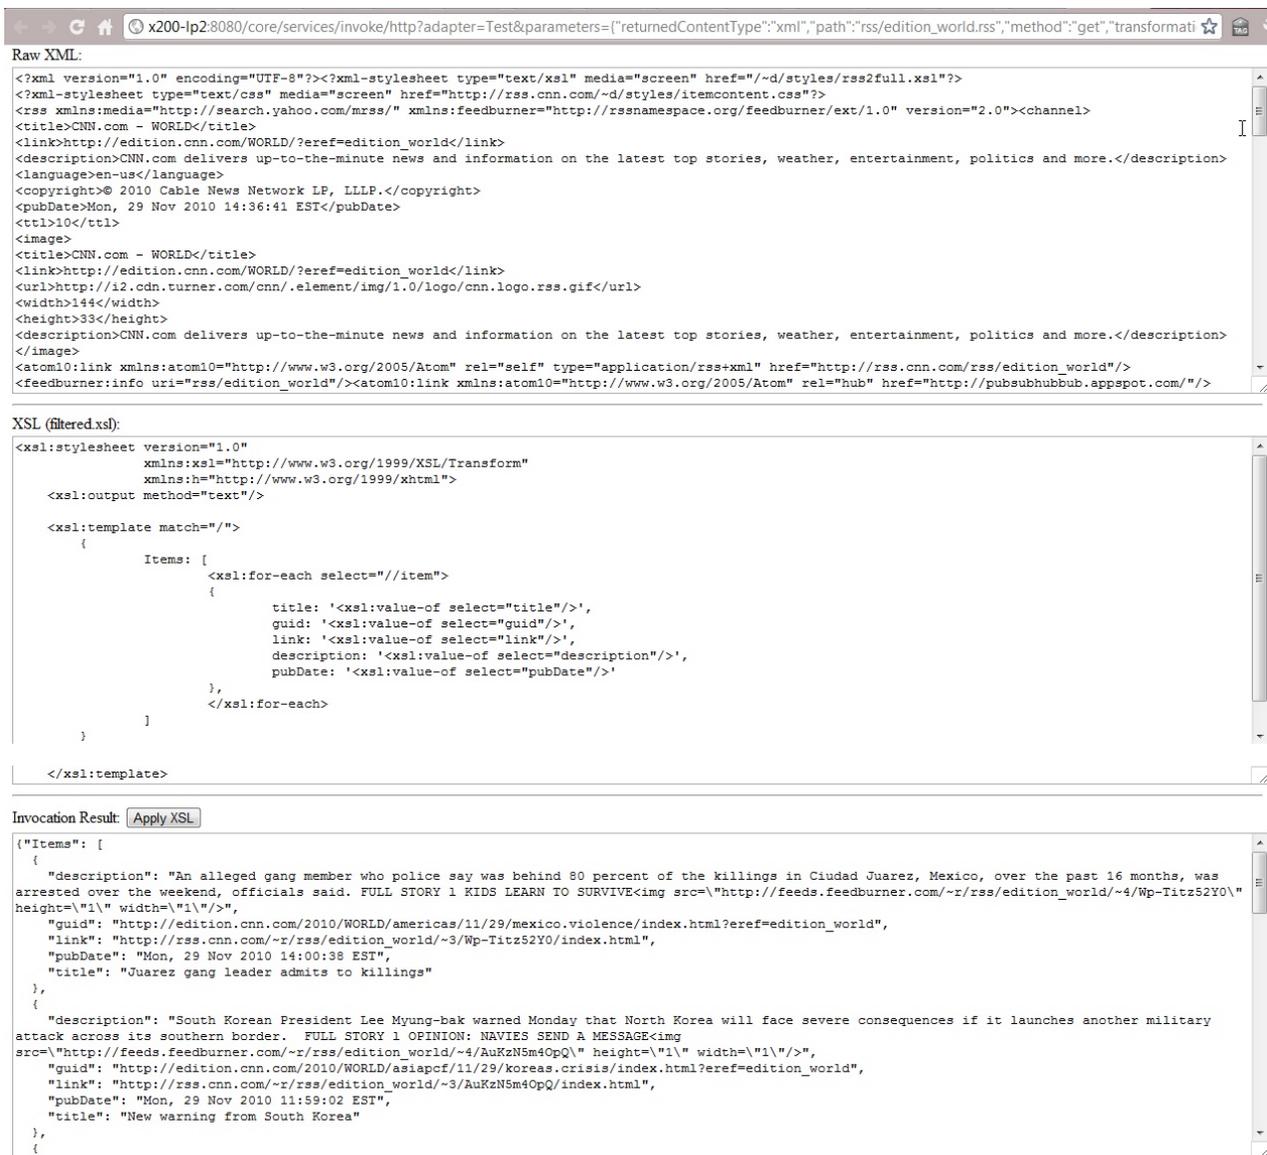

Figure 8-48. Browser window, showing retrieved data in XML and JSON format.

USSD Support

Unstructured Supplementary Service Data (USSD) is a communication technology that is used by GSM cellular telephones to send text messages between a mobile phone and an application program in the network.

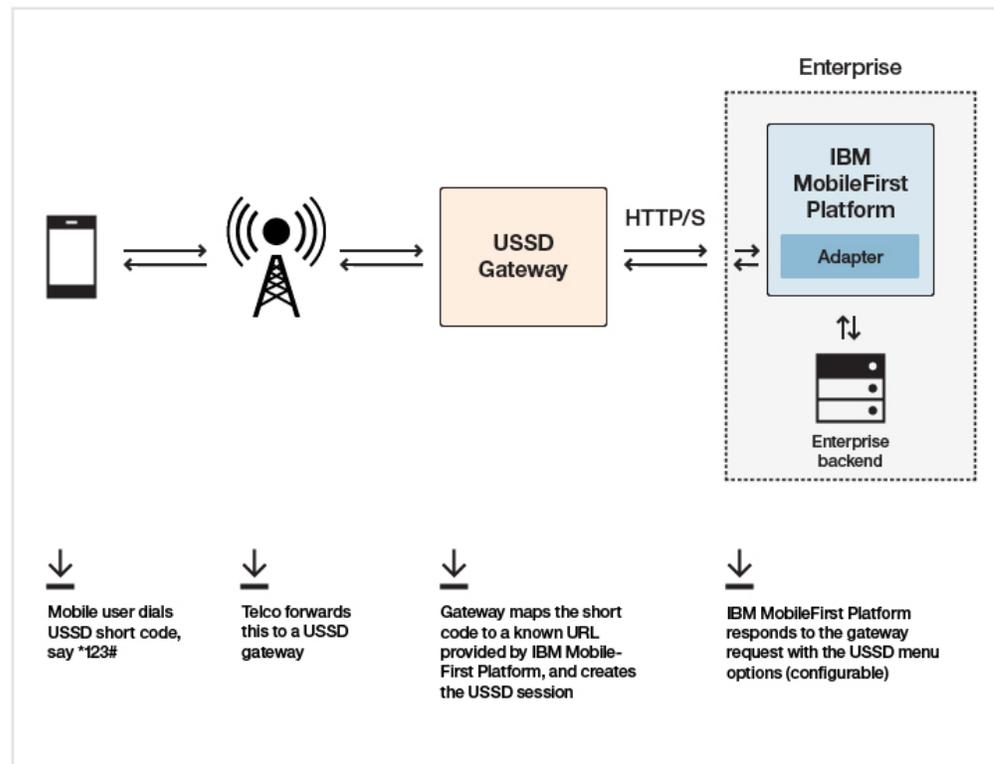

USSD establishes a real-time session between the mobile phone and the application that handles the service.

IBM MobileFirst Platform Foundation uses the HTTP/HTTPS protocol to communicate with the USSD gateway, which is a third-party entity. The USSD gateway routes USSD messages to the MobileFirst Server. Adapter procedures need to be defined to process these requests and send back a response. You need to define USSD event handler to route the requests to the adapter procedure that handles those requests.

Note: For more information, see the `WL.Server.createUSSDEventHandler` and `WL.Server.createUSSDResponse` APIs in `WL.Server`.

Here is a sample flow for USSD:

1. A mobile user enters a USSD short code, such as *123#.
2. The request is forwarded to a USSD gateway.
3. The gateway maps the short code to a known URL provided by IBM MobileFirst Platform Foundation, creates the USSD session, and forwards the request to the URL.
4. A MobileFirst adapter with the matching filter receives the request and responds to the gateway request with the configurable USSD menu/simple text.

Configuration required at USSD Gateway

`http://<hostname>:<port>/<contextroot>/ussd`

This URL can be followed by parameters specific to the gateway. Refer to your USSD Gateway documentation for more details.

Server-side APIs required at MobileFirst adapter side

To create a filter to process the USSD request:

```
WL.Server.setEventHandlers([ WL.Server.createUSSDEventHandler({  
  'shortcode' : '*123#'  
}, handleUSSDRequest) ]);
```

To send back a response:

```
WL.Server.createUSSDResponse("This is my response", "text/plain", true)
```

Security

To prevent entities with malicious intent from sending requests to the MobileFirst Server via a USSD URL, the USSD feature is protected by default. The `authenticationConfig.xml` file is configured to reject all requests to the USSD servlet with a rejecting login module. To allow restricted access to USSD, MobileFirst administrators must modify the `authenticationConfig.xml` file with appropriate authenticator and login modules, or comment the URL pattern `/ussd*` to allow unrestricted access. For example, the following configuration in the `authenticationConfig.xml` file ensures that only requests with a specific user name in the header of the HTTP request are allowed:

```
<staticResources>
  <resource id="subscribeServlet" securityTest="SubscribeServlet">
    <urlPatterns>/subscribeSMS*;ussd*</urlPatterns>
  </resource>
  ...
</staticResources>

<securityTests>
  <customSecurityTest name="SubscribeServlet">
    <test realm="SubscribeServlet" isInternalUserID="true"/>
  </customSecurityTest>
  ...
</securityTests>

<realms>
  <realm name="SubscribeServlet" loginModule="headerLogin">
    <className>com.worklight.core.auth.ext.HeaderAuthenticator</className>
  </realm>
  ...
</realms>

<loginModules>
  <loginModule name="headerLogin">
    <className>com.worklight.core.auth.ext.HeaderLoginModule</className>
    <parameter name="user-name-header" value="username"/>
  </loginModule>
  ...
</loginModules>
```

Invoking a back-end service for USSD

You can invoke a MobileFirst HTTP adapter to test the USSD functionality.

Before you begin

This feature is only available within MobileFirst Studio for HTTP adapters. It is not available when you run an adapter on a stand-alone server that is based on WebSphere Application Server or Tomcat.

About this task

In MobileFirst Studio, you can invoke an HTTP-based USSD adapter and see the results that are returned to the USSD gateway to verify that the adapter is performing correctly.

Procedure

1. Right-click an adapter file, and select **Run As > Invoke MobileFirst Back-end Service**.

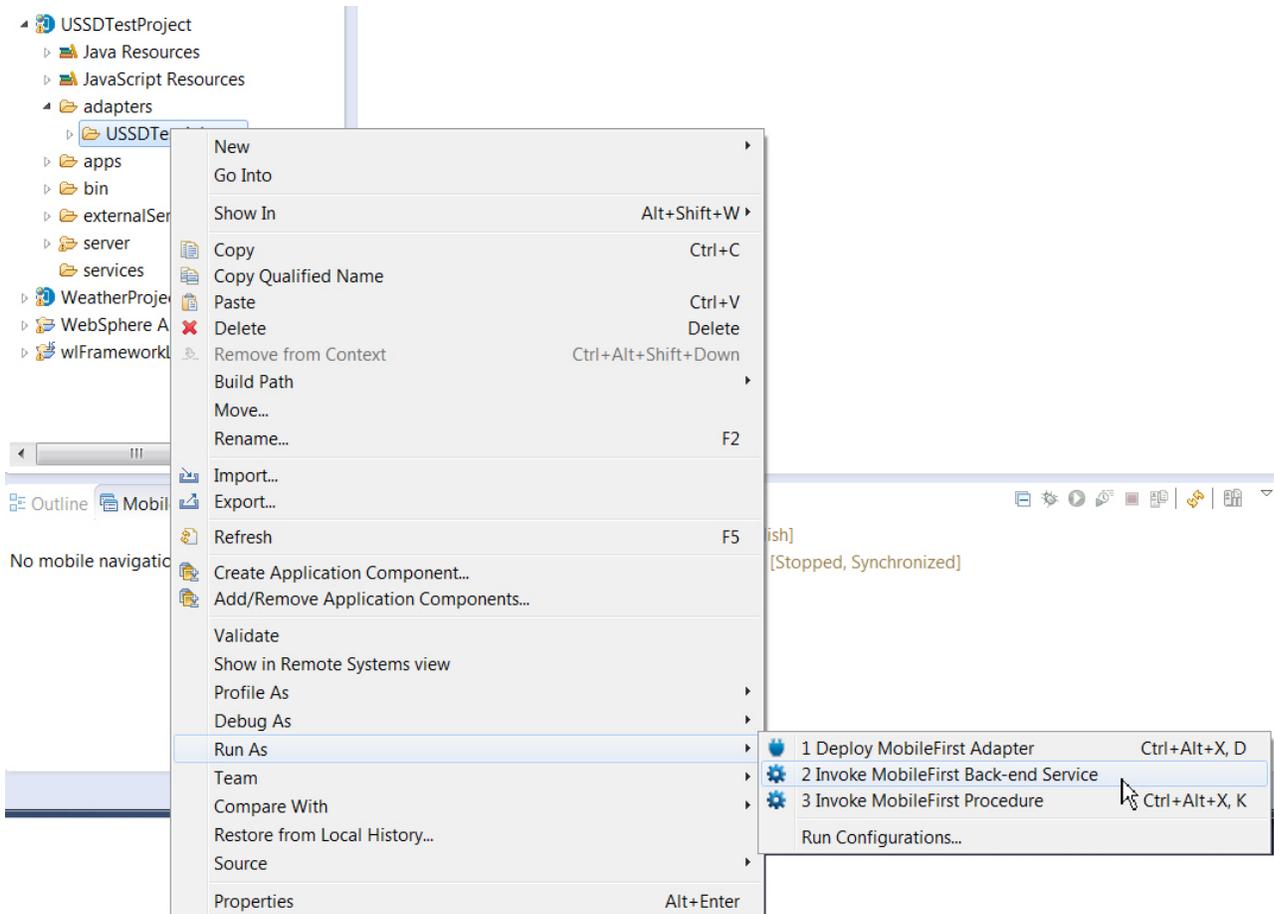

Figure 8-49. Invoking a MobileFirst back-end service

2. In the dialog box, from the **Connect as** drop-down list, select **gateway**. Then provide the options for invoking the USSD handler in the text box. The USSD gateway can send HTTP parameters, headers, cookies, or body.

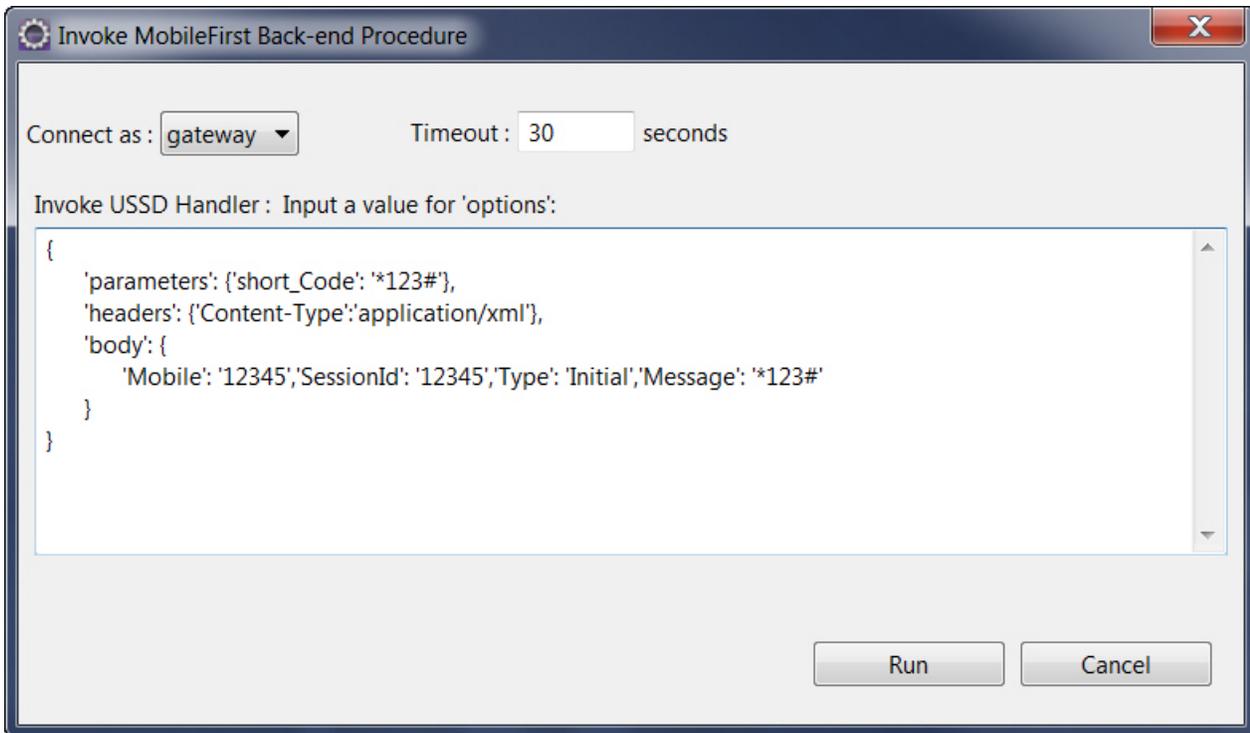

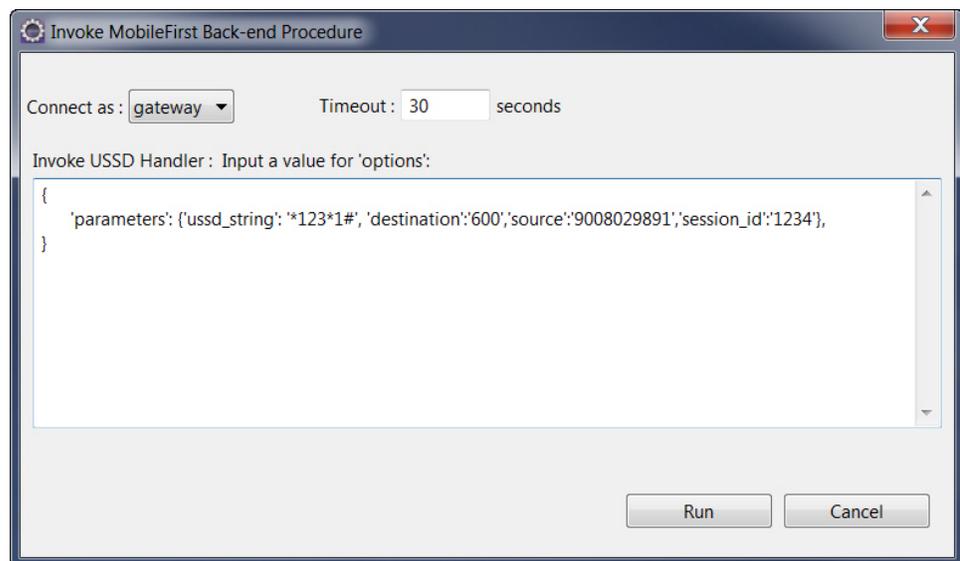

Figure 8-50. Invocation parameters.

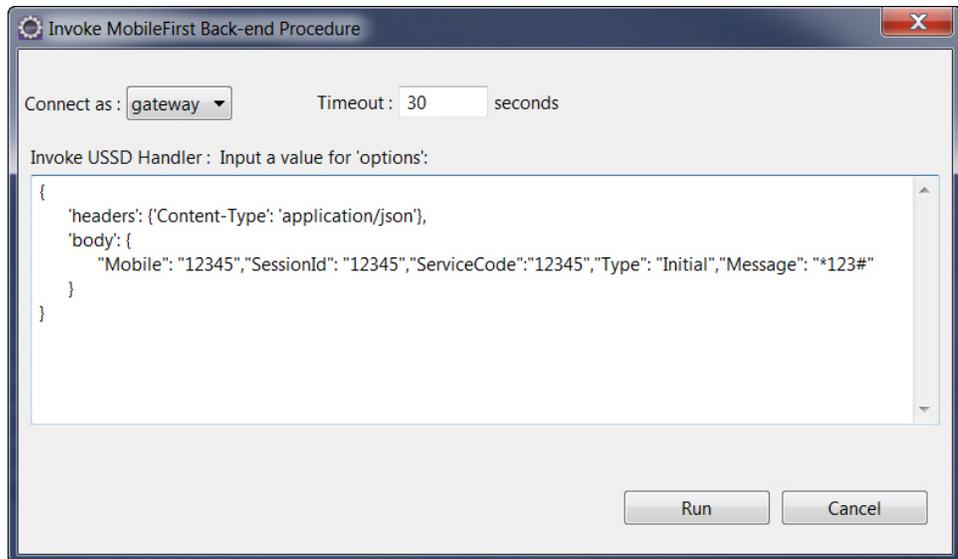

A browser window opens, displaying the result of the adapter invocation

3. You can follow this procedure as many times as required to test the menu flow with the USSD gateway. Here are some examples that use the different types of parameters that are passed from the USSD gateway.

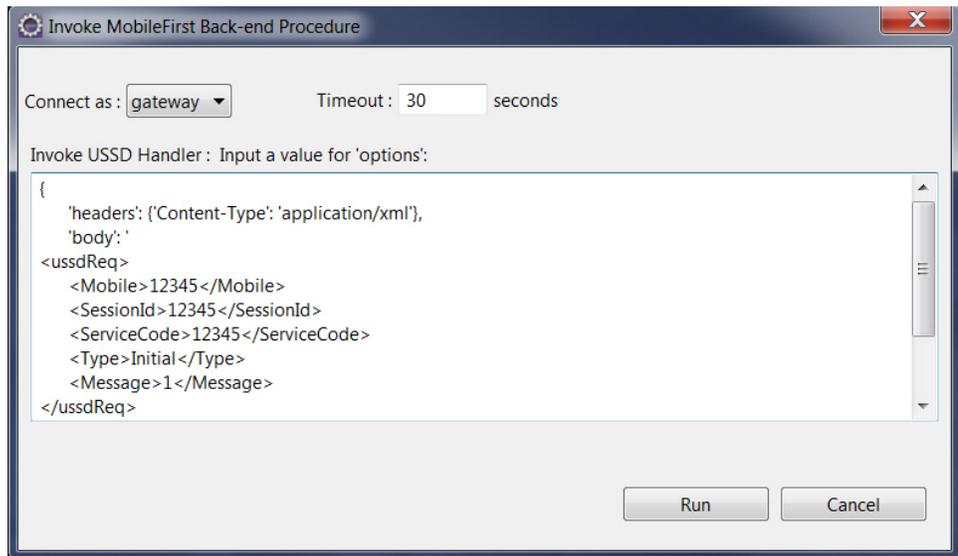

Example 1: Passing query string parameters.

Example 2: Passing JSON parameters in the body.

Example 3: Passing XML in the body.

Note: If the body that you pass is not a JSON object, then enclose the object in quotes (" "). If it is a JSON object, then surround it with curly brackets ({}).

Deploying adapters

In MobileFirst Studio, you can automatically deploy a new or modified adapter to the MobileFirst Server.

Procedure

Right-click the adapter folder and select **Run As > Deploy MobileFirst Adapter**.

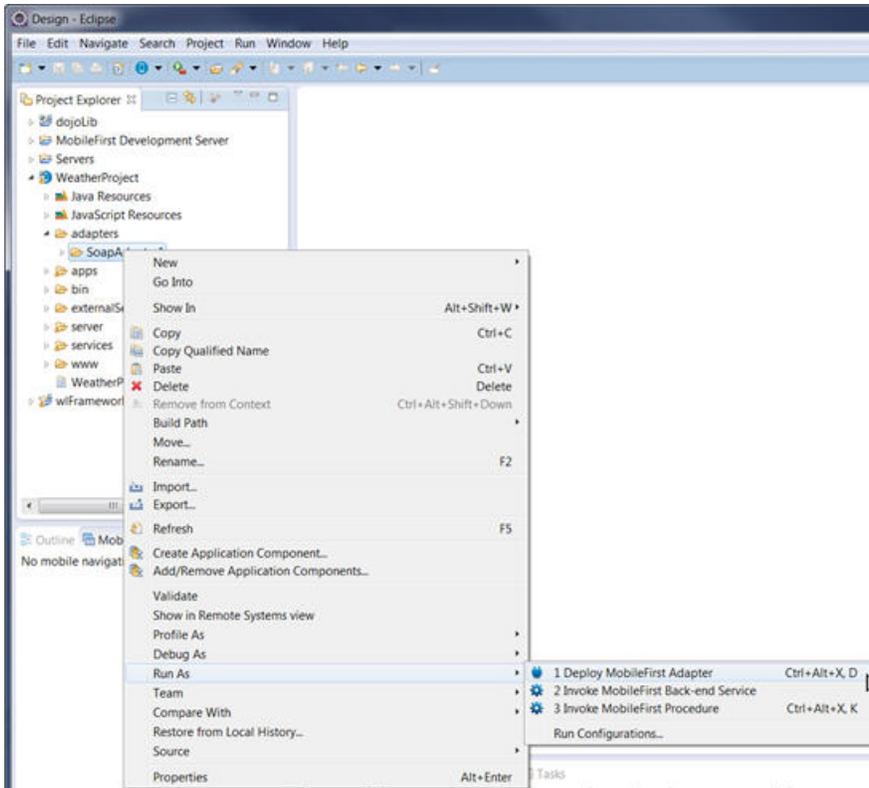

Figure 8-51. Deploying a MobileFirst adapter.

Results

A message is displayed, indicating whether the deployment action succeeded or failed.

Note: When the development server is started, adapters are automatically deployed after they are created or modified and saved. You can view this feature by clicking **Window > Preferences**. Select **MobileFirst**. To change this feature, clear the **Automatically Deploy Adapters on Change** check box. The default value of this feature is **true**. The **preview** command automatically deploys all adapters that are not deployed for a project if this preference is set to **true**.

Testing adapters

You can select a procedure, enter a set of parameters, and invoke the procedure on the MobileFirst Server.

This feature is available only when you are running MobileFirst Studio. It is not available when you run an adapter on a stand-alone server based on WebSphere Application Server or Tomcat.

Only procedure invocations are supported, with results displayed in a browser window. For each invoked procedure, MobileFirst Studio remembers the most recent parameter values. So, you can reinvoke the procedure without reentering parameter values.

Testing adapters with MobileFirst Studio

To test an adapter by using MobileFirst Studio, you must call the adapter.

To call an adapter, the adapter must be deployed on the MobileFirst Server.

To test an adapter, complete the following instructions.

1. Right-click the adapter and select **Run As > Call MobileFirst Adapter**. The Call MobileFirst Procedure window opens.
2. Select your preferences from the drop-down menus.
3. Complete the parameter annotation section. For more information about parameter annotations, see JAX-RS Parameter Annotations. Depending on what adapter you are calling, some of these options are not available.
4. Click **Run**. The adapter is called and a response is displayed in a new browser window.

Testing adapters with MobileFirst Platform Command Line Interface (CLI)

To test an adapter by using CLI, you must call the adapter.

To call an adapter by using CLI, run the **mfp adapter call** command. For more information about this command, see mfp adapter call.

Testing adapters with external tools such as Postman

MobileFirst Java adapters expose a full REST API. If you know the URL of a resource or procedure, you can use HTTP tools such as Postman to test requests and pass the following parameters.

- URL parameters
- Path parameters
- Body parameters
- Headers

If your resource is protected by a security scope, the request prompts you to provide a valid authorization header. The default value of this security scope is simple. Unless you disabled security, the endpoint is protected.

As a solution for testing, the development version of the Worklight Server includes a test token endpoint.

To receive a Test Token, create an HTTP POST request to `http(s)://{server_ip}:{server_port}/{project_name}/authorization/v1/testtoken` with your HTTP client (Postman).

You receive a JSON object with a temporary valid authorization token.

```
{
  "Authorization": "Bearer eyJhbGciOiJSUzI1NiIsImpwayI6eyJhbGciOiJSU0EiLCJleHAiOiJBUEFCIiwiaXNja3eEFkdjZILX1nTDdyOHFDTGRFLTNJMm2FPZU1xb2UtkcpBMHVadXcyckhowFozV1ZDZUt1e1JWY0NPWXRRTUUsbwWZ6NV8zby1ldjBVWXdyY1NPd0JCbDFFaHFJd1ZEEd09pZWcySk1HbDBFWHNQWmZrT1pJLUhVNG9NaWktVHJOT"
}
```

In your next requests to the adapter endpoints, add an HTTP header with the name `Authorization` and the value that you received that starts with `Bearer`.

Now that you have a valid token, you can access the resource by using the security framework.

For more information about the test token endpoint, see “The test token endpoint” on page 8-546.

Session-independent mode

Starting with V7.1.0, MobileFirst applications run by default in session-independent mode.

Overview

In previous versions of the product, the authentication context of clients (for example, whether they are logged in to a realm) was wholly dependent on an HTTP session. After logging in, the end user remained logged in only as long as the HTTP session was alive. Whenever the session ended, the user was automatically logged out. In addition, to ensure the continuity of an HTTP session, "sticky" sessions were required when using a load balancer.

The session-independent mode in V7.1.0 decouples the link between authentication context and HTTP sessions by using the attribute store module for saving the authentication context. The interaction between the client and MobileFirst Server no longer has to be session-dependent. IT can auto-scale the network as needed and use a load-balancer without requiring sticky HTTP sessions.

One advantage of this feature is that starting from V7.1.0, if your system is operating in session-independent mode and you choose to scale back or scale up any number of servers, the user experience is unaffected.

Restriction:

- By default, new projects that are created in V7.1.0 are *session independent*. Old projects, even after upgrade remain session dependent. For steps to upgrade older apps to work in session-independent mode in V7.1.0, see [Upgrading projects to work in session-independent mode](#).
- Session-independent mode is not supported in configurations of IBM MobileFirst Platform Foundation that include any of the following components or environments:
 - Blackberry
 - Windows Phone Silverlight 8 (native)
 - Adobe AIR
 - Desktop browser
 - Mobile web apps
 - JavaME native
 - Geolocation
 - USSD

Attribute store types for session-independent mode

The attribute store is where the authorization server stores the authentication context of clients (such as the state of authenticators and login modules).

There are three types of attribute store configurations that support session-independent mode: attribute store over the runtime database (default), attribute store over IBM WebSphere eXtreme Scale, and attribute store over IBM Data Cache for Bluemix.

Note: The attribute store type that you select has an impact on the scalability and performance of the IBM MobileFirst Platform Server. In general, when high throughput is required, optimal results can be achieved by using the attribute store

over IBM WebSphere eXtreme Scale. To choose the configuration that best fits your throughput and scalability requirements, see the Developer Center website for IBM MobileFirst Platform Foundation.

Attribute store over the runtime database (default)

Starting from V7.1.0, the attribute store in IBM MobileFirst Platform Server is persisted by default to the runtime database (Cloudant or relational database). Figure 1 illustrates a server cluster that employs this configuration.

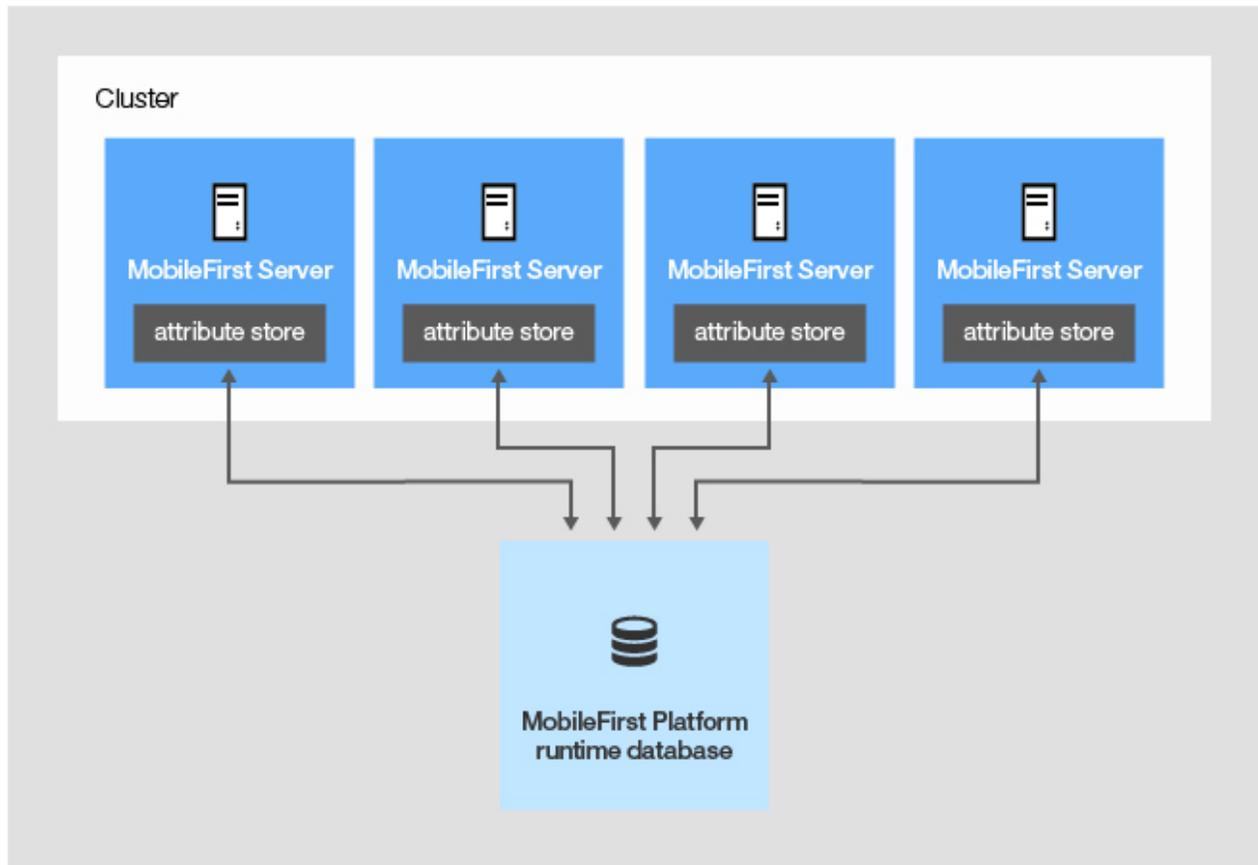

Figure 8-52. Attribute store over runtime database

The following settings in the `worklight.properties` file determine the default behavior:

- `mfp.attrStore.type` is set to `database` (default)
- `mfp.session.independent` is set to `true` (default)

Attribute store over IBM WebSphere eXtreme Scale

The attribute store can be cached in eXtreme Scale, with or without a Loader plug-in for persistence to an SQL or Cloudant database. For more information, see “Attribute store over IBM WebSphere eXtreme Scale” on page 8-327.

Attribute store over IBM Data Cache for Bluemix

The attribute store data for applications that are deployed in IBM Containers can be cached to IBM Data Cache. For more information, see “Deploying to the cloud in an IBM Container” on page 12-115 and IBM Data Cache for Bluemix.

Important:

- In a session-independent configuration, a request can be processed by one server in a cluster and the next request by another. This means that if you apply a fix pack or other change to a farm, particularly if the fix pack includes changes to authentication, all servers must be upgraded at the same time. If the fix pack is not applied to the entire farm at once, requests may fail as they move back and forth between servers where the fix pack has been applied and servers where it has not.
- The attribute store module uses serialized objects, so the Java Virtual Machine (JVM) of any server must be able to read what the JVM of other servers has serialized. Ensure that all members of a cluster use compatible serialization.

Session-dependent mode

V7.1.0 still allows you to run applications in session-dependent mode, where the attribute store is held in the HTTP session. To work in session-dependent mode, set the `mfp.attrStore.type` property to `httpsession`. Also, ensure that you have set the `mfp.session.independent` property to `false`, or MobileFirst Server will not come up and an error will be reported. See “Configuring session dependency” on page 12-54.

Upgrading projects to work in session-independent mode

Projects that are upgraded to work with MobileFirst Server V7.1.0 from earlier versions will remain in *session-dependent* mode by default.

For more information about upgrading old projects so that they work in session-independent mode, see [Upgrading projects to work in session-independent mode](#).

Developing apps to work in IBM MobileFirst Platform Foundation V7.1.0

- In previous versions, certain components of your projects could persist data in the HTTP session. This is no longer possible in session-independent mode:
 - **IBM MobileFirst Platform Foundation security framework:** In session-independent mode, the attribute store is used to save the security state, instead of the HTTP session, which was used in previous versions.
 - **Applicative state and custom security state:** If your existing applications store applicative state or custom security state in the HTTP session, you must adapt your code so that the applicative or security state is held elsewhere

For guidelines on refactoring existing apps away from HTTP sessions see the following topics:

- [Implementing JavaScript adapters to support session-independent mode](#)
- [Implementing security-based code to support session-independent mode](#)
- [Saving applicative state between requests in Java RESTful adapters](#)
- [When implementing or upgrading a custom authenticator, refer to the custom-authenticator guidelines for session-independent mode.](#)

Realm expiration

It is important to note that realm expiration is not new in V7.1.0. In previous versions, it was limited by the HTTP session lifespan, and starting from V7.1.0, it is not. To enforce a lifetime for a client's logged-in state, you must configure the

expiration of security realms. When the realm expires, the login session ends and the client app is forced to log in again if it tries to access a resource that is protected by this realm, or if it requests a token that contains this realm.

Version 7.0.0 introduced the optional `expirationInSeconds` configuration element, which you could use for each login module to define the expiration of its realm. Its default setting was -1 to indicate that there was no expiration period and that the login would remain valid until the end of the HTTP session.

Starting with V7.1.0, the login period is entirely dependent on the realm expiration, so **the default value for `expirationInSeconds` is now 3600 seconds** (one hour) and in session-independent mode, it is no longer possible to set the value to -1. For more information, see “Configuring login modules” on page 8-617.

Attribute store over IBM WebSphere eXtreme Scale

To support session-independent mode, you can cache authentication context by using eXtreme Scale.

About this task

Instructions are provided here for configuring an IBM MobileFirst Platform Server cluster to work with eXtreme Scale (Figure 1). It also provides instructions for persisting the cached data to relational and non-relational stores by using the Loader plug-ins that are provided with the product (see Figure 2 and Figure 3).

For more information about session-independent mode, see “Session-independent mode” on page 8-324.

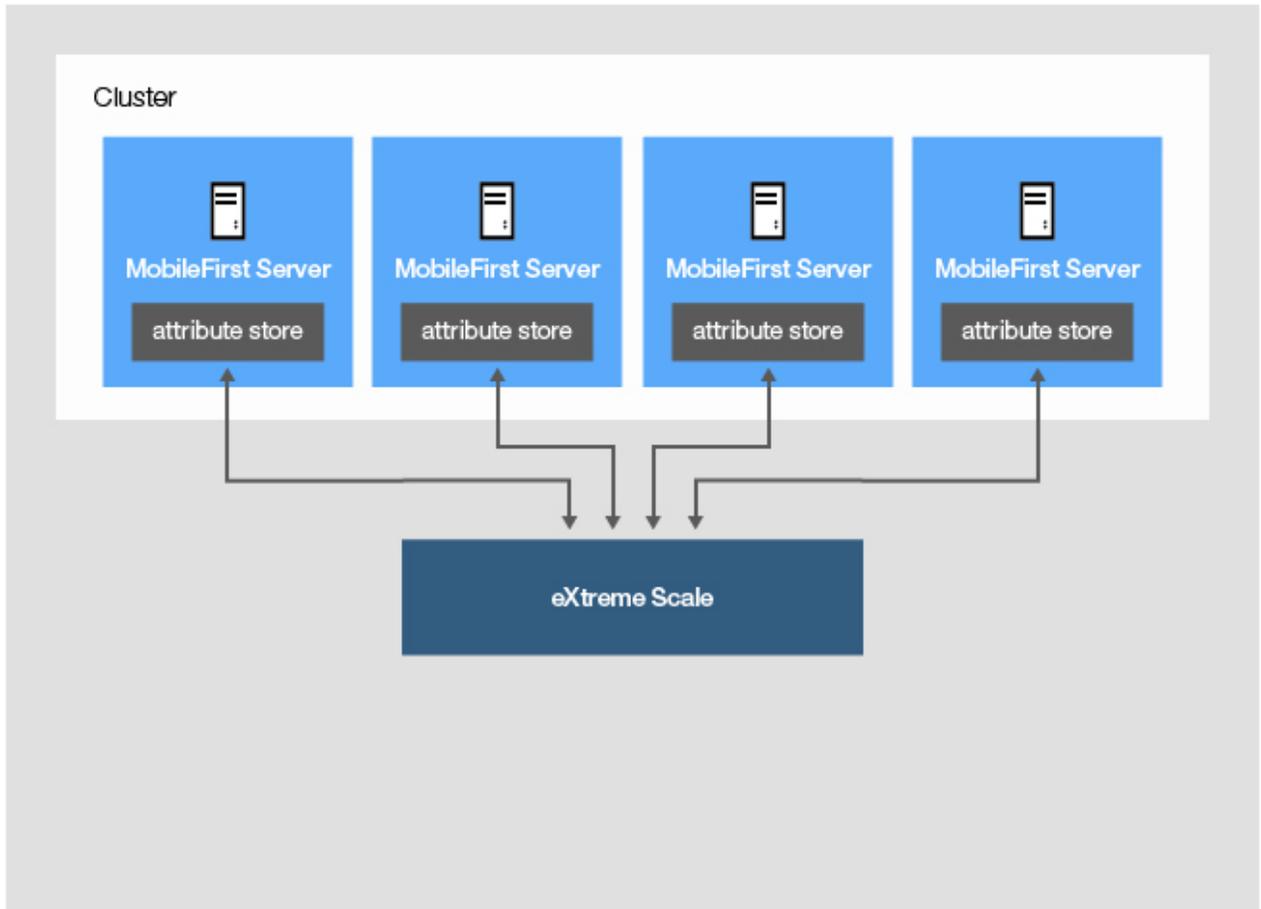

Figure 8-53. Attribute store over eXtreme Scale

eXtreme Scale Grid Definition

About this task

In the eXtreme Scale server, define a dedicated object grid and a backing map for usage of the attribute store table in IBM MobileFirst Platform Server. The recommended eXtreme Scale configurations are described in detail in the WebSphere eXtreme Scale V8.6 Knowledge Center.

Procedure

In the `objectgrid.xml` file, define a dedicated object grid and backing map. Here is an example:

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
  xmlns="http://ibm.com/ws/objectgrid/config">

  <objectGrids>
    <objectGrid name="MFPGGrid" txTimeout="30">
      <backingMap name="AttrStoreMap" copyMode="COPY_TO_BYTES"
        lockStrategy="PESSIMISTIC">
```

```

        nullValuesSupported="true" ttlEvictorType="LAST_ACCESS_TIME" timeToLive="10" nearCacheEnabled="true"
    </objectGrid>
</objectGrids>
</objectGridConfig>

```

Optionally, the map can be configured to use a Loader plug-in that persists the data. For more information, see “Persisting the eXtreme Scale cache to the IBM MobileFirst Platform Server relational database” on page 8-330.

IBM MobileFirst Platform Server configuration

About this task

In configuring IBM MobileFirst Platform Server, you must define several configuration properties that contain the eXtreme Scale connection parameters and add the eXtreme Scale client library JAR file to the class path.

Procedure

1. Define the following properties in the `worklight.properties` file or by using JNDI:

```

//Enable session independent mode
mfp.session.independent=true

//Indicates attribute store must be cached in eXtreme Scale
mfp.attrStore.type=eXtremeScale

//A comma-separated list of host-port pairs of the WebSphere eXtreme Scale catalog servers, in the format host:port
mfp.attrStore.xs.endpoint=9.111.27.160:2809

//The user name and password for connecting to the eXtreme Scale server. Leave empty if authentication is not required
mfp.attrStore.xs.username=
mfp.attrStore.xs.password=

//The names of the grid and backing map for the attribute store, as defined in objectgrid.xml
mfp.attrStore.xs.gridname=MFPGrid
mfp.attrStore.xs.mapname=AttrStoreMap

```

2. Add the eXtreme Scale client library JAR file to the class path of your MobileFirst project runtime application. For Liberty Profile, use `ogclient.jar` and for WebSphere Application Server, use `wsogclient.jar`. Both JAR files are in the eXtreme Scale installation folder, which is at `<eXtreme Scale_install_folder>\ObjectGrid\lib` by default.

- **In Liberty**

- a. Create a folder `WXS` under the Liberty shared resources folder and copy the JAR file to that folder.
- b. Add the location of the JAR file to the class loader configuration of your MobileFirst project.

```

<!-- Declare the IBM Worklight project runtime application. -->
<application id="worklight" name="worklight" location="worklight.war" type="war">
    <classloader delegation="parentLast">
        <privateLibrary id="worklightlib_worklight">
            <fileset dir="{shared.resource.dir}/worklight/lib" includes="worklight-jee-*.jar" />
            <fileset dir="{wlp.install.dir}/lib" includes="com.ibm.ws.crypto.passwordutil.jar" />
            <fileset dir="{shared.resource.dir}/WXS" includes="ogclient.jar" />
        </privateLibrary>
    </classloader>
</application>

```

Note: When you use eXtreme Scale client with the IBM MobileFirst Platform Server, a known JMX connection issue prevents the use of Oracle JDK. Use IBM JDK, as follows:

- a. In the IBM MobileFirst Platform Server folder, for example:
`/opt/IBM/WebSphere/Liberty/usr/servers/<my_username>`, edit the `jvm.options` file so that it contains the following lines. Replace the `yourServerName` folder with the one in your setup:

```
-Dcom.ibm.ws.jmx.connector.client.rest.readTimeout=180000  
-Djavax.net.ssl.trustStore=/opt/IBM/WebSphere/Liberty/usr/servers/<yourServerName>/resource  
-Djavax.net.ssl.trustStorePassword=worklight  
-Djavax.net.ssl.trustStoreType=jks  
-Djava.security.properties=./java.security.props
```

- b. In the same folder as the `server.xml` file, create a new file, `java.security.props` that contains the following two lines. Note that each SSL key has an empty value.

```
ssl.SocketFactory.provider=  
ssl.ServerSocketFactory.provider=
```

- **In WebSphere Application Server full profile:**

Copy the eXtreme Scale JAR file, `wsogclient.jar` to a local folder and add the path of this JAR file to the class path that is defined in the `WL_PLATFORM_LIB` shared library.

Persisting the eXtreme Scale cache to the IBM MobileFirst Platform Server relational database

About this task

eXtreme Scale can back up its data to a relational database with a Loader plug-in. For more information about eXtreme Scale and loaders, see [Plug-ins for communicating with databases](#).

In the configuration that is described in this section, the built-in MobileFirst relational database Loader is used to back up eXtreme Scale data to the IBM MobileFirst Platform Server SQL database.

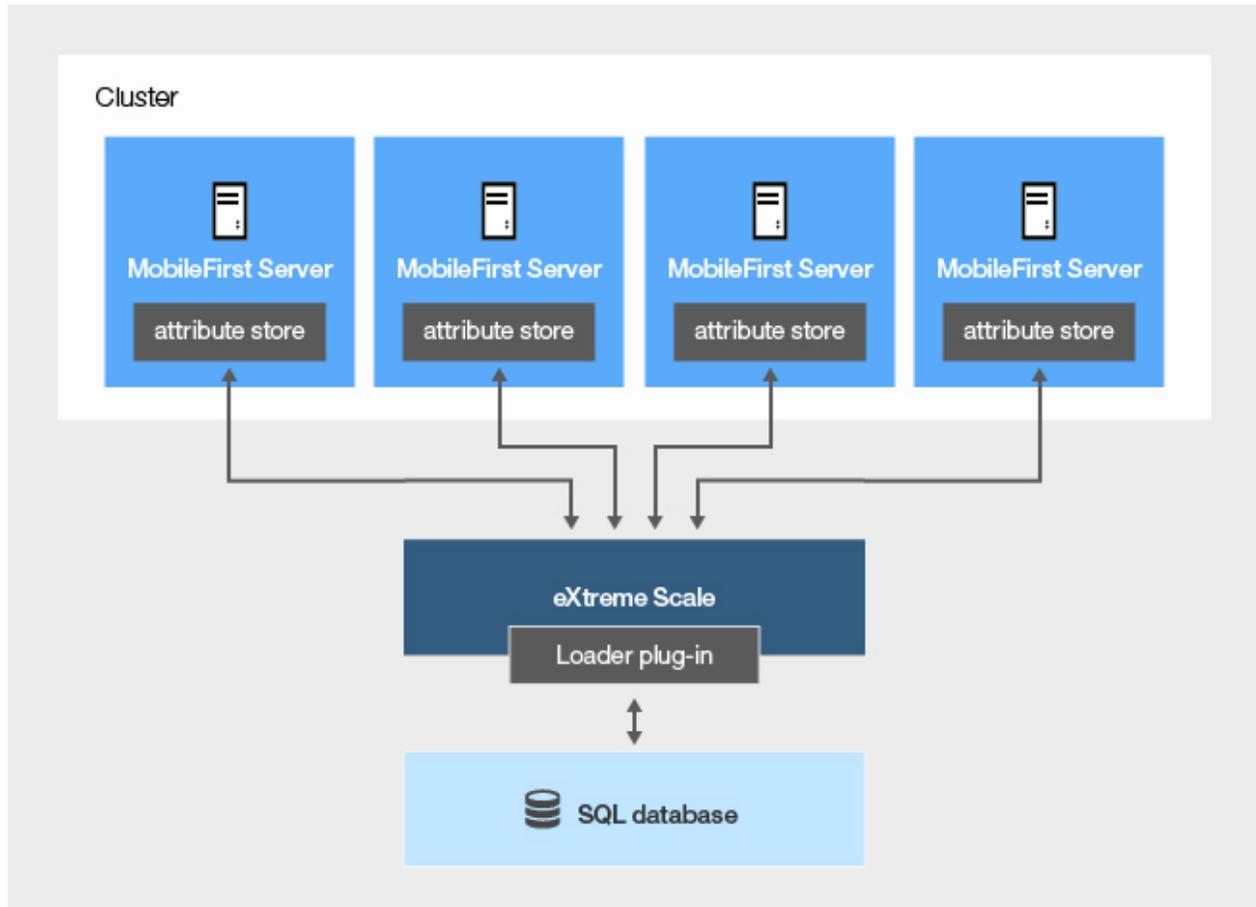

Figure 8-54. Attribute store over eXtreme Scale with SQL Loader plug-in

Note: IBM MobileFirst Platform Server also provides a default write-behind Loader plug-in for backing up eXtreme Scale data with Cloudant. For more information about configuring Cloudant as your database, see “Persisting the eXtreme Scale cache to Cloudant” on page 8-332.

Procedure

1. Find the Loader JAR file, `mfp-xs-loader.jar` in your MobileFirst Server installation folder. By default, it is in `<mfp_install_dir>/WorklightServer/external-server-libraries`.
2. Extract the `meta-inf/persistence.xml` file from the JAR file and replace the `<properties>` tag in the file according to the following example. This example applies to a DB2 database. For other types of database like MySQL or Oracle, you must change the driver class name to the class name for your database type.

```
<properties>
  <property name="openjpa.ConnectionProperties" value="DriverClassName=com.ibm.db2.jcc.DB2Dri
    Url=jdbc:db2://database_host_name:database_port/database_name, MaxActive=100, MaxWait=10
    Username=database_user_ID, Password=database_user_password"/>
  <property name="openjpa.ConnectionDriverName" value="org.apache.commons.dbcp.BasicDataSourc
</properties>
```

Replace `database_host_name`, `database_port`, `database_name`, `database_user_ID`, and `database_user_password` with values for your database.

3. Repackage the JAR file.

Note: As an alternative to providing these parameters in `persistence.xml`, you can override the parameters when you start the eXtreme Scale Server by using JVM arguments.

4. Add the `mfp-xs-loader.jar` to the classpath of your eXtreme Scale deployment.
5. Add the database driver JAR file to the classpath of your eXtreme Scale deployment.
6. In `objectgrid.xml`, add an entry with `className="com.worklight.core.persistence.xs.AttributeStoreDBLoader"` for `backingMapPluginCollection`

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
  xmlns="http://ibm.com/ws/objectgrid/config">

  <objectGrids>
    <objectGrid name="MFPGrid" txTimeout="30">
      <backingMap name="AttrStoreMap" copyMode="COPY_TO_BYTES" pluginCollectionRef="as"
        lockStrategy="PESSIMISTIC" writeBehind="T30;C20"
        nullValuesSupported="true" ttlEvictorType="LAST_ACCESS_TIME" timeToLive="10" nearCacheEnabled="true">
      </objectGrid>
    </objectGrids>
  <backingMapPluginCollections>
    <backingMapPluginCollection id="as">
      <bean id="Loader" className="com.worklight.core.persistence.xs.AttributeStoreDBLoader"/>
    </backingMapPluginCollection>
  </backingMapPluginCollections>
</objectGridConfig>
```

The `writeBehind` XML attribute is optional.

7. In `deployment.xml`, increase the **numberOfPartitions** attribute to 50. When you increase the number of partitions, you increase the number of loader threads connecting to the database. An increase in the number of loader threads improves the performance of persisting to the database.

Persisting the eXtreme Scale cache to Cloudant

About this task

In the configuration that is described in this section, the built-in MobileFirst Cloudant database Loader is used to persist eXtreme Scale data to a Cloudant database. This configuration can use either Cloudant Local, or Cloudant DBaaS.

Note: As an alternative, you can use the MobileFirst relational Loader to connect eXtreme Scale with the MobileFirst SQL database. For more information, see [Persisting the eXtreme Scale cache to the MobileFirst Server relational database](#).

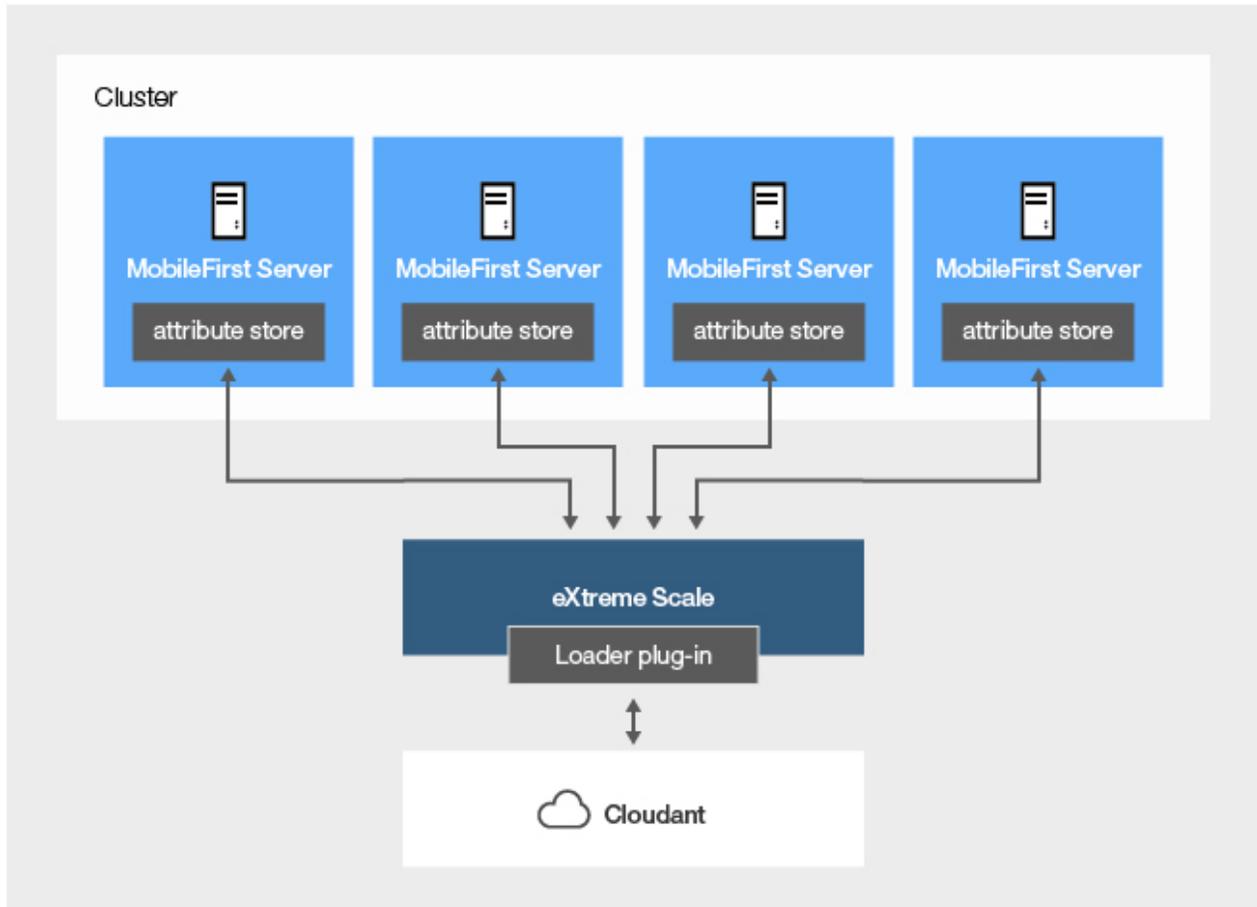

Figure 8-55. Attribute store over eXtreme Scale with Cloudant Loader plug-in

Procedure

1. Create a Cloudant account. Note the URL for the next steps.
2. Add `mfp-xs-loader.jar` to the classpath of your eXtreme Scale deployment.
3. In the `objectgrid.xml` file, add an entry with `className="com.worklight.core.persistence.xs.AttributeStoreCloudantLoader"` for `backingMapPluginCollection`

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
xmlns="http://ibm.com/ws/objectgrid/config">

  <objectGrids>
    <objectGrid name="MFPGrid" txTimeout="30">
      <backingMap name="AttrStoreMap" copyMode="COPY_TO_BYTES" pluginCollectionRef="as"
        lockStrategy="PESSIMISTIC" writeBehind="T60;C100"
        nullValuesSupported="true" ttlEvictorType="LAST_ACCESS_TIME" timeToLive="10" nearCache="">
      </objectGrid>
    </objectGrids>
  <backingMapPluginCollections>
    <backingMapPluginCollection id="as">
      <bean id="Loader" className="com.worklight.core.persistence.xs.AttributeStoreCloudantL
    </backingMapPluginCollection>
  </backingMapPluginCollections>
</objectGridConfig>
```

- Add your Cloudant database URL to the eXtreme Scale container start script by using a JVM property, as follows:

```
-Dcloudant_url= http://user:password@cloudant.com/attrstore
```

where attrstore is a Cloudant table name. If the table does not exist, it is created automatically.

- If Cloudant is behind a proxy, add a line for:

```
-Dcloudant_proxy_host=proxy.com
```

and a line for:

```
-Dcloudant_proxy_port=8989
```

In both lines, correct the host and port values to your proxy settings.

Client access to adapters

Clients can access adapters from three endpoints in the IBM MobileFirst Platform Server.

The following table summarizes the supported adapter types, HTTP methods, and security model for each MobileFirst Server endpoint.

Table 8-32. Client access to MobileFirst Server endpoints

Endpoint	Supported for Java adapters	Supported for JavaScript adapters	Permitted HTTP methods	Supported security model
/adapters	yes	yes	GET, POST, PUT, DELETE, HEAD, TRACE	OAuth 2.0-based
/apps/services/api/query	no	yes	POST	Pre-V7.0
/invoke	no	yes	GET, POST	Pre-V7.0

Accessing adapters from the /adapters endpoint

Clients can access both Java and JavaScript adapters from the /adapters endpoint on the server. You can access this endpoint from both mobile and non-mobile clients.

The URL pattern for accessing the /adapters endpoint is as follows:

```
http(s)://<server>:<port>/<Context>/adapters/<adapter-name>/*
```

For example, assuming that `http://mfp-server-host/project` is the IBM MobileFirst Platform Foundation project URL, and the project contains one Java adapter named `adapter1` and the adapter has a resource with path `/res1`, then `/res1` is accessible from the following URL:

```
http://mfp-server-host/project/adapters/adapter1/res1
```

Note: Using the /adapters endpoint is the recommended way to access IBM MobileFirst Platform Foundation adapters. This endpoint supports both JavaScript and Java adapters and is protected by the OAuth security mechanism, which was introduced beginning with MobileFirst V7.0.

Accessing adapters from a mobile client

IBM MobileFirst Platform Foundation provides a client API for accessing OAuth protected resources such as adapters. If you choose to use MobileFirst client for that purpose, it will automatically handle security for you. The following examples demonstrate how to use the client API to access an adapter resource:

Hybrid (JavaScript) client

```
var request = new WLResourceRequest("adapters/adapter1/res1", WLResourceRequest.GET);

request.send().then(
    function(response) {
        alert(JSON.stringify(response));
    },
    function(error) {
        alert(JSON.stringify(error));
    }
);
```

Native Android client

```
WLResourceRequest req = new WLResourceRequest(new URI("adapters/adapter1/res1"), WLResourceRequest.GET);
req.send(new WLResponseListener(){
    @Override
    public void onSuccess(WLResponse response) {
        // handle success
    }
    @Override
    public void onFailure(WLFailResponse response) {
        // handle failure
    }
});
```

Native iOS client

```
NSString static *const RESOURCE_URL = @"adapters/adapter1/res1";
WLResourceRequest *request = [WLResourceRequest requestWithURL:[NSURL URLWithString:RESOURCE_URL] method:WLHttpMethodGet];
[request sendWithCompletionHandler:^(WLResponse *response, NSError *error) {
    NSString *httpStatus = [NSString stringWithFormat:@"%d", [response status]];
    self.httpStatusTextField.text = httpStatus;
    if (error != nil) {
        [self updateView:[error description]];
    } else {
        [self updateView:[response.responseText]];
    }
}];
```

Native Windows 8 Universal and Native Windows Phone 8 Universal

```
WLResourceRequest req = new WLResourceRequest("adapters/adapter1/res1", WLResourceRequest.GET);
InvokeListener listener = new InvokeListener();
req.send(listener);

public class InvokeListener : WLResponseListener {
    public void onSuccess(WLResponse response){
        //handle success
    }

    public void onFailure(WLFailResponse response){
        //handle failure
    }
}
```

Accessing adapters from non-mobile clients

There are two ways to access an adapter from a non-mobile client:

- If you are testing adapter functionality, see Testing adapters.
- If you are accessing the adapter from a back-end system, see Exposing mobile services to non-mobile (confidential) clients.

RESTful access to JavaScript adapters

In addition to invoking JavaScript adapters over HTTP by using IBM MobileFirst Platform Foundation from the /adapter endpoint, you can call existing JavaScript adapter procedures over HTTP via REST URLs.

The URL pattern is as follows:

```
http(s)://<server>:<port>/<Context>/adapters/<adapter-name>/<procedure-name>
```

For example:

```
http://<hostname>:<port>/mfp/adapters/TodaysNews/getStories?params=['world']
```

Both the GET and POST methods can be used to call the adapter procedure. The procedure arguments are passed as the value of a parameter called **params**. This parameter is a query parameter for GET requests and a form parameter for POST requests. The value must be a JSON array of parameters that are provided in order.

Note:

For successful invocations, the status code of the HTTP response is set to 200 (OK). The response body contains the JSON output that resulted from the invocation of the JavaScript adapter. If an error occurred during adapter invocation, the status code is set to 500 (Internal Server Error).

Accessing adapters from the /apps/services/api/query endpoint

In versions of IBM MobileFirst Platform Foundation previous to V7.0 this endpoint was the preferred access point for clients.

The client API that can be used to access adapters from this endpoint is `invokeProcedure` in the `WLClient` class. For more information, see the following API reference topics:

- iOS: `WLClient iOS API`
- Native Android: `WLClient Android API`
- JavaScript: `WLClient JavaScript API`

Accessing adapters from the /invoke endpoint

JavaScript adapter procedures can be invoked by issuing an HTTP request to the MobileFirst /invoke endpoint.

The URL pattern for accessing the /invoke endpoint is as follows

```
http(s)://<server>:<port>/<Context>/invoke
```

Note: The usage of the /invoke endpoint is discouraged. Consider using the /adapters endpoint even when invoking a JavaScript adapter procedure. For more information, see “Accessing adapters from the /adapters endpoint” on page 8-334.

The following parameters are required:

Table 8-33. Parameters for adapter invocation

Property	Description
adapter	The name of the adapter
procedure	The name of the procedure
parameters	An array of parameter values

The request can be either GET or POST.

Note: The invocation service uses the same authentication framework as described in the “MobileFirst security framework” on page 8-527 section.

The default security test for adapter procedures contains Anti-XSRF protection, but this configuration can be overridden by either:

- Implementing your own authentication realm (see “Authenticators and login modules” on page 8-603 for more details).
- Disabling the authentication requirement for a specific procedure. You can do so by adding the **securityTest**="*wl_unprotected*" property to the <procedure> element in the adapter XML file.

Note: Disabling the authentication requirement on a procedure means that this procedure becomes completely unprotected and anyone who knows the adapter and the procedure name can access it.

Integrating with source control systems

Some source code files should be held in a version control system: others should not.

There are two types of files and folders in a standard MobileFirst project hierarchy:

- Your own source code files and some source code files that are provided in the MobileFirst device runtime libraries.
You should commit these files to a version control system.
- Files that are generated from your web source code and some JavaScript files that are provided with IBM MobileFirst Platform Foundation (such as `wlclient.js`).

These files and folders are added to the file system every build.

You should not commit them to a version control system.

In the next figure, these files and folders are marked with a star (*) after their names.

Project Name

```
+---Java Resources
+---JavaScript Resources
+---adapters
+---apps
  +---Application Name
    application-descriptor.xml
    build-settings.xml
  +---android
    +---css
    +---images
    +---js
    +---native
      Application Name.iml
      AndroidManifest.xml
      project.properties
    +---assets
      wlclient.properties
    +---featurelibs
    +---www (*)
    +---libs
    +---res
    +---src
    +---nativeResources
  +---blackberry
    +---css
    +---images
    +---js
    +---native
      config.xml
      icon.png

    index.html
    +---css
    +---images
    +---js
  +---ipad
    +---css
    +---images
    +---js
    +---native
      buildtime.sh
      config.xml
      Entitlements-Debug.plist
      Entitlements-Release.plist
      main.m
      Project Name Application NameIpad_Prefix.pch
      Project Name Application NameIpad-Info.plist
      README.txt
      worklight.plist
```

Note: In iOS environments, the Frameworks folder contains a default `.framework` file, `sqlcipher.framework`, that is automatically generated by the MobileFirst builder if it is not already in the Frameworks folder. The Frameworks folder should be committed to your source control system, but the `sqlcipher.framework` file can be ignored.

To ensure that your source code is always synchronized with your source control system, add the (*) files and folders to the ignore list in your source control system. For Subversion, for example, perform the following steps:

- **Step 1:** Using the Tortoise extension for Subversion, right-click each file or folder that is to be ignored and add it to the ignore list.
- **Step 2:** Go up one level in the file system and commit the change to the SVN repository. The changes take effect from now on for every developer who updates the code.

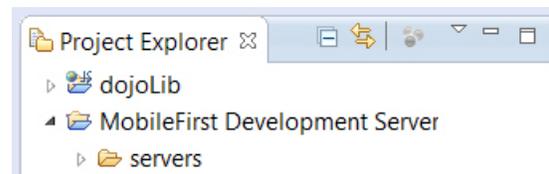

For more information about the folders that are shown in the figure, see “Anatomy of a MobileFirst application” on page 8-41.

The MobileFirst Development Server and the MobileFirst Operations Console

Learn about the MobileFirst Development Server, how it is viewed in the MobileFirst Operations Console, and how to access it for Java remote debugging.

In IBM Worklight V6.0.0, the Jetty server was replaced with an embedded instance of WebSphere Application Server Liberty profile. This Liberty profile server is installed with MobileFirst Studio, and becomes the default test server.

As a result, you see a **MobileFirst Development Server** element in your Eclipse Project Explorer view, even before you begin creating new projects and working with them.

Viewing the MobileFirst Development Server in the MobileFirst Operations Console

A menu item in MobileFirst Studio allows you to open this console even more easily. You can automatically redeploy applications in Eclipse studio if you click **Project > Open MobileFirst Operations Console..** If a development server does not have any applications that are deployed, the server deploys all applications under the project. Any updated applications that require redeployment will automatically be deployed again by using this command.

You can work with additional instances of MobileFirst Server other than the embedded MobileFirst Development Server. For example, if you have an additional instance of WebSphere Application Server Liberty profile or Apache Tomcat that is installed in your development environment, you can change the context root to the correct server when building, deploying, or viewing its actions in the console. To

do this, you use the *Changing the MobileFirst Server associated with a project* procedure described in “Working with multiple MobileFirst Server instances in MobileFirst Studio” on page 8-23.

Note: The MobileFirst Development Server is secured with the credentials of a user named admin and the password admin. The user name and password cannot be changed in the MobileFirst Development Server. When you open the MobileFirst Operations Console through MobileFirst Studio, it is not necessary to enter the user name and password. If you keep the window of the MobileFirst Operations Console open a very long time, you might receive a request to reconfirm the password.

Creating a URL to access the MobileFirst Operations Console directly

In previous releases of MobileFirst Studio, the URL of the MobileFirst Operations Console used to view the development test server in a browser had the following format:

```
http://localhost:<port>/console
```

Starting from IBM Worklight Foundation V6.2.0, in MobileFirst Studio, the URL of the MobileFirst Operations Console has the following format:

```
http://localhost:<port>/worklightconsole
```

The default <port> after the installation of MobileFirst Studio is 10080. Therefore, the URL of the MobileFirst Operations Console becomes:

```
http://localhost:10080/worklightconsole
```

The MobileFirst Operations Console can be used to manage several projects. If only one project is deployed, this project is included directly in the URL of the console. If several projects are deployed, you can select a project from a page. Starting from IBM MobileFirst Platform Foundation V7.0.0, the format of the URL of a project selected in this way is:

```
http://localhost:<port>/worklightconsole/index.html#/main/<projectname>
```

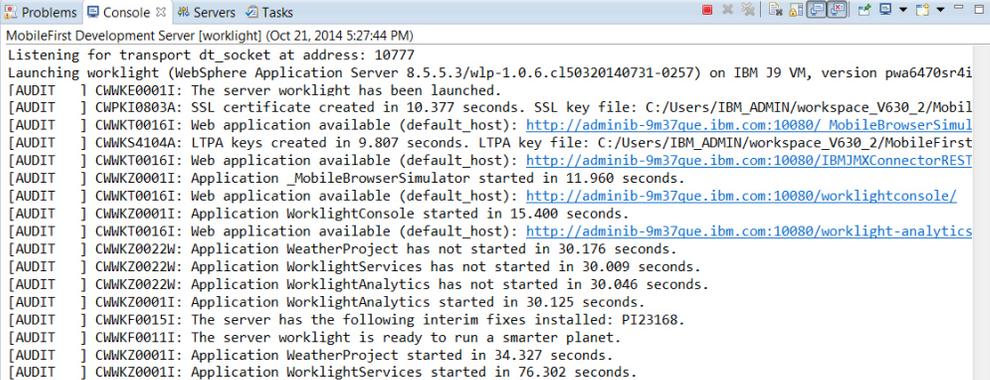

The URL of the MobileFirst Operations Console for a project named “myProject” becomes:

```
http://localhost:10080/worklightconsole/index.html#/main/myProject
```

Note: The **Open MobileFirst Operations Console** menu command in MobileFirst Studio can only point to one instance of MobileFirst Server at a time. It displays the console for the server instance for which the context root was set by using the **Run As > Build Settings and Deploy Target** command. If you need to work with several different servers for test purposes (for example, one instance of Liberty profile and another of Apache Tomcat), you should save the URLs for the MobileFirst Operations Console of these servers as bookmarks in your default browser.

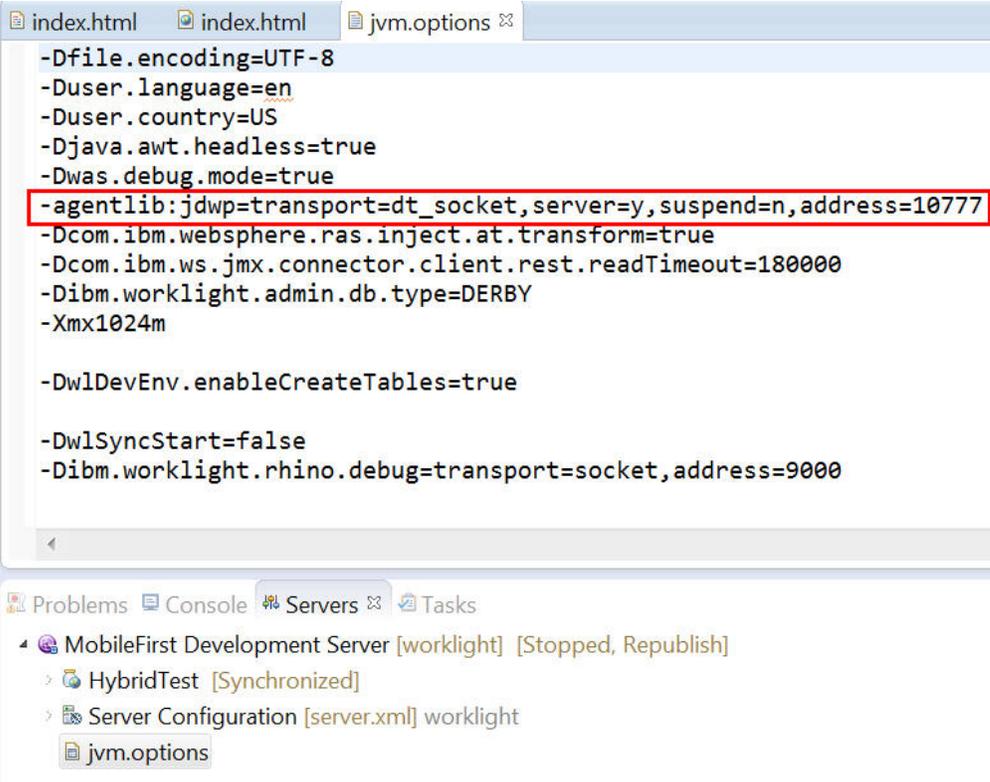

Java remote debug and the MobileFirst Development Server

Since IBM Worklight V6.1.0, the Liberty profile instance used as the MobileFirst Development Server has Java remote debug enabled. The default port is 10777, and can be viewed in the Console view of MobileFirst Studio when the server is started:

```
MobileFirst Development Server [worklight] (Oct 21, 2014 5:27:44 PM)
Listening for transport dt_socket at address: 10777
Launching worklight (WebSphere Application Server 8.5.5.3/wlp-1.0.6.cl50320140731-0257) on IBM J9 VM, version pwa6470sr4i
[AUDIT ] CWMKE0001I: The server worklight has been launched.
[AUDIT ] CWPKI0803A: SSL certificate created in 10.377 seconds. SSL key file: C:/Users/IBM_ADMIN/workspace_V630_2/Mobil
[AUDIT ] CWMKT0016I: Web application available (default_host): http://adminib-9m37que.ibm.com:10080/ MobileBrowserSimul
[AUDIT ] CWMKS4104A: LTPA keys created in 9.807 seconds. LTPA key file: C:/Users/IBM_ADMIN/workspace_V630_2/MobileFirst
[AUDIT ] CWMKT0016I: Web application available (default_host): http://adminib-9m37que.ibm.com:10080/IBMJMXConnectorREST
[AUDIT ] CWMKZ0001I: Application MobileBrowserSimulator started in 11.960 seconds.
[AUDIT ] CWMKT0016I: Web application available (default_host): http://adminib-9m37que.ibm.com:10080/worklightconsole/
[AUDIT ] CWMKZ0001I: Application WorklightConsole started in 15.400 seconds.
[AUDIT ] CWMKT0016I: Web application available (default_host): http://adminib-9m37que.ibm.com:10080/worklight-analytics
[AUDIT ] CWMKZ0022W: Application WeatherProject has not started in 30.176 seconds.
[AUDIT ] CWMKZ0022W: Application WorklightServices has not started in 30.009 seconds.
[AUDIT ] CWMKZ0022W: Application WorklightAnalytics has not started in 30.046 seconds.
[AUDIT ] CWMKZ0001I: Application WorklightAnalytics started in 30.125 seconds.
[AUDIT ] CWMKF0015I: The server has the following interim fixes installed: PI23168.
[AUDIT ] CWMKF0011I: The server worklight is ready to run a smarter planet.
[AUDIT ] CWMKZ0001I: Application WeatherProject started in 34.327 seconds.
[AUDIT ] CWMKZ0001I: Application WorklightServices started in 76.302 seconds.
```

This default port can be changed by editing the `jvm.options` file in MobileFirst Development Server/servers/worklight:

```
-Dfile.encoding=UTF-8
-Duser.language=en
-Duser.country=US
-Djava.awt.headless=true
-Dwas.debug.mode=true
-agentlib:jdwp=transport=dt_socket,server=y,suspend=n,address=10777
-Dcom.ibm.websphere.ras.inject.at.transform=true
-Dcom.ibm.ws.jmx.connector.client.rest.readTimeout=180000
-Dibm.worklight.admin.db.type=DERBY
-Xmx1024m

-DwlDevEnv.enableCreateTables=true

-DwlSyncStart=false
-Dibm.worklight.rhino.debug=transport=socket,address=9000
```

Problems Console Servers Tasks

- MobileFirst Development Server [worklight] [Stopped, Republish]
 - HybridTest [Synchronized]
 - Server Configuration [server.xml] worklight
 - jvm.options

Connecting to MobileFirst Server

By default, an application starts in offline mode. You can make it start in online mode or connect to MobileFirst Server later.

About this task

By default, an application starts in offline mode. You can connect your application to MobileFirst Server either when it starts or at some appropriate point in its processing. You are responsible for maintaining the offline or online state within your application, and ensuring that your application can recover from failed attempts to connect to the server. For example, before the application logs in a new user or accesses the server under a new user, the application must ensure that the server received a successful logout.

Procedure

- To make your application begin communicating with MobileFirst Server as soon as it starts, use the `WL.Client.connect` method in `common/js/main.js` inside the `WLCommonInit` method.
- To make your application communicate with the server at a later stage, call the `WL.Client.connect` method, as defined in the `WL.Client` class.

Call this method only once, before any other `WL.Client` methods that communicate with the server. Remember to implement the `onSuccess` and `onFailure` callback functions. For example:

```
WL.Client.connect({
    onSuccess: onConnectSuccess,
    onFailure: onConnectFailure
});
```

Note: `UserPrefs` are updated only after the call to the `WL.Client.connect` method.

Removing a project from MobileFirst Operations Console

You can undeploy a MobileFirst project from the development test server in the **Servers** view in Eclipse.

About this task

Since the version of MobileFirst Studio available in IBM MobileFirst Platform Foundation V6.2.0, you can use MobileFirst Operations Console to administer several MobileFirst projects. When a new project is deployed, it is added to the development test server. If the project is no longer required, you must undeploy it manually from the development test server.

Procedure

1. To undeploy projects, open the **Servers** view in Eclipse.
2. Select **MobileFirst Development Server**.
3. Right-click to display the menu and select **Add and remove**.
4. Remove any projects that are no longer required. MobileFirst Operations Console automatically detects that you have removed the projects.

The `jvm.options` file

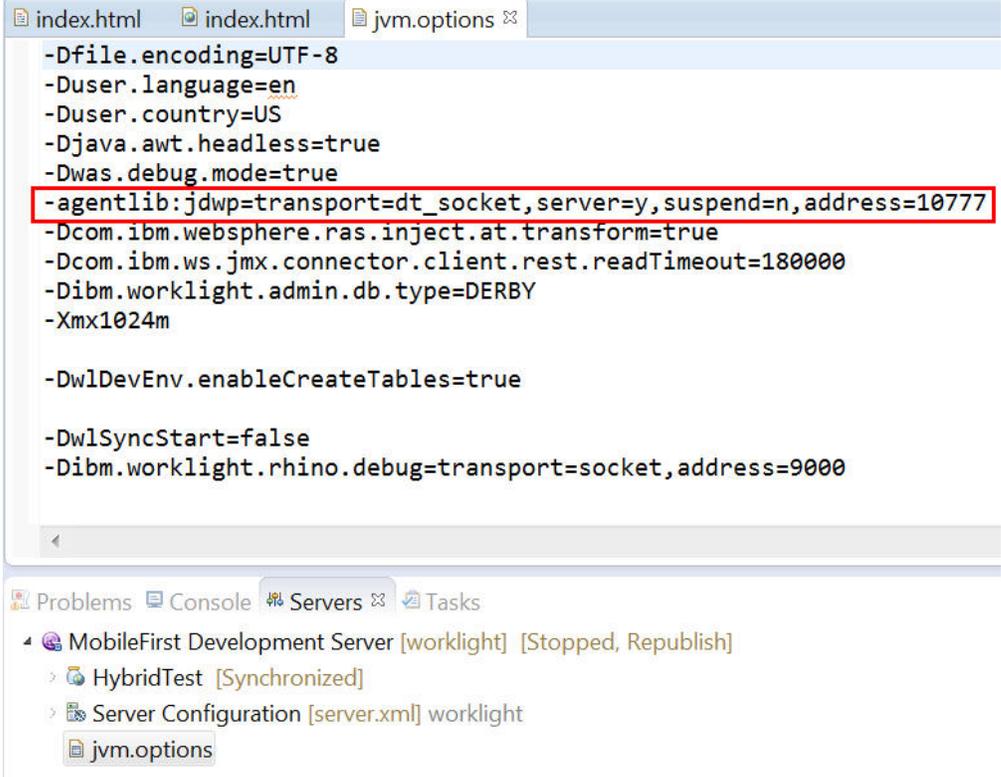

The `jvm.options` file specifies the Java Virtual Machine (JVM) arguments that are used with the MobileFirst Development Server. You can find this file in `MobileFirst Development Server/servers/worklight`.

Java remote debug and the MobileFirst Development Server

The Liberty profile instance used as the MobileFirst Development Server has Java remote debug enabled. The default port is 10777 can be viewed in either of the following ways:

- MobileFirst Studio: In the **Console** view when the server is started
- CLI: Run the **mfp console** command when the server is started. For more information, see “**console**” on page 16-8.

This default port can be changed by editing this argument:

```
index.html index.html jvm.options ✕
-Dfile.encoding=UTF-8
-Duser.language=en
-Duser.country=US
-Djava.awt.headless=true
-Dwas.debug.mode=true
-agentlib:jdwp=transport=dt_socket,server=y,suspend=n,address=10777
-Dcom.ibm.websphere.ras.inject.at.transform=true
-Dcom.ibm.ws.jmx.connector.client.rest.readTimeout=180000
-Dibm.worklight.admin.db.type=DERBY
-Xmx1024m

-DwlDevEnv.enableCreateTables=true

-DwlSyncStart=false
-Dibm.worklight.rhino.debug=transport=socket,address=9000
```

Problems Console Servers Tasks

- MobileFirst Development Server [worklight] [Stopped, Republish]
 - HybridTest [Synchronized]
 - Server Configuration [server.xml] worklight
 - jvm.options

Mobile Browser Simulator

The Mobile Browser Simulator is a web application that helps you test mobile web applications without having to install device vendor native SDK.

Important: The Mobile Browser Simulator supports the following web browsers:

- Firefox version 3.6 and later.
- Chrome 17 and later. However, Chrome will soon block the use of the MBS applet. Please use Firefox for applet simulation.
- Safari 5 and later.

You can use the Mobile Browser Simulator to preview applications on Android, iPhone, iPad, BlackBerry 6 and 7 (deprecated. See Table 3-2 on page 3-21), BlackBerry 10, Windows Phone Silverlight 8, Windows Phone 8 Universal, and mobile web application environments.

Restriction: Mobile Browser Simulator is not deployed to the production console.

When you preview an application on an Android, iPhone, iPad, BlackBerry 6 and 7, BlackBerry 10, Windows Phone Silverlight 8, or Windows Phone 8 Universal environment, only the devices for the created environments are available. For example, if you preview an application on an Android environment, you can select from both the list of available Android devices and from the device lists from any other environments that were added to your application.

You can also use the Ripple emulator to simulate the WebWorks API in your BlackBerry application.

1. Using Chrome as your web browser, click **Open Simple Preview** in the simulator.

A new tab opens in Chrome with your application loaded.

2. Open the Ripple emulator from this tab.

You can preview all environments from the application folder. Each environment-specific preview allows for the addition of devices from available environments.

In the Mobile Browser Simulator, you can test skins per device. Only the skins that are available for that platform are shown. You can save a file in Rich Page Editor and then instantly preview it by clicking **Go/Refresh**.

You can select the link icon on the device toolbar to debug an application in a separate, simple preview.

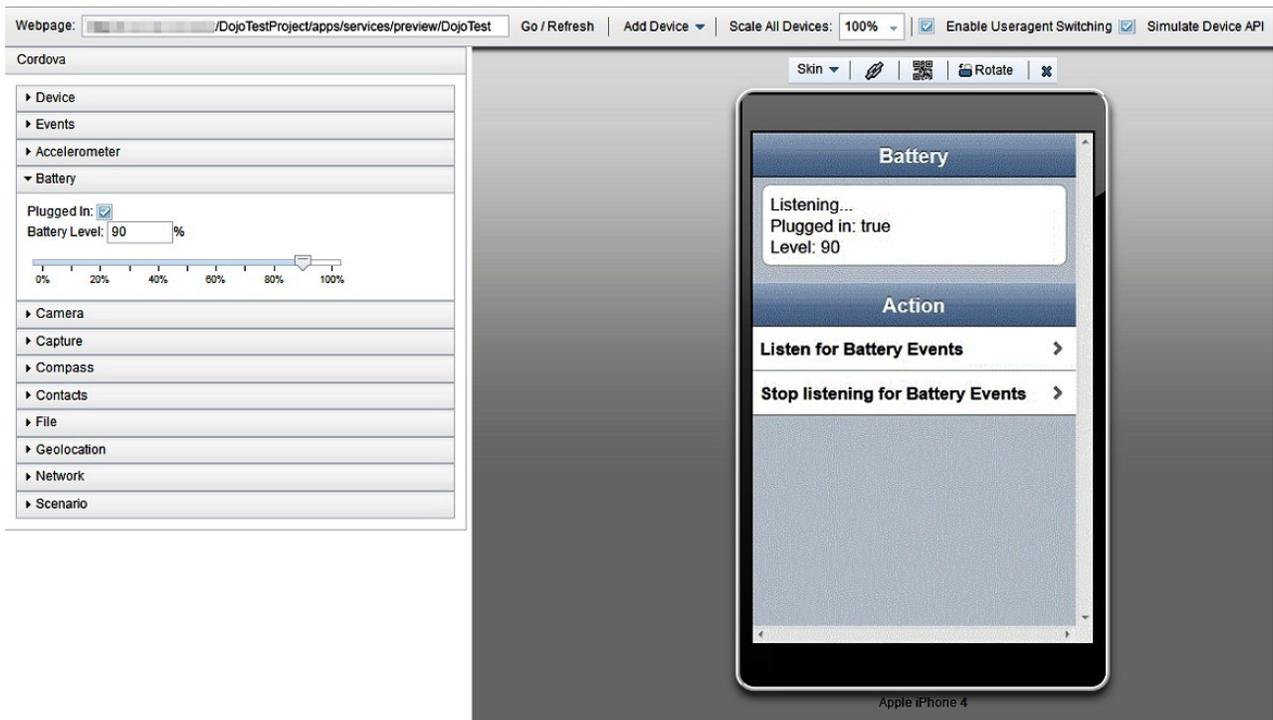

Whenever a new environment or skin is added to an app, you must restart the Mobile Browser Simulator from Eclipse. Only from the Eclipse Studio does the **Run As > Preview** command supports skin changes. The console preview does not support skin changes.

You can select the Quick Response (QR) code icon on the device toolbar to show a QR code that is specific to the environment URL. This QR code generator therefore allows for quick testing on a physical device.

The Mobile Browser Simulator contains a frame that emulates a target device. It shows what your page looks like inside the mobile device browser. You can switch the frame to emulate different screen resolutions and form factors, including BlackBerry 6 and 7, BlackBerry 10, Android, iPad, iPhone, and Windows Phone 8 mobile devices. You can also rotate the frame to mimic orientation change (portrait or landscape). You can add multiple devices to the frame to view the various displays simultaneously. If a device detection servlet is configured for your web project, the simulator emulates requests from different device-specific agents.

Mobile Browser Simulator

The Mobile Browser Simulator displays mobile web pages in a variety of mobile browser sizes and shapes.

Testing mobile applications with the Mobile Browser Simulator

You can use the Mobile Browser Simulator to emulate various mobile devices and test your mobile applications without the need to install device vendor native SDK.

Before you begin

You must have a MobileFirst project with at least one environment. Moreover, your project's `index.html` page must contain HTML tags and UI widgets.

About this task

The Mobile Browser Simulator supports the following web browsers:

- Firefox version 3.6 and later.
- Chrome 17 and later.
- Safari 5 and later.

Procedure

1. In Eclipse, select **Window > Preferences > Web Browser**. Then, select **Use external web browser**.
2. Right-click your environment folder or Application folder name and select **Run As > Preview**.

What to do next

After your web page is running in the Mobile Browser Simulator, you can view how your page renders in different devices.

Switching devices Before you begin

To view your web application in the simulated devices by using the appropriate stylesheets, ensure that these tasks are completed:

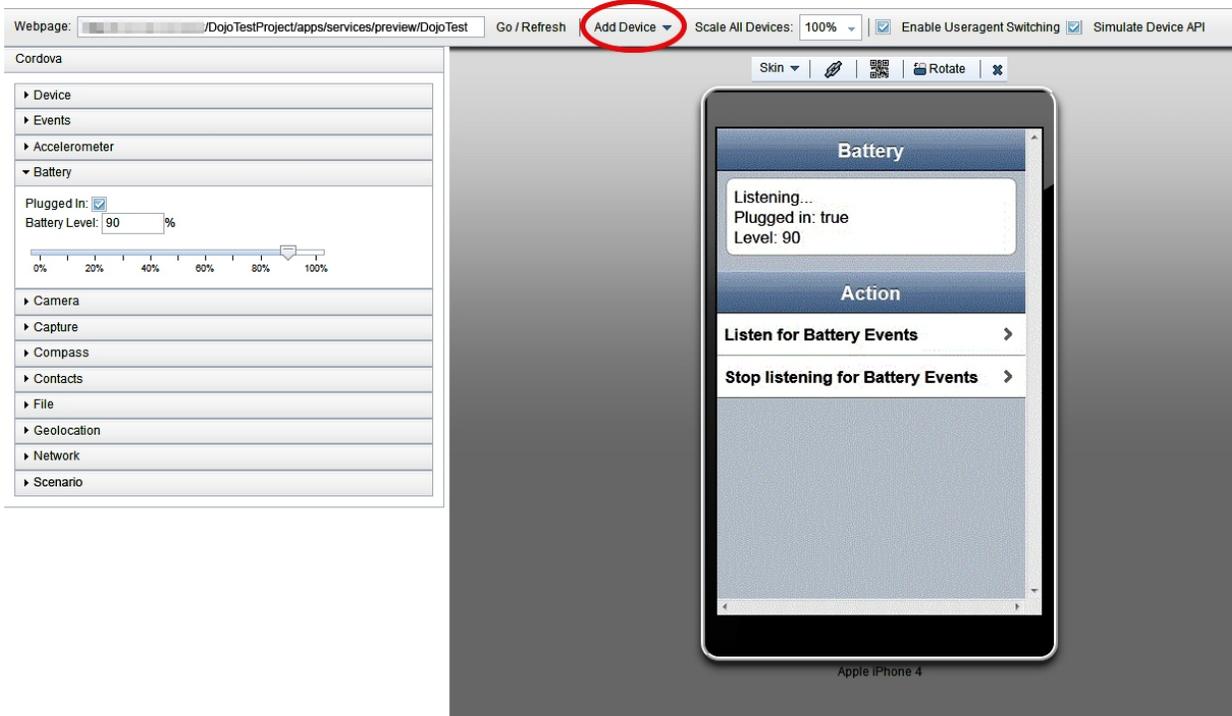

1. “Creating web pages for mobile devices” on page 8-126
2. Enable user agent switching

Procedure

In the simulator, click the device list and then select the device that you want to simulate.

Mobile Browser Simulator

The Mobile Browser Simulator displays mobile web pages in a variety of mobile browser sizes and shapes.

Adding devices Before you begin

To view your web application in the simulated devices by using the appropriate stylesheets, ensure that these tasks are completed:

1. “Creating web pages for mobile devices” on page 8-126
2. Enable user agent switching

Procedure

In the simulator, click **Add Device** and then select the device that you want to simulate.

Tip: You can customize the list of device options that are available in the Mobile Browser Simulator.

1. In MobileFirst Studio, select **Window > Preferences > Web > Target Devices**.
2. Add your custom device to the current list of target devices, and then start the simulator again.

The custom device that you added is now available as an option from the **Add Device** list in the simulator.

Calibrating the Mobile Browser Simulator

Because browsers cannot accurately paint physical dimensions, you must calibrate the Mobile Browser Simulator.

Before you begin

Test your application by using the Mobile Browser Simulator.

Procedure

1. From the **Scale All Devices** list, select **Physical device size**.
2. Click **Calibrate Physical Size** to open the Physical Size Calibration dialog box.
3. Follow the instructions to calibrate your Mobile Browser Simulator.
4. After you complete all of the steps, close the dialog box.

Enabling user agent switching

You can use the Mobile Browser Simulator to render your web applications on different mobile devices. To render your web applications with the appropriate style sheets and theme, you must enable user agent switching.

Before you begin

- Enable the detect device option when you create your web page.
- Test your application by using the Mobile Browser Simulator.

About this task

The Useragent Switcher Extension is a browser extension that provides the user agent switching feature. The Mobile Browser Simulator supports implementations of this browser extension for the following web browsers:

- Mozilla Firefox.
