- Chrome 17 and later, with limitations.

Useragent Switcher Extension for Chrome

The Useragent Switcher Extension emulates requests from different device-specific agents. When a web application checks the user agent on the server to create content, it is correctly simulated.

The Useragent Switcher Extension includes support for Dojo Mobile 1.7 and later. If you enabled the detect device option when you created your Dojo Mobile page, the Useragent Switcher Extension uses the automatic device detection and theme loading for Dojo Mobile to select the appropriate theme.

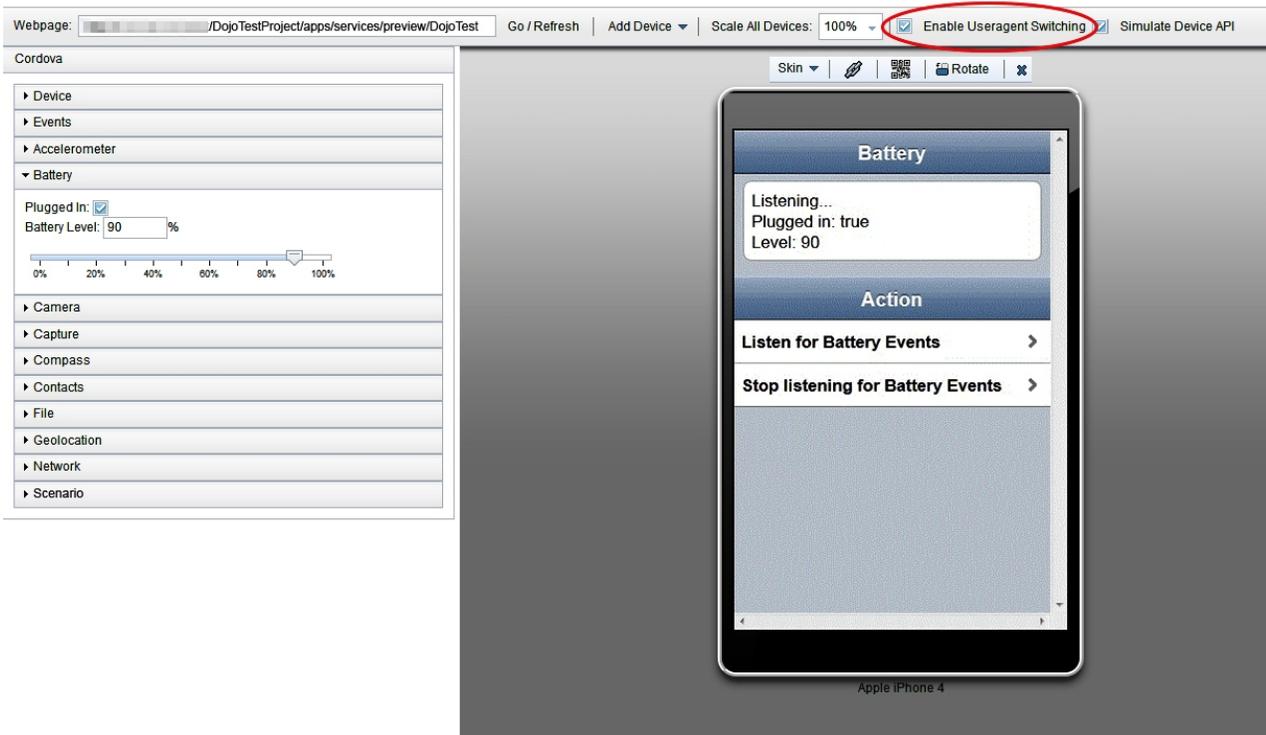

Procedure

1. Click **Enable Useragent Switching**.
2. If the latest version of the Useragent Switcher Extension is not installed, the Install Useragent Switcher Extension dialog opens. Click **Install Browser Extension**. If you are using Chrome, you can download the extension from the

Chrome Web Store.

Mobile Browser Simulator

The Mobile Browser Simulator displays mobile web pages in a variety of mobile browser sizes and shapes.

Results

You can now view your web application with the appropriate style sheets and theme in the simulated mobile devices.

Previewing your MobileFirst applications

You can use the Mobile Browser Simulator to preview MobileFirst applications on iPhone, iPad, Android phones and tablets, BlackBerry 6 and 7 (deprecated. See Table 3-2 on page 3-21), BlackBerry 10, Windows Phone 8, Windows 8 desktop and tablets, and Mobile web app environments. You can simulate several mobile devices simultaneously.

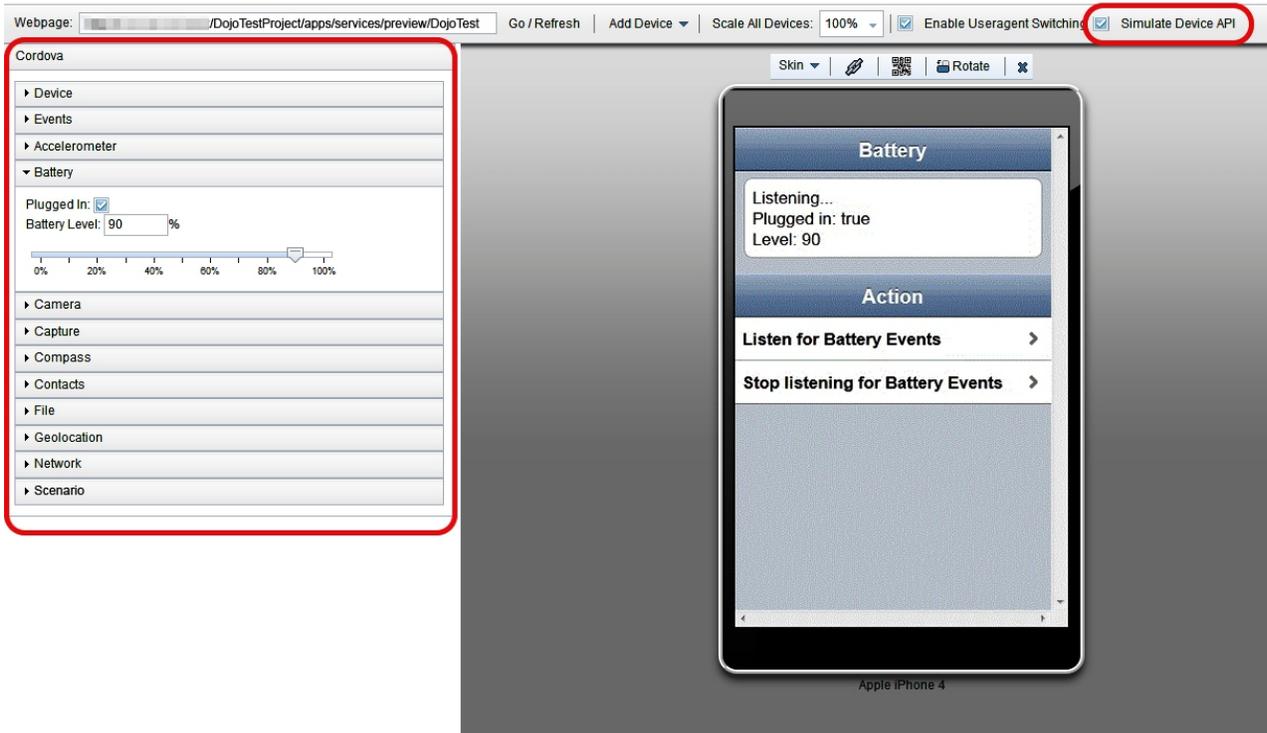

This preview is only available when the `com.ibm.imp.worklight.simulation.ui` plug-in is enabled.

The Apache Cordova API simulation user interface is packaged with the Mobile Browser Simulator. When the Mobile Browser Simulator opens, the various data types and values that are used by Cordova are displayed in the left side. The Cordova simulation is available on the following environments:

- Android
- BlackBerry 10
- iPhone
- iPad
- Windows Phone 8
- Windows 8 desktop and tablets environments

Mobile Browser Simulator

The Mobile Browser Simulator displays mobile web pages in a variety of mobile browser sizes and shapes.

Tip: If you do not want to use the Cordova simulation to preview your MobileFirst applications, clear **Cordova** to disable the Cordova simulation.

Device

Shows the property values for the `window.device` object of each simulated device. This data is read-only. To show the values for other devices, click **Previous** or **Next**.

▼ Device	
Select Device:	Previous Next
Name:	Apple iPhone 4
Platform:	iOS - iPhone
Version:	No version info
Size:	640 x 960 (w x h pixels)
Orientation:	<input checked="" type="radio"/> Profile <input type="radio"/> Landscape
Cordova:	1.6.0

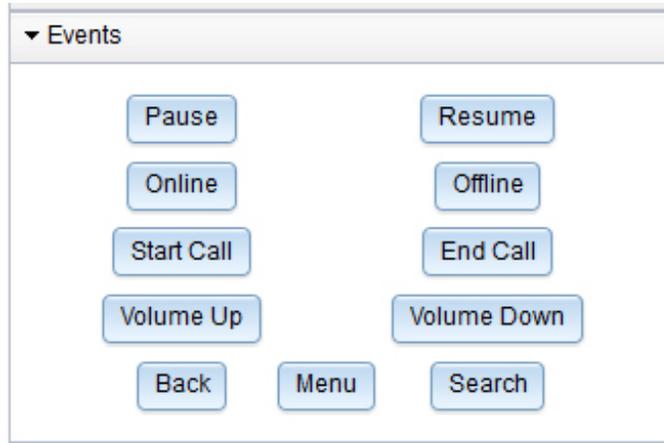

Events

Triggers any of the following Cordova events:

- pause
- resume
- online

- offline
- backbutton
- menubutton
- searchbutton
- startcallbutton
- endcallbutton
- volumedownbutton
- volumeupbutton

To trigger a Cordova event, click the corresponding button:

Accelerometer

Defines the Accelerometer values returned by the Cordova API when querying Accelerometer data. To generate a new set of values, click **Next**. To generate the values periodically, click **Start**.

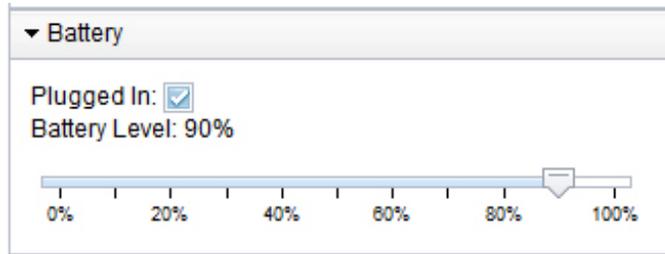

Battery

Defines battery-related data, such as the battery level. You can use the slider to change the battery level and trigger a batterystatus event. The following battery levels trigger events:

- Twenty percent triggers the batterylow event
- Five percent triggers the batterycritical event

To define the plugged in status of your mobile device, select or clear **Plugged In**.

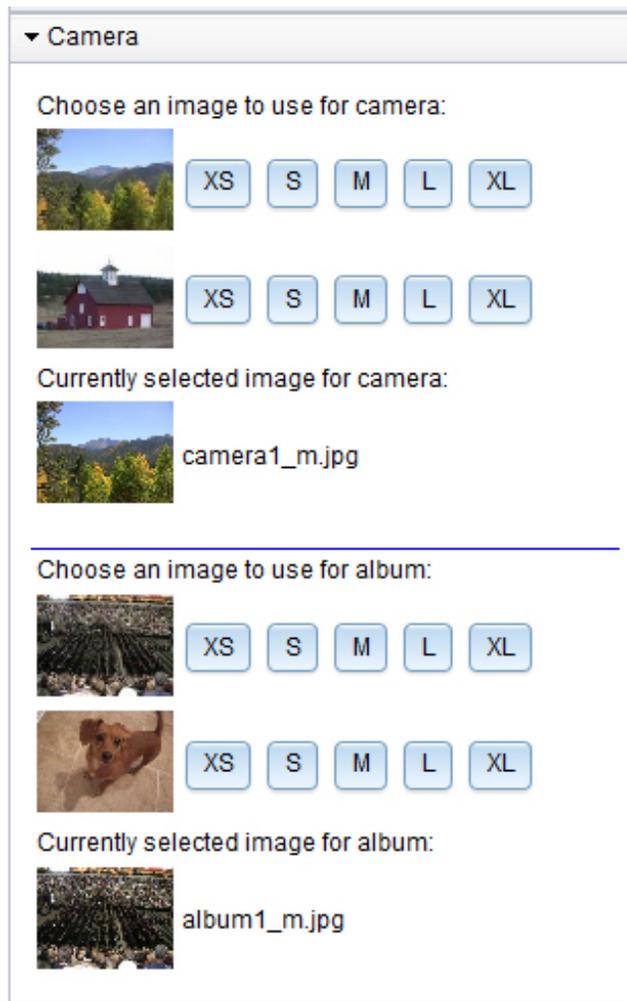

Camera

Specifies which image to use for the camera and for the album:

- Simulate a photo taken with the camera (Camera.sourceType == Camera.PictureSourceType.CAMERA)
- Photo from the device photo album or library (Camera.sourceType == Camera.PictureSourceType.PHOTOLIBRARY or Camera.sourceType == Camera.PictureSourceType.SAVEDPHOTOALBUM)

To change the size of the selected photos, click **XS**, **S**, **M**, **L**, or **XL**.

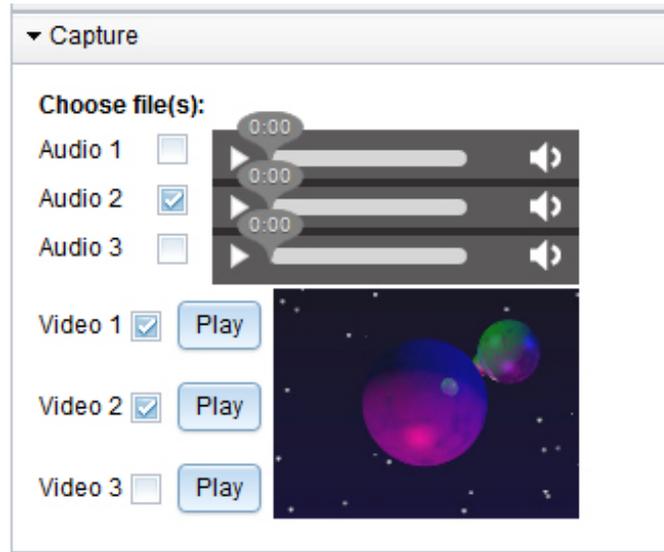

Capture

Simulates the Cordova capture API by using the following methods:

- capture.captureAudio
- capture.captureVideo

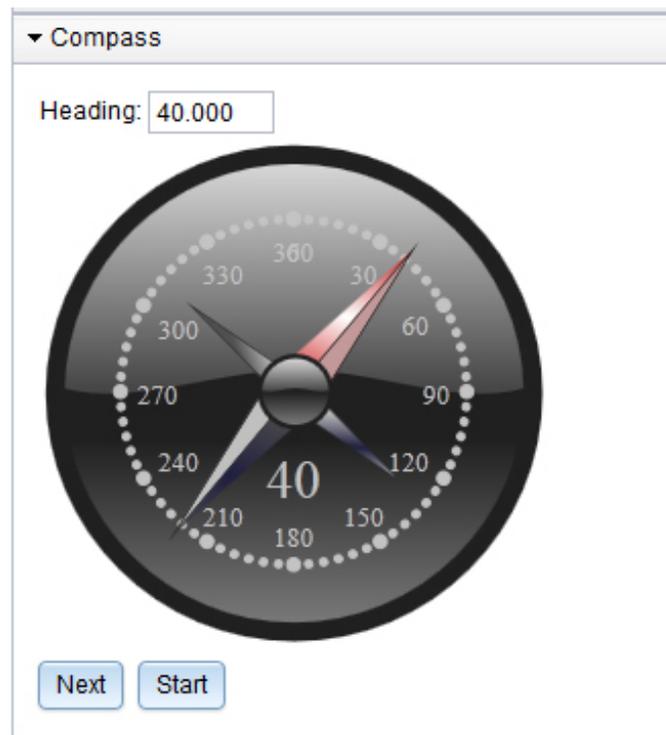

You can select the audio and video recordings that you want to use, and play these recordings by using the HTML5 players.

Note: The Capture section is available on both Mozilla Firefox and Google Chrome. For improved support of the HTML 5 players, upgrade these browsers to the latest version.

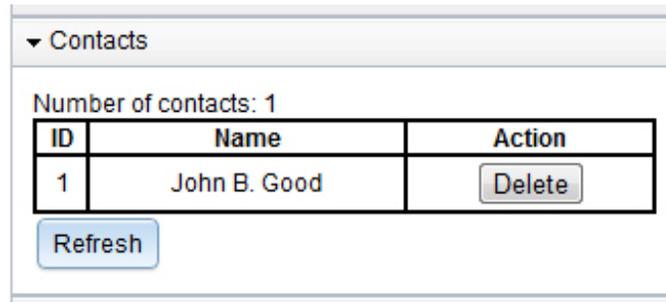

Compass

Defines the values returned by the Cordova API when querying Compass data. To generate a new set of values, click **Next**. To generate the values periodically, click **Start**. You can also set the compass values by directly interacting with the compass widget.

Contacts

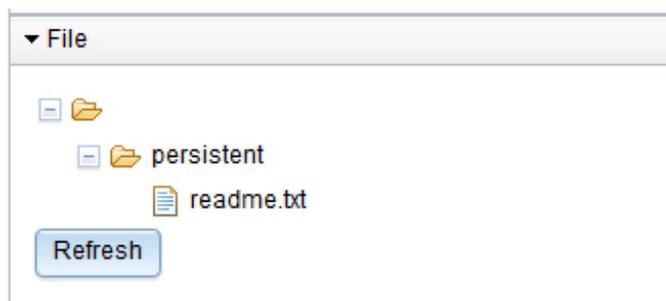

Shows the available contacts for the mobile device. You can delete contacts and refresh the list of available contacts.

To create new contacts for the mobile device, use the Cordova Contacts API from your simulated mobile web page. The contacts are stored in the Web SQL Database which is supported by default by Google Chrome and Safari. To simulate the Contacts API with Firefox, you must install an Add-on in your browser that adds basic WebSQL support to Firefox.

File

Simulates the Cordova File API by running an applet. To update the display of the file system that you can access through the Cordova API, click **Refresh**. Use the Cordova API to access this file system to read and write.

Double click anywhere on the file tree to open a file viewer. The file viewer allows for manual manipulation of your simulated file system.

Geolocation

Generates the Geolocation values returned by the Cordova API when querying Geolocation data. To generate a new set of values, click **Next**. To generate the values periodically, click **Start**.

▼ Geolocation

Latitude	<input type="text" value="49.77"/>
Longitude	<input type="text" value="-2.82"/>
Accuracy	<input type="text" value="71.7"/>
Altitude	<input type="text" value="3672.10"/>
Altitude Accuracy	<input type="text" value="1"/>
Heading	<input type="text" value="244.10077603068203"/>
Velocity	<input type="text" value="57.2"/>

Network

Defines the active connection of the device.

▼ Network

- None
- Ethernet Network
- Wifi Network
- 2G Network
- 3G Network
- 4G Network
- Unknown Network

The Cordova API also contains media simulation. Media simulation is available only for audio playback; audio recording is not supported. The media simulation uses an HTML audio player and audio playback is supported on Mozilla Firefox and Google Chrome. Since some browsers might not support all audio file formats, use OGG audio files.

The Cordova Notification API is simulated but does not require any user interface in the Mobile Browser Simulator.

Previewing web resource changes on an emulator or mobile device

During development, you can build and deploy a hybrid application to an emulator or to an actual native device to test its function.

Before you begin

If the web resources are still being changed frequently, some additional setup to the deployed test application can speed up the preview process between revisions. With the modified configuration, the native app can update itself to use the latest web artifacts in your MobileFirst Studio workspace without the need to rebuild and redeploy the application after each change.

To enable the faster preview and refresh cycle, replace the name of the application's main page with the full URL of the application that is running on the preview server. To find the correct preview URL, follow these steps:

Procedure

1. Under the hybrid application's root folder, find the environment folder that you plan to test on a native device. For example: Android or iPad.
2. Right-click the folder and select **Run As > Preview** to open the Mobile Browser Simulator with the page. This action starts the MobileFirst Development Server if necessary.
3. When the page opens in the Mobile Browser Simulator, find and click the **Link** icon in the toolbar above the preview page: A new page opens in the browser that points directly to the specific environment's preview page.
4. Copy the URL of the preview page. `http://[servername]:10080/[project name]/apps/services/preview/[app name]/[environment]/1.0/default/index.html`
5. Paste this URL into the relevant configuration file within the native application resources.
 - a. Select the application's folder in the navigator and perform **Run As > Build Only (All Environments)**. The native resources are built from the current project source. This action overwrites the configuration files that you changed in the previous process. You can continue to develop and preview the web resources in your hybrid application without doing any rebuilds. Then, you can run the build action again after application development is complete to generate the final native applications. If it is necessary to rebuild frequently, re-execute the previous steps to restore the faster preview function.
 - b. Underneath the environment folder that you plan to test natively, find the native folder. The configuration file is located under this folder.
 - For Android environments, edit `/native/assets/wlclient.properties`.
 - For iPhone and iPad environments, edit `/native/worklight.plist`.
 - c. Find the value of the `wlMainFilePath` or `wlMainFile` configuration parameter (whichever is present). The default page name is `index.html`.
 - d. Replace the page name with the full URL that you previously copied from the Mobile Browser Simulator page.

A prompt appears to change the file from a read-only state.

6. Select **Yes** to commit your changes and save the file.

7. Start the application on the native emulator or mobile device by using the normal process for the environment that you are previewing.

What to do next

As you continue to develop your web resources, you can update the native application.

- Close the application and relaunch it within the emulator or native device. When the application restarts, it retrieves the latest web resources from the MobileFirst Development Server.

Note:

- This preview feature is for web resource preview only, and does not use the native device features.
- The MobileFirst Development Server must be running for the application to function correctly under this modified configuration. An error message indicates whether the application cannot connect to the preview server.

Testing hybrid location service applications

You can use the Mobile Browser Simulator to test applications within a browser, and preview MobileFirst applications on Android, iOS, and Windows Phone 8. Location services only support these platforms, other platforms must be removed. With the Geolocation, Network and Scenario widgets, you can test applications in Mobile Browser Simulator that use the JavaScript location service APIs.

Mobile Browser Simulator geolocation widget

The geolocation widget can be used to provide a simulation of the device's geolocation information to the application. The application can access this information by using the W3C geolocation APIs or MobileFirst location services APIs for hybrid applications.

Note: Location services for hybrid applications are only supported for Android, iOS, and Windows Phone 8. Other platforms must be removed.

The geolocation information can be directly configured in the widget.

▼ Geolocation

▼ Coordinates

Longitude <input type="text" value="2.293685978646826"/>	Latitude <input type="text" value="48.85800879773006"/>
Accuracy <input type="text" value="67.9"/>	
Altitude <input type="text" value="4096.78"/>	Altitude Accuracy <input type="text" value="1"/>
Heading° <input type="text" value="247"/>	Speed(m/s) <input type="text" value="66.35"/>

▼ Map

POSITION_UNAVAILABLE ▼

You can use the **Latitude** and **Longitude** options to set specific GPS coordinates. You can click the map to update the latitude and longitude. A **Heading** of 0° corresponds to North. By clicking the **Play**, the device's movement is simulated from the current location in the direction that is given by **Heading**, at the speed specified. An update is given once a second. After you click **Play**, the button changes to **Stop**, and clicking it stops the simulation. Alternatively, a single 1-second step can be taken by using **Step**.

To simulate various errors that might occur, select the appropriate error and click **Generate Error**. This action causes the next call to a geolocation API to have its failure function is called with the selected error.

Accuracy is used to set the accuracy of the position, and can affect geofences when you are using the **confidenceLevel** parameter. For more information, see “Triggers” on page 8-657.

Altitude and **Altitude Accuracy** appear in the position information, but are not used by location services APIs.

You can use **Step** and **Play** to simulate the movement of devices. For example, if the **Speed** setting is increased, you can see the effect in the simulator window by clicking **Step** to generate a new set of values for the app, or **Play** to generate new values periodically.

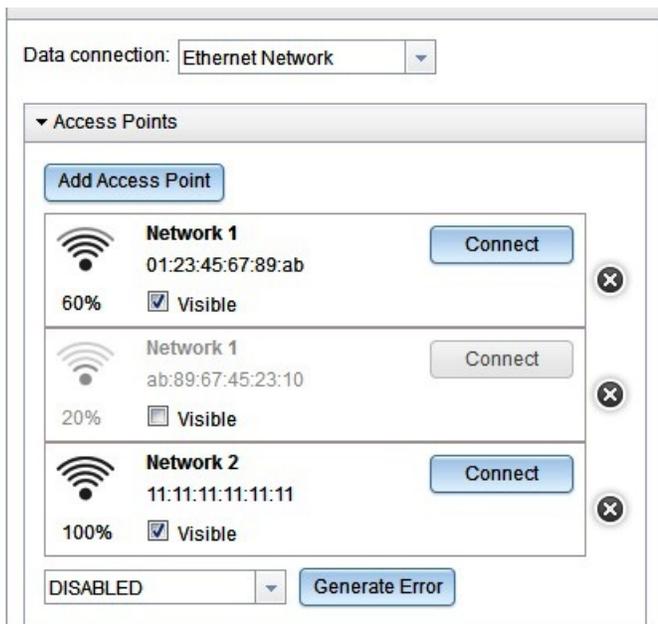

Mobile Browser Simulator network widget

The network widget can be used to provide network information, for example information that is accessible by the `WL.Device.getNetworkInfo` API or that can activate WiFi based triggers in MobileFirst location services.

WiFi access points can be configured in this widget for testing the use of location services, for example see the section on WiFi triggers in “Triggers” on page 8-657.

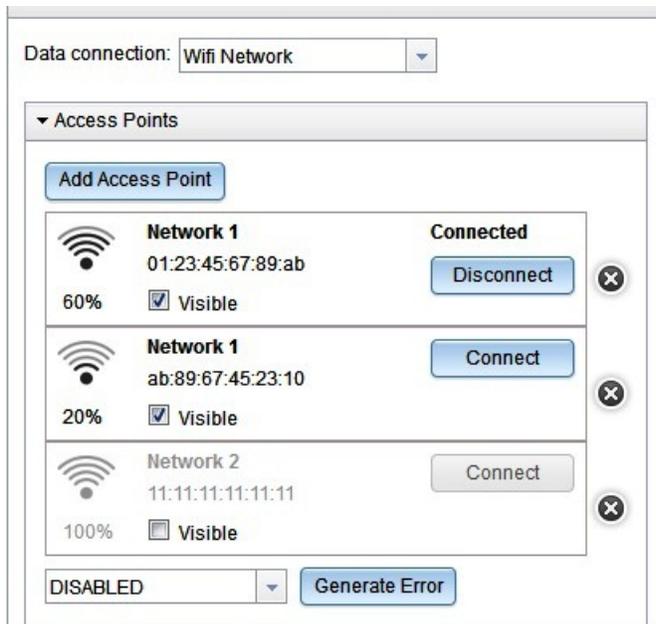

Click **Add Access Point** to define a new access point. There you must define the **SSID** and **MAC** addresses. You can also specify visibility and signal strength.

Click an access point to open a dialog to edit its properties.

The **Visible** check box indicates whether the access point is visible to the device, and whether it could be returned by a call to `WL.Device.Wifi.acquireVisibleAccessPoints`.

Click **Connect** to set an access point to be the connected access point, and **Disconnect** to disconnect it. Clicking **Connect** also changes the data connection to WiFi Network.

Only one access point can be connected at a time. The access point is connected to the data network, which switches to WiFi. When you switch the network to something that is not WiFi, then the connected access point is disconnected.

To simulate various errors that can occur, select the appropriate error from the drop-down list and click **Generate Error**. This action causes the next acquisition that is performed to call its failure function with the selected error.

Developing accessible applications

To develop *accessible* applications, easily used by people with disabilities, this topic helps you to learn about resources available to improve the accessibility of your apps.

When you build an application for your business, it is important to consider the user experience of individuals with a disability or impairment. Taking steps to consider enablement of tools like screen magnification, audio assistance, or other assistive technologies can extend the reach of your business.

In general, mobile applications can be made highly accessible. This following sections provide resources to help you make your mobile application as accessible as possible. IBM MobileFirst Platform Foundation provides a strong foundation for building accessible applications because it supports industry standards and allows you to leverage them. But accessibility features vary among target environments, depending on the native operating system or the hybrid library vendor.

Native application accessibility

If your application is native, the ability to make it accessible is determined by the capabilities of the target platform itself. The links that follow provide resources for the supported mobile platforms, laying out available options and capabilities.

iOS

Hybrid application accessibility

If your application is hybrid, options are available from a number of JavaScript libraries. Dojo Mobile and jQuery Mobile are popular examples, but there are several others. Useful references for writing accessible hybrid applications are provided in the following links. Note that if you are using Dojo Mobile, version 1.9 or later is highly suggested because it has better accessibility coverage than previous versions

Optimizing MobileFirst applications

MobileFirst Studio has several features that you can use to reduce the size of your application or otherwise improve its performance or reduce its load time.

During development, the applications you develop can perform well. But when these apps are used by mobile devices, performance can be impacted by a number of factors.

The large size of applications can make initial download times from the Application Center too long for users. Inclusion of multiple JavaScript files in Desktop Browser and Mobile Web applications can require multiple requests to retrieve them when the app is started, increasing start time. Unused resources such as large images or unneeded files included in the generated Cache Manifest file can further slow start time for these types of applications.

MobileFirst Studio includes a number of features that can reduce the size of your MobileFirst web applications, such as minification or removing unused features such as JSONStore. It also includes features that can improve performance and user satisfaction by enabling them to start faster, such as concatenation and editing the Cache Manifest. These features are described in the following topics.

Including and excluding application features

If features such as JSONStore are not used in your application or in certain environments, you can reduce the application size by excluding them.

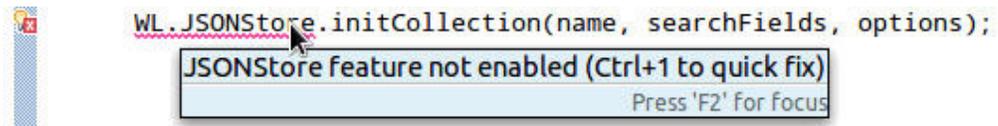

With IBM MobileFirst Platform Foundation, you can include or exclude features from the application build if those features are not required. For example, JSONStore offers many benefits, if code that references it is actually used in the application. If it is not used, the JSONStore resources greatly increase the application size, and thus slow both initial app download time and app start time.

There is a new <features> element in the Application Descriptor that controls the inclusion or exclusion of resources. In the application-descriptor.xml file itself, this element appears similar to the following example, which shows JSONStore resources being included in the build:

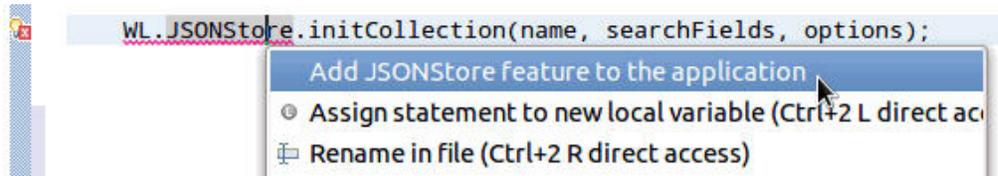

```
<application xmlns="http://www.worklight.com/application-descriptor" id="myApp" platformVersion="6"
  ...
  <features>
    <JSONStore/>
  </features>
  ...
</application>
```

For more information about Application Descriptor attributes, see “The application descriptor” on page 8-50.

When you first create a MobileFirst application, the <features> tag is automatically created in the application-descriptor.xml file, with no contents. What this means is that if you use JSONStore in your code, it is not automatically added to the builds. When you run the application, you receive an error, as shown in the following screen capture:

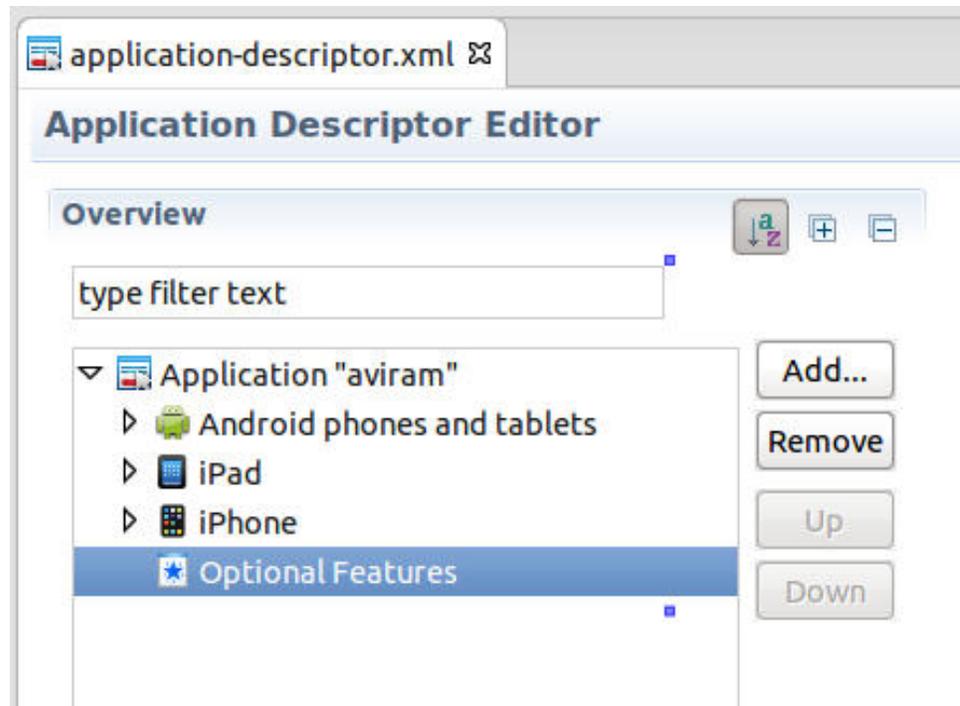

You can resolve this situation by using an Eclipse QuickFix:

But you can also choose which features to include in the build with the MobileFirst Studio editor, as shown in the following procedure.

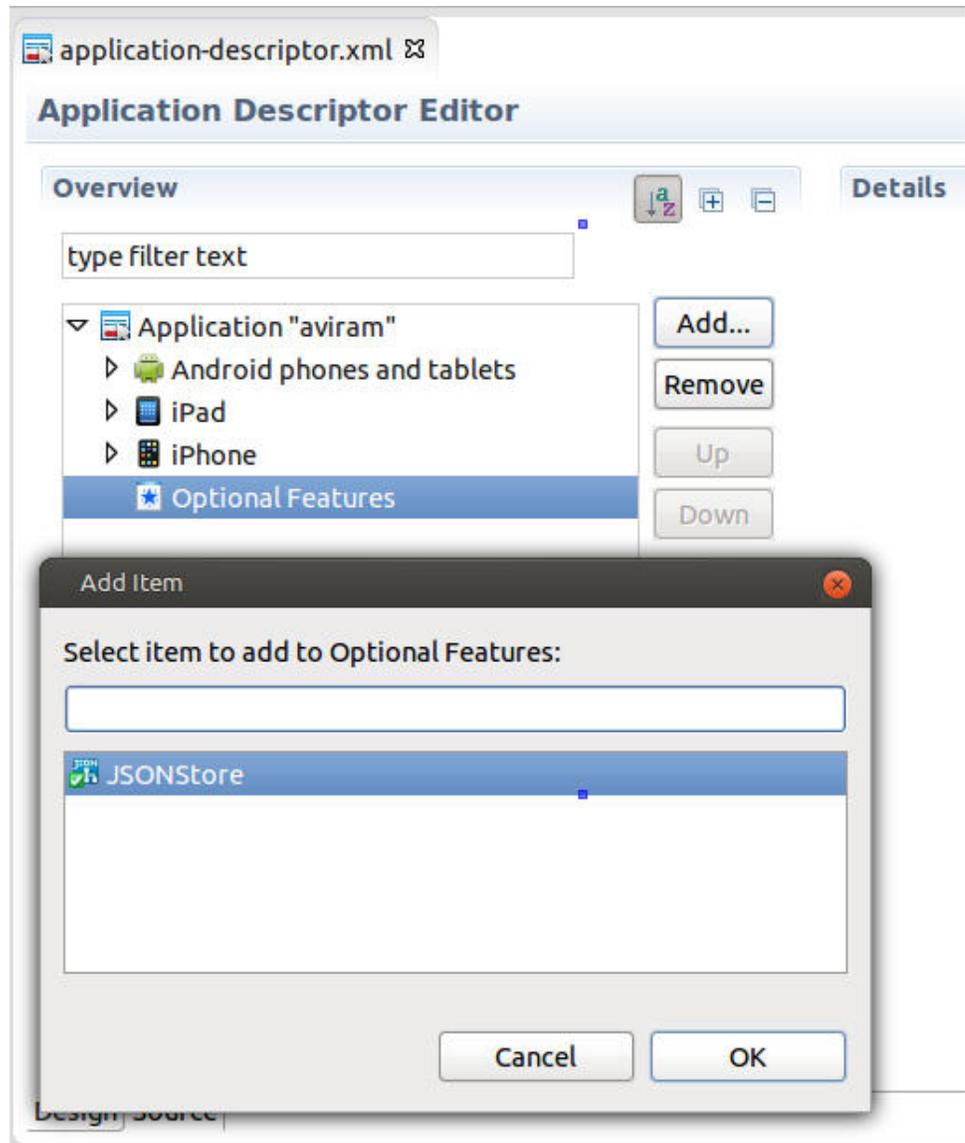

To include or exclude features in MobileFirst Studio

1. In MobileFirst Studio, open the application-descriptor.xml file for your application with the Application Descriptor Editor:

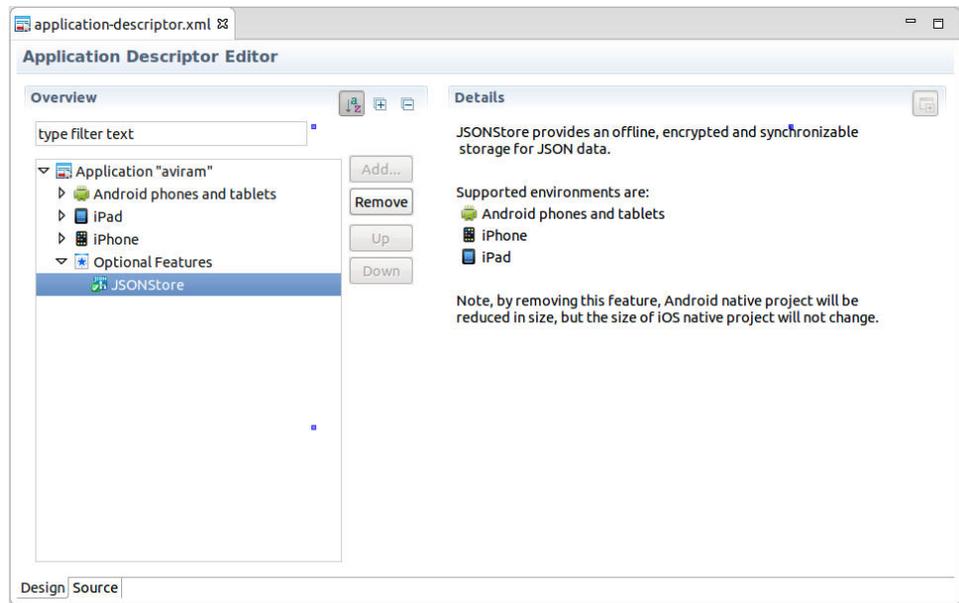

If the **Optional Features** element is empty (as in the screen capture), no features such as JSONStore are included in the build.

2. To add features, click **Add** to display the Add Item window:

3. Choose the feature that you want to add to the build (in this example, **JSONStore**), and click **OK**.
4. The Application Description Editor now displays **JSONStore** as an attribute of **Optional Features**, along with **Details** about the feature:

- To remove a feature, select it in the Overview panel and click **Remove**.

Application cache management in Desktop Browser and Mobile Web apps

MobileFirst Studio provides mechanisms by which you can control the contents of the application cache for Desktop Browser and Mobile Web environments.

The application cache

Ideally, you want mobile and desktop web applications to be able to work when the user is offline. Older browsers had their own caching mechanisms, but they were not always reliable. The release of HTML5 addressed this need with the introduction of the *application cache*, which provides users three advantages:

- Offline browsing – users can work with the application when they are offline.
- Speed – cached resources are local, and thus load faster.
- Reduced server load – the browser only downloads resources that are updated or changed from the server.

For more information, see HTML5 Application Cache.

The application cache manifest

The *Cache Manifest* is a simple text file that lists the resources that the browser is to cache for offline access. It contains a list of resources that are explicitly cached after the first time they are downloaded. The Cache Manifest can contain three sections:

- **CACHE** – Files and resources that are listed under this heading (or immediately after the **CACHE MANIFEST** heading if no sections are present) will be explicitly cached after the first time they are downloaded.
- **NETWORK** – Files listed under this heading are white-listed resources that require a connection to the server. All requests to these resources bypass the cache, even if the user is offline.

- **FALLBACK** – An optional section that specifies fallback pages if a resource is inaccessible. The first URI listed is the primary resource, and the second URI is the fallback. Both URIs must be relative and from the same origin as the manifest file.

When the browser opens a document that includes the manifest attribute, the browser loads the document and then fetches all the entries that are listed in the Cache Manifest file. If no application cache exists, the browser creates the first version of the application cache.

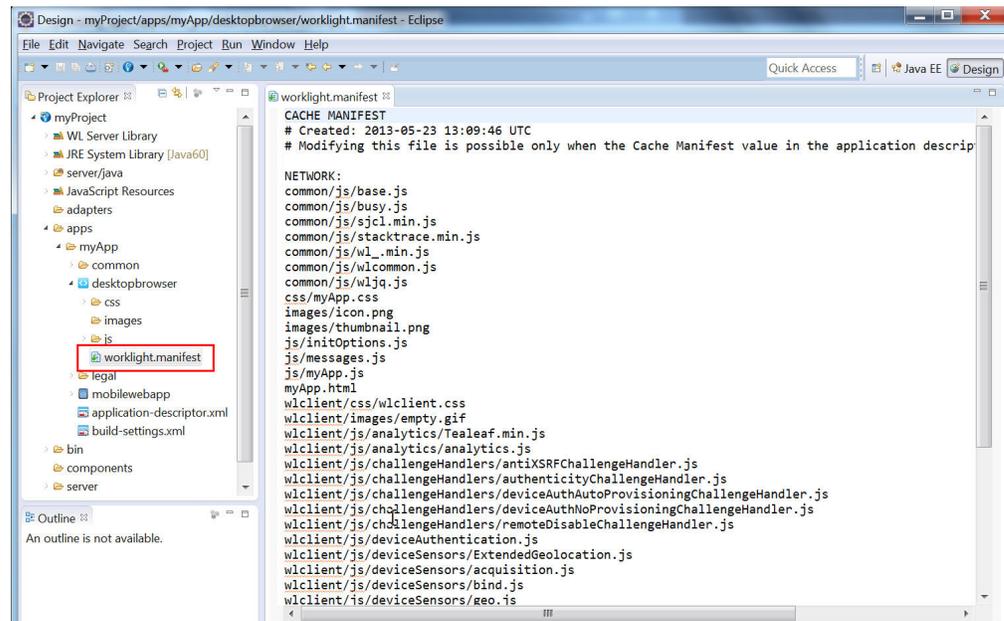

If unnecessary or redundant files are included, they must all be fetched before the application can start, which can create a poor user experience. The procedure that follows documents ways in which you can edit the Cache Manifest to reduce the start time for your Desktop Browser and Mobile Web applications.

Managing the application Cache Manifest in MobileFirst Studio

The procedures for managing and editing the contents of the application cache for Desktop Browser and Mobile Web applications are listed in this section.

With IBM MobileFirst Platform Foundation, you can control the Cache Manifest in web environments (Desktop Browser and Mobile Web). The name of the Cache Manifest file is `worklight.manifest`. This file is located in the folder for each of these types of environments.

You can now view (and edit) the contents of this file in MobileFirst Studio, as shown in the following screen capture:

A new attribute now exists in the Application Descriptor (`application-descriptor.xml`) for Desktop Browser and Mobile Web elements. The current setting of this attribute, called `<cacheManifest>`, can be easily viewed, as shown in the following screen capture:

```

<!-- Attribute id must be identical to application folder name -->
<application xmlns="http://www.worklight.com/application-descriptor" id="lala" platformVersion=
<displayName>222</displayName>
<description>lala22</description>
<author>
<name>application's author</name>
<email>application author's e-mail</email>
<homepage>http://mycompany.com</homepage>
<copyright>Copyright My Company</copyright>
</author>
<mainFile>lala.html</mainFile>
<thumbnailImage>common/images/thumbnail.png</thumbnailImage>
<iphone bundleId="com.lala" version="1.0">
<worklightSettings include="true"/>
<security>
<encryptWebResources enabled="false"/>
<testWebResourcesChecksum enabled="false" ignoreFileExtensions="png, jpg, jpeg, gif" />
</security>
</iphone>
<mobileWebApp cacheManifest="#"/>
<worklightServerRootURL>http://$local.IPAD
</application>

```

For more information about Application Descriptor attributes, see “The application descriptor” on page 8-50.

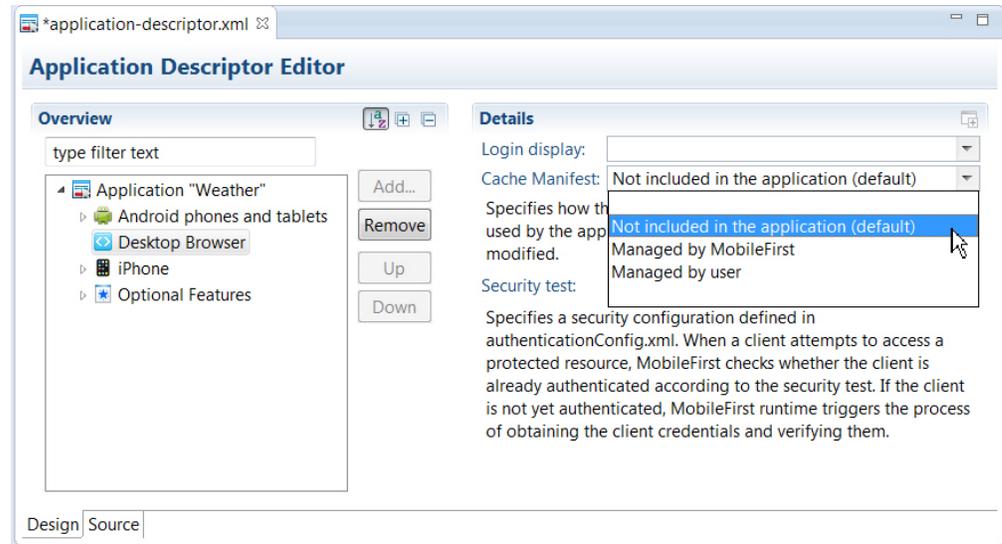

The `<cacheManifest>` attribute accepts three values, as shown in the following table. No matter which value or mode is selected, if the Cache Manifest does not exist, the MobileFirst Studio builder generates the default Cache Manifest to give you something to start with. But after creating this file, the builder leaves the resulting Cache Manifest file in its default **no-use** mode unless you explicitly change the setting.

Table 8-34. *cacheManifest* properties

Property	Description
generated	<p>In this mode, the MobileFirst Studio builder generates a default Cache Manifest and includes it in the application's HTML files. The default Cache Manifest is generated depending on the environment:</p> <ul style="list-style-type: none"> • For Desktop Browser environments – all resources are under NETWORK, which means: no cache at all. • For Mobile Web environments – all resources are under CACHE, which means: cache everything. <p>In generated mode, in addition to creating the Cache Manifest, the builder creates a backup of the previous Cache Manifest, called <code>worklight.manifest.bak</code>. This file is overwritten in every build.</p>
no-use	<p>In this mode (which is the default), the Cache Manifest is not included in the application's HTML files. This setting means that there is no Cache Manifest and that decisions about which resources are cached are up to the browser.</p>
user	<p>In this mode, the MobileFirst Studio builder does not generate the Cache Manifest, but it does include it in the application's HTML files. This setting means that the user must maintain the Cache Manifest manually.</p>

Editing the Cache Manifest

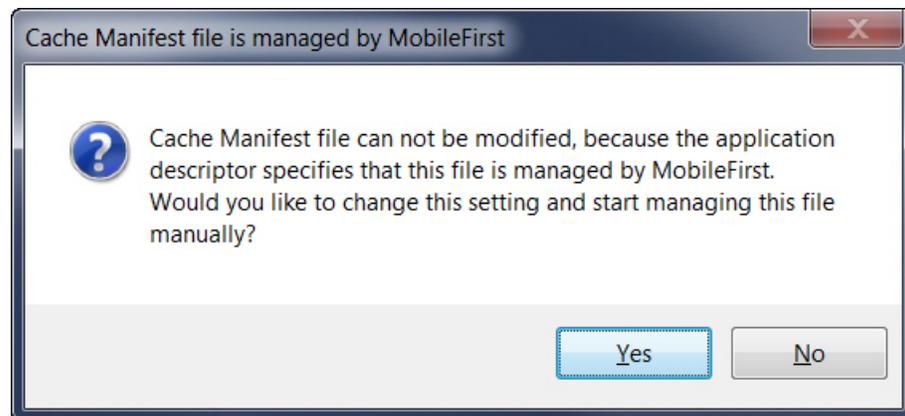

If you select the Application Descriptor (application-descriptor.xml file) in Design view, you can view and set the current mode of the `<cacheManifest>` attribute:

In this view, each of these attribute options is given a description:

- **Not Included in the application (default)** corresponds to **no-use** mode
- **Managed by MobileFirst** corresponds to **generated** mode
- **Managed by user** corresponds to **user** mode

The only `<cacheManifest>` mode that enables the user to edit the Cache Manifest is **user**. If you attempt to edit the file in any other mode, MobileFirst Studio displays the following message:

If you click **Yes** on this window, you can change the `<cacheManifest>` mode interactively and then continue to edit the file. You can also change the `<cacheManifest>` mode at any time with MobileFirst Studio DDE editor.

The default `<cacheManifest>` setting for new MobileFirst projects is **Not Included in the application (no-use mode)**.

If your testing reveals that certain resources can be removed from the generated Cache Manifest, you can change the setting to **Managed by user (user mode)**. Then, you can edit the Cache Manifest and conduct more performance tests before you deploy to the production environment.

For example, you might notice that the Cache Manifest contains large images or other resources that are not used by the web application but need to remain in the development environment for other platforms. If you edit the Cache Manifest, you can remove them so that the web versions of this app load more quickly.

An example of a generated Cache Manifest file for a Desktop Browser environment is shown in the following sample:

```

MobileFirst application build settings

You can use minification to reduce the size of JavaScript and CSS files in your application. You can also use concatenation to improve the start time of the application. To use concatenation and minification, you can use the MobileFirst build settings.

Since IBM Worklight V6.0.0, a file that is named `build-settings.xml` is created when a new MobileFirst application is created, on the same level as `application-descriptor.xml`. The purpose of the file is to prepare minification and concatenation configurations for each environment. These configurations are then used by the minify and concatenation engines during the build process.

Starting with IBM MobileFirst Platform Foundation V7.1.0, environments are automatically added to the `build-settings.xml` file upon their creation. These methods of creation include the new project wizard, the add environment wizard, or directly adding the environment to the `application-descriptor.xml` file. Additionally, any environment that exists in the project and is missing in the `build-settings.xml` file is automatically added during the build. If the environment exists in the `build-settings.xml` file but not the project, the environment is removed from the `build-settings.xml` file.

Also, starting with IBM MobileFirst Platform Foundation V7.1.0, you are no longer able to add and remove environments from the **Build Settings Editor**. You can manually add and remove them directly using the `build-settings.xml` file.

The structure of the `build-settings.xml` file is as shown in the following example:

```
<buildSettings xmlns="http://www.ibm.worklight.com/build-settings">
  <common>
    <minification level="simple" includes="*" excludes="**/css/**"/>
    <concatenation includes="*" excludes="**/*.js"/>
  </common>
  <desktopBrowser>
    <minification level="simple" includes="*" excludes="**/css/**"/>
    <concatenation includes="*" excludes="**/*.txt"/>
  </desktopBrowser>
  <mobileWebApp>
    <minification level="simple" includes="*" excludes="**/css/**"/>
    <concatenation includes="*" excludes="**/*.js"/>
  </mobileWebApp>
</buildSettings>
```

The names of elements are aligned with names of environments. Starting in IBM MobileFirst Platform Foundation V7.1.0, all environments can be minified or concatenated. The `<common>` element contains configurations that are common to all environments.

All three elements – `<common>`, `<desktopBrowser>`, and `<mobileWebApp>` – are optional.

If any of these three elements are used, the `<minification>` attribute is mandatory within each one. Its `level` attribute specifies the compilation level of minification process and resources that can or cannot be used. Minification level options are listed in *Minification of JS and CSS files - Table 1*.

The `includes` and `excludes` attributes must be followed by a list of file names or regular expressions as used by Ant, separated by semicolons. Only JavaScript (.js) and Cascading Style Sheet (.css) files can be listed. Wildcard characters are allowed, with the following rules:

- `**` – includes or excludes all files and folders
- `**/foldername/**` – includes or excludes all files and folders under `foldername`
- `**/*.css` – includes or excludes all files in all folders that have an extension of `.css`

The `includes` and `excludes` attributes can be used in combination, such as in the following examples:

- `includes="**"` and `excludes="**/*.css"` contains all files except `.css` files
- `includes="**"` and `excludes="**/css/**"` contains all files except files under the `css` folder
- `includes="**/js/**"` contains only files that are found under the `js` folder
- `includes="**/*.js"` contains only files that have an extension of `.js`
- `includes="**/*.js"` and `excludes="**/*.css"` contains no files at all

For instructions about how to configure minification, see “Minification of JS and CSS files” on page 8-371.

The `<concatenation>` element is optional. It contains no `level` attribute, and its `includes` and `excludes` attributes use the same syntax that is listed for the `<minification>` element.

For instructions about how to configure concatenation, see “Concatenation of JS and CSS files” on page 8-373.

To turn on minification or concatenation for an environment

To instruct MobileFirst Studio to use minification, concatenation, or both when it builds the application:

1. In MobileFirst Studio, right-click the element of your application (or the main application node) and choose **Run As > Build Settings and Deploy Target** from the menu.

The Configure MobileFirst Build and Deploy Target window is displayed.

2. In the **Build optimization** area of the dialog, select the check box of the feature or features you want to use when you build this environment.
3. Click **OK**.

Note: This action does not trigger an automatic build. To build or rebuild by using these new settings, you must use either the **Run As > Run on MobileFirst Development Server** or the **Run As > Build...** menu commands.

Building with the `build-settings.xml` file

At build time, the MobileFirst Studio builder minifies or concatenates all the files that are included and not excluded, as defined in the `build-settings.xml` file.

During the build process, when either minification or concatenation is specified for an environment, the builder reads the `build-settings.xml` file and configures the

compilation level and included and excluded files for that environment. Each environment is minified or concatenated according to its own configuration, and according to the following rules:

- The `compilation level` value of the environment overrides the `compilation level` specified in the `<common>` element.
- The `includes` attribute of each environment overrides an `includes` attribute of `<common>`.
- The `excludes` attribute of each environment is concatenated to the `excludes` attribute of `<common>`.

By editing the `build-settings.xml` file, you can essentially create different configurations for minification and concatenation, depending on the stage of the development cycle. For example, you might have one setting that is commonly used during development, in which the minification level is set to **none** and the concatenation feature is disabled. But when you move the application to production, you can edit the build settings to use a minification level of **simple** and to enable concatenation.

Minification of JS and CSS files

You can minimize the size of JavaScript and CSS files that are deployed with your applications by using MobileFirst Studio settings.

Minification is the process that minifies web resources to make them smaller. The smaller size of the resources means less traffic between the MobileFirst application and MobileFirst Server. This is true both when the app is being initially downloaded by users, and at application start time.

Starting in IBM MobileFirst Platform Foundation V7.1.0, you can use minification with all environments.

The feature is a counterpart to another build optimization, *concatenation*, and is almost always used with it. Use of these features can either improve the applications' start time (concatenation), or reduce the size of the application (minification).

Minification is done at build time by the Google Closure Compiler. You can use three levels of minification in a MobileFirst application, as listed in the following table:

Table 8-35. Options for the `minification level` attribute

Value	Description
none	No minification is done on your code by the MobileFirst Studio builder.
whitespaces	Removes comments from your code and also removes line breaks, unnecessary spaces, and other white space. The output JavaScript is functionally identical to the source JavaScript. (In the MobileFirst Studio Build Settings Editor, this attribute is called Remove whitespaces and comments .)

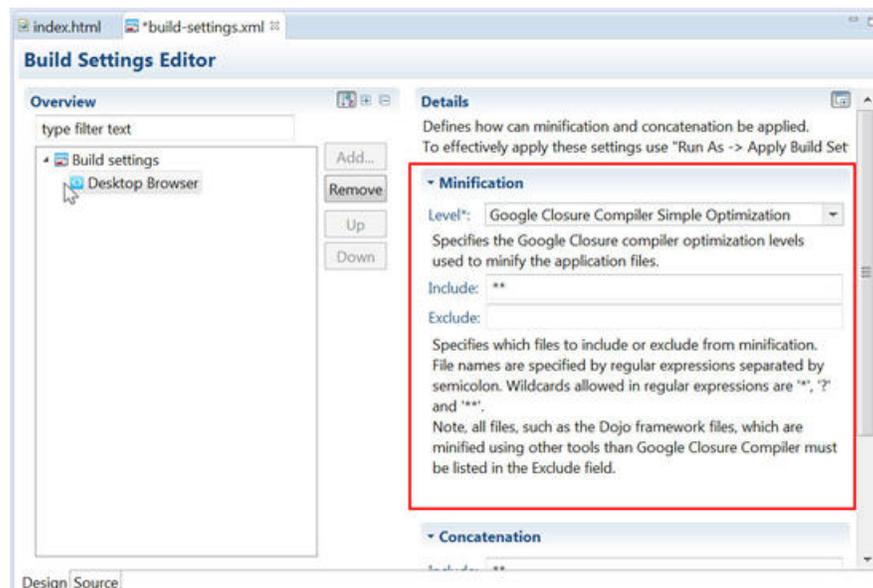

Table 8-35. Options for the minification level attribute (continued)

Value	Description
simple	Removes the same white space and comments as whitespaces , but also optimizes expressions and functions, including renaming local variables and function parameters to shorter names. Renaming variables to shorter names makes the code smaller. Because the simple setting renames only symbols that are local to functions, it does not interfere with the interaction between the compiled JavaScript and other JavaScript. Compilation with this setting always preserves the functionality of syntactically valid JavaScript, if the code does not access local variables with string names, for example, by using <code>eval()</code> statements. (In the MobileFirst Studio Build Settings Editor, this attribute is called Google Closure Compiler Simple Optimization .)

To configure minification in MobileFirst Studio

You create a minification configuration for your application in two steps. First, you edit the Build Settings for the application, and then you turn on minification for the individual environments.

1. To configure minification, in MobileFirst Studio, double-click the **build-settings.xml** element of your application to display the Build Settings Editor and select the environment:

2. Select the wanted minification level from the **Level** field:
 - **None (Default)** specifies the **none** attribute in Table 8-35 on page 8-371.
 - **Remove whitespaces and comments** specifies the **whitespaces** attribute in Table 8-35 on page 8-371.
 - **Google Closure Compiler Simple Optimization** specifies the **simple** attribute in Table 8-35 on page 8-371.
3. Enter the list of files to be minified or excluded from minification in the **Include** and **Exclude** fields. When you save, these settings become part of the application code.
Use the Ant syntax that is described in “MobileFirst application build settings” on page 8-369.

4. To instruct MobileFirst Studio to use minification during the build, in MobileFirst Studio, right-click the element of your application (or the main application node) and choose **Run As > Build Settings and Deploy Target** from the menu.

The Configure MobileFirst Build and Deploy Target window is displayed.

5. In the **Build optimization** area of the dialog, select **Use minification to reduce the size of JavaScript and CSS files**.
6. Click **OK**.
7. Rebuild your application. No changes take place after an edit of the minification parameters until after the next build.

You can also edit the `build-settings.xml` file with a standard XML editor, and you can invoke this file by using Ant scripts. See “MobileFirst application build settings” on page 8-369 for examples of the XML syntax.

Concatenation of JS and CSS files

MobileFirst Studio allows concatenation of multiple JavaScript and CSS files that are deployed with your applications.

Since IBM Worklight V6.0.0, the *concatenation* feature allows concatenation of the multiple web resources that are used by the application (JavaScript and CSS files) into a smaller number of files. Reducing the total number of files that are referenced by the application HTML results in fewer browser requests when the application starts. This allows the application to start more quickly.

Starting with IBM MobileFirst Platform Foundation V7.1.0, you can use concatenation with all environments. The feature is a counterpart to another build optimization, *minification*, and is almost always used with it. Use of these features can either reduce the size of MobileFirst applications (minification) or improve their start time (concatenation).

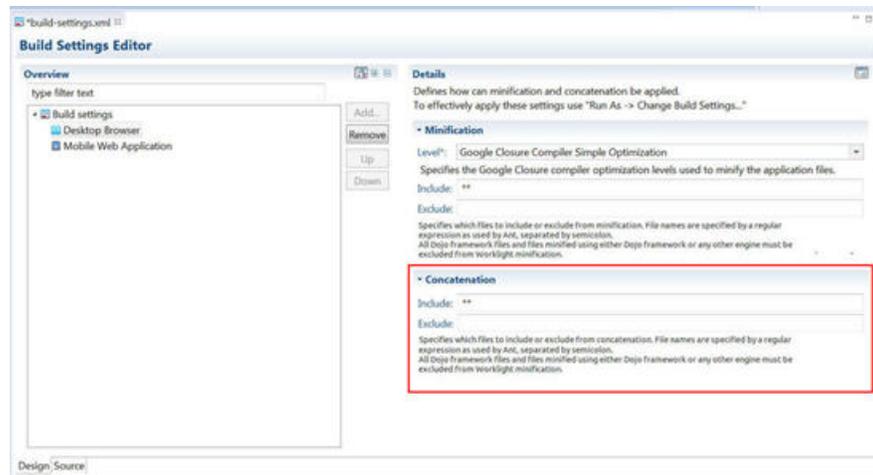

During concatenation, several resources (for example, JavaScript files and inline scripts) are copied into a new file, which is then referenced by the application HTML. References to the original resources are removed from the HTML. So, there is less communication between the device and web server is required to retrieve the application code.

At build time, the concatenation algorithm determines which resources to concatenate into which files. Concatenation is controlled by a number of different parameters, such as the structure of the HTML, the type of the resources to be concatenated, and the attributes of these resources. The order of the resources in the HTML is preserved. As a result, the concatenation process does not have any negative effects in terms of code dependencies or functionality.

To configure concatenation in MobileFirst Studio

You create a concatenation configuration for your application in two steps. First, you edit the Build Settings for the individual environments, and then you turn on concatenation for the application.

1. To enter the list of files to be concatenated, in MobileFirst Studio, double-click the **build-settings.xml** element of your application to display the Build Settings Editor and select the environment:

2. Enter the list of files to be concatenated or not concatenated in the **includes** and **excludes** fields. When you save, these settings become part of the application code.
Use the Ant syntax that is described in the following “Syntax and examples” section and in “MobileFirst application build settings” on page 8-369.
3. To instruct MobileFirst Studio to use concatenation during the build, in MobileFirst Studio, right-click the appropriate element of your application (or the main application node) and choose **Run As > Build Settings and Deploy Target** from the menu.
The Configure MobileFirst Build and Deploy Target window is displayed.
4. In the **Build optimization** area of the dialog, select **Use concatenation to reduce the number of JavaScript and CSS files**.
5. Click **OK**.
6. Rebuild your application. No changes take place after an edit of the concatenation parameters until after the next build.

The build-settings.xml can also be edited with a standard XML editor, and can be invoked by using Ant scripts.

Syntax and examples

The includes and excludes attributes must be followed by a list of file names or regular expressions as used by Ant. Only JavaScript (.js) and Cascading Style Sheet (.css) files can be listed. Wildcard characters are allowed, with the following rules:

- ** – includes or excludes all files and folders
- **/foldername/** – includes or excludes all files and folders under foldername
- **/*.css – includes or excludes all files in all folders that have an extension of .css
- Multiple file names or regular expressions are separated by semicolons.
- Included files are concatenated (all files are included by default).
- Excluded files are not concatenated (no files are excluded by default).
- Files that are excluded or not included are not part of the concatenation process.
- In most cases, setting the included list to ** (the default value – all files) and modifying only the excluded list is sufficient to achieve the wanted results

In practice, users often create more specific excludes definitions, relying on wildcards to include the remaining files. For example, JavaScript files with the `async` attribute might be good candidates for exclusion, as it might not make sense to concatenate their content with other files.

The following example shows an HTML file that contains the standard resources that are provided by this product, along with other resources defined by the user:

```
<html>
<head>
...
  <link rel="stylesheet" href="css/main.css">
  <link rel="stylesheet" href="css/myStyle.css">
  <link rel="stylesheet" href="css/myStyle2.css">
  <link rel="stylesheet" href="css/myStyle3.css">

  <script>window.$ = window.jQuery = WLJQ;</script>
  <script src="js/myJSFile.js"></script>
  <script src="js/myJSFile2.js"></script>
  <script src="js/myJSFile3.js" async></script>
  <script src="js/myJSFile4.js"></script>
  <script src="js/myJSFile5.js"></script>

</head>
<body id="content" style="display: none;">
  ...
  <script src="js/initOptions.js"></script>
  <script src="js/main.js"></script>
  <script src="js/messages.js"></script>
</body>
</html>
```

After the concatenation process (as part of the build), the resulting HTML file has the following structure:

```
<html>
  <head>
    ...
    <link href="wlclient/css/wlclient.css" rel="stylesheet">
    ...
    <link href="css/wlconcatenated0.css" rel="stylesheet">

    <script>

      ... WL framework initialization code ...

    </script>

    <script src="common/js/wljq.js"></script>
    <script src="wlconcatenatedhead0.js"></script>
    <script src="wlconcatenatedhead1.js"></script>
    <script async="" src="js/myJSFile3.js"></script>
    <script src="wlconcatenatedhead2.js"></script>

  </head>

  <body>
    ...
    <script src="wlconcatenatedbody0.js"></script>
  </body>
</html>
```

The following changes were made to the HTML in the concatenation process:

- All of the CSS files under the `css` folder were concatenated into a single file, `wlconcatenated0.css`. Note the file `wlclient.css`, which is not concatenated, because it is located under a separate folder.
- All of the MobileFirst framework files were concatenated into two files – `wljq.js` and `wlconcatenatedhead0.js`.
- The inline script and the files `myJSFile.js` and `myJSFile2.js` were concatenated into the file `wlconcatenatedhead1.js`.
- The file `myJSFile3.js` contains the `async` attribute, and so it was not concatenated into another file.
- The files `myJSFile4.js` and `myJSFile5.js` were concatenated into the file `wlconcatenatedhead2.js`.
- In the body, the files `initOptions.js`, `main.js`, and `messages.js` were concatenated into the file `wlconcatenatedbody0.js`.

In this example, the number of resources that are referenced by the HTML is greatly reduced. The number of application resources and user-defined resources is reduced from 12 to 5, and only three files are used for all of the MobileFirst framework resources. This reduction results in fewer requests by the browser, leading to a faster application start time.

Optimizing MobileFirst applications for use over slow networks

If your MobileFirst applications are meant to run under limited network conditions, you can follow these guidelines to build your applications and improve performance.

The data transfer rates, in places where the Internet is accessed through GSM, GPRS, or EDGE, might be a few hundred of kilobits per second. The networks with such limited connectivity are considered as *slow networks*.

When mobile devices, running a MobileFirst application, access the server over a slow network, it is important to reduce the amount of data transfer between the device and the server. This reduction ensures faster interaction with the user. Even when the amount of data transfer is minimized, it is equally important to keep the user apprised of the estimated time to complete an operation over the network. Use the following guidelines in MobileFirst applications development to optimize the mobile user experience over slow networks.

Use compressed response

From IBM Worklight V6.0 on, it is possible for MobileFirst applications to request data in a compressed format in response to the **invokeProcedure** calls. Because the data is returned by the MobileFirst Server in JSON format, compressing the adapter responses greatly reduces the amount of data that is transferred. The time to complete a response is reduced, too.

The following code snippet demonstrates how to request a compressed response from the server in a hybrid application.

```
var invocationData = {
  adapter : 'adapter-name',
  procedure : 'procedure-name',
  parameters : [],
  compressResponse : true
}
WL.Client.invokeProcedure(invocationData, options);
```

Configure adapter timeout

By default, each **invokeProcedure** call that is made by the device times out after 30 seconds. If your **invokeProcedure** call expects a large amount of data from the adapter over a slow network, you must increase the timeout.

The following code snippet demonstrates how to set the adapter timeout to 60 seconds.

```
var invocationData = {
    adapter : 'adapter-name',
    procedure : 'procedure-name',
    parameters : [],
    compressResponse : true
}
var ONE_MINUTE = 60 * 1000;

var options = { timeout : ONE_MINUTE,
    onSuccess : successCallback,
    onFailure : failureCallback
};

WL.Client.invokeProcedure(invocationData, options);
```

Response time from the adapter

Another factor that influences the **invokeProcedure** timeout on the device is the actual time that is taken by the adapter to respond. If your adapter takes a significant amount of time to fetch data from the back end, consider this factor in the timeout value that you set during the call to the procedure.

In general, make sure that the following equation applies:

$$(\text{invokeProcedure timeout}) \geq (\text{Adapter response time}) + (\text{Transmission time over the network})$$

Adapt application behavior to timeout

Slow networks are often unpredictable in terms of the speed and reliability. To take this fact into account, build resilience to timeout within your applications. For example, your applications can try again a timed-out operation with a larger timeout value.

The following code snippet demonstrates a typical JSON response from the MobileFirst Server when a timeout occurs. This response can be accessed in the **onFailure** callback.

```
{
  "invocationContext" : null,
  "errorCode" : "REQUEST_TIMEOUT",
  "errorMsg" : "Request timed out for <REQUEST_URL>. Make sure the host address is available to the app (especially relevant for Android and iPhone apps)."
```

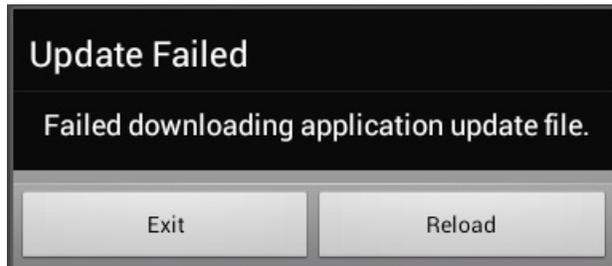

Use of Application Center

The Application Center provides a mobile client that can be used to download and update applications. Delivering application updates through the Application Center provides the devices with capabilities such as resumable downloads and automatic reload of broken downloads. These features are useful especially for the devices that install and update applications over slow networks.

Direct update consideration

Successful direct update of applications over slow networks depends on sustained reliability of the mobile network over a large period while the update is being downloaded. Frequent loss of signal, network congestion can lead to direct update failure. You must keep the application footprint as small as possible to minimize risks of direct update failure. IBM MobileFirst Platform Foundation sends a compressed version of the update file to the client to minimize data charges and to increase chances of a successful direct update over slow networks. When direct update fails over slow networks, the user must be advised to resume the direct update when a better network, such as WiFi, is available.

The user is prompted with an error message when the direct update fails as a result of network troubles.

Turn on compression by default

MobileFirst Server provides the **compress.response.threshold** configuration property. The responses to an `invokeProcedure` call from a device that are above this threshold are automatically compressed by the server. This setting ensures that network performance is optimal even when a client application does not request compressed data, due either to ignorance or underestimation of the payload size. The default value of the **compress.response.threshold** property is 20480 bytes. For more information, see “Miscellaneous settings” on page 12-61.

Configuring and customizing direct update

Direct update is the direct delivery of updated web resources to deployed applications. Subject to the terms and conditions of the target platform, organizations are not required to upload new app versions to the app store or market. In IBM MobileFirst Platform Foundation, this option is available for iPhone, iPad, Windows Phone Silverlight 8, and Android apps.

For an introduction to direct updates of app versions to mobile devices, see “Direct updates of app versions to mobile devices” on page 8-379. A direct updates mechanism is available for desktop apps. For more information, see “Direct updates of app versions to desktop apps” on page 8-382.

The MobileFirst Server can push data at the rate of 250 MB per second. For example, if an application is 5 MB in size, assuming that the network bandwidth is not a bottleneck, the MobileFirst Server can serve 50 direct updates per second, and a MobileFirst Server cluster of four servers can serve 200 direct updates per second.

To serve direct updates at higher rates, consider using a CDN (content delivery network) instead of the MobileFirst Server.

Direct updates of app versions to mobile devices

Direct Update allows you to quickly update application web resources (HTML, JavaScript, and CSS) without going through the vendor (Apple/Google) app store review process.

When you deploy the latest build without changing its version to the MobileFirst Server, the next time the app tries to access the server, it will automatically retrieve the latest web resources after prompting the user to accept the update. Direct Update cannot be used to update native code.

For client apps built on versions of IBM Worklight Foundation up to V6.2.0.1, the entire web resources package is downloaded to the application during the Direct Update process.

Client applications built on IBM MobileFirst Platform Foundation V6.3 and later:

- Receive a *differential* direct update by default if the web resources of the application are only *one* build behind those in the application now being deployed. Only the web resources that were changed since the last deployment are downloaded and updated.
- Receive a *full* direct update if the web resources of the application are more than one build behind those in the application now being deployed.

Note: The differential direct update is applicable for Android and iOS only. It is not available for Windows Phone Silverlight 8. The client apps of Windows Phone Silverlight 8 receive full direct update.

See “Upgrading MobileFirst Studio in the Consumer or Enterprise Editions to MobileFirst Studio V7.1.0” on page 7-5 for instructions to reenable direct update after an upgrade of MobileFirst Server.

When the app connects to the MobileFirst Server, it starts downloading the newly deployed resources, as shown in the following figures. If the download fails mid-way, the direct update will resume from where the download was broken the previous time.

Note: The user notifications seen in the following figures show the default method of implementing Direct update. You can customize the direct update process and interface of apps developed in MobileFirst Studio, V6.2.0 and later. For more information, see “Customizing the direct update interface and process” on page 8-390.

Direct updates of app versions to desktop apps

A direct updates mechanism is available for desktop apps as well as for mobile devices.

When you redeploy a desktop app with a new version, the MobileFirst Server automatically pushes the app to the user's desktop. When the desktop app connects to the MobileFirst Server and an update is available, it displays a dialog box for the user, asking the user to accept a new version. If the user accepts the new version, it is automatically downloaded to the user's desktop. The user must then open the downloaded app to install it on the desktop.

This option is only available for Adobe AIR applications.

Direct Update as a security realm

Since IBM Worklight Foundation V6.2.0, Direct Update has been part of the MobileFirst security framework, and is defined as a security realm.

The incorporation of Direct Update into the MobileFirst security framework provides greater flexibility and consistency. Direct Update is enabled by default on all supported platforms, including iPhone, iPad, Android, and Microsoft Windows Phone Silverlight 8. Checks for Direct Update occur during requests to the server. If an update is available, the client displays a confirmation dialog. When the user accepts, the new resources are downloaded from the MobileFirst Server and the app restarts.

Configuring the Direct Update realm

You configure Direct Update in the `authenticationConfig.xml` file. A Direct Update test can be added to any mobile security test or custom security test.

Example of a Direct Update test in a mobile security test

```
<mobileSecurityTest name="mobileWithDirectUpdate">
  <testDirectUpdate mode="perRequest"/>
  <testDeviceId provisioningType="none"/>
  <testUser realm="wl_anonymousUserRealm"/>
</mobileSecurityTest>
```

Example of a Direct Update test in a custom security test

```
<customSecurityTest name="customWithDirectUpdate">
  <test realm="wl_directUpdateRealm" mode="perRequest" step="1"/>
  <test realm="wl_anonymousUserRealm" isInternalUserID="true" step="1"/>
  <test realm="wl_deviceNoProvisioningRealm" isInternalDeviceID="true" step="2"/>
</customSecurityTest>
```

Mode

You can use the optional mode property to configure when the server checks for direct updates. The following table describes the possible modes:

Table 8-36. Values of the mode attribute

Mode	Description
perSession	The server checks whether a Direct Update is available (and if so, delivers it) once per session, on the first request to the server. This is the default mode.
perRequest	The server checks whether a Direct Update is available (and if so, delivers it) on every request to the server.
disabled	The server never checks whether a Direct Update is available (not even during an explicit call to <code>WL.Client.login</code> , as described in “Check for Direct Update on demand” on page 8-384).

Note: If code that uses the Direct Update realm accesses a resource that is protected by OAuth authentication, and the client has a valid token, the MobileFirst Server is not called. As a result, the server does not check for an available Direct Update, regardless of the value of the mode property. The MobileFirst Server is called when the token expires or when the Direct Update realm inside the token expires. When the realm expires, the Direct Update authenticator is invoked and the server checks for an available Direct Update.

Mobile security test

If a Direct Update test is not specified in a mobile security test, it is enabled with the default `perSession` mode. To change the direct update mode to `perRequest` in a mobile security test, add a direct update test with `mode="perRequest"` to a mobile security test: `<testDirectUpdate mode="perRequest"/>`. To disable direct update in a mobile security test, add a direct update test with `mode="disabled"` to the mobile security test: `<testDirectUpdate mode="disabled"/>`.

Custom security test

To add a Direct Update test to a custom security test, add the following test to the security test: `<test realm="wl_directUpdateRealm"/>`. The default mode is `perSession`. To change the mode, specify a value for the mode attribute: `<test realm="wl_directUpdateRealm" mode="perRequest"/>`. To disable automatic Direct

Update in a custom security test, either set the mode to disabled or do not add a test with a Direct Update realm.

Changes from previous versions of IBM MobileFirst Platform Foundation

In IBM Worklight V6.1.0 and earlier versions, the server checks for direct updates as part of the `WL.Client.connect()` request. Since IBM Worklight Foundation V6.2.0, the server checks for updates outside the `WL.Client.connect()` request. Because Direct Update is now part of the security framework, the server can check for direct updates on every request from the client to the server, on first request, or not at all, depending on the configuration.

In IBM Worklight V6.1.0 and earlier versions, returning the application to the foreground triggered a server request to check for direct updates. Since IBM Worklight Foundation V6.2.0, you can configure MobileFirst Server to check for direct updates on every request; therefore direct updates are no longer explicitly checked when the application returns to the foreground. You can impose the behavior of earlier versions by listening to the “resume” event fired by Cordova and manually checking for direct updates:

```
$(document).on("resume", function(){
    WL.Client.login("wl_directUpdateRealm", {onSuccess:..., onFailure:...});
});
```

Check for Direct Update on demand

You can configure Direct Update so that the server checks for direct updates only when there is an explicit call to do so. To apply this setting, protect the application with a custom security test that does **not** contain a test with `wl_directUpdateRealm`. In the application code, use `WL.Client.login("wl_directUpdateRealm", {onSuccess:..., onFailure:...})`, which causes the server to check for direct updates. (See the documentation for the `login` method of `WL.Client`.) This configuration does not work if the custom security test that protects the application contains `wl_directUpdateRealm` with `mode="disabled"`.

Native applications and Direct Update

Direct Update is supported only by the JavaScript `WL.Client`. For applications that are protected by a direct update realm that is configured to use `perSession` mode, when such applications initiate a server session by using a native `WLClient` call, the server assumes that Direct Update is not required for this session even if subsequent requests are made by using a JavaScript `WL.Client` call. In such cases, to enable Direct Update to work when using the JavaScript `WL.Client`, configure the direct update realm to use `perRequest` mode.

Direct Update Customization

Developers can customize the Direct Update process for hybrid applications on iOS, Android, and Microsoft Windows Phone Silverlight 8. For more information, see “Customizing the direct update interface and process” on page 8-390.

Upgrading projects

When you import a project from Worklight Studio V6.1.0 or earlier versions into MobileFirst Studio, the following Direct Update test is added automatically to every custom security test in the project `authenticationConfig.xml` file: `<test`

realm="wl_directUpdateRealm" step="1"/>. Direct Update then continues to work in a similar way to how it worked in versions earlier than V6.2 (that is, Direct Update checks are made once per session).

Enabling Direct Update Authenticity checks

You can configure client applications to check the authenticity of a direct update package downloaded from the MobileFirst Server or CDN.

About this task

When you enable the Direct Update Authenticity feature, the direct update package is digitally signed during deployment. After the client has downloaded the package, it performs a security check on it to validate its authenticity. This means that if the direct update package has been altered or replaced, the client will not install it. Additionally, the client reports direct update authenticity failure to the MobileFirst Server. These reports appear in the server logs with a log level SEVERE. For more information, see “Customizing the direct update interface and process” on page 8-390.

The Direct Update Authenticity feature is not enabled by default. Follow the instructions below to enable this feature for new applications and for existing applications that have been upgraded. The instructions are for all supported environments

Procedure

1. In the MobileFirst project, under the **server** folder, in the `conf/worklight.properties` file, update the keystore data. The following properties must be updated:
 - **wl.ca.keystore.path** - The path to the keystore, relative to the **server** folder in the MobileFirst project, for example: `conf/default.keystore`.
 - **wl.ca.keystore.type** - The type of the keystore file. Valid values are `jks` or `pkcs12`.
 - **wl.ca.keystore.password** - The password to the keystore file, for example: `mobile`.
 - **wl.ca.key.alias** - The alias of the entry where the private key and certificate are stored, in the keystore, for example: `keypair1`.
 - **wl.ca.key.alias.password** - The password to the alias in the keystore for example: `mobile`.

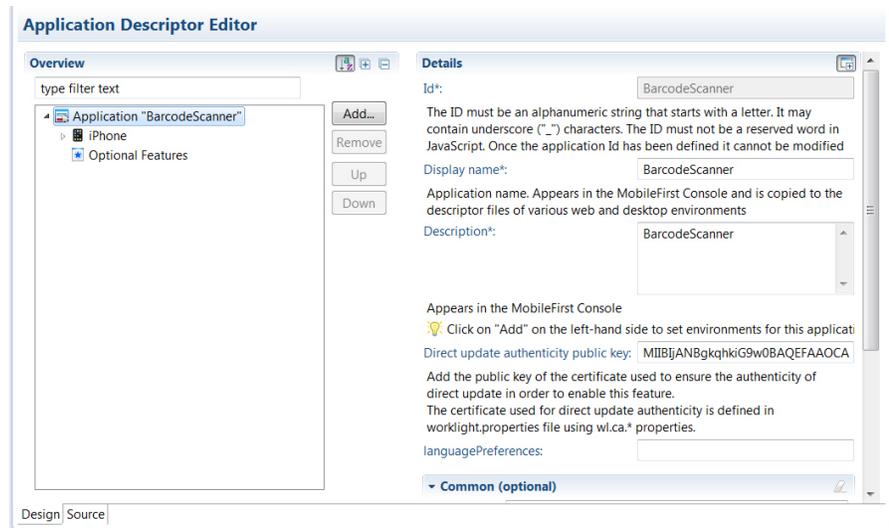

Note: The maximum permitted key length is 3072 bits.

2. In the `applicationDescriptor.xml` file for your app, update the client with the public key that will be used to authenticate the direct update zip file.

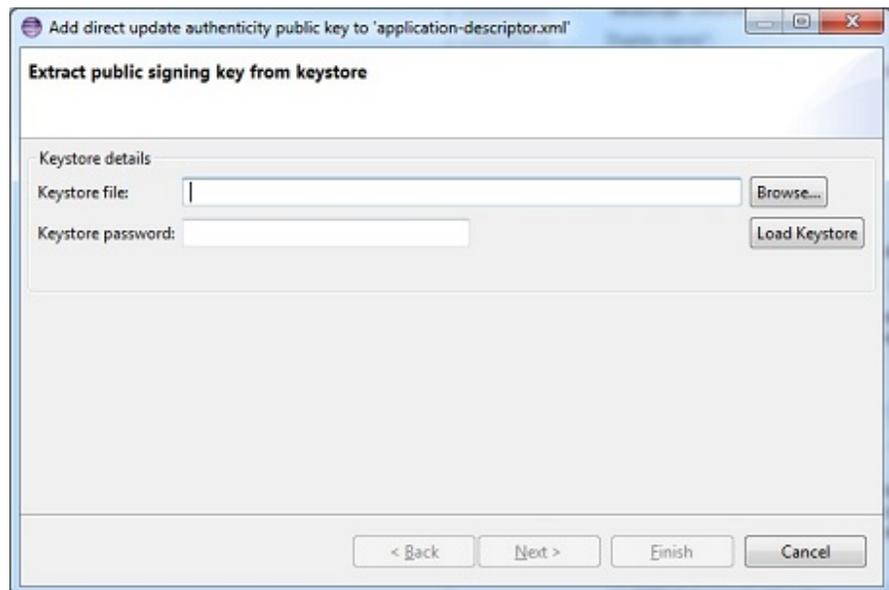

Note: The public key must use Base64 encoding.

Use any of the following three ways to update the file:

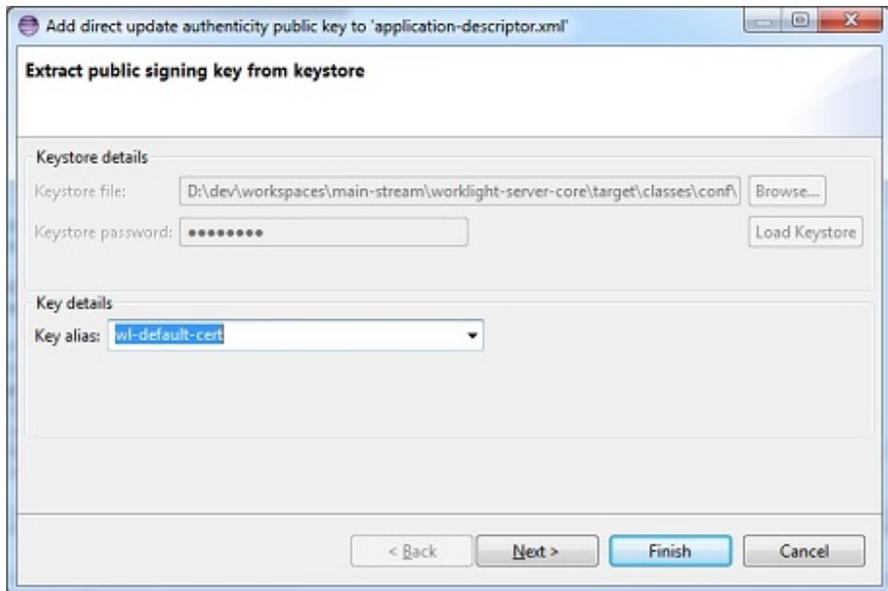

- Edit source code manually:
Use your preferred text editor to edit the `application-descriptor.xml` file directly, in the `<application>` section. For example:
`<directUpdateAuthenticityPublicKey>public_key</directUpdateAuthenticityPublicKey>`
- Use the Application Descriptor Editor:
 - a. Click the **Design** view to display the **Application Descriptor Editor**.

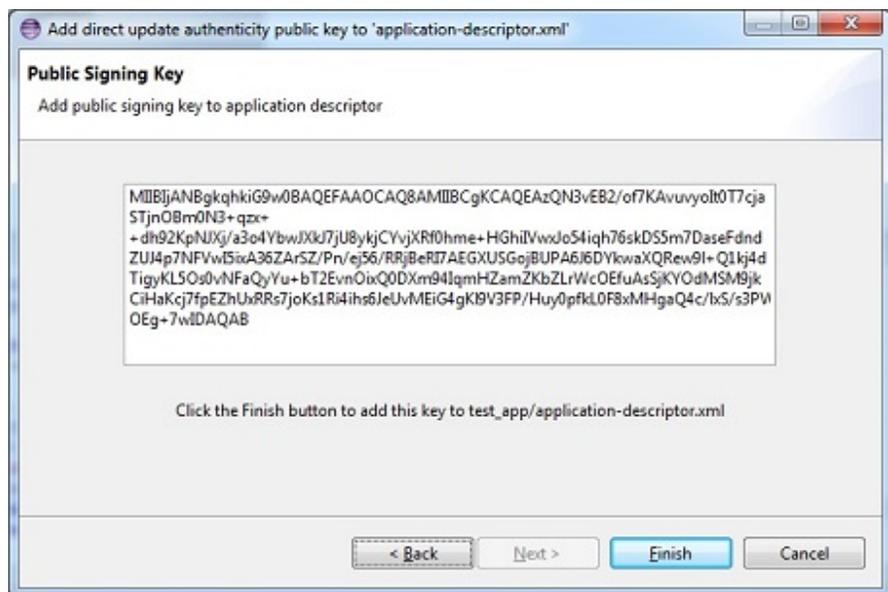

- b. In the **Direct update authenticity public key** field, enter the authenticity public key.
- Use the public key extraction wizard:
 - a. Right-click the **apps/app** folder in your project.
 - b. Select **Extract public key for direct update authenticity** to display the **Extract public signing key from keystore** wizard.

- c. Specify the location and password of the keystore file and click **Load Keystore**.

d. Select **Key alias** and click **Next** to display the key.

e. Click **Finish** to insert the key into the application-descriptor.xml file.

3. After you have updated the required information, rebuild and redeploy your application to IBM MobileFirst Platform Server.

Serving direct update requests from a CDN

You can configure direct update requests to be served from a CDN (content delivery network) instead of from the MobileFirst Server.

Advantages of using a CDN

Using a CDN instead of the MobileFirst Server to serve direct update requests has the following advantages:

- Removes network overheads from the MobileFirst Server.

- Increases transfer rates above the 250 MB/second limit when serving requests from a MobileFirst Server.
- Ensures a more uniform direct update experience for all users regardless of their geographical location.

General requirements

To serve direct update requests from a CDN, ensure that your configuration conforms to the following conditions:

- The CDN must be a reverse proxy in front of the MobileFirst Server (or in front of another reverse proxy if needed).
- When building the application from MobileFirst Studio or from the command line interface, you need to supply the CDN host and port instead of the host and port of the MobileFirst Server.
- In the CDN administration panel, you need to mark the following direct update URLs for caching to ensure that the CDN passes all requests to the MobileFirst Server except for the direct update requests. For direct update requests, the CDN determines if it has already obtained the content. If it has, it returns it without going to the MobileFirst Server; if not, it goes to the MobileFirst Server, gets the direct update zip file, and stores it for the next requests for that specific URL.
 - For applications that are built with versions of MobileFirst Studio earlier than V6.2.0, the direct update URL is: `PROTOCOL://DOMAIN:PORT/CONTEXT_PATH/apps/services/api/APP_NAME/ENVIRONMENT/updates?skin=SKIN_NAME&x-wl-app-version=VERSION`.
 - For applications that are built with MobileFirst Studio V6.2.x, the direct update URL is: `PROTOCOL://DOMAIN:PORT/CONTEXT_PATH/directUpdate/APP_NAME/ENVIRONMENT/VERSION?skin=SKIN_NAME`.
 - For applications that are built with MobileFirst Studio V6.3.0 and later, the direct update URL is: `PROTOCOL://DOMAIN:PORT/CONTEXT_PATH/directUpdate/APP_NAME/ENVIRONMENT/VERSION/CHECKSUM/TYPE/SKIN_NAME`. Where *CHECKSUM* is a numeric value, and *TYPE* is either full or delta.

Note: The prefix `PROTOCOL://DOMAIN:PORT/CONTEXT_PATH` is constant for all runtime requests and cannot be changed just for direct update requests.

- The CDN must support TTL on the direct update response. This is needed to support multiple direct updates for the same version.
- The CDN must not change or remove the HTTP headers that are used in the MobileFirst server-client protocol.
- The CDN must allow caching of the request parameters. Two different direct update zip files might differ only by the request parameters (x-wl-app-version or skin).

Example configuration

This example is based on using an Akamai CDN configuration that caches the direct update zip file. The following tasks are completed by the network administrator, the MobileFirst administrator, and the Akamai administrator:

Network administrator:

1. Create an additional domain in the DNS for your MobileFirst Server. For example if your server domain is `yourcompany.com` you need to create an additional domain such as `cdn.yourcompany.com`.

- In the DNS for the new `cdn.yourcompany.com` domain, set a CNAME to the domain name that is provided by Akamai; for example, `yourcompany.com.akamai.net`.

MobileFirst administrator:

- Set the new `cdn.yourcompany.com` domain as the MobileFirst Server URL for the MobileFirst applications. For example, for the Ant builder task, the property is: `<property name="wl.server" value="http://cdn.yourcompany.com/${contextPath}"/>`

Akamai administrator :

- Open the Akamai property manager and set the property host name to the value of the new domain.

HOSTNAME	EDGE HOSTNAME
cdn.yourcompany.com	yourcompany.com.akamai.net

- On the Default Rule tab, configure the original MobileFirst Server host and port, and set the **Custom Forward Host Header** value to the newly created domain.

- From the **Caching Option** list, select No Store.

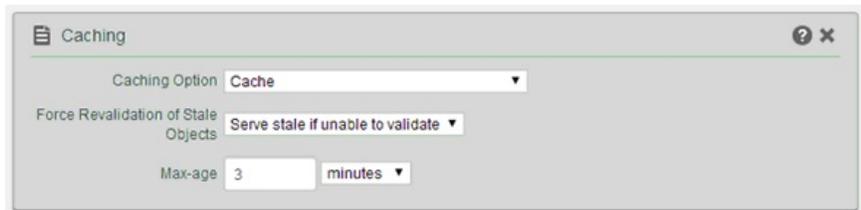

- From the Static Content configuration tab, configure the matching criteria according to the direct update URL of the application. For example, create a condition that states If Path matches one of `direct_update_URL`.

- Set values similar to the following values to configure the caching behavior to make cache the direct update URL and to set TTL.

Table 8-37. Configuring caching.

Field	Value
Caching Option	Cache
Force Revaluation of Stale Objects	Serve stale if unable to validate
Max-age	3 minutes

- Configure the cache key behavior to use all request parameters in the cache key (you must do this to cache different direct update zip files for different applications or versions). For example, from the **Behavior** list, select Include all parameters (preserve order from request).

- Save and activate the configuration.

Customizing the direct update interface and process

You can change the default user interface for the direct update dialog boxes and the messages that are displayed to the user. You can also control when an application checks for a direct update, run the direct update process without presenting a user interface to the user, link the checking for available direct updates to a call to an adapter, and control what happens when the direct update process fails.

Use the `handleDirectUpdate` function of the direct update challenge handler to customize the direct update process and interface on iOS, Android, and Windows Phone 8. The `handleDirectUpdate` function has the following format:

```
wl_directUpdateChallengeHandler.handleDirectUpdate = function (directUpdateData,directUpdateContext){...}
```

The function accepts the following arguments:

directUpdateData

A JSON object that contains the `downloadSize` property that represents the files size in bytes of the update package to be downloaded from server.

directUpdateContext

A JavaScript object that exposes `.start()` and `.stop()` functions that start and stop the direct update flow.

If the web resources are more recent on the MobileFirst Server than in the application, direct update challenge data is added to the server response. Whenever the MobileFirst client-side framework detects this direct update challenge, it starts the `wl_directUpdateChallengeHandler.handleDirectUpdate` function.

The function provides a default direct update look and feel: a default message dialog that is displayed when a direct update is available and a default progress screen that is displayed when the direct update process is initiated. For examples of default screens, see “Direct updates of app versions to mobile devices” on page 8-379. You can implement custom direct update user interface behavior or customize the direct update dialog box by overriding this function and implementing your own logic.

The following example `handleDirectUpdate` function implements a custom message in the direct update dialog:

```
wl_directUpdateChallengeHandler.handleDirectUpdate = function(directUpdateData,directUpdateContext) {  
  
    var customDialogTitle = 'Custom Title Text';  
    var customDialogMessage = 'Custom Message Text';  
    var customButtonText = 'Custom Button Text';  
  
    WL.SimpleDialog.show(customDialogTitle, customDialogMessage, [{  
        text : customButtonText,  
        handler : function() {  
            directUpdateContext.start();  
        }  
    }]);  
};
```

You can start the direct update process by running the `directUpdateContext.start()` method whenever the user clicks the pop-up dialog button. This method supports the following types of invocation:

- When no parameters are specified, IBM MobileFirst Platform Foundation uses the default progress screen, which resembles the one in IBM Worklight V6.1.0.
- When a listener function such as `directUpdateContext.start(directUpdateCustomListener)` is supplied, the direct update process runs in the background while the process sends lifecycle events to the listener. The custom listener must implement the following methods:

```
var directUpdateCustomListener = {  
    onStart: function(totalSize){  
  
    },  
    onProgress: function(status,totalSize,completedSize){  
  
    },  
    onFinish: function(status){  
  
    }  
};
```

The listener methods are started during the direct update process according to following rules:

- `onStart` is called with the `totalSize` parameter that holds the size of the update file.

- onProgress is called multiple times with status DOWNLOAD_IN_PROGRESS, totalSize, and completedSize (the volume that is downloaded so far).
- onProgress is called with status UNZIP_IN_PROGRESS.
- onFinish is called with one of the following final status codes:

Table 8-38. Status codes for the onFinish rule

Status code	Description
SUCCESS	Direct update finished with no errors.
CANCELED	Direct update was canceled (for example, because the stop() method was called).
FAILURE_NETWORK_PROBLEM	There was a problem with a network connection during the update.
FAILURE_DOWNLOADING	The file was not downloaded completely.
FAILURE_NOT_ENOUGH_SPACE	There is not enough space on the device to download and unpack the update file.
FAILURE_UNZIPPING	There was a problem unpacking the update file.
FAILURE_ALREADY_IN_PROGRESS	The start method was called while direct update was already running.
FAILURE_INTEGRITY	Authenticity of update file cannot be verified.
FAILURE_UNKNOWN	Unexpected internal error.

If you implement a custom direct update listener, you must ensure that the app is reloaded when the direct update process is complete and the onFinish() method has been called. You must also call wl_directUpdateChallengeHandler.submitFailure() if the direct update process fails to complete successfully.

The following example shows an implementation of a custom direct update listener:

```
var directUpdateCustomListener = {
  onStart: function(totalSize){
    //show custom progress dialog
  },
  onProgress: function(status,totalSize,completedSize){
    //update custom progress dialog
  },
  onFinish: function(status){

    if (status == 'SUCCESS'){
      //show success message
      WL.Client.reloadApp();
    }
    else {
      //show custom error message

      //submitFailure must be called is case of error
      wl_directUpdateChallengeHandler.submitFailure();
    }
  }
};

wl_directUpdateChallengeHandler.handleDirectUpdate = function(directUpdateData, directUpdateContext){
  WL.SimpleDialog.show('Update Availible', 'Press update button to download version 2.0', [{
```

```

    text : 'update',
    handler : function() {
        directUpdateContext.start(directUpdateCustomListener);
    }
  }]);
};

```

Scenario: Running UI-less direct updates

IBM MobileFirst Platform Foundation supports UI-less direct update when the application is in the foreground.

To run UI-less direct updates, implement `directUpdateCustomListener`. Provide empty function implementations to the `onStart` and `onProgress` methods. Empty implementations cause the direct update process to run in the background.

To complete the direct update process, the application must be reloaded. The following options are available:

- The `onFinish` method can be empty as well. In this case, direct update will apply after the application has restarted.
- You can implement a custom dialog that informs or requires the user to restart the application. (See the following example.)
- The `onFinish` method can enforce a reload of the application by calling `WL.Client.reloadApp()`.

Here is an example implementation of `directUpdateCustomListener`:

```

var directUpdateCustomListener = {
  onStart: function(totalSize){
  },
  onProgress: function(status,totalSize,completeSize){
  },
  onFinish: function(status){
    WL.SimpleDialog.show('New Update Available', 'Press reload button to update to new version', [ {
      text : WL.ClientMessages.reload,
      handler : WL.Client.reloadApp
    }
  ]]);
  }
};

```

Implement the `wl_directUpdateChallengeHandler.handleDirectUpdate` function. Pass the `directUpdateCustomListener` implementation that you have created as a parameter to the function. Make sure `directUpdateContext.start(directUpdateCustomListener)` is called. Here is an example `wl_directUpdateChallengeHandler.handleDirectUpdate` implementation:

```

wl_directUpdateChallengeHandler.handleDirectUpdate = function(directUpdateData, directUpdateContext){
  directUpdateContext.start(directUpdateCustomListener);
};

```

Note: When the application is sent to the background, the direct-update process is suspended.

Scenario: Triggering direct updates on demand

By default, the application checks for direct updates once per session. You can program the application to check for direct updates at a different point in time, for example, you can trigger a check for direct updates whenever a user clicks a button.

The mobile security test that is provided by default (in the authenticationConfig.xml file under the server/conf folder) contains a direct update security test. You must disable this test if you want to trigger direct update on demand. For example:

Custom security test:

```
<customSecurityTest name="customNoDirectUpdate">
  <test realm="wl_anonymousUserRealm" isInternalUserID="true" step="1"/>
  <test realm="wl_deviceNoProvisioningRealm" isInternalDeviceID="true" step="2"/>
</customSecurityTest>
```

Mobile security test:

```
<mobileSecurityTest name="mobileTests">
  <testDeviceId provisioningType="none" />
  <testUser realm="wl_anonymousUserRealm" />
</mobileSecurityTest>
```

In your JavaScript code, when you decided to run direct update (for example, through a WiFi connection or when the application is in the background) call WL.Client.checkForDirectUpdate(). This call triggers direct update on demand.

Scenario: Checking for direct updates when a specific adapter is called

This scenario shows how you can link the checking for direct updates to adapter calls.

Program your application to use a custom security test without direct update. The following example shows such a custom security test in the authenticationConfig.xml file:

```
<customSecurityTest name="customNoDirectUpdate">
  <test realm="wl_anonymousUserRealm" isInternalUserID="true" step="1"/>
  <test realm="wl_deviceNoProvisioningRealm" isInternalDeviceID="true" step="2"/>
</customSecurityTest>
```

Program your adapter to use a custom security test with direct update defined. The following example shows such a custom security test in the authenticationConfig.xml file:

```
<customSecurityTest name="customWithDirectUpdateRequest">
  <test realm="wl_directUpdateRealm" mode="perRequest"/>
  <test realm="wl_anonymousUserRealm" isInternalUserID="true" step="1"/>
  <test realm="wl_deviceNoProvisioningRealm" isInternalDeviceID="true" step="2"/>
</customSecurityTest>
```

In this case, the application does not require direct update even if it is available on the server until the adapter is called from your JavaScript code as shown in the following example:

```
WL.Client.invokeProcedure({adapter : 'RSSReader', procedure : 'getFeeds'});
```

Scenario: Handling a direct update failure

This scenario shows how to handle a direct update failure that might be caused, for example, by loss of connectivity. In this scenario, the user is prevented from using the app even in offline mode. A dialog is displayed offering the user the option to try again.

Create a global variable to store the direct update context so that you can use it subsequently when the direct update process fails. For example:

```
var savedDirectUpdateContext;
```

Implement a direct update challenge handler. Save the direct update context here.
For example:

```
wl_directUpdateChallengeHandler.handleDirectUpdate = function(directUpdateData, directUpdateContext){
    savedDirectUpdateContext = directUpdateContext; // save direct update context

    var downloadSizeInMB = (directUpdateData.downloadSize /
1048576).toFixed(1).replace(".", WL.App.getDecimalSeparator());
    var directUpdateMsg = WL.Utills.formatString(WL.ClientMessages.directUpdateNotificationMessage, downloadSizeInMB);

    WL.SimpleDialog.show(WL.ClientMessages.directUpdateNotificationTitle, directUpdateMsg, [{
        text : WL.ClientMessages.update,
        handler : function() {
            directUpdateContext.start(directUpdateCustomListener);
        }
    }]);
};
```

Create a function that starts the direct update process by using the direct update context. For example:

```
restartDirectUpdate = function () {
    savedDirectUpdateContext.start(directUpdateCustomListener);
// use saved direct update context to restart direct update
};
```

Implement directUpdateCustomListener. Add status checking in the onFinish method. If the status starts with "FAILURE", open a modal only dialog with the option "Try Again". For example:

```
var directUpdateCustomListener = {
    onStart: function(totalSize){
        alert('onStart: totalSize = ' + totalSize + 'Byte');
    },
    onProgress: function(status,totalSize,completeSize){
        alert('onProgress: status = ' + status + ' completeSize = ' + completeSize + 'Byte');
    },
    onFinish: function(status){
        alert('onFinish: status = ' + status);
        var pos = status.indexOf("FAILURE");
        if (pos > -1) {
            WL.SimpleDialog.show('Update Failed', 'Press try again button', [ {
                text : "Try Again",
                handler : restartDirectUpdate // restart direct update
            }]);
        }
    }
};
```

When the user clicks the **Try Again** button, the application restarts the direct update process.

Updating mobile apps with IBM MobileFirst Platform Foundation and the Application Center

You can choose among different ways to update a mobile application depending on the context.

When you build applications for internal use in your organization and that are not to be delivered through public app stores such as Google play or Apple App Store, you could use the Application Center to deliver these applications over the air. There are several scenarios that you might want to consider.

Changing the web part of a hybrid application

When you want to deliver a MobileFirst hybrid application that consists mainly of HTML5 with CSS and JavaScript, and you must change the hybrid part of the application to provide new features or to fix a defect, you do not have to ask the application users to update it on their devices. You can use the MobileFirst direct update mechanism to deploy new HTML with CSS and JavaScript for your application without changing the application version on the mobile device. To perform this kind of update, you do not recreate a native version of the application. You only redeploy the MobileFirst application (wlapp) in the MobileFirst Operations Console for the same application version. See “Deploying applications and adapters to MobileFirst Server” on page 12-87.

You can implement this type of update in a way that the application user has nothing to do to trigger it. Alternatively, you can provide a menu entry in your application to check for available updates and to trigger the direct update mechanism. For more details, see “Direct Update as a security realm” on page 8-382.

If you use the direct update mechanism, you will not have to redeploy a new binary version of your application to the Application Center. When new users install applications from the Application Center, they get the latest version of the hybrid part of the application through the direct update mechanism when they start the application for the first time or when they use the menu option that is implemented in the application to check for updates.

Delivering a new version of native code

The main reason that you would want to deliver a new version of an application is probably because your application uses native code and you want to provide new features or deliver fixes that require changes in the native code. You might also need to provide a new native version of the application, even if your MobileFirst application is completely written by using web technologies, to accommodate new mobile operating systems supported only in later versions of IBM MobileFirst Platform Foundation. You cannot use the direct update mechanism in either of these cases. You must build and deploy a new version of the application.

You can provide the update through the Application Center.

Start by uploading the new application binary (APK, IPA, or other) to the Application Center console. The application is listed as a new available version of the application. For the Application Center to consider the application as a new version of an existing application, you must keep the application identification unchanged; for example, it must have the same package name for Android or the same bundle ID for iOS. You change the internal version of the application; for example, **versionCode** on Android or **CFBundleVersion** on iOS. For more information about application properties in the Application Center console, see “Application properties” on page 13-94.

If you configured the Application Center to send push notifications for updates, users would receive a notification as soon as the new version is deployed. The content of this message enables the user to open the Application Center mobile client on the update page of the mobile application, so that he or she can trigger an over-the-air installation.

To streamline the update process, you can remotely disable the previous version of the MobileFirst application from the MobileFirst Operations Console. See “Remotely disabling application connectivity” on page 13-3. By remotely disabling the previous version, you can make sure that your users do not use the old version anymore.

When you disable the previous version, you must provide the URL of the latest application version, so that users have an easy way to fetch the new version.

In the Application Center, if you want to direct users of the mobile application to the update page of the mobile client, you can use a custom URL of the format:

```
ibmappctr://show-app? Package-name
```

Where *Package-name* is the package name of the application that you have updated to a new version.

The exact URL is listed in the “Application properties” page of the Application Center console. For more information, see “Application properties” on page 13-94.

When a user launches a disabled application version, the user is directed to get the update on the main page of the application in the Application Center mobile client. An Update button gives access to over-the-air update of the application.

Updating the Application Center application

Since IBM Worklight Foundation V6.2.0, when a new version of the Application Center becomes available, users do not have to uninstall the mobile application before downloading and installing the new version on their mobile devices. For example, when a new version of the Application Center is made available to support new mobile operating systems. Users can be automatically notified when a new version of the mobile client is available in the Application Center repository. In your role as Administrator of the Application Center, you have only to upload the new binary version of the mobile client application to the catalog.

Accelerating application development by reusing resources

Use application components, MobileFirst project templates, and mobile patterns to accelerate the development of applications by reusing resources.

This section describes application components and MobileFirst project templates. For information about mobile patterns, see “Mobile patterns” on page 8-128.

Configuring application component and template preferences

You can configure the location of your local download folder. The download folder is the place where IBM MobileFirst Platform Foundation searches for MobileFirst project templates and application components whenever you add an application component to a project or create a project from a template.

About this task

You can use the default folder `<USER_HOME>/IBM/templates`, or you can specify an alternative folder. If you want to use an alternative folder, you must specify it before you create application components and templates.

Procedure

1. In MobileFirst Studio, click **Window > Preferences**.
2. In the left panel, click **MobileFirst > Templates and Components**.
3. In the right panel, click **Browse**, and then select the folder that you want to use as your download folder.

Application components

Application components are reusable libraries that you can add to the applications you develop. An application component can be a client-side library or a server runtime block. Typical libraries might handle basic functions such as login or payments. They can also contain various elements such as non-visual runtime objects, visual components, integration adapters, and user interface screen packages.

Consider the example of a banking application. The application might require an image-processing library for processing checks, a non-visual runtime object, and an integration adapter to connect to the banking system for verification. A developer might consider assembling these reusable building blocks into application components, and then add them to multiple MobileFirst projects to accelerate the development of applications for a range of different devices.

An application component can help simplify and speed up the delivery of high quality mobile applications across multiple devices. An application component can also help developers in their interactions with customers, can provide value-added services, and can help developers understand how consumers use their mobile applications.

Creating application components from MobileFirst projects

You can create an application component based on a MobileFirst project. You define metadata information such as the name of the component and its version number, and you select the project resources that you want to include in the application component.

Procedure

1. From the Explorer view in MobileFirst Studio, right-click the MobileFirst project and click **Create Application Component**.
2. Provide metadata information in the fields listed in the following table:

Table 8-39. Application component metadata

Field	Description
Name	Name of the application component. Spaces are allowed in this field.
ID	Unique identifier for the application component. This is a read-only field. The identifier is the combination of information specified in the Name field (using uppercase characters and without spaces) together with unique identifiers.
Author	Author or provider of the application component.
Version	Version of the application component expressed in VRM (version, release, modification) format; for example, 1.0.1.

Table 8-39. Application component metadata (continued)

Field	Description
Description	Short description of the application component.
Image	Thumbnail image that represents the application component. Supported resolution: 15x12 pixels.

Note: If you enter metadata information using certain non-Western character sets, the information might be displayed in XML encoded format in the component.wcp file. This does not affect the usability of the application component in any way. The characters are interpreted correctly by XML processors; for example, when you view the file using a web browser such as Firefox, it will display the correct character set.

3. From the **Application** list, select the application that you want to use as a basis for the application component, and then click **Next**.
4. In the panel that displays the project resources, select the check box next to each resource that you want to include in the application component. Consider including the files that you think would be useful as a component. Do not try to include the files that are in any case generated by default by a MobileFirst project.
5. Click **Browse** and specify the location and filename of the application component, and then click **Finish**. The file extension must be .wlc or .zip.

Results

The application component is created with the location and filename you specified.

What to do next

You can now view the contents of the application component and add hooks to facilitate automation.

Viewing the contents of an application component

You can open an application component to view its contents by using a file compression tool.

The application component contains folders based on the MobileFirst project resources that were selected when the application component was created, as well as a mandatory COMPONENT-DATA folder.

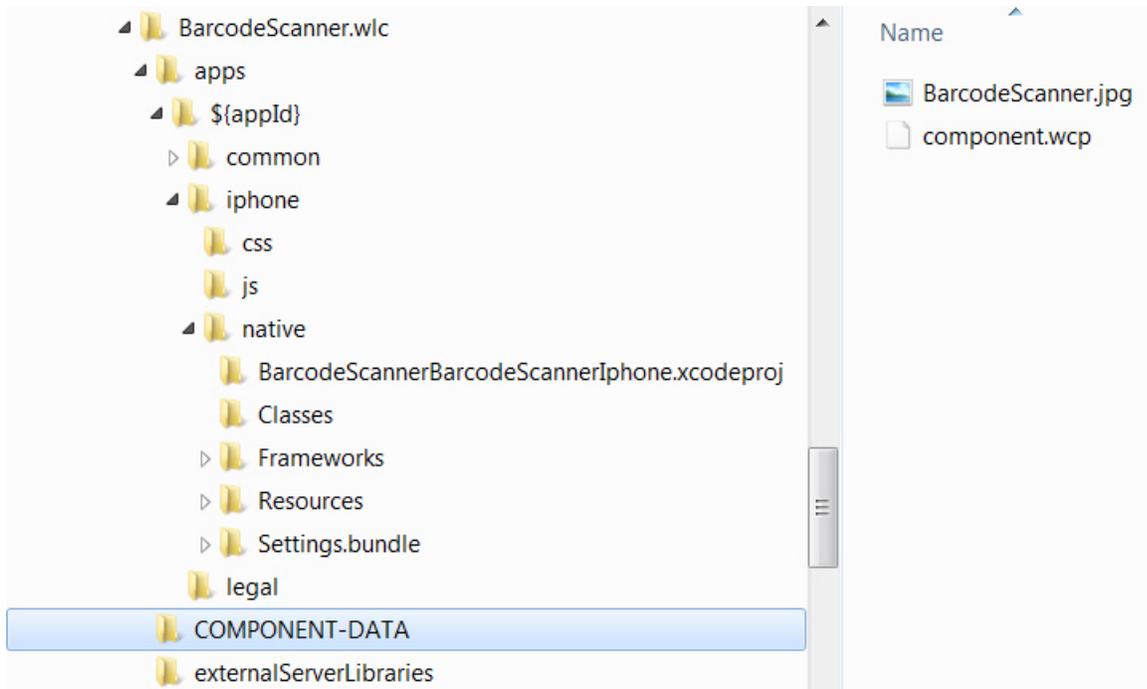

Figure 8-63. File structure of a typical application component

The COMPONENT-DATA folder contains the following files:

- The thumbnail image file that was selected when the application component was created.
- A Component Processor file named `component.wcp`, which contains the metadata information that was specified when the application component was created.

The following contents are present in the `component.wcp` file:

- Component ID
- Component name
- Component author name
- Component description
- Component version
- Component thumbnail
- IBM MobileFirst Platform Foundation version number

The following example shows the contents of a typical `component.wcp` file:

```
<ComponentData>
  <ID>BarCodeScannerUniqueID</ID>
  <Name>Barcode Scanner_iOS</Name>
  <Author>IBM</Author>
  <Description>Barcode Scanner for iOS by IBM</Description>
  <Version>1.0.0</Version>
  <Image>BarcodeScanner.jpg</Image>
  <WLVersion>6.3.0</WLVersion>
</ComponentData>
```

Note: Do not modify the contents of the COMPONENT-DATA folder except to add additional hooks to the `component.wcp` file according to the schema described in “Adding hooks to an application component” on page 8-401.

Adding hooks to an application component

You add hooks to an application component to facilitate automation when the component is added to a MobileFirst project. These additional hooks are optional.

To add hooks, you need to edit the component.wcp file by adding XML inner elements. If you do this directly within MobileFirst Studio, the edited component.wcp file is included in the next version of the application component. If you edit the component.wcp file outside MobileFirst Studio, you must copy the edited file manually into the MobileFirst Studio workspace location and then run the Create Application Component command again so that the application component is updated with the latest version of the component.wcp file.

Before you add hooks, you need to add the appropriate environment element according to the environment that the application component supports. The following table lists the element that you add for each supported environment:

Table 8-40. Elements for supported environments

Environment	Element
Android	<Android>
iPhone	<IPhone>
iPad	<IPad>

The following example component.wcp file includes the **Android** environment tag:

```
<ComponentData>
  <ID>BarcodeScannerUniqueID</ID>
  <Name>Barcode Scanner Android</Name>
  <Author>IBM</Author>
  <Description>Barcode Scanner for Android by IBM</Description>
  <Version>1.0.0</Version>
  <Image>barcodeIcons.jpg</Image>
  <WLVersion>6.1.0</WLVersion>
  <Android></Android>
</ComponentData>
```

Table 8-41 lists the inner elements that are supported on Android and the order in which they must appear in the schema.

Table 8-41. Order of inner elements for the Android environment

Order	Inner element
1	CordovaPlugin
2	Activities
3	UserPermissions
4	Receivers
5	Strings
6	ExternalLibraries
7	Libraries

Table 8-42 lists the inner elements that are supported on iOS and the order in which they must appear in the schema.

Table 8-42. Order of inner elements for the iPhone and iPad environments

Order	Inner element
1	CordovaPlugin

Table 8-42. Order of inner elements for the iPhone and iPad environments (continued)

Order	Inner element
2	Files
3	Libraries

Note: Some hooks result in the insertion of properties in the config.xml file or the AndroidManifest.xml file when the associated application component is added to a MobileFirst project. Every insertion is enclosed in comments that mention the element and application component unique name. For example:

```
<!--BEGIN ANDROID CORDAVA-PLUGIN AUTOINSERTION FOR BarCodeScannerUniqueID -->
<!--END ANDROID CORDAVA-PLUGIN AUTOINSERTION FOR BarCodeScannerUniqueID -->
```

Adding and removing Android library projects

Additional Android projects can be packaged as part of the component.wlc file.

Additional projects are packaged in the COMPONENT-DATA folder under the folder ExternalProjects. Any compressed file under that folder is considered to be an “external project” and will be automatically added.

When the component is added to a MobileFirst project, the following things happen:

- Any additional projects are added to the Workspace.
- The additional projects are referenced from the MobileFirst project.
- If the external projects use a higher Android API level than is used by the MobileFirst Android project, the developer is prompted to upgrade to the higher API level.

When the component is removed, the following things happen:

- The additional projects are deleted from the Workspace (and from the file system).
- References to those external projects are removed from the MobileFirst project.

CordovaPlugin element:

This element integrates the Cordova plug-in into the application component by capturing the class name and its fully qualified name. When you add the application component to a MobileFirst project, the CordovaPlugin properties are automatically inserted into the config.xml file.

Element name

```
<CordovaPlugin>
```

Parameters

Table 8-43. CordovaPlugin elements

Element	Description	Occurrences
Name	Name of the plug-in that uses the Cordova plug-in.	1

Table 8-43. CordovaPlugin elements (continued)

Element	Description	Occurrences
ClassName	Qualified class name of the plug-in implementation that uses the Cordova plug-in.	1

Environments supported

- Android
- iPhone
- iPad

Example

```
<ComponentData>
  <ID>BarCodeScannerUniqueID</ID>
  <Name>Barcode Scanner Android</Name>
  <Author>IBM</Author>
  <Description>Barcode Scanner for Android by IBM</Description >
  <Version>1.0.0</Version>
  <Image>barcodeIcons.jpg</Image>
  <WLVersion>6.1.0</WLVersion>
  <Android>
    <CordovaPlugin>
      <Name>BarcodeScanner</Name>
      <ClassName>com.phonegap.plugins.barcodescanner.BarcodeScanner</ClassName>
    </CordovaPlugin>
  </Android>
</ComponentData>
```

Automation

When an application component that includes this element is added to a MobileFirst project, the config.xml file of the MobileFirst project is automatically updated to reflect the CordovaPlugin properties. The following example shows an updated config.xml file:

```
<feature name="InAppBrowser">
  <param name="android-package" value="org.apache.cordova.inappbrowser.InAppBrowser"/>
</feature>
<feature name="Vibration">
  <param name="android-package" value="org.apache.cordova.vibration.Vibration"/>
</feature>
<!--BEGIN ANDROID CORDOVA-PLUGIN AUTOINSERTION FOR BarCodeScannerUniqueID -->
<feature name="BarcodeScanner">
  <param name="android-package" value="com.phonegap.plugins.barcodescanner.BarcodeScanner"/>
</feature>
<!--END ANDROID CORDOVA-PLUGIN AUTOINSERTION FOR BarCodeScannerUniqueID -->
</widget>
```

Activities element:

This element enables you to add activities information to the application component. The information is declared in the Android manifest file in any MobileFirst project that imports the component. The activities specified in the XMLContent element get appended in the Android manifest under the application element.

Element name

```
<Activities>
```

Parameters

Table 8-44. Activities elements

Element	Description	Occurrences
XmlContent	The XML content of the activities information that needs to be placed in the Android manifest file. You can specify one or more activity elements within the XMLContent element to be appended.	1

Environments supported

- Android

Example

```
<ComponentData>
  <ID>BarCodeScannerUniqueID</ID>
  <Name>Barcode Scanner Android</Name>
  <Author>IBM</Author>
  <Description>Barcode Scanner for Android by IBM</Description >
  <Version>1.0.0</Version>
  <Image>barcodeIcons.jpg</Image>
  <WLVersion>6.1.0</WLVersion>
  <Android>
    <CordovaPlugin>
      <Name>BarcodeScanner</Name>
      <ClassName>com.phonegap.plugins.barcodescanner.BarcodeScanner</ClassName>
    </CordovaPlugin>
    <Activities>
      <XmlContent>
        <![CDATA[
          <!-- ZXing activities -->
          <activity
            android:name="com.google.zxing.client.android.CaptureActivity"
            android:screenOrientation="landscape"
            android:clearTaskOnLaunch="true"
            android:configChanges="orientation|keyboardHidden"
            android:theme="@android:style/Theme.NoTitleBar.Fullscreen"
            android:windowSoftInputMode="stateAlwaysHidden"
            android:exported="false">
            <intent-filter>
              <action android:name="com.phonegap.plugins.barcodescanner.SCAN"/>
              <category android:name="android.intent.category.DEFAULT"/>
            </intent-filter>
          </activity>
          <activity
            android:name="com.google.zxing.client.android.encode.EncodeActivity"
            android:label="@string/share_name">
            <intent-filter>
              <action android:name="com.phonegap.plugins.barcodescanner.ENCODE"/>
              <category android:name="android.intent.category.DEFAULT"/>
            </intent-filter>
          </activity>
          <activity
            android:name="com.google.zxing.client.android.HelpActivity"
            android:label="@string/share_name">
            <intent-filter>
              <action android:name="android.intent.action.VIEW"/>
              <category android:name="android.intent.category.DEFAULT"/>
            </intent-filter>
          </activity>
        ]]>
      </XmlContent>
    </Activities>
  </Android>
</ComponentData>
```

```

        </activity>
    ]]>
</XmlContent>
</Activities>
</Android>
</ComponentData>

```

Automation

When a component that includes this element is added to a MobileFirst project, the AndroidManifest.xml file of the MobileFirst project is automatically updated to reflect the activities information. The following example shows an updated AndroidManifest.xml file:

```

<!--BEGIN ANDROID AUTOINSERTION FOR BarCodeScannerUniqueID -->
<!--ZXing activities -->
<activity android:clearTaskOnLaunch="true" android:configChanges="orientation/keyboard+hidden" ...>
    <intent-filter>
        <action android:name="com.phonegap.plugins.barcodescanner.SCAN"/>
        <category android:name="android.intent.category.DEFAULT"/>
    </intent-filter>
</activity>
<activity android:label="@string/share_name" android:name="com.google.zxing.client.android.encode ...>
    <intent-filter>
        <action android:name="com.phonegap.plugins.barcodescanner.ENCODE"/>
        <category android:name="android.intent.category.DEFAULT"/>
    </intent-filter>
</activity>
<activity android:label="@string/share_name" android:name="..." ...>
    <intent-filter>
        <action android:name="android.intent.action.VIEW"/>
        <category android:name="android.intent.category.DEFAULT"/>
    </intent-filter>
</activity>
<!--END ANDROID ACTIVITY AUTOINSERTION FOR BarCodeScannerUniqueID -->

```

UserPermissions element:

This element enables you to add information about user permissions to the application component. The information controls end-user access to the native functions of a device, such as its camera or GPS functions.

Element name

```
<UserPermissions>
```

Parameters

Table 8-45. UserPermissions elements

Element	Description	Occurrences
permission	Android-specific permission constant.	1..∞

Environments supported

- Android

Example

```

<ComponentData>
    <ID>BarCodeScannerUniqueID</ID>
    <Name>Barcode Scanner Android</Name>

```

```

<Author>IBM</Author>
<Description>Barcode Scanner for Android by IBM</Description >
<Version>1.0.0</Version>
<Image>barcodeIcons.jpg</Image>
<WLVersion>6.1.0</WLVersion>
<Android>
  <UserPermissions>
    <permission>android.permission.CAMERA</permission>
    <permission>android.permission.FLASHLIGHT</permission>
  </UserPermissions>
</Android>
</ComponentData>

```

Automation

When an application component that includes this element is added to a MobileFirst project, the `AndroidManifest.xml` file of the MobileFirst project is automatically updated to reflect the user permission information. The following example shows an `AndroidManifest.xml` file that is updated with user permission information:

```

<!--BEGIN ANDROID USER-PERMISSION AUTOINSERTION FOR BarCodeScannerUniqueID -->
<uses-permission android:name="android.permission.CAMERA"/>
<uses-permission android:name="android.permission.FLASHLIGHT"/>
<!--END ANDROID USER-PERMISSION AUTOINSERTION FOR BarCodeScannerUniqueID -->

```

Receivers element:

This element enables you to add information about broadcast receivers to the application component. The information is declared in the Android manifest file in any MobileFirst project that imports the component.

Element name

```
<Receivers>
```

Parameters

Table 8-46. Receivers elements

Element	Description	Occurrences
XmlContent	XML content of the broadcast receiver information that must be placed in the Android manifest file. You can specify one or more receiver elements within the XmlContent element to be appended.	1

Environments supported

- Android

Example

```

<ComponentData>
  <ID>BarCodeScannerUniqueID</ID>
  <Name>Barcode Scanner Android</Name>
  <Author>IBM</Author>
  <Description>Barcode Scanner for Android by IBM</Description >
  <Version>1.0.0</Version>

```

```

<Image>barcodeIcons.jpg</Image>
<WLVersions>6.1.0</WLVersions>
<Android>
  <Receivers>
    <XmlContent>
      <![CDATA[
        <receiver android:name="com.phonegap.plugin.localnotification.AlarmReceiver">
        </receiver>
        <receiver android:name="com.phonegap.plugin.localnotification.AlarmRestoreOnBoot" >
          <intent-filter>
            <action android:name="android.intent.action.BOOT_COMPLETED" />
          </intent-filter>
        </receiver>
      ]]>
    </XmlContent>
  </Receivers>
</Android>
</ComponentData>

```

Automation

When an application component that includes this element is added to a MobileFirst project, the AndroidManifest.xml file of the MobileFirst project is automatically updated to reflect the broadcast receiver information. The following example shows an AndroidManifest.xml file that is updated with broadcast receivers information:

```

<!--BEGIN ANDROID RECEIVER AUTOINSERTION FOR BarCodeScannerUniqueID -->
  <receiver android:name="com.phonegap.plugin.localnotification.AlarmReceiver">
  </receiver>
  <receiver android:name="com.phonegap.plugin.localnotifisation.AlarmRestoreOnBoot">
    <intent-filter>
      <action android:name="android.intent.action.BOOT_COMPLETED"/>
    </intent-filter>
  </receiver>
<!--END ANDROID RECEIVER AUTOINSERTION FOR BarCodeScannerUniqueID -->

```

Strings element:

This element enables you to add information about strings to the application component. The information is declared in the android/native/res/values/strings.xml file in any MobileFirst project that adds the application component.

Element name

```
<Strings>
```

Parameters

Table 8-47. Strings inner elements

Element	Description	Occurrences
XmlContent	The XML content of the string information that needs to be placed in the android/native/res/values/strings.xml file. You can specify one or more string elements within the XmlContent element to be appended.	1

Environments supported

- Android

Example

```
<ComponentData>
  <ID>BarCodeScannerUniqueID</ID>
  <Name>Barcode Scanner Android</Name>
  <Author>IBM</Author>
  <Description>Barcode Scanner for Android by IBM</Description >
  <Version>1.0.0</Version>
  <Image>barcodeIcons.jpg</Image>
  <WLVersion>6.1.0</WLVersion>
  <Android>
    <Strings>
      <XmlContent>
        <![CDATA[
          <string name="app_picker_name">Applications</string>
          <string name="bookmark_picker_name">Bookmarks</string>
          <string name="button_add_calendar">Add to calendar</string>
        ]]>
      </XmlContent>
    </Strings>
  </Android>
</ComponentData>
```

Automation

When a component that includes this element is added to a MobileFirst project, the android/native/res/values/strings.xml file of the project is automatically updated to reflect the strings information. The following example shows an updated strings.xml file:

```
<!--BEGIN ANDROID STRING AUTOINSERTION FOR BarCodeScannerUniqueID -->
  <string name="app_picker_name">Applications</string>
  <string name="bookmark_picker_name">Bookmarks</string>
  <string name="button_add_calendar">Add to calendar</string>
<!--END ANDROID STRING AUTOINSERTION FOR BarCodeScannerUniqueID -->
```

Libraries element (Android):

This element enables you to add required libraries to the application component. The libraries are added to the android\native\libs folder in any MobileFirst project that imports the component.

Element name

```
<Libraries>
```

Parameters

Table 8-48. Libraries elements

Element	Description	Occurrences
Path	Path to the archive file relative to the root location of the application component. The libraries should be kept only in the COMPONENT_DATA folder.	1..∞

Note: Do not copy libraries to the ExternalProject folder.

Environments supported

- Android

Example

```
<ComponentData>
  <ID>BarCodeScannerUniqueID</ID>
  <Name>Barcode Scanner Android</Name>
  <Author>IBM</Author>
  <Description>Barcode Scanner for Android by IBM</Description >
  <Version>1.0.0</Version>
  <Image>barcodeIcons.jpg</Image>
  <WLVersion>6.1.0</WLVersion>
  <Android>
    <Libraries>
      <Path>zxing.jar</Path>
    </Libraries>
  </Android>
</ComponentData>
```

Automation

When an application component that includes this element is added to a MobileFirst project, the `android\native\libs` folder of the MobileFirst project is automatically updated to reflect the dependent libraries information. Figure 8-64 shows an updated `android\native\libs` folder based on the example `<Libraries>` element.

Figure 8-64. Example of updated `libs` folder

ExternalLibraries element:

This element enables you to add information about external libraries to the application component. The information provides pointers to external libraries that are to be downloaded by the developer who adds the application component to a MobileFirst project. Typically, these libraries are additional libraries that are not packaged as part of the application component.

Element name

```
<ExternalLibraries>
```

Parameters

Table 8-49. `ExternalLibraries` elements

Element	Description	Occurrences
URL	URL from where the external library can be retrieved.	1
Message	Instructional message about addition of external libraries that need to be displayed to the developer after importing the component.	1

Environments supported

- Android

Example

```
<ComponentData>
  <ID>BarCodeScannerUniqueID</ID>
  <Name>Barcode Scanner Android</Name>
  <Author>IBM</Author>
  <Description>Barcode Scanner for Android by IBM</Description >
  <Version>1.0.0</Version>
  <Image>barcodeIcons.jpg</Image>
  <WLVersion>6.1.0</WLVersion>
  <Android>
    <ExternalLibraries>
      <URL>http://get-library-here.com</URL >
      <Message>Please download VeryUsefullLibrary and copy into the native folder of your project</Message>
    </ExternalLibraries>
  </Android>
</ComponentData>
```

Automation

When an application component that includes this element is added to a MobileFirst project, a dialog box displays the specified message.

Files element:

This element enables you to add information about files that are required for the application component to work. These files are required by the native project of iPhone or iPad. The information specifies files that need to be added to the Xcode project in a MobileFirst project. The information is displayed as a list in a dialog box whenever a developer adds the application component to a MobileFirst project. The files are not actually copied; instead, the developer is prompted to copy them.

Element name

<Files>

Parameters

Table 8-50. Files elements

Element	Description	Occurrences
file	Name of each file.	1..∞

Note: The dialog box only displays the list of files to be added to the XCode project. These files must be added manually to the XCode project. The files must be included as part of the application component.

Environments supported

- iPhone
- iPad

Example

```
<ComponentData>
  <ID>BarCodeScannerUniqueID</ID>
  <Name>Barcode Scanner Android</Name>
  <Author>IBM</Author>
  <Description>Barcode Scanner for Android by IBM</Description >
  <Version>1.0.0</Version>
  <Image>barcodeIcons.jpg</Image>
  <WLVersion>6.1.0</WLVersion>
  <IPhone>
    <Files>
      <file>CDVBarcodeScanner.mm</file>
      <file>zxing-all-in-one.cpp</file>
    </Files>
  </IPhone>
</ComponentData>
```

Automation

When a component that includes this element is added to a MobileFirst project, a dialog box displays a message prompting the developer to add the listed files to the Xcode project manually.

Note: Automatic modification of Xcode projects after adding components is currently not supported.

Libraries element (iPhone and iPad):

This element enables you to add information about libraries to be added to the application component. The information specifies libraries that need to be added to the Xcode project in a MobileFirst project. The information is displayed as a list in a dialog box whenever a developer imports the application component into a MobileFirst project.

Element name

```
<Libraries>
```

Parameters

Table 8-51. Libraries elements

Element	Description	Occurrences
library	Name of each library.	1..∞

Note: The dialog box only displays the list of libraries to be added to the XCode project. These libraries must be added manually to the XCode project.

Environments supported

- iPhone
- iPad

Example

```
<ComponentData>
  <ID>BarCodeScannerUniqueID</ID>
  <Name>Barcode Scanner Android</Name>
  <Author>IBM</Author>
  <Description>Barcode Scanner for Android by IBM</Description >
```

```

<Version>1.0.0</Version>
<Image>barcodeIcons.jpg</Image>
<WLVersion>6.1.0</WLVersion>
<IPhone>
  <Libraries>
    <library>CoreVideo.framework</library>
    <library>AVFoundation.framework</library>
  </Libraries>
</IPhone>
</ComponentData>

```

Automation

When a component that includes this element is added to a MobileFirst project, a dialog box displays a message prompting the developer to add the listed libraries to the Xcode project manually.

Note: Automatic modification of Xcode projects after adding components is currently not supported.

Validating application components

After creating an application component and adding hooks, you must validate the component.wcp file to ensure that it conforms to the correct syntax.

About this task

Follow this procedure to validate the component.wcp file.

Procedure

1. Import the application component into a MobileFirst project. The component.wcp file is validated during import.
2. Look for error messages in the MobileFirst Operations Console. The following example error message indicates that the `ClassName` parameter is not specified in the `CordovaPlugin` element:

```

Component = BarcodeScannerIOS.wlc
Found component.wcp
In component.wcp, one or more property values(s) are empty/invalid. For details, see below:
Reason:cvc-complex-type.2.4.b: the content of element 'CordovaPlugin' is not complete.
One of '{ClassName}' is expected.

```

3. Correct the errors by using information in the message text and by referring to the topics under “Adding hooks to an application component” on page 8-401 that describe the syntax.

Adding application components to MobileFirst projects

After you have created and validated application components, you can add them to your MobileFirst projects.

Before you begin

Before you add application components, you need to complete the following tasks:

1. Create a MobileFirst project with an initial hybrid application. You can only add application components to MobileFirst projects that have been created with an initial hybrid application (See “Creating MobileFirst projects with MobileFirst Studio” on page 8-6.)
2. Set up new MobileFirst environments that the application components require. If you do not add all the required environments, error messages are displayed

when you add application components. (See “Setting up a new MobileFirst environment for your application” on page 8-58.)

Note: Adding an environment takes some time before it is deployed. Ensure that the environments you add are deployed before you proceed to the next step.

3. Copy the application component files to your download folder. (For information about specifying a download folder, see “Configuring application component and template preferences” on page 8-397.)

About this task

Automatic modification of Xcode projects after adding components is currently not supported.

Procedure

1. In the Explorer view in MobileFirst Studio, right-click the application and click **Add/Remove Application Component(s)**. The Add/Remove Application Component(s) window opens.
2. From the **Application** list, select the relevant application.
3. Select the check box for each application component you want to add, and then click **Finish**.

Results

The selected application components are added to the MobileFirst project. Each application component file is marked with the application component identifier.

Removing application components from MobileFirst projects

You can remove application components from a MobileFirst project if they are no longer required.

About this task

Automatic modification of Xcode projects after removing components is currently not supported.

Procedure

1. In the Explorer view in MobileFirst Studio, right-click the application and click **Add/Remove Application Component(s)**. The Add/Remove Application Component(s) window opens.
2. From the **Application** list, select the relevant application.
3. Clear **In Use** for each application component you want to remove, and then click **Finish**. In some cases, an information message might be displayed, or you might be prompted to confirm that you want to remove an application component.

Results

The application component files are removed from the MobileFirst project, and the project is restored to its former state.

Troubleshooting adding and removing application components

Whenever you add or remove an application component, the existing MobileFirst project files are backed up.

The backup of each original file is named `<orig filename>.backup_<add/remove>_<component id>_<date and time>`, where:

- `<orig filename>` is the full name of the file being modified (for example, `AndroidManifest.xml`).
- `<add/remove>` is the word “add” or the word “remove” according to the operation being performed.
- `<component id>` is the ID of the component being added or removed.
- `<date and time>` is the timestamp of the operation in the format `YYYYMMDD_HHMMSS`.

For example, when adding the barcode scanner for the Android component, the file `config.xml` is backed up to `config.xml.backup_add_BarCodeScannerUniqueID_20131015_190032`.

MobileFirst project templates

MobileFirst project templates enable you to accelerate the development of applications by not having to start from scratch. You can use MobileFirst project templates to provide value added services and you can add elements that are consistent with the look and feel of your brand.

Creating MobileFirst project templates

You can create MobileFirst project templates by exporting MobileFirst projects. You define metadata information such as the name of the template, and you select the MobileFirst project that you want to use as the basis for the template.

Before you begin

If you want to identify the source code that can be configured by developers who use the MobileFirst project template, add FIX Me task tags in the configurable source code before you create a template.

About this task

The following limitations apply:

- Only hybrid MobileFirst projects can be used as a basis for MobileFirst project templates.
- You can create MobileFirst project templates only from MobileFirst projects that contain single applications.

Procedure

1. From the Explorer view In MobileFirst Studio, right-click the required MobileFirst project, and then click **Export**.
2. Expand **IBM MobileFirst**, select **MobileFirst Project Template**, and then click **Next**.
3. Provide information in the fields listed in the following table, and then click **Finish**:

Table 8-52. MobileFirst project template metadata

Field	Description
Template Name	Name of the MobileFirst project template. Spaces are allowed.
Author	Author or provider of the MobileFirst project template.
Description	Brief description of the MobileFirst project template.
Thumbnail	Thumbnail image to identify the MobileFirst project template. Valid file formats: .jpg, .jpeg, .png, .gif. Maximum size: 40x40 pixels.
Template Archive	Location and filename of the template. Valid filename extensions: .wlt and .zip.

Results

The MobileFirst project template is created with the location and filename you specified.

Viewing MobileFirst project templates

You can open a MobileFirst project template to view its contents by using a file compression tool.

The MobileFirst project template contains folders taken from the MobileFirst project on which it is based, as well as a mandatory TEMPLATE-DATA folder.

Note: Do not modify the contents of the TEMPLATE-DATA folder.

The TEMPLATE-DATA folder contains the following files:

- The thumbnail image file that was selected when the MobileFirst project template was created.
- A template properties file named `template.properties`, which contains the metadata information that was specified when the MobileFirst project template was created.

The following contents are present in the `template.properties` file:

- Template title
- IBM MobileFirst Platform Foundation version used to create the template
- Template ID
- Template author
- Template description
- Template thumbnail
- IBM MobileFirst Platform Foundation version number

The following example shows the contents of a typical `template.properties` file:

```
title=Simple RSS Reader
wl_version=6.1.0.
id=RSS-09e1ac62-5c34-432e-8597-c6349eade74c
```

author=IBM
description=Displays entries from an RSS feed (www.example.com). The user can click an entry to read the contents without leaving the app.
image=rss_reader3.png

Creating MobileFirst projects from MobileFirst project templates

You can use MobileFirst project templates to create MobileFirst projects. You can select templates that are available in your download folder.

Before you begin

If the owner of a MobileFirst project template has provided FIXME tasks, they are displayed in the Tasks tab. To view them, you need to enable the FIXME tasks view:

1. In MobileFirst Studio, click **Project > Properties > General > Editors > Structured Text Editors > Task Tags**.
2. Click **Enable searching for Task Tags**.
3. Click **Apply > OK**. The Task tab is displayed. When you create a MobileFirst project from a MobileFirst project template, the Task tab lists any FIX Me tasks to be completed.

Procedure

1. In MobileFirst Studio, click **File > New > MobileFirst Project**. The New MobileFirst Project window opens.
2. In the **Name** field, enter a name for the MobileFirst project.
3. From the **Project Templates** pane, click **Shared Templates**, and then click **Next**. For information about the Hybrid Application, Inner Application, Native API, and Shell Component options, see “Creating MobileFirst projects with MobileFirst Studio” on page 8-6.
4. In the **Application name** field, enter a name for your application, and then click one of the templates available from the list. The list displays templates available in the download folder. (For information about configuring the download folder, see “Configuring application component and template preferences” on page 8-397.)
5. To complete the creation of the MobileFirst project from the highlighted project template, click **Finish**. The Design perspective is opened. The Tasks view shows the FIX Me tasks available (if any) within the template content. Links are provided to positions within the template, and accompanying descriptions explain what is configurable.
6. Optional: Review the list of FIX Me tasks available in the Tasks view, and apply any appropriate fixes.

Results

The new MobileFirst project is added to the Explorer view in MobileFirst Studio. The project includes all resources that are included in the selected template.

JSONStore

Learn about JSONStore.

JSONStore overview

JSONStore features add the ability to store JSON documents in MobileFirst applications.

JSONStore is a lightweight, document-oriented storage system that is included as a feature of IBM MobileFirst Platform Foundation, and enables persistent storage of JSON documents. Documents in an application are available in JSONStore even when the device that is running the application is offline. This persistent, always-available storage can be useful for customers, employees, or partners, to give them access to documents when, for example, there is no network connection to the device.

For JSONStore API reference information for hybrid applications, see `WL.JSONStore` in the API reference section. Hybrid applications are supported for iOS, Android, Windows 8, and Windows 8 Phone.

For JSONStore API reference information for native iOS applications, see the `JSONStore Class Reference` in the API reference section.

For JSONStore API reference information for native Android applications, see the `com.worklight.jsonstore.api Package` in the API reference section.

Here is a high-level summary of what JSONStore provides:

- A developer-friendly API that gives developers the ability to populate the local store with documents, and to update, delete, and search across documents.
- Persistent, file-based storage matches the scope of the application.
- AES 256 encryption of stored data provides security and confidentiality. You can segment protection by user with password-protection, in the case of more than one user on a single device.
- Ability to keep track of local changes.

A single store can have many collections, and each collection can have many documents. It is also possible to have a MobileFirst application that contains multiple stores. For information, see “JSONStore multiple user support” on page 8-456.

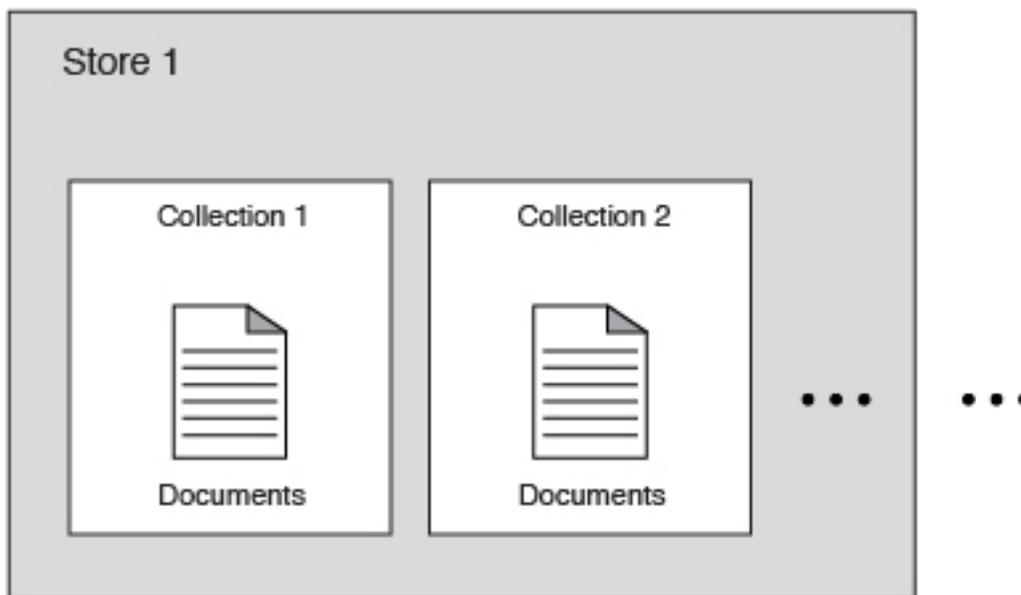

Figure 8-65. A basic graphic representation of JSONStore.

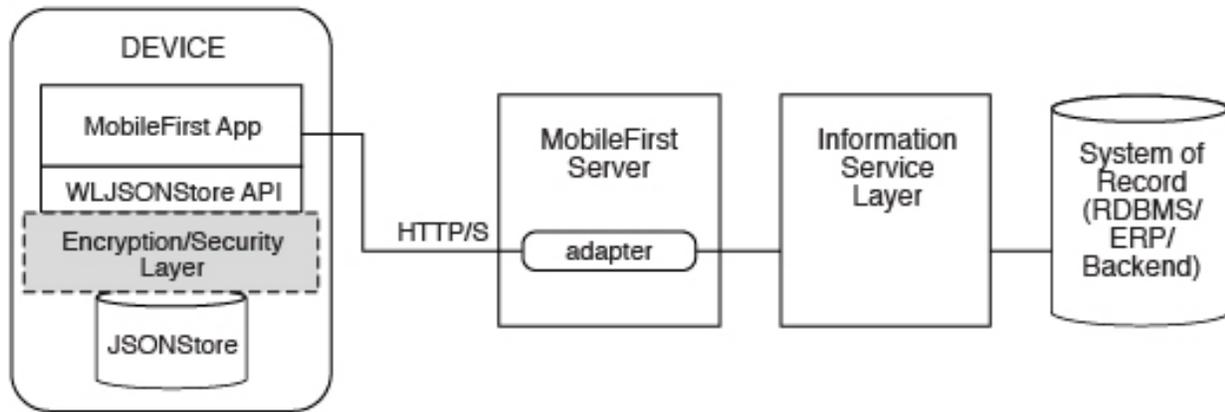

Figure 8-66. Components and their interaction with the server when you use JSONStore for data synchronization.

Note: Because it is familiar to developers, relational database terminology is used in this documentation at times to help explain JSONStore. There are many differences between a relational database and JSONStore however. For example, the strict schema that is used to store data in relational databases is different from JSONStore's approach. With JSONStore, you can store any JSON content, and index the content that you need to search.

Features table

Compare JSONStore features to those features of other data storage technologies and formats.

JSONStore is a JavaScript API for storing data inside hybrid MobileFirst applications, an Objective-C API for native iOS applications, and a Java API for native Android applications. For reference, here is a comparison of different JavaScript storage technologies to see how JSONStore compares to them.

JSONStore is similar to technologies such as LocalStorage, Indexed DB, Cordova Storage API, Cordova File API, and MobileFirst Encrypted Cache. The table shows how some features that are provided by JSONStore compare with other technologies. The JSONStore feature is only available on iOS and Android devices and simulators.

Table 8-53. A comparison of data storage technologies..

	JSONStore	Encrypted Cache	LocalStorage	IndexedDB	Cordova Storage	Cordova File
Android Support (Hybrid & Native Applications)	△	△	△	△	△	△
iOS Support (Hybrid & Native Applications)	△	△	△	△	△	△

Table 8-53. A comparison of data storage technologies. (continued).

	JSONStore	Encrypted Cache	LocalStorage	IndexedDB	Cordova Storage	Cordova File
Windows 8 and Windows 8 Phone Support	⊕	⊕	⊕	⊕	-	⊕
Web	<i>Dev Only</i> (See Note 1)	⊕	⊕	⊕	-	-
Data encryption	⊕	⊕	-	-	-	-
Maximum Storage	Available Space	~5 MB	~5 MB	>5 MB	Available Space	Available Space
Reliable Storage (See Note 2)	⊕	-	-	-	⊕	⊕
Keep Track of Local Changes	⊕	-	-	-	-	-
Multi-user support	⊕	-	-	-	-	-
Indexing	⊕	-	-	⊕	⊕	-
Type of Storage	JSON Documents	Key/Value Pairs	Key/Value Pairs	JSON Documents	Relational (SQL)	Strings

Note: 1. *Dev Only* means designed only for development, with no security features and a ~5 MB storage space limit.

Note: 2. *Reliable Storage* means that your data is not deleted unless one of the following events occurs:

- The application is removed from the device.
- One of the methods that removes data is called.

General JSONStore terminology

Learn about general JSONStore terminology.

JSONStore document

A document is the basic building block of JSONStore.

A JSONStore document is a JSON object with an automatically generated identifier (`_id`) and JSON data. It is similar to a record or a row in database terminology. The value of `_id` is always a unique integer inside a specific collection. Some functions like the `add`, `replace`, and `remove` methods in the `JSONStoreInstance` class take an Array of Documents/Objects. These methods are useful to perform operations on various Documents/Objects at a time.

Example

Single document

```
var doc = { _id: 1, json: {name: 'carlos', age: 99} };
```

Example

Array of documents

```
var docs = [  
  { _id: 1, json: {name: 'carlos', age: 99} },  
  { _id: 2, json: {name: 'tim', age: 100} }  
]
```

JSONStore collection

A JSONStore collection is similar to a table, in database terminology

Example

Customer collection

```
[  
  { _id: 1, json: {name: 'carlos', age: 99} },  
  { _id: 2, json: {name: 'tim', age: 100} }  
]
```

This code is not the way that the documents are stored on disk, but it is a good way to visualize what a collection looks like at a high level.

JSONStore store

A store is the persistent JSONStore file that contains one or more collections.

A store is similar to a relational database, in database terminology. A store is also referred to as a JSONStore.

JSONStore search fields

A search field is a key/value pair.

Search fields are keys that are indexed for fast lookup times, similar to column fields or attributes, in database terminology.

Extra search fields are keys that are indexed but that are not part of the JSON data that is stored. These fields define the key whose values (in the JSON collection) are indexed and can be used to search more quickly.

Valid data types are: string, boolean, number, and integer. These types are only type hints, there is no type validation. Furthermore, these types determine how indexable fields are stored. For example, {age: 'number'} will index 1 as 1.0 and {age: 'integer'} will index 1 as 1.

Examples

Search fields and extra search fields.

```
var searchField = {name: 'string', age: 'integer'};  
var additionalSearchField = {key: 'string'};
```

It is only possible to index keys inside an object, not the object itself. Arrays are handled in a pass-through fashion, meaning that you cannot index an array or a specific index of the array (`arr[n]`), but you can index objects inside an array.

Indexing values inside an array.

```
var searchFields = {
    'people.name' : 'string', // matches carlos and tim on myObject
    'people.age' : 'integer' // matches 99 and 100 on myObject
};

var myObject = {
    people : [
        {name: 'carlos', age: 99},
        {name: 'tim', age: 100}
    ]
};
```

JSONStore queries

Queries are objects that use search fields or extra search fields to look for documents.

The example presumes that the name search field is of type string and the age search field is of type integer.

Examples

Find documents with name that matches carlos:

```
var query1 = {name: 'carlos'};
```

Find documents with name that matches carlos and age matches 99:

```
var query2 = {name: 'carlos', age: 99};
```

JSONStore query parts

Query parts are used to build more advanced searches. Some JSONStore operations, such as some versions of `find` or `count` take query parts. Everything within a query part is joined by AND statements, while query parts themselves are joined by OR statements. The search criteria returns a match only if everything within a query part is true. You can use more than one query part to search for matches that satisfy one or more of the query parts.

Find with query parts operate only on top-level search fields. For example: `name`, and not `name.first`. Use multiple collections where all search fields are top-level to get around this. The query parts operations that work with non top-level search fields are: `equal`, `notEqual`, `like`, `notLike`, `rightLike`, `notRightLike`, `leftLike`, and `notLeftLike`. The behavior is undetermined if you use non-top-level search fields.

Enabling JSONStore

To use JSONStore in IBM Worklight V6.0 and later, you must take steps to enable it.

About this task

If you are using IBM MobileFirst Platform Foundation without the latest interim fix installed, you can import the `JSONStore.h` header file to use the JSONStore API

in a native MobileFirst iOS application. For more information about creating native MobileFirst iOS applications, see “Developing native applications for iOS” on page 8-185.

After you install the latest interim fix of IBM MobileFirst Platform Foundation, JSONStore becomes an optional feature for native MobileFirst iOS applications. To use JSONStore in a native MobileFirst iOS application, you must import the `<IBMMobileFirstPlatformFoundationJSONStore/IBMMobileFirstPlatformFoundationJSONStore.h>` umbrella header file. You can obtain the JSONStore feature in two ways:

- You can import the JSONStore framework from the worklight api folder. For more information, see “Copying SDK and configuration files from the project” on page 8-190.
- You can use CocoaPods.

To use JSONStore in a native MobileFirst iOS application, you must enable it by adding the JSONStore SDK with CocoaPods. Your application must use CocoaPods for dependency management. Specifically,

- You must have CocoaPods, the dependency manager for Xcode projects, installed in your development environment. For more information, see the “Getting Started” guide for CocoaPods installation.
- Your application must be set up to use CocoaPods. For more information, see Using CocoaPods.
- You must have an existing Podfile. If one does not exist, create one by using the **pod init** command. For more information, see Using CocoaPods.

1. Create a Podfile file or edit an existing one.
 - a. Create a new file that is named Podfile and save it in the root directory of the project.
 - b. Open the Podfile file that is in the root directory of the project with a text editor.
 - c. Add the following lines and save the file:

```
source 'https://github.com/CocoaPods/Specs.git'  
pod 'IBMMobileFirstPlatformFoundationJSONStore'
```

Note: The pod example assumes you are using the latest version of the MobileFirst pod. If you are not using the latest version of MobileFirst, you need to indicate the version. For example, for importing the latest pod for 7.1.0 IBMMobileFirstPlatformFoundation the line would look like this:

```
pod 'IBMMobileFirstPlatformFoundationJSONStore', '~> 7.1.0'
```

2. Open **Terminal** and navigate to the location of the Podfile file.
3. Verify that the Xcode project is closed.
4. Type `pod install` to run the **pod install** command.

This command installs the JSONStore Framework for IBM MobileFirst Platform Foundation, called the `IBMMobileFirstPlatformFoundationJSONStore.framework` component, and integrates it with the mobile application Xcode project.

For more information about creating native MobileFirst iOS applications, see “Developing native applications for iOS” on page 8-185.

For native Android applications, you must copy the JAR files that are generated by IBM MobileFirst Platform Foundation into your application's `libs` folder. After you do so, you can use the classes inside the `com.worklight.jsonstore.api` package to

use JSONStore. For more information about creating native MobileFirst Android applications, see “Copying SDK and configuration files from the MobileFirst project” on page 8-204.

For hybrid applications, JSONStore is an optional feature in IBM Worklight V6.0 and later. To use JSONStore in a hybrid application, you must enable it by modifying the `application-descriptor.xml` file.

Note: If you are using the latest interim fix of IBM MobileFirst Platform Foundation and are upgrading your hybrid iOS application from a previous version, you must first complete the following steps.

1. Delete the existing iOS Environment (iPhone/iPad) from the hybrid project.
2. Add a new environment to the same hybrid project and select **iOS Environment (iPhone/iPad)**.

Procedure

1. Using the Application Descriptor Editor, open the file `application-descriptor.xml`
2. Click the **Design** tab.
3. Under **Overview**, expand Application *[your application's name]*.
4. Click **Optional Features**.
5. Click **Add**.
6. Select JSONStore.
7. Click **Ok**.
8. In the **Project Explorer** view, right-click the folder that is titled with your application name.
9. Click **Run As**.
10. Click **Run on MobileFirst Development Server**.

JSONStore API concepts

JSONStore provides API reference information for hybrid Android, iOS, Windows 8 Universal, and Windows Phone Silverlight 8, and native Android and iOS applications.

Store

Open and initialize a collection

Starts one or more collections. Starting or provisioning a JSONStore collection means that the persistent storage that is used to contain collections and documents is created, if it does not exist. If the store is encrypted and a correct password is passed, the required security procedures to make the data accessible are run. There is minimal effort in initializing all the collections when an application starts.

After you open a collection, an accessor to the collection is available, which gives access to collection APIs. It allows developers to call functions such as `find`, `add`, and `replace` on an initialized collection.

It is possible to initialize multiple times with different collections. New collections are initialized without affecting collections that are already initialized.

Destroy

Completely wipes data for all users, destroys the internal storage, and clears security artifacts. The destroy function removes the following data:

- All documents.
- All collections.
- All stores. For more information, see “JSONStore multiple user support” on page 8-456.
- All JSONStore metadata and security artifacts. For more information, see “JSONStore security” on page 8-453.

Close all

Locks access to all the collections in a store until the collections are reinitialized. Where initialize can be considered a login, close can be considered a logout.

Start, commit, and rollback transaction

A transaction is a set of operations that must all succeed for the operations to manipulate the store. If any operation fails, the transaction can be rolled back to revert the store to its previous state. After a transaction is started, it is important that you handle committing or rolling back your transactions to prevent excess processing. Three operations exist in the Store API for transactions:

-

Start transaction

Begin a snapshot in which the store is reverted to if the transaction fails.

-

Commit transaction

Inform the store that all operations in the transaction succeeded, and all changes can be finalized.

-

Rollback transaction

Inform the store that an operation in the transaction failed, and all changes must be discarded.

Note: Due to system limitations with multi-threaded transactions, transactions are not supported in Android 2.3.x for hybrid applications. To use transactions in a hybrid application in Android 2.3.x, you can create a Cordova plug-in that uses the native Android JSONStore API to execute the code for the transaction. The whole transaction must be done in the same thread because multi-threaded transactions do not work properly in Android 2.3.x.

Collection

Store and add a document

You can add a document or array of documents to a collection. You can also pass an array of objects (for example `[{name: 'carlos'}, {name: 'tim'}]`) instead of a single object. Every object in the array is stored as a new document inside the collection.

Remove a document

Marks one or more documents as removed from a collection. Removed documents are not returned by the find or count operations.

Find All Documents, Find Documents by Id, and Find With Query

You can find documents in a collection by their search fields and extra search fields. An internal search field, `_id`, holds a unique integer identifier that can be used to find the document (Find by Id). You can search for documents with the following APIs:

-

Find All Documents

Returns every document in a collection.

-

Find All Dirty Documents

Returns every document in a collection that is marked dirty.

-

Find by Id

Find the document with the corresponding `_id` search key value.

-

Find With Query or Query Parts

Find all documents that match a query or all query parts. For more information, see the Search Query format section at “Additional references” on page 8-426.

Filter returns what is being indexed, which might be different than what was saved to a collection. Some examples of unexpected results are:

1. If your search field has uppercase letters, the result is returned in all lowercase letters.
2. If you pass something that is not a string, it is indexed as a string. For example, 1 is '1', 1.0 is '1.0', true is '1', and false is '0'.
3. If your filter criteria includes non top-level search fields, you might get a single string with all the terms that are joined by a special identifier (-@-). For example, 'carlos-@-mike-@-dgonz'.

Replace a document and change documents

You can use the Replace API to replace the contents of a document in the collection with new data, which is based on the `_id`. If the data contains the `_id` field of a document in the database, the document is replaced with the data and all search fields are reindexed for that document.

The Change API is similar to the Replace API, but the Replace is based on a set of search field criteria instead of `_id`. The Replace API can be emulated by performing the Change API with the search field criteria of only `_id`. All search fields in the search field criteria must exist in the documents in the store, and in the data that is passed to the Change API.

Count All Documents, Count All Dirty Documents, and Count With Query

The Count API returns an integer number by counting the total number of documents that match the query. There are three Count APIs:

-

Count All Documents

Give the total count of all documents in the collection.

-

Count All Dirty Documents

Give the total number of documents in the collection that are currently marked dirty.

-

Count With Query or Query Parts

Give the total number of documents that match a specific search query. For more information, see the Search Query format section at "Additional references."

Remove Collection and Clear Collection

Removing a collection deletes all data that is associated with a collection, and causes the collection accessor to be no longer usable.

Clearing a collection deletes all documents in the collection. This operation keeps the collection open after it completes.

Mark Clean

The Mark Clean API is used to remove the dirty flag from a document in the collection, and deletes the document completely from the collection if it was marked dirty by a remove document operation. The Mark Clean API is useful when used with the Find All Dirty Documents API to sync the collection with a remote database.

Additional references

Search Query format

When an API requires a search query, a common format is followed for the collection. A query consists of an array of objects where each key/value pair is ANDed together. Each object in the array is ORed together. For example:

```
[{fn: "Mike", age: 30}, {fn: "Carlos", age: 36}]
```

is represented as (with fuzzy search):

```
(fn LIKE "%Mike%" AND age LIKE "%30%") OR (fn LIKE "%Carlos%" AND age LIKE "%36%")
```

Search Query Parts format

The following examples use pseudocode to convey how query parts work. A query such as {name: 'carlos', age: 10} can be passed a modifier such as {exact: true}, which ensures only items that exactly match name and age are returned. Query parts give you the flexibility of adding modifiers to any part of the query. For example:

```
queryPart1 = QueryPart().like('name', 'carlos').lessThan('age', 10);
```

The previous example is transformed into something like:

```
('name' LIKE %carlos%) AND (age < 10)
```

You can also create another query part, for example:

```
queryPart2 = QueryPart().equal('name', 'mike')
```

When you add various query parts with the `find` API, for example:

```
find([queryPart1, queryPart2])
```

You get something like:

```
( ('name' LIKE %carlos%) AND (age < 10) ) OR (name EQUAL 'mike')
```

Limit and Offset

Passing a limit to an API's options restricts the number of results by the number specified. It is also possible to pass an offset to skip results by the number specified. To pass an offset, a limit must also be passed. This API is useful for implementing pagination or for optimization. By limiting the data to a subset that is necessary, the memory and processing power is reduced.

Fuzzy Search versus Exact Search

The default behavior is fuzzy searching, which means that queries return partial results. For example, the query `{name: 'carl'}` finds 'carlos' and 'carl' (for example, `name LIKE '%carl%'`). When `{exact: true}` is passed, matches are exact but not case-sensitive. For example, 'hello' matches 'Hello' (for example, `name.toLowerCase() = 'hello'`). Integer matching is not type-sensitive. For example, "1" matches both "1" and "1.0". Numbers are stored as their decimal representation. For example, "1" is stored as "1.0". Boolean values are indexed as 1 (true) and 0 (false).

Troubleshooting JSONStore

Find information to help resolve issues that you might encounter when you use the JSONStore API.

JSONStore troubleshooting overview

Find information to help resolve issues that you might encounter when you use the JSONStore API.

Provide information when you ask for help

It is better to provide more information than to risk not providing enough information. The following list is a good starting point for the information that is required to help with JSONStore issues.

- Operating system and version. For example, Windows XP SP3 Virtual Machine or Mac OSX 10.8.3.
- Eclipse version. For example, Eclipse Indigo 3.7 Java EE.
- JDK version. For example, Java SE Runtime Environment (build 1.7).
- IBM MobileFirst Platform Foundation version. For example, IBM Worklight V5.0.6 Developer Edition.
- iOS version. For example, iOS Simulator 6.1 or iPhone 4S iOS 6.0 (deprecated, see "Deprecated features and API elements" on page 3-20).

- Android version. For example, Android Emulator 4.1.1 or Samsung Galaxy Android 4.0 API Level 14.
- Windows version. For example, Windows 8, Windows 8.1, or Windows Phone 8.1.
- adb version. For example, Android Debug Bridge version 1.0.31.
- Logs, such as Xcode output on iOS or logcat output on Android.

Try to isolate the issue

Follow these steps to isolate the issue to more accurately report a problem.

1. Reset the emulator (Android) or simulator (iOS) and call the destroy API to start with a clean system.
2. Ensure that you are running on a supported production environment.
 - Android >= 2.3 ARM v7/ARM v8/x86 emulator or device
 - iOS >= 6.0 simulator or device (deprecated)
 - Windows Phone Silverlight 8.0 ARM/x86 emulator or device
 - Windows 8.0-8.1 ARM/x86/x64 simulator or device
3. Try to turn off encryption by not passing a password to the init or open APIs.
4. Look at the SQLite database file that is generated by JSONStore. Encryption must be turned off.
 - Android emulator:

```
$ adb shell
$ cd /data/data/com.<app-name>/databases/wljsonstore
$ sqlite3 jsonstore.sqlite
```

- iOS simulator:

```
$ cd ~/Library/Application Support/iPhone Simulator/7.1/Applications/<id>/Documents/wljsonstore
$ sqlite3 jsonstore.sqlite
```

- Windows Phone Silverlight 8:

```
$ cd C:\Data\Users\DefApps\AppData\<id>\Local\wljsonstore
$ sqlite3 jsonstore.sqlite
```

- Windows 8 Universal simulator

```
$ cd C:\Users\<username>\AppData\Local\Packages\<id>\LocalState\wljsonstore
$ sqlite3 jsonstore.sqlite
```

•

Note: JavaScript only implementation that runs on a web browser (Firefox, Chrome, Safari, Internet Explorer) does not use an SQLite database. The file is stores in HTML5 LocalStorage.

- Look at the searchFields with .schema and select data with SELECT * FROM <collection-name>;. To exit sqlite3, type .exit. If you pass a user name to the init method, the file is called <username>.sqlite. If you do not pass a user name, the file is called jsonstore.sqlite by default.

5. (Android only) Enable verbose JSONStore.

```
adb shell setprop log.tag.jsonstore-core VERBOSE
adb shell getprop log.tag.jsonstore-core
```

6. Use the debugger.

Common issues

Understanding the following JSONStore characteristics can help resolve some of the common issues that you might encounter.

- The only way to store binary data in JSONStore is to first encode it in base64. Store file names or paths instead of the actual files in JSONStore.
- Accessing JSONStore data from native code is possible only in IBM MobileFirst Platform Foundation V6.2.0.
- There is no limit on how much data you can store inside JSONStore, beyond limits that are imposed by the mobile operating system.
- JSONStore provides persistent data storage. It is not only stored in memory.
- The `init` API fails when the collection name starts with a digit or symbol. IBM Worklight V5.0.6.1 and later returns an appropriate error:
4 BAD_PARAMETER_EXPECTED_ALPHANUMERIC_STRING
- There is a difference between a number and an integer in search fields. Numeric values like 1 and 2 are stored as 1.0 and 2.0 when the type is number. They are stored as 1 and 2 when the type is integer.
- If an application is forced to stop or crashes, it always fails with error code -1 when the application is started again and the `init` or `open` API is called. If this problem happens, call the `closeAll` API first.
- The JavaScript implementation of JSONStore expects code to be called serially. Wait for an operation to finish before you call the next one.
- Transactions are not supported in Android 2.3.x for hybrid applications. For more information, see “JSONStore API concepts” on page 8-423.
- When you use JSONStore on a 64-bit device, you might see the following error:

```
java.lang.UnsatisfiedLinkError: dlopen failed: "... " is 32-bit instead of 64-bit
```

This error means that you have 64-bit native libraries in your Android project, and JSONStore does not currently work when you use these libraries. To confirm, go to `src/main/libs` or `src/main/jniLibs` under your Android project, and check whether you have the `x86_64` or `arm64-v8a` folders. If you do, delete these folders, and JSONStore can work again.

Store internals

See an example of how JSONStore data is stored.

The key elements in this simplified example:

- `_id` is the unique identifier (for example, AUTO INCREMENT PRIMARY KEY).
- `json` contains an exact representation of the JSON object that is stored.
- `name` and `age` are search fields.
- `key` is an extra search field.

Example

Table 8-54. Contents of a store in JSONStore

<code>_id</code>	<code>key</code>	<code>name</code>	<code>age</code>	<code>JSON</code>
1	c	carlos	99	{name: 'carlos', age: 99}
2	t	time	100	{name: 'tim', age: 100}

When you search by using one of the following queries or a combination of them: `{_id : 1}`, `{name: 'carlos'}`, `{age: 99}`, `{key: 'c'}`, the returned document is `{_id: 1, json: {name: 'carlos', age: 99} }`.

The other internal JSONStore fields are:

`_dirty`

Determines whether the document was marked as dirty or not. This field is useful to track changes to the documents. For more information, see “JSONStore API concepts” on page 8-423 or “Work with external data” on page 8-459.

`_deleted`

Marks a document as deleted or not. This field is useful to remove objects from the collection, to later use them to track changes with your backend and decide whether to remove them or not.

`_operation`

A string that reflects the last operation to be performed on the document (for example, replace).

JSONStore errors

Learn about JSONStore errors.

Possible JSONStore error codes that are returned are listed in “JSONStore error codes” on page 8-431.

JavaScript

JSONStore uses an error object to return messages about the cause of failures.

When an error occurs during a JSONStore operation (for example the find, and add methods in the JSONStoreInstance class) an error object is returned. It provides information about the cause of the failure.

Example

```
var errorObject = {
  src: 'find', // Operation that failed.
  err: -50, // Error code.
  msg: 'PERSISTENT_STORE_FAILURE', // Error message.
  col: 'people', // Collection name.
  usr: 'jsonstore', // User name.
  doc: { _id: 1, {name: 'carlos', age: 99}}, // Document that is related to the failure.
  res: {...} // Response from the server.
}
```

Not all the key/value pairs are part of every error object. For example, the doc value is only available when the operation failed because of a document (for example the remove method in the JSONStoreInstance class) failed to remove a document.

Objective-C

All of the APIs that might fail take an error parameter that takes an address to an NSError object. If you don not want to be notified of errors, you can pass in nil. When an operation fails, the address is populated with an NSError, which has an error and some potential userInfo. The userInfo might contain extra details (for example, the document that caused the failure).

Example

```
// This NSError points to an error if one occurs.
NSError* error = nil;

// Perform the destroy.
[JSONStore destroyDataAndReturnError:&error];
```

Java

All of the Java API calls throw a certain exception, depending on the error that happened. You can either handle each exception separately, or you can catch `JSONStoreException` as an umbrella for all `JSONStore` exceptions.

Example

```
try {
    WL.JSONStore.closeAll();
}

catch(JSONStoreException e) {
    // Handle error condition.
}
```

JSONStore error codes

Definitions of the error codes that are related to `JSONStore`.

-100 UNKNOWN_FAILURE

Unrecognized error.

-75 OS_SECURITY_FAILURE

This error code is related to the `requireOperatingSystemSecurity` flag. It can occur if the `destroy` API fails to remove security metadata that is protected by operating system security (Touch ID with passcode fallback), or the `init` or `open` APIs are unable to locate the security metadata. It can also fail if the device does not support operating system security, but operating system security usage was requested.

-50 PERSISTENT_STORE_NOT_OPEN

`JSONStore` is closed. Try calling the `open` method in the `JSONStore` class first to enable access to the store.

-48 TRANSACTION_FAILURE_DURING_ROLLBACK

There was a problem with rolling back the transaction.

-47 TRANSACTION_FAILURE_DURING_REMOVE_COLLECTION

Cannot call `removeCollection` while a transaction is in progress.

-46 TRANSACTION_FAILURE_DURING_DESTROY

Cannot call `destroy` while there are transactions in progress.

-45 TRANSACTION_FAILURE_DURING_CLOSE_ALL

Cannot call `closeAll` while there are transactions in place.

-44 TRANSACTION_FAILURE_DURING_INIT

Cannot initialize a store while there are transactions in progress.

-43 TRANSACTION_FAILURE

There was a problem with transactions.

-42 NO_TRANSACTION_IN_PROGRESS

Cannot commit to rolled back a transaction when there is no transaction in progress.

- 41 **TRANSACTION_IN_PROGRESS**
Cannot start a new transaction while another transaction is in progress.
- 40 **FIPS_ENABLEMENT_FAILURE**
Something is wrong with FIPS. See the tutorial on the Getting Started page.
- 24 **JSON_STORE_FILE_INFO_ERROR**
Problem getting the file information from the file system.
- 23 **JSON_STORE_REPLACE_DOCUMENTS_FAILURE**
Problem replacing documents from a collection.
- 22 **JSON_STORE_REMOVE_WITH_QUERIES_FAILURE**
Problem removing documents from a collection.
- 21 **JSON_STORE_STORE_DATA_PROTECTION_KEY_FAILURE**
Problem storing the Data Protection Key (DPK).
- 20 **JSON_STORE_INVALID_JSON_STRUCTURE**
Problem indexing input data.
- 12 **INVALID_SEARCH_FIELD_TYPES**
Check that the types that you are passing to the searchFields are **stringinteger,number, orboolean**.
- 11 **OPERATION_FAILED_ON_SPECIFIC_DOCUMENT**
An operation on an array of documents, for example the replace method can fail while it works with a specific document. The document that failed is returned and the transaction is rolled back. On Android, this error also occurs when trying to use JSONStore on unsupported architectures.
- 10 **ACCEPT_CONDITION_FAILED**
The accept function that the user provided returned false.
- 9 **OFFSET_WITHOUT_LIMIT**
To use offset, you must also specify a limit.
- 8 **INVALID_LIMIT_OR_OFFSET**
Validation error, must be a positive integer.
- 7 **INVALID_USERNAME**
Validation error (Must be [A-Z] or [a-z] or [0-9] only).
- 6 **USERNAME_MISMATCH_DETECTED**
To log out, a JSONStore user must call the closeAll method first. There can be only one user at a time.
- 5 **DESTROY_REMOVE_PERSISTENT_STORE_FAILED**
A problem with the destroy method while it tried to delete the file that holds the contents of the store.
- 4 **DESTROY_REMOVE_KEYS_FAILED**
Problem with the destroy method while it tried to clear the keychain (iOS) or shared user preferences (Android).
- 3 **INVALID_KEY_ON_PROVISION**
Passed the wrong password to an encrypted store.
- 2 **PROVISION_TABLE_SEARCH_FIELDS_MISMATCH**
Search fields are not dynamic. It is not possible to change search fields without calling the destroy method or the removeCollection method before you call the init or openmethod with the new search fields. This error can occur if you change the name or type of the search field. For example: {key: 'string'} to {key: 'number'} or {myKey: 'string'} to {theKey: 'string'}.

- 1 PERSISTENT_STORE_FAILURE**
Generic Error. A malfunction in native code, most likely calling the `init` method.
- 0 SUCCESS**
In some cases, JSONStore native code returns 0 to indicate success.
- 1 BAD_PARAMETER_EXPECTED_INT**
Validation error.
- 2 BAD_PARAMETER_EXPECTED_STRING**
Validation error.
- 3 BAD_PARAMETER_EXPECTED_FUNCTION**
Validation error.
- 4 BAD_PARAMETER_EXPECTED_ALPHANUMERIC_STRING**
Validation error.
- 5 BAD_PARAMETER_EXPECTED_OBJECT**
Validation error.
- 6 BAD_PARAMETER_EXPECTED_SIMPLE_OBJECT**
Validation error.
- 7 BAD_PARAMETER_EXPECTED_DOCUMENT**
Validation error.
- 8 FAILED_TO_GET_UNPUSHED_DOCUMENTS_FROM_DB**
The query that selects all documents that are marked dirty failed. An example in SQL of the query would be: `SELECT * FROM [collection] WHERE _dirty > 0`.
- 9 NO_ADAPTER_LINKED_TO_COLLECTION**
To use functions like the `push` and `load` methods in the `JSONStoreCollection` class, an adapter must be passed to the `init` method.
- 10 BAD_PARAMETER_EXPECTED_DOCUMENT_OR_ARRAY_OF_DOCUMENTS**
Validation error
- 11**
INVALID_PASSWORD_EXPECTED_ALPHANUMERIC_STRING_WITH_LENGTH_GREATER_THAN_ZERO
Validation error
- 12 ADAPTER_FAILURE**
Problem calling `WL.Client.invokeProcedure`, specifically a problem in connecting to the MobileFirst Server adapter. This error is different from a failure in the adapter that tries to call a backend.
- 13 BAD_PARAMETER_EXPECTED_DOCUMENT_OR_ID**
Validation error
- 14 CAN_NOT_REPLACE_DEFAULT_FUNCTIONS**
Calling the `enhance` method in the `JSONStoreCollection` class to replace an existing function (`find` and `add`) is not allowed.
- 15 COULD_NOT_MARK_DOCUMENT_PUSHED**
Push sends the document to an adapter but JSONStore fails to mark the document as not dirty.
- 16 COULD_NOT_GET_SECURE_KEY**
To initiate a collection with a password there must be connectivity to the MobileFirst Server because it returns a 'secure random token'. IBM Worklight 5.0.6 and later allows developers to generate the secure random token locally passing `{localKeyGen: true}` to the `init` method via the options object.

- 17 FAILED_TO_LOAD_INITIAL_DATA_FROM_ADAPTER**
Could not load data because `WL.Client.invokeProcedure` called the failure callback.
- 18 FAILED_TO_LOAD_INITIAL_DATA_FROM_ADAPTER_INVALID_LOAD_OBJ**
The load object that was passed to the `init` method did not pass the validation.
- 19 INVALID_KEY_IN_LOAD_OBJECT**
There is a problem with the key used in the load object when you call the `add` method.
- 20 UNDEFINED_PUSH_OPERATION**
No procedure is defined for pushing dirty documents to the server. For example: the `init` method (new document is dirty, `operation = 'add'`) and the `push` method (finds the new document with `operation = 'add'`) were called, but no `add` key with the `add` procedure was found in the adapter that is linked to the collection. Linking an adapter is done inside the `init` method.
- 21 INVALID_ADD_INDEX_KEY**
Problem with extra search fields.
- 22 INVALID_SEARCH_FIELD**
One of your search fields is invalid. Verify that none of the search fields that are passed in are `_id`, `json`, `deleted`, or `_operation`.
- 23 ERROR_CLOSING_ALL**
Generic Error. An error occurred when native code called the `closeAll` method.
- 24 ERROR_CHANGING_PASSWORD**
Unable to change the password. The old password passed was wrong, for example.
- 25 ERROR_DURING_DESTROY**
Generic Error. An error occurred when native code called the `destroy` method.
- 26 ERROR_CLEARING_COLLECTION**
Generic Error. An error occurred in when native code called the `removeCollection` method.
- 27 INVALID_PARAMETER_FOR_FIND_BY_ID**
Validation error.
- 28 INVALID_SORT_OBJECT**
The provided array for sorting is invalid because one of the JSON objects is invalid. The correct syntax is an array of JSON objects, where each object contains only a single property. This property searches the field with which to sort, and whether it is ascending or descending. For example: `{searchField1 : "ASC"}`.
- 29 INVALID_FILTER_ARRAY**
The provided array for filtering the results is invalid. The correct syntax for this array is an array of strings, in which each string is either a search field or an internal JSONStore field. For more information, see "Store internals" on page 8-429.
- 30 BAD_PARAMETER_EXPECTED_ARRAY_OF_OBJECTS**
Validation error when the array is not an array of only JSON objects.
- 31 BAD_PARAMETER_EXPECTED_ARRAY_OF_CLEAN_DOCUMENTS**
Validation error.

Validation error.

JSONStore examples

Learn about how to get started with JSONStore examples.

JavaScript API examples

You can use JSONStore for MobileFirst hybrid applications.

The following sections contain example implementations for JavaScript with JSONStore APIs. Other helpful topics include:

- “JSONStore overview” on page 8-416 - Learn about key concepts.
- “Enabling JSONStore” on page 8-421 - Learn how to enable JSONStore in different environments.
- “JSONStore API concepts” on page 8-423 - Learn about general information about the APIs that apply to all implementations of the JSONStore API.
- “Troubleshooting JSONStore” on page 8-427 - Learn how to debug and understand possible errors.
- “JSONStore advanced topics” on page 8-453 - Learn about security, multiple user support, performance, and concurrency.
- Class JSONStoreInstance - Learn about JSONStore APIs for JavaScript.
- “Work with external data” on page 8-459 - Explains how to get data from an external source and send changes back to the external source.

Initialize and open connections, get an Accessor, and add data

```
var collectionName = 'people';

// Object that defines all the collections.
var collections = {

    // Object that defines the 'people' collection.
    people : {

        // Object that defines the Search Fields for the 'people' collection.
        searchFields : {name: 'string', age: 'integer'}
    }
};

// Optional options object.
var options = {

    // Optional username, default 'jsonstore'.
    username : 'carlos',

    // Optional password, default no password.
    password : '123',

    // Optional local key generation flag, default false.
    localKeyGen : false
};

WL.JSONStore.init(collections, options)

.then(function () {

    // Data to add, you probably want to get
    // this data from a network call (e.g. MobileFirst Adapter).
    var data = [{name: 'carlos', age: 10}];
```

```

// Optional options for add.
var addOptions = {

    // Mark data as dirty (true = yes, false = no), default true.
    markDirty: true
};

// Get an accessor to the people collection and add data.
return WL.JSONStore.get(collectionName).add(data, addOptions);
})

.then(function (numberOfDocumentsAdded) {
    // Add was successful.
})

.fail(function (errorObject) {
    // Handle failure for any of the previous JSONStore operations (init, add).
});

```

Find - locate documents inside the Store

```

var collectionName = 'people';

// Find all documents that match the queries.
var queryPart1 = WL.JSONStore.QueryPart()
    .equal('name', 'carlos')
    .lessOrEqualThan('age', 10)

var options = {
    // Returns a maximum of 10 documents, default no limit.
    limit: 10,

    // Skip 0 documents, default no offset.
    offset: 0,

    // Search fields to return, default: ['_id', 'json'].
    filter: ['_id', 'json'],

    // How to sort the returned values, default no sort.
    sort: [{name: WL.constant.ASCENDING}, {age: WL.constant.DESENDING}]
};

WL.JSONStore.get(collectionName)

// Alternatives:
// - findById(1, options) which locates documents by their _id field
// - findAll(options) which returns all documents
// - find({'name': 'carlos', age: 10}, options) which finds all documents
// that match the query.
.advancedFind([queryPart1], options)

.then(function (arrayResults) {
    // arrayResults = [{_id: 1, json: {name: 'carlos', age: 99}}]
})

.fail(function (errorObject) {
    // Handle failure.
});

```

Replace - change the documents that are already stored inside a Collection

```

var collectionName = 'people';

// Documents will be located with their '_id' field
// and replaced with the data in the 'json' field.
var docs = [{_id: 1, json: {name: 'carlitos', age: 99}}];

```

```

var options = {
    // Mark data as dirty (true = yes, false = no), default true.
    markDirty: true
};

WL.JSONStore.get(collectionName)

.replace(docs, options)

.then(function (numberOfDocumentsReplaced) {
    // Handle success.
})

.fail(function (errorObject) {
    // Handle failure.
});

```

Remove - delete all documents that match the query

```

var collectionName = 'people';

// Remove all documents that match the queries.
var queries = [{_id: 1}];

var options = {

    // Exact match (true) or fuzzy search (false), default fuzzy search.
    exact: true,

    // Mark data as dirty (true = yes, false = no), default true.
    markDirty: true
};

WL.JSONStore.get(collectionName)

.remove(queries, options)

.then(function (numberOfDocumentsRemoved) {
    // Handle success.
})

.fail(function (errorObject) {
    // Handle failure.
});

```

Count - gets the total number of documents that match a query

```

var collectionName = 'people';

// Count all documents that match the query.
// The default query is '{}' which will
// count every document in the collection.
var query = {name: 'carlos'};
var options = {

    // Exact match (true) or fuzzy search (false), default fuzzy search.
    exact: true
};

WL.JSONStore.get(collectionName)

.count(query, options)

.then(function (numberOfDocumentsThatMatchedTheQuery) {
    // Handle success.
})

```

```
.fail(function (errorObject) {  
  // Handle failure.  
});
```

Destroy - wipes data for all users, destroys the internal storage, and clears security artifacts

```
WL.JSONStore.destroy()
```

```
.then(function () {  
  // Handle success.  
})  
  
.fail(function (errorObject) {  
  // Handle failure.  
});
```

Security - close access to all opened Collections for the current user

```
WL.JSONStore.closeAll()
```

```
.then(function () {  
  // Handle success.  
})  
  
.fail(function (errorObject) {  
  // Handle failure.  
});
```

Security - change the password that is used to access a Store

```
// The password should be user input.  
// It is hard-coded in the example for brevity.  
var oldPassword = '123';  
var newPassword = '456';  
  
var clearPasswords = function () {  
  oldPassword = null;  
  newPassword = null;  
};  
  
// Default username if none is passed is: 'jsonstore'.  
var username = 'carlos';  
  
WL.JSONStore.changePassword(oldPassword, newPassword, username)  
  
.then(function () {  
  
  // Make sure you do not leave the password(s) in memory.  
  clearPasswords();  
  
  // Handle success.  
})  
  
.fail(function (errorObject) {  
  
  // Make sure you do not leave the password(s) in memory.  
  clearPasswords();  
  
  // Handle failure.  
});
```

Push - get all documents that are marked as dirty, send them to a MobileFirst adapter, and mark them clean

```
var collectionName = 'people';
var dirtyDocs;

WL.JSONStore.get(collectionName)

.getAllDirty()

.then(function (arrayOfDirtyDocuments) {
    // Handle getAllDirty success.

    dirtyDocs = arrayOfDirtyDocuments;

    var invocationData = {
        adapter : 'adapter-name',
        procedure : 'procedure-name-1',
        parameters : [dirtyDocs],
        compressResponse: true
    };

    return WL.Client.invokeProcedure(invocationData);
})

.then(function (responseFromAdapter) {
    // Handle invokeProcedure success.

    // You may want to check the response from the adapter
    // and decide whether or not to mark documents as clean.
    return WL.JSONStore.get(collectionName).markClean(dirtyDocs);
})

.then(function () {
    // Handle markClean success.
})

.fail(function (errorObject) {
    // Handle failure.
});
```

Pull - get new data from a MobileFirst adapter

```
var collectionName = 'people';

var invocationData = {
    adapter : 'adapter-name',
    procedure : 'procedure-name-2',
    parameters : [],
    compressResponse: true
};

WL.Client.invokeProcedure(invocationData)

.then(function (responseFromAdapter) {
    // Handle invokeProcedure success.

    // The following example assumes that the adapter returns an arrayOfData,
    // (which is not returned by default),
    // as part of the invocationResult object,
    // with the data that you want to add to the collection.
    var data = responseFromAdapter.invocationResult.arrayOfData;

    // Example:
    // data = [{id: 1, ssn: '111-22-3333', name: 'carlos'}];

    var changeOptions = {
```

```

// The following example assumes that 'id' and 'ssn' are search fields,
// default will use all search fields
// and are part of the data that is received.
replaceCriteria : ['id', 'ssn'],

// Data that does not exist in the Collection will be added, default false.
addNew : true,

// Mark data as dirty (true = yes, false = no), default false.
markDirty : false
};

return WL.JSONStore.get(collectionName).change(data, changeOptions);
})

.then(function () {
  // Handle change success.
})

.fail(function (errorObject) {
  // Handle failure.
});

```

Check whether a document is dirty

```

var collectionName = 'people';
var doc = {_id: 1, json: {name: 'carlitos', age: 99}};

WL.JSONStore.get(collectionName)

.isDirty(doc)

.then(function (isDocumentDirty) {
  // Handle success.

  // isDocumentDirty - true if dirty, false otherwise.
})

.fail(function (errorObject) {
  // Handle failure.
});

```

Check the number of dirty documents

```

var collectionName = 'people';

WL.JSONStore.get(collectionName)

.countAllDirty()

.then(function (numberOfDirtyDocuments) {
  // Handle success.
})

.fail(function (errorObject) {
  // Handle failure.
});

```

Remove a Collection

```

var collectionName = 'people';

WL.JSONStore.get(collectionName)

.removeCollection()

.then(function () {
  // Handle success.

```

```

    // Note: You must call the 'init' API to re-use the empty collection.
    // See the 'clear' API if you just want to remove all data that is inside.
  })

  .fail(function (errorObject) {
    // Handle failure.
  });

```

Clear all data that is inside a Collection

```

var collectionName = 'people';

WL.JSONStore.get(collectionName)

.clear()

.then(function () {
  // Handle success.

  // Note: You might want to use the 'removeCollection' API
  // instead if you want to change the search fields.
})

.fail(function (errorObject) {
  // Handle failure.
});

```

Start a transaction, add some data, remove a document, commit the transaction and roll back the transaction if there is a failure

```

WL.JSONStore.startTransaction()

.then(function () {
  // Handle startTransaction success.
  // You can call every JSONStore API method except:
  // init, destroy, removeCollection, and closeAll.

  var data = [{name: 'carlos'}];

  return WL.JSONStore.get(collectionName).add(data);
})

.then(function () {
  var docs = [{_id: 1, json: {name: 'carlos'}}];

  return WL.JSONStore.get(collectionName).remove(docs);
})

.then(function () {
  return WL.JSONStore.commitTransaction();
})

.fail(function (errorObject) {
  // Handle failure for any of the previous JSONStore operation.
  //(startTransaction, add, remove).

  WL.JSONStore.rollbackTransaction()

  .then(function () {
    // Handle rollback success.
  })

  .fail(function () {

```

```

        // Handle rollback failure.
    })
});

```

Get file information

```

WL.JSONStore.fileInfo()
.then(function (res) {
    //res => [{isEncrypted : true, name : carlos, size : 3072}]
})

.fail(function () {
    // Handle failure.
});

```

Search with like, rightLike, and leftLike

```

// Match all records that contain the search string on both sides.
// %searchString%
var arr1 = WL.JSONStore.QueryPart().like('name', 'ca'); // returns {name: 'carlos', age: 10}
var arr2 = WL.JSONStore.QueryPart().like('name', 'los'); // returns {name: 'carlos', age: 10}

// Match all records that contain the search string on the left side and anything on the right side.
// searchString%
var arr1 = WL.JSONStore.QueryPart().rightLike('name', 'ca'); // returns {name: 'carlos', age: 10}
var arr2 = WL.JSONStore.QueryPart().rightLike('name', 'los'); // returns nothing

// Match all records that contain the search string on the right side and anything on the left side.
// %searchString
var arr = WL.JSONStore.QueryPart().leftLike('name', 'ca'); // returns nothing
var arr2 = WL.JSONStore.QueryPart().leftLike('name', 'los'); // returns {name: 'carlos', age: 10}

```

Objective-C API examples

You can use JSONStore for MobileFirst applications.

The following sections contain example implementations for iOS devices with JSONStore APIs. Other helpful topics include:

- “JSONStore overview” on page 8-416 - Learn about key concepts.
- “Enabling JSONStore” on page 8-421 - Learn how to enable JSONStore in different environments.
- “JSONStore API concepts” on page 8-423 - Learn about general information about the APIs that apply to all implementations of the JSONStore API.
- “Troubleshooting JSONStore” on page 8-427 - Learn how to debug and understand possible errors.
- “JSONStore advanced topics” on page 8-453 - Learn about security, multiple user support, performance, and concurrency.
- JSONStore Class Reference - Learn about JSONStore APIs for Objective-C.
- “Work with external data” on page 8-459 - Explains how to get data from an external source and send changes back to the external source.

Initialize and open connections, get an Accessor, and add data

```

// Create the collections object that will be initialized.
JSONStoreCollection* people = [[JSONStoreCollection alloc] initWithName:@"people"];
[people setSearchField:@"name" withType:JSONStore_String];
[people setSearchField:@"age" withType:JSONStore_Integer];

// Optional options object.
JSONStoreOpenOptions* options = [JSONStoreOpenOptions new];
[options setUsername:@"carlos"]; //Optional username, default 'jsonstore'
[options setPassword:@"123"]; //Optional password, default no password

// This object will point to an error if one occurs.
NSError* error = nil;

```

```

// Open the collections.
[[JSONStore sharedInstance] openCollections:@[people] withOptions:options error:&error];

// Add data to the collection
NSArray* data = @[ @{@"name" : @"carlos", @"age": @10} ];
int newDocsAdded = [[people addData:data andMarkDirty:YES withOptions:nil error:&error] intValue];

```

Initialize with a secure random token from the server

```

[WLSecurityUtils getRandomStringFromServerWithBytes:32
 timeout:1000
 completionHandler:^(NSURLResponse *response,
                      NSData *data,
                      NSError *connectionError) {

    // You might want to see the response and the connection error
    // before moving forward.

    // Get the secure random string by using the data that is
    // returned from the generator on the server.
    NSString* secureRandom = [[NSString alloc] initWithData:data encoding:NSUTF8StringEncoding];

    JSONStoreCollection* ppl = [[JSONStoreCollection alloc] initWithName:@"people"];
    [ppl setSearchField:@"name" ofType:JSONStore_String];
    [ppl setSearchField:@"age" ofType:JSONStore_Integer];

    // Optional options object.
    JSONStoreOptions* options = [JSONStoreOptions new];
    [options setUsername:@"carlos"]; //Optional username, default 'jsonstore'
    [options setPassword:@"123"]; //Optional password, default no password
    [options setSecureRandom:secureRandom]; //Optional, default one will be generated locally

    // This points to an error if one occurs.
    NSError* error = nil;

    [[JSONStore sharedInstance] openCollections:@[ppl] withOptions:options error:&error];

    // Other JSONStore operations (e.g. add, remove, replace, etc.) go here.
}];

```

Find - locate documents inside the Store

```

// Get the accessor to an already initialized collection.
JSONStoreCollection* people = [[JSONStore sharedInstance] getCollectionWithName:@"people"];

// This object will point to an error if one occurs.
NSError* error = nil;

// Add additional find options (optional).
JSONStoreQueryOptions* options = [JSONStoreQueryOptions new];
[options setLimit:@10]; // Returns a maximum of 10 documents, default no limit.
[options setOffset:@0]; // Skip 0 documents, default no offset.

// Search fields to return, default: ['_id', 'json'].
[options filterSearchField:@"_id"];
[options filterSearchField:@"json"];

// How to sort the returned values , default no sort.
[options sortBySearchFieldAscending:@"name"];
[options sortBySearchFieldDescending:@"age"];

// Find all documents that match the query part.
JSONStoreQueryPart* queryPart1 = [[JSONStoreQueryPart alloc] init];
[queryPart1 searchField:@"name" equal:@"carlos"];
[queryPart1 searchField:@"age" lessOrEqualThan:@10];

NSArray* results = [people findWithQueryParts:@[queryPart1] andOptions:options error:&error];

// results = @[ @{@"_id" : @1, @"json" : @{@"name": @"carlos", @"age" : @10}} ];

for (NSDictionary* result in results) {

    NSString* name = [result valueForKeyPath:@"json.name"]; // carlos.
    int age = [[result valueForKeyPath:@"json.age"] intValue]; // 10
    NSLog(@"Name: %@, Age: %d", name, age);
}

```

Replace - change the documents that are already stored inside a Collection

```
// Get the accessor to an already initialized collection.
JSONStoreCollection* people = [[JSONStore sharedInstance] getCollectionWithName:@"people"];

// Find all documents that match the queries.
NSArray* docs = @[ @{@"_id" : @1, @"json" : @{ @"name": @"carlitos", @"age" : @99}} ];

// This object will point to an error if one occurs.
NSError* error = nil;

// Perform the replacement.
int docsReplaced = [[people replaceDocuments:docs andMarkDirty:NO error:&error] intValue];
```

Remove - delete all documents that match the query

```
// Get the accessor to an already initialized collection.
JSONStoreCollection* people = [[JSONStore sharedInstance] getCollectionWithName:@"people"];

// This object will point to an error if one occurs.
NSError* error = nil;

// Find document with _id equal to 1 and remove it.
int docsRemoved = [[people removeWithIds:@[@1] andMarkDirty:NO error:&error] intValue];
```

Count - gets the total number of documents that match a query

```
// Get the accessor to an already initialized collection.
JSONStoreCollection* people = [[JSONStore sharedInstance] getCollectionWithName:@"people"];

// Count all documents that match the query.
// The default query is @{} which will
// count every document in the collection.
JSONStoreQueryPart *queryPart = [[JSONStoreQueryPart alloc] init];
[queryPart searchField:@"name" equal:@"carlos"];

// This object will point to an error if one occurs.
NSError* error = nil;

// Perform the count.
int countResult = [[people countWithQueryParts:@[queryPart] error:&error] intValue];
```

Destroy - wipes data for all users, destroys the internal storage, and clears security artifacts

```
// This object will point to an error if one occurs.
NSError* error = nil;

// Perform the destroy.
[[JSONStore sharedInstance] destroyDataAndReturnError:&error];
```

Security - close access to all opened Collections for the current user

```
// This object will point to an error if one occurs.
NSError* error = nil;

// Close access to all collections in the store.
[[JSONStore sharedInstance] closeAllCollectionsAndReturnError:&error];
```

Security - change the password that is used to access a Store

```
// The password should be user input.
// It is hardcoded in the example for brevity.
NSString* oldPassword = @"123";
NSString* newPassword = @"456";
NSString* username = @"carlos";

// This object will point to an error if one occurs.
NSError* error = nil;

// Perform the change password operation.
[[JSONStore sharedInstance] changeCurrentPassword:oldPassword withNewPassword:newPassword forUsername:username error:&error];

// Remove the passwords from memory.
oldPassword = nil;
newPassword = nil;
```

Push - get all documents that are marked as dirty, send them to a MobileFirst adapter, and mark them clean

```
// Get the accessor to an already initialized collection.
JSONStoreCollection* people = [[JSONStore sharedInstance] getCollectionWithName:@"people"];

// This object will point to an error if one occurs
NSError* error = nil;

// Return all documents marked dirty
NSArray* dirtyDocs = [people allDirtyAndReturnError:&error];

// ACTION REQUIRED: Handle the dirty documents here
// (e.g. send them to a MobileFirst Adapter).

// Mark dirty documents as clean
int numCleaned = [[people markDocumentsClean:dirtyDocs error:&error] intValue];
```

Pull - get new data from a MobileFirst adapter

```
// Get the accessor to an already initialized collection.
JSONStoreCollection* people = [[JSONStore sharedInstance] getCollectionWithName:@"people"];

// This object will point to an error if one occurs.
NSError* error = nil;

// ACTION REQUIRED: Get data (e.g. MobileFirst Adapter).
// For this example, it is hardcoded.
NSArray* data = @[ @{@"id" : @"1", @"ssn": @"111-22-3333", @"name": @"carlos"} ];

int numChanged = [[people changeData:data withReplaceCriteria:@{@"id", @"ssn"} addNew:YES markDirty:NO error:&error] intValue];
```

Check whether a document is dirty

```
// Get the accessor to an already initialized collection.
JSONStoreCollection* people = [[JSONStore sharedInstance] getCollectionWithName:@"people"];

// This object will point to an error if one occurs.
NSError* error = nil;

// Check if document with _id '1' is dirty.
BOOL isDirtyResult = [people isDirtyWithDocumentId:1 error:&error];
```

Check the number of dirty documents

```
// Get the accessor to an already initialized collection.
JSONStoreCollection* people = [[JSONStore sharedInstance] getCollectionWithName:@"people"];

// This object will point to an error if one occurs.
NSError* error = nil;

// Check if document with _id '1' is dirty.
int dirtyDocsCount = [[people countAllDirtyDocumentsWithError:&error] intValue];
```

Remove a Collection

```
// Get the accessor to an already initialized collection.
JSONStoreCollection* people = [[JSONStore sharedInstance] getCollectionWithName:@"people"];

// This object will point to an error if one occurs.
NSError* error = nil;

// Remove the collection.
[people removeCollectionWithError:&error];
```

Clear all data that is inside a Collection

```
// Get the accessor to an already initialized collection.
JSONStoreCollection* people = [[JSONStore sharedInstance] getCollectionWithName:@"people"];

// This object will point to an error if one occurs.
NSError* error = nil;

// Remove the collection.
[people clearCollectionWithError:&error];
```

Start a transaction, add some data, remove a document, commit the transaction and roll back the transaction if there is a failure

```
// Get the accessor to an already initialized collection.
JSONStoreCollection* people = [[JSONStore sharedInstance] getCollectionWithName:@"people"];
```

```

// These objects will point to errors if they occur.
NSError* error = nil;
NSError* addError = nil;
NSError* removeError = nil;

// You can call every JSONStore API method inside a transaction except:
// open, destroy, removeCollection and closeAll.
[[JSONStore sharedInstance] startTransactionAndReturnError:&error];

[people addData:@{@"name" : @"carlos"} ] andMarkDirty:NO withOptions:nil error:&addError];

[people removeWithIds:@[1] andMarkDirty:NO error:&removeError];

if (addError != nil || removeError != nil) {

    // Return the store to the state before start transaction was called.
    [[JSONStore sharedInstance] rollbackTransactionAndReturnError:&error];
} else {
    // Commit the transaction thus ensuring atomicity.
    [[JSONStore sharedInstance] commitTransactionAndReturnError:&error];
}

```

Get file information

```

// This object will point to an error if one occurs
NSError* error = nil;

// Returns information about files JSONStore uses to persist data.
NSArray* results = [[JSONStore sharedInstance] fileInfoAndReturnError:&error];
// => [{"isEncrypted" : @(true), @"name" : @"carlos", @"size" : @3072}]

```

Java API examples

You can use JSONStore for MobileFirst hybrid applications.

The following sections contain example implementations for Android devices with JSONStore APIs. Other helpful topics include:

- “JSONStore overview” on page 8-416 - Learn about key concepts.

- “JSONStore API concepts” on page 8-423 - Learn about general information about the APIs that apply to all implementations of the JSONStore API.
- “Troubleshooting JSONStore” on page 8-427 - Learn how to debug and understand possible errors.
- “JSONStore advanced topics” on page 8-453 - Learn about security, multiple user support, performance, and concurrency.
- Package `com.worklight.jsonstore.api` - Learn about JSONStore APIs for Java.
- “Work with external data” on page 8-459 - Explains how to get data from an external source and send changes back to the external source.

Initialize and open connections, get an Accessor, and add data

```

// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
    List<JSONStoreCollection> collections = new LinkedList<JSONStoreCollection>();
    // Create the collections object that will be initialized.
    JSONStoreCollection peopleCollection = new JSONStoreCollection("people");
    peopleCollection.setSearchField("name", SearchFieldType.STRING);
    peopleCollection.setSearchField("age", SearchFieldType.INTEGER);
    collections.add(peopleCollection);

    // Optional options object.
    JSONStoreInitOptions initOptions = new JSONStoreInitOptions();
    // Optional username, default 'jsonstore'.
    initOptions.setUsername("carlos");
    // Optional password, default no password.
}

```

```

initOptions.setPassword("123");

// Open the collection.

WLJSONStore.getInstance(ctx).openCollections(collections, initOptions);

// Add data to the collection.
JSONObject newDocument = new JSONObject("{\"name: 'carlos', age: 10}");
JSONStoreAddOptions addOptions = new JSONStoreAddOptions();
addOptions.setMarkDirty(true);
peopleCollection.addData(newDocument, addOptions);
}
catch (JSONStoreException ex) {
    // Handle failure for any of the previous JSONStore operations (init, add).
    throw ex;
} catch (JSONException ex) {
    // Handle failure for any JSON parsing issues.
    throw ex;
}

```

Initialize with a secure random token from the server

```

// Fill in the blank to get the Android application context.
Context ctx = getContext();

// Do an AsyncTask because networking cannot occur inside the activity.
AsyncTask<Context, Void, Void> aTask = new AsyncTask<Context, Void, Void>() {
    protected Void doInBackground(Context... params) {
        final Context context = params[0];

        // Create the request listener that will have the
        // onSuccess and onFailure callbacks:
        WLRequestListener listener = new WLRequestListener() {
            public void onFailure(WLFailResponse failureResponse) {
                // Handle Failure.
            }

            public void onSuccess(WLResponse response) {
                String secureRandom = response.getResponseText();

                try {
                    List<JSONStoreCollection> collections = new LinkedList<JSONStoreCollection>();
                    // Create the collections object that will be initialized.
                    JSONStoreCollection peopleCollection = new JSONStoreCollection("people");
                    peopleCollection.setSearchField("name", SearchFieldType.STRING);
                    peopleCollection.setSearchField("age", SearchFieldType.INTEGER);
                    collections.add(peopleCollection);

                    // Optional options object.
                    JSONStoreInitOptions initOptions = new JSONStoreInitOptions();

                    // Optional username, default 'jsonstore'.
                    initOptions.setUsername("carlos");

                    // Optional password, default no password.
                    initOptions.setPassword("123");

                    initOptions.setSecureRandom(secureRandom);

                    // Open the collection.
                    WLJSONStore.getInstance(context).openCollections(collections, initOptions);

                    // Other JSONStore operations (e.g. add, remove, replace, etc.) go here.
                }
                catch (JSONStoreException ex) {
                    // Handle failure for any of the previous JSONStore operations (init, add).
                    ex.printStackTrace();
                }
            }
        };
    }
}

```

```

    }
};

// Get the secure random from the server:
// The length of the random string, in bytes (maximum is 64 bytes).
int byteLength = 32;
SecurityUtils.getRandomStringFromServer(byteLength, context, listener);
return null;
}
};
aTask.execute(ctx);

```

Find - locate documents inside the Store

```

// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
    // Get the already initialized collection.
    JSONStoreCollection peopleCollection = WLJSONStore.getInstance(ctx).getCollectionByName("people");

    JSONStoreQueryParts findQuery = new JSONStoreQueryParts();
    JSONStoreQueryPart part = new JSONStoreQueryPart();
    part.addLike("name", "carlos");
    part.addLessThan("age", 99);
    findQuery.addQueryPart(part);

    // Add additional find options (optional).
    JSONStoreFindOptions findOptions = new JSONStoreFindOptions();

    // Returns a maximum of 10 documents, default no limit.
    findOptions.setLimit(10);
    // Skip 0 documents, default no offset.
    findOptions.setOffset(0);

    // Search fields to return, default: ['_id', 'json'].
    findOptions.addSearchFilter("_id");
    findOptions.addSearchFilter("json");

    // How to sort the returned values, default no sort.
    findOptions.sortBySearchFieldAscending("name");
    findOptions.sortBySeachFieldDescending("age");

    // Find documents that match the query.
    List<JSONObject> results = peopleCollection.findDocuments(findQuery, findOptions);
}
catch (JSONStoreException ex) {
    // Handle failure for any of the previous JSONStore operations
    throw ex;
}

```

Replace - change the documents that are already stored inside a Collection

```

// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
    // Get the already initialized collection.
    JSONStoreCollection peopleCollection = WLJSONStore.getInstance(ctx).getCollectionByName("people");

    // Documents will be located with their '_id' field
    //and replaced with the data in the 'json' field.
    JSONObject replaceDoc = new JSONObject("{\"_id\": 1, json\": {name: 'carlitos', age: 99}}");

    // Mark data as dirty (true = yes, false = no), default true.
    JSONStoreReplaceOptions replaceOptions = new JSONStoreReplaceOptions();

```

```

replaceOptions.setMarkDirty(true);

// Replace the document.
peopleCollection.replaceDocument(replaceDoc, replaceOptions);
}
catch (JSONStoreException ex) {
// Handle failure for any of the previous JSONStore operations.
throw ex;
}

```

Remove - delete all documents that match the query

```

// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
// Get the already initialized collection.
JSONStoreCollection peopleCollection = WLJSONStore.getInstance(ctx).getCollectionByName("people");

// Documents will be located with their '_id' field.
int id = 1;

JSONStoreRemoveOptions removeOptions = new JSONStoreRemoveOptions();

// Mark data as dirty (true = yes, false = no), default true.
removeOptions.setMarkDirty(true);

// Replace the document.
peopleCollection.removeDocumentById(id, removeOptions);
}
catch (JSONStoreException ex) {
// Handle failure for any of the previous JSONStore operations
throw ex;
}
catch (JSONException ex) {
// Handle failure for any JSON parsing issues.
throw ex;
}
}

```

Count - gets the total number of documents that match a query

```

// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
// Get the already initialized collection.
JSONStoreCollection peopleCollection = WLJSONStore.getInstance(ctx).getCollectionByName("people");

// Count all documents that match the query.
JSONStoreQueryParts countQuery = new JSONStoreQueryParts();
JSONStoreQueryPart part = new JSONStoreQueryPart();

// Exact match.
part.addEqual("name", "carlos");
countQuery.addQueryPart(part);

// Replace the document.
int resultCount = peopleCollection.countDocuments(countQuery);
JSONObject doc = peopleCollection.findDocumentById(resultCount);
peopleCollection.replaceDocument(doc);
}
catch (JSONStoreException ex) {
throw ex;
}
}

```

Destroy - wipes data for all users, destroys the internal storage, and clears security artifacts

```
// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
    // Destroy the Store.
    WLJSONStore.getInstance(ctx).destroy();
}
catch (JSONStoreException ex) {
    // Handle failure for any of the previous JSONStore operations
    throw ex;
}
```

Security - close access to all opened Collections for the current user

```
// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
    // Close access to all collections.
    WLJSONStore.getInstance(ctx).closeAll();
}
catch (JSONStoreException ex) {
    // Handle failure for any of the previous JSONStore operations.
    throw ex;
}
```

Security - change the password that is used to access a Store

```
// The password should be user input.
// It is hard-coded in the example for brevity.
String username = "carlos";
String oldPassword = "123";
String newPassword = "456";

// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
    WLJSONStore.getInstance(ctx).changePassword(oldPassword, newPassword, username);
}
catch (JSONStoreException ex) {
    // Handle failure for any of the previous JSONStore operations.
    throw ex;
}
finally {
    // It is good practice to not leave passwords in memory
    oldPassword = null;
    newPassword = null;
}
```

Push - get all documents that are marked as dirty, send them to a MobileFirst adapter, and mark them clean

```
// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
    // Get the already initialized collection.
    JSONStoreCollection peopleCollection = WLJSONStore.getInstance(ctx).getCollectionByName("people");

    // Check if document with _id 3 is dirty.
    List<JSONObject> allDirtyDocuments = peopleCollection.findAllDirtyDocuments();

    // Handle the dirty documents here (e.g. calling an adapter).
```

```

    peopleCollection.markDocumentsClean(allDirtyDocuments);
} catch (JSONStoreException ex) {
    // Handle failure for any of the previous JSONStore operations
    throw ex;
}

```

Pull - get new data from a MobileFirst adapter

```

// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
    // Get the already initialized collection.
    JSONStoreCollection peopleCollection = WLJSONStore.getInstance(ctx).getCollectionByName("people");

    // Pull data here and place in newDocs. For this example, it is hard-coded.
    List<JSONObject> newDocs = new ArrayList<JSONObject>();
    JSONObject doc = new JSONObject("{\"id: 1, ssn: '111-22-3333', name: 'carlos'\"");
    newDocs.add(doc);

    JSONStoreChangeOptions changeOptions = new JSONStoreChangeOptions();

    // Data that does not exist in the collection will be added, default false.
    changeOptions.setAddNew(true);

    // Mark data as dirty (true = yes, false = no), default false.
    changeOptions.setMarkDirty(true);

    // The following example assumes that 'id' and 'ssn' are search fields,
    // default will use all search fields
    // and are part of the data that is received.
    changeOptions.addSearchFieldToCriteria("id");
    changeOptions.addSearchFieldToCriteria("ssn");

    int changed = peopleCollection.changeData(newDocs, changeOptions);
}
catch (JSONStoreException ex) {
    // Handle failure for any of the previous JSONStore operations.
    throw ex;
}
catch (JSONException ex) {
    // Handle failure for any JSON parsing issues.
    throw ex;
}

```

Check whether a document is dirty

```

// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
    // Get the already initialized collection.
    JSONStoreCollection peopleCollection = WLJSONStore.getInstance(ctx).getCollectionByName("people");

    // Check if document with id '3' is dirty.
    boolean isDirty = peopleCollection.isDocumentDirty(3);
}
catch (JSONStoreException ex) {
    // Handle failure for any of the previous JSONStore operations.
    throw ex;
}

```

Check the number of dirty documents

```

// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {

```

```

// Get the already initialized collection.
JSONStoreCollection peopleCollection = WLJSONStore.getInstance(ctx).getCollectionByName("people");

// Get the count of all dirty documents in the people collection.
int totalDirty = peopleCollection.countAllDirtyDocuments();
}
catch (JSONStoreException ex) {
// Handle failure for any of the previous JSONStore operations.
throw ex;
}

```

Remove a Collection

```

// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
// Get the already initialized collection.
JSONStoreCollection peopleCollection = WLJSONStore.getInstance(ctx).getCollectionByName("people");

// Remove the collection. The collection object is
// no longer usable.
peopleCollection.removeCollection();
}
catch (JSONStoreException ex) {
// Handle failure for any of the previous JSONStore operations.
throw ex;
}

```

Clear all data that is inside a Collection

```

// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
// Get the already initialized collection.
JSONStoreCollection peopleCollection = WLJSONStore.getInstance(ctx).getCollectionByName("people");

// Clear the collection.
peopleCollection.clearCollection();
}
catch (JSONStoreException ex) {
// Handle failure for any of the previous JSONStore operations.
throw ex;
}

```

Start a transaction, add some data, remove a document, commit the transaction and roll back the transaction if there is a failure

```

// Fill in the blank to get the Android application context.
Context ctx = getContext();

try {
// Get the already initialized collection.
JSONStoreCollection peopleCollection = WLJSONStore.getInstance(ctx).getCollectionByName("people");

WLJSONStore.getInstance(ctx).startTransaction();

JSONObject docToAdd = new JSONObject("{\"name: 'carlos', age: 99}");
// Find documents that match query.
peopleCollection.addData(docToAdd);

//Remove added doc.
int id = 1;
peopleCollection.removeDocumentById(id);

WLJSONStore.getInstance(ctx).commitTransaction();
}

```

```

}
catch (JSONStoreException ex) {
    // Handle failure for any of the previous JSONStore operations.

    // An exception occurred. Take care of it to prevent further damage.
    WLJSONStore.getInstance(ctx).rollbackTransaction();

    throw ex;
}
catch (JSONException ex) {
    // Handle failure for any JSON parsing issues.

    // An exception occurred. Take care of it to prevent further damage.
    WLJSONStore.getInstance(ctx).rollbackTransaction();

    throw ex;
}

```

Get file information

```

Context ctx = getContext();
List<JSONStoreFileInfo> allFileInfo = WLJSONStore.getInstance(ctx).getFileInfo();

for(JSONStoreFileInfo fileInfo : allFileInfo) {
    long fileSize = fileInfo.getFileSizeBytes();
    String username = fileInfo.getUsername();
    boolean isEncrypted = fileInfo.isEncrypted();
}

```

JSONStore advanced topics

Learn about JSONStore advanced topics.

JSONStore security

You can secure all of the collections in a store by encrypting them.

To encrypt all of the collections in a store, pass a password to the `init` (JavaScript) or `open` (Native iOS and Native Android) API. If no password is passed, none of the documents in the store collections are encrypted.

Some security artifacts (for example *salt*) are stored in the keychain (iOS), shared preferences (Android), isolated storage (Windows 8 Phone), or the credential locker (Windows 8). The store is encrypted with a 256-bit Advanced Encryption Standard (AES) key. All keys are strengthened with Password-Based Key Derivation Function 2 (PBKDF2).

Data encryption is only available on Android, iOS, Windows 8 Phone, and Windows 8 environments. You can choose to encrypt data collections for an application, but you cannot switch between encrypted and plain-text formats, or to mix formats within a store.

The key that protects the data in the store is based on the user password that you provide. The key does not expire, but you can change it by calling the `changePassword` API.

The data protection key (DPK) is the key that is used to decrypt the contents of the store. The DPK is kept in the iOS keychain even if the application is uninstalled. To remove both the key in the keychain and everything else that JSONStore puts in the application, use the `destroy` API. This process is not applicable to Android because the encrypted DPK is stored in shared preferences and wiped out when the application is uninstalled.

The first time that JSONStore opens a collection with a password, which means that the developer wants to encrypt data inside the store, JSONStore needs a random token. That random token can be obtained from the client or from the server.

When the `localKeyGen` key is present in the JavaScript implementation of the JSONStore API, and it has a value of `true`, a cryptographically secure token is generated locally. Otherwise, the token is generated by contacting the server, thus requiring connectivity to the MobileFirst Server. This token is required only the first time that a store is opened with a password. The native implementations (Objective-C and Java) generate a cryptographically secure token locally by default, or you can pass one through the `secureRandom` option.

The trade-off is between opening a store offline and trusting the client to generate that random token (less secure), or opening the store with access to the MobileFirst Server (requires connectivity) and trusting the server (more secure).

Windows 8 Universal and Windows Phone Silverlight 8 encryption:

You can secure all of the collections in a store by encrypting them.

JSONStore uses SQLCipher as its underlying database technology. SQLCipher is a build of SQLite that is produced by Zetetic, LLC that adds a layer of encryption to the database.

JSONStore uses SQLCipher on all platforms. On Android and iOS a free, open source version of SQLCipher is available, known as the Community Edition and is incorporated into the versions of JSONStore that is included in IBM MobileFirst Platform Foundation. The Windows versions of SQLCipher are only available under a commercial license and cannot be directly redistributed by IBM MobileFirst Platform Foundation.

Instead, JSONStore for Windows 8 Universal and Windows Phone Silverlight 8 include SQLite as the underlying database. If you need to encrypt data for either of these platforms, you need to acquire your own version of SQLCipher and swap out the SQLite version that is included in IBM MobileFirst Platform Foundation. For more information, see “SQLCipher on Windows Phone Silverlight 8 and Windows 8 Universal.”

If you do not need encryption, the JSONStore is fully functional (minus encryption) by using the SQLite version in IBM MobileFirst Platform Foundation.

SQLCipher on Windows Phone Silverlight 8 and Windows 8 Universal:

To use JSONStore encryption on Windows, you must replace SQLite with SQLCipher.

Replacing SQLite with SQLCipher for Windows Phone Silverlight 8:

To use JSONStore encryption on Windows Phone Silverlight 8, you must replace SQLite with SQLCipher.

Procedure

1. Run the SQLCipher for Windows Phone extension that comes with the SQLCipher for Windows Phone Commercial Edition.

2. After the extension finishes installing, locate the SQLCipher version of the `sqlite3.dll` file that was just created. There is one for x86, one for x64, and one for ARM.

`C:\Program Files (x86)\Microsoft SDKs\Windows Phone\v8.0\ExtensionSDKs\SQLCipher.WP80\3.0.1\Redist\Retail\<platform>`

3. Copy and replace this file to your MobileFirst application.

`<Worklight project name>\apps\<application name>\windowsphone8\native\buildtarget\<platform>`

Replacing SQLite with SQLCipher for Windows 8 Universal:

To use JSONStore encryption on Windows 8 Universal, you must replace SQLite with SQLCipher.

Procedure

1. Run the SQLCipher for Windows Runtime 8.1 extension that comes with the SQLCipher for Windows Runtime Commercial Edition.
2. After the extension finishes installing, locate the SQLCipher version of the `sqlite3.dll` file that was just created. There is one for x86, one for x64, and one for ARM.

`C:\Program Files (x86)\Microsoft SDKs\Windows\v8.1\ExtensionSDKs\SQLCipher.WinRT81\3.0.1\Redist\Retail\<platform>`

3. Copy and replace this file to your MobileFirst application.

`<Worklight project name>\apps\<application name>\windows8\native\buildtarget\<platform>`

Setting up Touch ID support for JSONStore:

Developers can use Touch ID to store passwords in a protected keychain on iOS that can be unlocked only with the user's fingerprint. This feature can be used to store a password that can be used to decrypt a user's JSONStore. The first time a user opens a JSONStore instance, a random password is generated and stored in the keychain. This password is used to encrypt the JSONStore. The second time a user opens a JSONStore instance, the password can be fetched from the keychain, which is retrieved with Touch ID authentication.

Before you begin

You must compile your iOS project against the iOS SDK, version 8 or later, for Touch ID support. As a result, you must use XCode 6 or later.

About this task

You can download the sample application at `Touch_ID_for_JSONStore.zip`. The following list of files are included:

- `KeychainSecurityUtilities.h`: Native header file for JSONStore specific Touch ID methods. See this file for method documentation.
- `KeychainSecurityUtilities.m`: Native implementation file for JSONStore specific Touch ID methods.
- `KeychainSecurityUtilitiesPlugin.h`: Native header file for the Cordova plug-in.
- `KeychainSecurityUtilitiesPlugin.m`: Native implementation file for the Cordova plug-in.
- `JSONStoreTouchIdPlugin.js`: JavaScript wrapper file for Cordova hybrid calls that connecting JavaScript to the native Cordova plug-in.
- `main.js`: Example use of the hybrid API calls.

Note: The JSONStore destroy API does not work with Touch ID.

Procedure

1. For Touch ID to work, you must link against the Apple-provided `LocalAuthentication.framework`. Add the framework under **Project Settings > Build Phases > Link Binary with Libraries**.
2. For native, copy the `KeychainSecurityUtilities.h` and `KeychainSecurityUtilities.m` files to your native project's classes folder. If your project is a hybrid project, copy the `KeychainSecurityUtilitiesPlugin.h` and `KeychainSecurityUtilitiesPlugin.m` files too.
3. Optional: For hybrid, add the JavaScript interface for the Cordova plug-in (`JSONStoreTouchIdPlugin.js`) in the `www/default/js/` folder. For more information about how to use the Cordova plug-in in a MobileFirst hybrid application, see the `main.js` file.
4. Optional: Add the following feature tag to the application's `config.xml` file to add the `KeychainSecurityUtilitiesPlugin` to the available plug-ins at run time.

```
<feature name="KeychainSecurityUtilitiesPlugin">
  <param name="ios-package" value="KeychainSecurityUtilitiesPlugin" />
</feature>
```

Results

When you run the sample application the first time, the application does not prompt for Touch ID because an existing password is not in the keychain. Internally, a random password is generated and stored in the keychain. Data is added and retrieved without a Touch ID prompt. On subsequent runs, Touch ID authentication is prompted because the password is available in the keychain. After the `JSONStore` instance is unlocked, the password is retrieved and used as the password to decrypt the user's `JSONStore`.

JSONStore multiple user support

With `JSONStore`, you can create multiple stores that contain different collections in a single MobileFirst application.

The `init` (JavaScript) or `open` (Native iOS and Native Android) API can take an options object with a user name. Different stores are separate files in the file system. The user name is used as the file name of the store. These separate stores can be encrypted with different passwords for security and privacy reasons. Calling the `closeAll` API removes access to all the collections. It is also possible to change the password of an encrypted store by calling the `changePassword` API.

An example use case would be various employees that share a physical device (for example an iPad or Android tablet) and MobileFirst application. In addition, if the employees work different shifts and handle private data from different customers while they use the MobileFirst application, multiple user support is useful.

JSONStore performance

Learn about the factors that can affect `JSONStore` performance.

Network

- IBM MobileFirst Platform Foundation provides APIs for getting information about the network, for example, `WL.Device.getNetworkInfo` (JavaScript). Ideally, getting and sending data from and to a MobileFirst adapter should be done when the application is using a WiFi network.
- Check network connectivity before you perform operations, such as sending all dirty documents to a MobileFirst adapter.

- The amount of data that is sent over the network to a client heavily affects performance. Send only the data that is required by the application, instead of copying everything inside your backend database.
- If you are using a MobileFirst adapter, consider setting the `compressResponse` flag to `true`. That way, responses are compressed, which generally uses less bandwidth and has a faster transfer time than without compression.

Memory

- When you use the JavaScript API, JSONStore documents are serialized and deserialized as Strings between the Native (Objective-C, Java, or C#) Layer and the JavaScript Layer. One way to mitigate possible memory issues is by using `limit` and `offset` when you use the `find` API. That way, you limit the amount of memory that is allocated for the results and can implement things like pagination (show X number of results per page).
- Instead of using long key names that are eventually serialized and deserialized as Strings, consider mapping those long key names into smaller ones (for example: `myVeryVeryVerLongKeyName` to `k` or `key`). Ideally, you map them to short key names when you send them from the adapter to the client, and map them to the original long key names when you send data back to the backend.
- Consider splitting the data inside a store into various collections. Have small documents over various collections instead of monolithic documents in a single collection. This consideration depends on how closely related the data is and the use cases for said data.
- When you use the `add` API with an array of objects, it is possible to run into memory issues. To mitigate this issue, call these methods with fewer JSON objects at a time.
- JavaScript and Java have garbage collectors, while Objective-C has Automatic Reference Counting. Allow it to work, but do not depend on it entirely. Try to null references that are no longer used and use profiling tools to check that memory usage is going down when you expect it to go down.

CPU

- The amount of search fields and extra search fields that are used affect performance when you call the `add` method, which does the indexing. Only index the values that are used in queries for the `find` method.
- By default, JSONStore tracks local changes to its documents. This behavior can be disabled, thus saving a few cycles, by setting the `markDirty` flag to `false` when you use the `add`, `remove`, and `replace` APIs.
- Enabling security adds some overhead to the `init` or `open` APIs and other operations that work with documents inside the collection. Consider whether security is genuinely required. For example, the `open` API is much slower with encryption because it must generate the encryption keys that are used for encryption and decryption.
- The `replace` and `remove` APIs depend on the collection size as they must go through the whole collection to replace or remove all occurrences. Because it must go through each record, it must decrypt every one of them, which makes it much slower when encryption is used. This performance hit is more noticeable on large collections.
- The `count` API is relatively expensive. However, you can keep a variable that keeps the count for that collection. Update it every time that you store or remove things from the collection.
- The `find` APIs (`find`, `findAll`, and `findById`) are affected by encryption, since they must decrypt every document to see whether it is a match or not. For `find`

by query, if a limit is passed, it is potentially faster as it stops when it reaches the limit of results. JSONStore does not need to decrypt the rest of the documents to figure out if any other search results remain.

More information

For more information about JSONStore performance, see the JSONStore performance blog post.

JSONStore concurrency

Learn about JSONStore concurrency.

JavaScript

Most of the operations that can be performed on a collection, such as add and find, are asynchronous. These operations return a jQuery promise that is resolved when the operation completes successfully and rejected when a failure occurs. These promises are similar to success and failure callbacks.

A jQuery Deferred is a promise that can be resolved or rejected. The following examples are not specific to JSONStore, but are intended to help you understand their usage in general.

The Options Object with onSuccess and onFailure callbacks that were used in JSONStore for IBM Worklight V5.0.5 are deprecated in favor of promises.

Instead of promises and callbacks, you can also listen to JSONStore success ('WL/JSONSTORE/SUCCESS') and failure ('WL/JSONSTORE/FAILURE') events. Perform actions that are based on the arguments that are passed to the event listener.

Example promise definition

```
var asyncOperation = function () {
  // Assumes that you have jQuery defined via $ in the environment
  var deferred = $.Deferred();

  setTimeout(function() {
    deferred.resolve('Hello');
  }, 1000);

  return deferred.promise();
};
```

Example promise usage

```
// The function that is passed to .then is executed after 1000 ms.
asyncOperation.then(function (response) {
  // response = 'Hello'
});
```

Example callback definition

```
var asyncOperation = function (callback) {
  setTimeout(function() {
    callback('Hello');
  }, 1000);
};
```

Example callback usage

```
// The function that is passed to asyncOperation is executed after 1000 ms.
asyncOperation(function (response) {
  // response = 'Hello'
});
```

Example events

```
$(document.body).on('WL/JSONSTORE/SUCCESS', function (evt, data, src, collectionName) {  
  
    // evt - Contains information about the event  
    // data - Data that is sent after the operation (add, find, etc.) finished  
    // src - Name of the operation (add, find, push, etc.)  
    // collectionName - Name of the collection  
});
```

Objective-C

When you use the Native iOS API for JSONStore, all operations are added to a synchronous dispatch queue. This behavior ensures that operations that touch the store are executed in order on a thread that is not the main thread. For more information, see the Apple documentation at Grand Central Dispatch (GCD).

Java

When you use the Native Android API for JSONStore, all operations are executed on the main thread. You must create threads or use thread pools to have asynchronous behavior. All store operations are thread-safe.

Work with external data

Learn about the different concepts that are required to work with external data.

For the actual API examples, see “JSONStore examples” on page 8-435.

Pull

Many systems use the term *pull* to refer to getting data from an external source.

There are three important pieces:

External Data Source

This source can be a database, a REST or SOAP API, or many others. The only requirement is that it must be accessible from either the MobileFirst Server or directly from the client application. Ideally, you want this source to return data in JSON format.

Transport Layer

This source is how you get data from the external source into your internal source, a JSONStore collection inside the store. One alternative is a MobileFirst adapter.

Internal Data Source API

This source is the JSONStore APIs that you can use to add JSON data to a collection.

Note: You can populate the internal store with data that is read from a file, an input field, or hardcoded data in a variable. It does not have to come exclusively from an external source that requires network communication.

Example pull scenario

All of the following code examples are written in pseudocode that looks similar to JavaScript.

Note: Use MobileFirst adapters for the Transport Layer. Some of the advantages of using MobileFirst adapters are XML to JSON, security, filtering, and decoupling of server-side code and client-side code.

External Data Source: Backend REST endpoint

Imagine that you have a REST endpoint that read data from a database and returns it as an array of JSON objects.

```
app.get('/people', function (req, res) {  
    var people = database.getAll('people');  
    res.json(people);  
});
```

The data that is returned can look like the following example:

```
[{id: 0, name: 'carlos', ssn: '111-22-3333'},  
 {id: 1, name: 'mike', ssn: '111-44-3333'},  
 {id: 2, name: 'dgonz' ssn: '111-55-3333'}]
```

Transport Layer: MobileFirst adapter

Imagine that you created an adapter that is called `people` and you defined a procedure that is called `getPeople`. The procedure calls the REST endpoint and returns the array of JSON objects to the client. You might want to do more work here, for example, return only a subset of the data to the client.

```
function getPeople () {  
    var input = {  
        method : 'get',  
        path : '/people'  
    };  
    return WL.Server.invokeHttp(input);  
}
```

On the client, you can use the `WL.Client.invokeProcedure` API to get the data. Additionally, you might want to pass some parameters from the client to the MobileFirst adapter. One example is a date with the last time that the client got new data from the external source through the MobileFirst adapter.

```
WL.Client.invokeProcedure({  
    adapter : 'people',  
    procedure : 'getPeople',  
    parameters : []  
})  
  
.then(function (responseFromAdapter) {  
    // ...  
});
```

Note: You might want to take advantage of the `compressResponse`, `timeout`, and other parameters that can be passed to the `invokeProcedure` API.

Alternatively, you can skip the MobileFirst adapter and use something like `jQuery.ajax` to directly contact the REST endpoint with the data that you want to store.

```
$.ajax({  
    type: 'GET',  
    url: 'http://example.org/people',
```

```

    })
    .then(function (responseFromEndpoint) {
        // ...
    });

```

Internal Data Source API: JSONStore

After you have the response from the backend, you can work with that data by using JSONStore.

JSONStore provides a way to track local changes. It enables some APIs to mark documents as dirty. The API records the last operation that was performed on the document, and when the document was marked as dirty. You can then use this information to implement features like data synchronization.

The change API takes the data and some options:

replaceCriteria

These search fields are part of the input data. They are used to locate documents that are already inside a collection. For example, if you select:

```
['id', 'ssn']
```

as the replace criteria, pass the following array as the input data:

```
[{id: 1, ssn: '111-22-3333', name: 'Carlos'}]
```

and the people collection already contains the following document:

```
{_id: 1, json: {id: 1, ssn: '111-22-3333', name: 'Carlitos'}}
```

The change operation locates a document that matches exactly the following query:

```
{id: 1, ssn: '111-22-3333'}
```

Then the change operation performs a replacement with the input data and the collection contains:

```
{_id: 1, json: {id:1, ssn: '111-22-3333', name: 'Carlos'}}
```

The name was changed from Carlitos to Carlos. If more than one document matches the replace criteria, then all documents that match are replaced with the respective input data.

addNew

When no documents match the replace criteria, the change API looks at the value of this flag. If the flag is set to true, the change API creates a new document and adds it to the store. Otherwise, no further action is taken.

markDirty

Determines whether the change API marks documents that are replaced or added as dirty.

An array of data is returned from the MobileFirst adapter:

```

.then(function (responseFromAdapter) {

    var accessor = WL.JSONStore.get('people');

    var data = responseFromAdapter.invocationResult.array;

    var changeOptions = {
        replaceCriteria : ['id', 'ssn'],

```

```

        addNew : true,
        markDirty : false
    };

    return accessor.change(data, changeOptions);
})

.then(function() {
    // ...
})

```

You can use other APIs to track changes to the local documents that are stored. Always get an accessor to the collection that you perform operations on.

```
var accessor = WL.JSONStore.get('people')
```

Then, you can add data (array of JSON objects) and decide whether you want it to be marked dirty or not. Typically, you want to set the `markDirty` flag to `false` when you get changes from the external source. Then, set the flag to `true` when you add data locally.

```
accessor.add(data, {markDirty: true})
```

You can also replace a document, and opt to mark the document with the replacements as dirty or not.

```
accessor.replace(doc, {markDirty: true})
```

Similarly, you can remove a document, and opt to mark the removal as dirty or not. Documents that are removed and marked dirty do not show up when you use the `find` API. However, they are still inside the collection until you use the `markClean` API, which physically removes the documents from the collection. If the document is not marked as dirty, it is physically removed from the collection.

```
accessor.remove(doc, {markDirty: true})
```

Push

Many systems use the term *push* to refer to sending data to an external source.

There are three important pieces:

Internal Data Source API

This source is the `JSONStore` API that returns documents with local-only changes (dirty).

Transport Layer

This source is how you want to contact the external data source to send the changes.

External Data Source

This source is typically a database, REST or SOAP endpoint, among others, that receives the updates that the client made to the data.

Example push scenario

All of the following code examples are written in pseudocode that looks similar to JavaScript.

Note: Use `MobileFirst` adapters for the Transport Layer. Some of the advantages of using `MobileFirst` adapters are XML to JSON, security, filtering, and decoupling of server-side code and client-side code.

Internal Data Source API: JSONStore

After you have an accessor to the collection, you can call the `getAllDirty` API to get all documents that are marked as dirty. These documents have local-only changes that you want to send to the external data source through a transport layer.

```
var accessor = WL.JSONStore.get('people');

accessor.getAllDirty()

.then(function (dirtyDocs) {
  // ...
});
```

The `dirtyDocs` argument looks like the following example:

```
[{_id: 1,
  json: {id: 1, ssn: '111-22-3333', name: 'Carlos'},
  _operation: 'add',
  _dirty: '1395774961,12902'}]
```

The fields are:

`_id`

Internal field that JSONStore uses. Every document is assigned a unique one.

`json`

The data that was stored.

`_operation`

The last operation that was performed on the document. Possible values are `add`, `store`, `replace`, and `remove`.

`_dirty`

A time stamp that is stored as a number to represent when the document was marked dirty.

Transport Layer: MobileFirst adapter

You can choose to send dirty documents to a MobileFirst adapter. Assume that you have a `people` adapter that is defined with an `updatePeople` procedure.

```
.then(function (dirtyDocs) {

  return WL.Client.invokeProcedure({
    adapter : 'people',
    procedure : 'updatePeople',
    parameters : [ dirtyDocs ]
  });
})

.then(function (responseFromAdapter) {
  // ...
})
```

Note: You might want to take advantage of the `compressResponse`, `timeout`, and other parameters that can be passed to the `invokeProcedure` API. On the MobileFirst Server, the adapter has the `updatePeople` procedure, which might look like the following example:

```
function updatePeople (dirtyDocs) {

  var input = {
    method : 'post',
    path : '/people',
```

```

        body: {
            contentType : 'application/json',
            content : JSON.stringify(dirtyDocs)
        }
    };

    return WL.Server.invokeHttp(input);
}

```

Instead of relaying the output from the `getAllDirty` API on the client, you might have to update the payload to match a format that is expected by the backend. You might have to split the replacements, removals, and inclusions into separate backend API calls.

Alternatively, you can iterate over the `dirtyDocs` array and check the `_operation` field. Then, send replacements to one procedure, removals to another procedure, and inclusions to another procedure. The previous example sends all dirty documents in bulk to the MobileFirst adapter.

```

var len = dirtyDocs.length;
var arrayOfPromises = [];

while (len--) {

    var currentDirtyDoc = dirtyDocs[len];

    switch (currentDirtyDoc._operation) {

        case 'add':
        case 'store':

            arrayOfPromises.push(WL.Client.invokeProcedure({
                adapter : 'people',
                procedure : 'addPerson',
                parameters : [ currentDirtyDoc ]
            }));

            break;

        case 'replace':
        case 'refresh':

            arrayOfPromises.push(WL.Client.invokeProcedure({
                adapter : 'people',
                procedure : 'replacePerson',
                parameters : [ currentDirtyDoc ]
            }));

            break;

        case 'remove':
        case 'erase':

            arrayOfPromises.push(WL.Client.invokeProcedure({
                adapter : 'people',
                procedure : 'removePerson',
                parameters : [ currentDirtyDoc ]
            }));

    }
}

$.when.apply(this, arrayOfPromises)
.then(function () {
    var len = arguments.length;

```

```

        while (len--) {
            // Look at the responses in arguments[len]
        }
    });

```

Alternatively, you can skip the MobileFirst adapter and contact the REST endpoint directly.

```

.then(function (dirtyDocs) {

    return $.ajax({
        type: 'POST',
        url: 'http://example.org/updatePeople',
        data: dirtyDocs
    });
})

.then(function (responseFromEndpoint) {
    // ...
});

```

External Data Source: Backend REST endpoint

The backend accepts or rejects changes, and then relays a response back to the client. After the client looks at the response, it can pass documents that were updated to the markClean API.

```

.then(function (responseFromAdapter) {

    if (responseFromAdapter is successful) {
        WL.JSONStore.get('people').markClean(dirtyDocs);
    }
})

.then(function () {
    // ...
})

```

After documents are marked as clean, they do not show up in the output from the getAllDirty API.

JSONStore wizard (JavaScript only)

The MobileFirst JSONStore wizard can help you create a template JavaScript file that is based on search fields that are selected from the backend that you provide. Using the wizard is optional.

Procedure

1. In MobileFirst Studio, create an application.
 - a. In the Project Explorer tab, right-click the project name.
 - b. Click **New > MobileFirst Hybrid Application**. The Hybrid Application window opens.
 - c. Enter the appropriate information into the fields in this window and click **Finish**. A standard application structure is created.
2. In MobileFirst Studio, create and deploy an adapter.
 - a. In the Project Explorer tab, right-click the project name.
 - b. Click **New > MobileFirst Adapter**. The New MobileFirst Adapter window opens.
 - c. Select the appropriate adapter type, enter an adapter name, and select the **JSON Data available offline** check box.
 - d. Optional: To change the suggested procedure names, type over them.
 - e. Click **Finish**. A standard adapter structure is created.

- f. Deploy the adapter.
3. Retrieve a JSON object with the adapter:
 - a. Right-click the adapter name.
 - b. Click **Run As > Invoke MobileFirst Procedure**. The Edit Configuration window opens.
 - c. Select the procedure that is used for retrieving JSON data and click **Run**. The JSON object that is returned by the procedure is displayed.
4. Create a local JSONStore:
 - a. In MobileFirst Studio, click **File > New > MobileFirst JSONStore** and select the project and app names. The Create JSON Collection wizard starts.
 - b. Follow the instructions in the wizard to start the adapter, name the collection, and specify the searchable fields.
 - c. Optional: To encrypt collections for an application, select the **Encrypt collections** check box in the wizard. The wizard creates a JavaScript file that is named `collection_nameCollection.js` in the application's `common/js` directory, where `collection_name` is the name you specified in the wizard.
5. Review the `collection_nameCollection.js` file and include its content manually in your application's `.js` file.

Note: The input data for the JSONStore wizard must be encoded with UTF-8. Other data encoding is not supported.

JSONStore analytics

You can enable the collection of analytics information for Android and iOS.

Overview

You can collect key pieces of analytics information that are related to JSONStore with the MobileFirst platform.

File information

File information is collected once per application session if the JSONStore API is called with the analytics flag set to true. An application session is defined as loading the application into memory and removing it from memory. You can use this information to determine how much space is being used by JSONStore content in the application.

Performance metrics

Performance metrics are collected every time a JSONStore API is called with information about the start and end times of an operation. You can use this information to determine how much time various operations take in milliseconds.

Examples

iOS

```
JSONStoreOpenOptions* options = [JSONStoreOpenOptions new];
[options setAnalytics:YES];

[[JSONStore sharedInstance] openCollections:@[...] withOptions:options error:nil];
```

Android

```
JSONStoreInitOptions initOptions = new JSONStoreInitOptions();
initOptions.setAnalytics(true);

WLJSONStore.getInstance(...).openCollections(..., initOptions);
```

JavaScript

This example applies only when the application is running on the Android or iOS environments.

```
var options = {
  analytics : true
};

WL.JSONStore.init(..., options);
```

JSONStore security utilities

Learn about JSONStore security utilities.

JSONStore security utilities overview

The MobileFirst client-side API provides some security utilities to help protect your user's data. Features like JSONStore are great if you want to protect JSON objects. However, it is not recommended to store binary blobs in a JSONStore collection.

Instead, store binary data on the file system, and store the file paths and other metadata inside a JSONStore collection. If you want to protect files like images, you can encode them as base64 strings, encrypt it, and write the output to disk. When it is time to decrypt the data, you can look up the metadata in a JSONStore collection, read the encrypted data from the disk, and decrypt it using the metadata that was stored. This metadata can include the key, *salt*, Initialization Vector (IV), type of file, path to the file, and others.

At a high level, the SecurityUtils API provides the following APIs:

- Key generation - Instead of passing a password directly to the encryption function, this key generation function uses Password Based Key Derivation Function v2 (PBKDF2) to generate a strong 256-bit key for the encryption API. It takes a parameter for the number of iterations. The higher the number, the more time it takes an attacker to brute force your key. Use a value of at least 10,000. The salt must be unique and it helps ensure that attackers have a harder time using existing hash information to attack your password. Use a length of 32 bytes.
- Encryption - Input is encrypted by using the Advanced Encryption Standard (AES). The API takes a key that is generated with the key generation API. Internally, it generates a secure IV, which is used to add randomization to the first block cipher. Text is encrypted. If you want to encrypt an image or other binary format, turn your binary into base64 text by using these APIs. This encryption function returns an object with the following parts:
 - ct (cipher text, which is also called the encrypted text)
 - IV
 - v (version, which allows the API to evolve while still being compatible with an earlier version)
- Decryption - Takes the output from the encryption API as input, and decrypts the cipher or encrypted text into plain text.

- Remote random string - Gets a random hex string by contacting a random generator on the MobileFirst Server. The default value is 20 bytes, but you can change the number up to 64 bytes.
- Local random string - Gets a random hex string by generating one locally, unlike the remote random string API, which requires network access. The default value is 32 bytes and there is not a maximum value. The operation time is proportional to the number of bytes.
- Encode base64 - Takes a string and applies base64 encoding. Incurring a base64 encoding by the nature of the algorithm means that the size of the data is increased by approximately 1.37 times the original size.
- Decode base64 - Takes a base64 encoded string and applies base64 decoding.

JSONStore security utilities setup

Ensure that you import the following files to use the JSONStore security utilities APIs.

iOS

```
#import "WLSecurityUtils.h"
```

Android

```
import com.worklight.wlclient.api.SecurityUtils
```

JavaScript

No setup is required.

JSONStore security utilities examples

Encryption and decryption

```
// User provided password, hardcoded only for simplicity.
NSString* password = @"HelloPassword";

// Random salt with recommended length.
NSString* salt = [WLSecurityUtils generateRandomStringWithBytes:32];

// Recommended number of iterations.
int iterations = 10000;

// Populated with an error if one occurs.
NSError* error = nil;

// Call that generates the key.
NSString* key = [WLSecurityUtils generateKeyWithPassword:password
                        andSalt:salt
                        andIterations:iterations
                        error:&error];

// Text that is encrypted.
NSString* originalString = @"My secret text";
NSDictionary* dict = [WLSecurityUtils encryptText:originalString
                        withKey:key
                        error:&error];

// Should return: 'My secret text'.
NSString* decryptedString = [WLSecurityUtils decryptWithKey:key
                        andDictionary:dict
                        error:&error];
```

Encode and decode base64

```
// Input string.
NSString* originalString = @"Hello world!";

// Encode to base64.
NSData* originalStringData = [originalString dataUsingEncoding:NSUTF8StringEncoding];
NSString* encodedString = [WLSecurityUtils base64StringFromData:originalStringData length:originalString.length];

// Should return: 'Hello world!'.
NSString* decodedString = [[NSString alloc] initWithData:[WLSecurityUtils base64DataFromString:encodedString] encoding:NSUTF8StringEncoding];
```

Get remote random

```
[WLSecurityUtils getRandomStringFromServerWithBytes:32
    timeout:1000
    completionHandler:^(NSURLResponse *response, NSData *data, NSError *connectionError) {

    // You might want to see the response and the connection error before moving forward.

    // Get the secure random string.
    NSString* secureRandom = [[NSString alloc] initWithData:data encoding:NSUTF8StringEncoding];
}];
```

Get local random

```
NSString* secureRandom = [WLSecurityUtils generateRandomStringWithBytes:32];
```

JSONStore security utilities Android examples:

Learn about JSONStore security utilities Android examples.

Encryption and decryption

```
String password = "HelloPassword";
String salt = SecurityUtils.getRandomString(32);
int iterations = 10000;

String key = SecurityUtils.generateKey(password, salt, iterations);

String originalText = "Hello World!";

JSONObject encryptedObject = SecurityUtils.encrypt(key, originalText);

// Deciphered text will be the same as the original text.
String decipheredText = SecurityUtils.decrypt(key, encryptedObject);
```

Encode and decode base64

```
import android.util.Base64;

String originalText = "Hello World";
byte[] base64Encoded = Base64.encode(text.getBytes("UTF-8"), Base64.DEFAULT);

String encodedText = new String(base64Encoded, "UTF-8");

byte[] base64Decoded = Base64.decode(text.getBytes("UTF-8"), Base64.DEFAULT);

// Decoded text will be the same as the original text.
String decodedText = new String(base64Decoded, "UTF-8");
```

Get remote random

```
Context context; // This is the current Activity's context.
int byteLength = 32;

// Listener calls the callback functions after it gets the response from the server.
WLRequestListener listener = new WLRequestListener(){
    @Override
    public void onSuccess(WLResponse wLResponse) {
        // Implement the success handler.
    }

    @Override
    public void onFailure(WLFailResponse wLFailResponse) {
        // Implement the failure handler.
    }
};

SecurityUtils.getRandomStringFromServer(byteLength, context, listener);
```

Get local random

```
int byteLength = 32;
String randomString = SecurityUtils.getRandomString(byteLength);
```

JSONStore security utilities JavaScript examples:

Learn about JSONStore security utilities JavaScript examples.

Encryption and decryption

```
// Keep the key in a variable so that it can be passed to the encrypt and decrypt API.
var key;

// Generate a key.
WL.SecurityUtils.keygen({
  password: 'HelloPassword',
  salt: Math.random().toString(),
  iterations: 10000
})

.then(function (res) {

  // Update the key variable.
  key = res;

  // Encrypt text.
  return WL.SecurityUtils.encrypt({
    key: key,
    text: 'My secret text'
  });
})

.then(function (res) {

  // Append the key to the result object from encrypt.
  res.key = key;

  // Decrypt.
  return WL.SecurityUtils.decrypt(res);
})

.then(function (res) {

  // Remove the key from memory.
  key = null;

  //res => 'My secret text'
})

.fail(function (err) {
  // Handle failure in any of the previously called APIs.
});
```

Encode and decode base64

```
WL.SecurityUtils.base64Encode('Hello World!')
.then(function (res) {
  return WL.SecurityUtils.base64Decode(res);
})
.then(function (res) {
  //res => 'Hello World!'
})
.fail(function (err) {
  // Handle failure.
});
```

Get remote random

```
WL.SecurityUtils.remoteRandomString(32)
.then(function (res) {
  // res => deba58e9601d24380dce7dda85534c43f0b52c342ceb860390e15a638baecc7b
})
.fail(function (err) {
  // Handle failure.
});
```

Get local random

```
WL.SecurityUtils.localRandomString(32)
.then(function (res) {
  // res => 40617812588cf3ddc1d1ad0320a907a7b62ec0abee0cc8c0dc2de0e24392843c
})
.fail(function (err) {
  // Handle failure.
});
```

Storing mobile data in Cloudant

You can store data for your mobile application in a Cloudant database. Cloudant is an advanced NoSQL database that can handle a wide variety of data types, such as JSON, full-text, and geospatial data. The SDK is available for Java , Objective-C, and Swift.

CloudantToolkit and IMFData frameworks are deprecated

Use the CDTDatstore SDK as a replacement for CloudantToolkit and IMFData frameworks.

Use the Cloudant Sync Android SDK as a replacement for CloudantToolkit and IMFData frameworks. With Cloudant Sync, you can persist data locally and replicate with a remote data store.

If you want to access remote stores directly, use REST calls in your application and refer to the Cloudant API Reference.

Cloudant versus JSONStore

You might consider using JSONStore instead of Cloudant in the following scenarios:

- When you are storing data on the mobile device that must be stored in a FIPS 140-2 compliant manner.
- When you need to synchronize data between the device and the enterprise.
- When you are developing a hybrid application.

For more information about JSONStore, see “JSONStore” on page 8-416.

Integrating MobileFirst and Cloudant security

Adapter sample

To download the sample, see Sample: mfp-bluelist-on-premises.

To understand the MobileFirst adapter that is included with the Bluelist sample, you must understand both Cloudant security and “MobileFirst security framework” on page 8-527.

The Bluelist adapter sample has two primary functions:

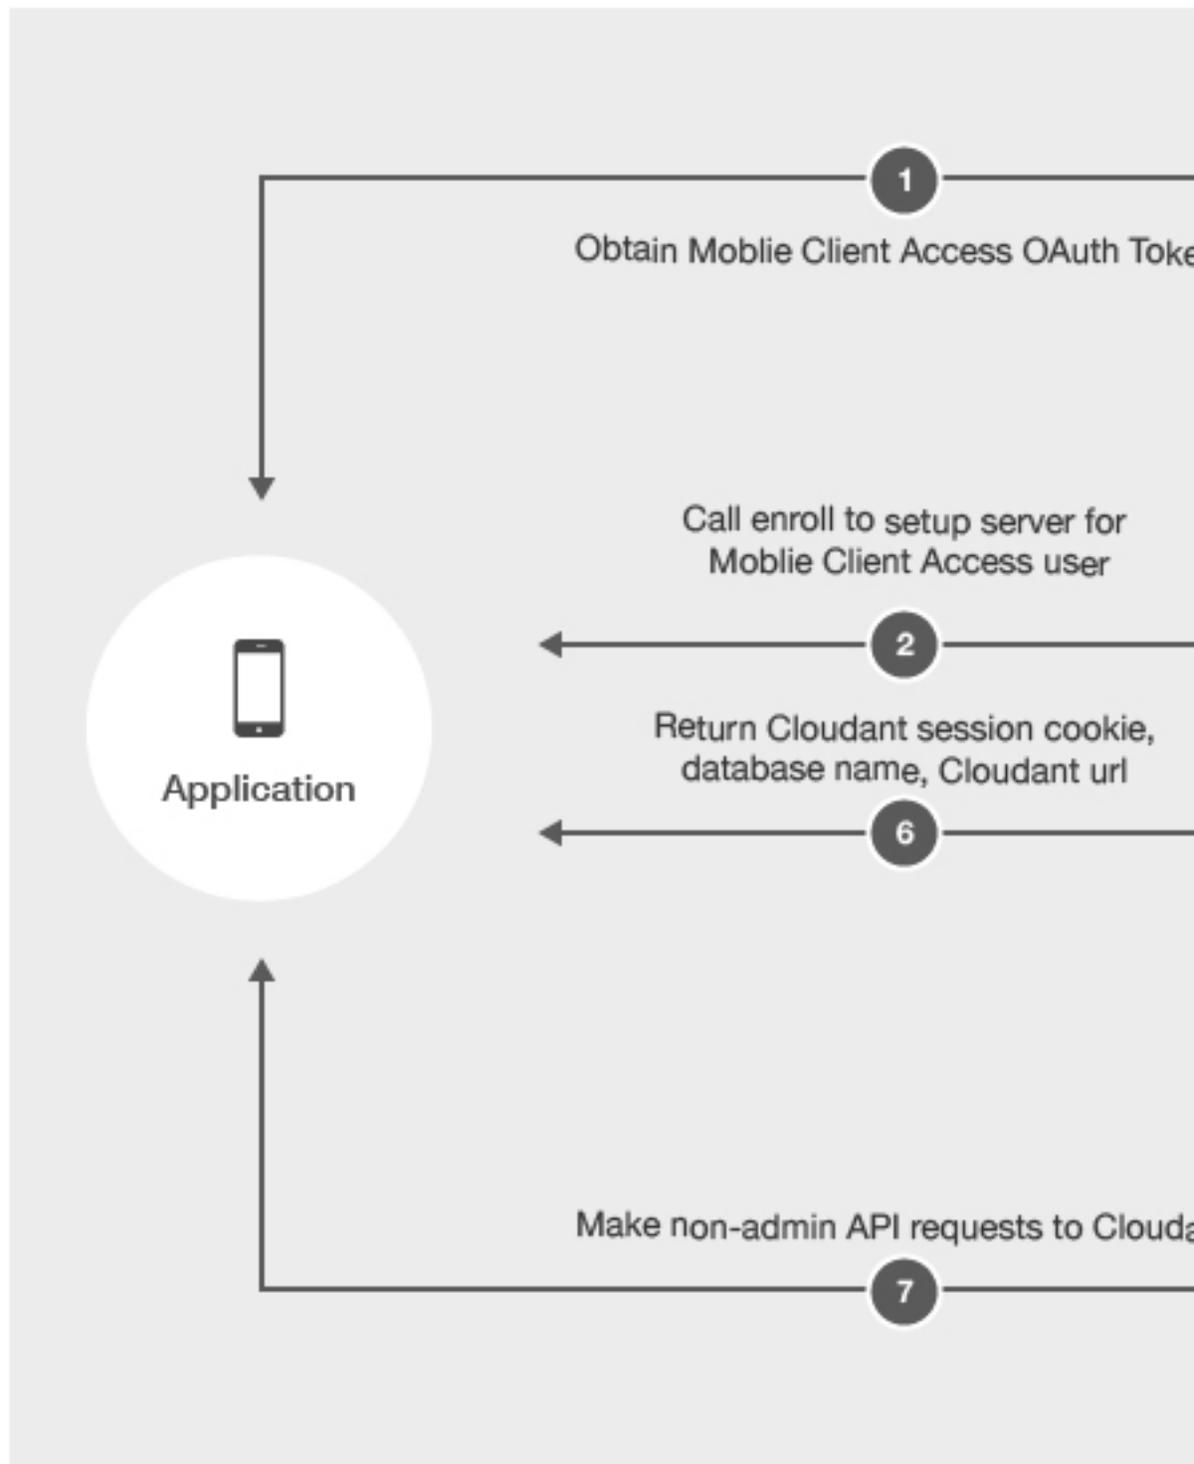

- Exchange MobileFirst OAuth tokens for Cloudant session cookies
- Perform the required admin requests to Cloudant from the Bluelist sample.

The sample demonstrates how to perform API requests that require admin access on the server where it is secure. While it is possible to place your admin credentials on the mobile device, it is a better practice to restrict access from mobile devices.

The Bluelist sample integrates MobileFirst security with Cloudant security. The MobileFirst adapter sample maps a MobileFirst identity to a Cloudant identity. The mobile device receives a Cloudant session cookie to perform non-admin API requests. The sample uses the Couch Security model.

Enroll REST endpoint

The following diagram illustrates the integration performed by the Bluelist adapter sample /enroll endpoint.

1. Mobile device obtains the MobileFirst OAuth token from the MobileFirst Server.
2. Mobile device calls the /enroll endpoint on the MobileFirst adapter.
3. The MobileFirst adapter sample validates the MobileFirst OAuth token with the MobileFirst Server.

4. If valid, performs admin API requests to Cloudant. The sample checks for an existing Cloudant user in the `_users` database.
 - If the user exists, look up Cloudant user credentials in the `_users` database.
 - If a new user is passed, use the Cloudant admin credentials, create a new Cloudant user and store in the `_users` database.
 - Generate a unique database name for the user and create a remote database on Cloudant with that name.
 - Give the Cloudant user permissions to read/write the newly created database.
 - Create the required indexes for the Bluelist application.
5. Request a new Cloudant session cookie.
6. The MobileFirst adapter sample returns a Cloudant session cookie, remote database name, and Cloudant URL to the mobile device.
7. Mobile device makes requests directly to Cloudant until the session cookie expires.

sessioncookie REST Endpoint

In the case of an expired session cookie, the mobile device can exchange a valid MobileFirst OAuth token for a Cloudant session cookie with the `/sessioncookie` endpoint.

Creating databases

Accessing local data stores

You can use a local data store to store data on the client device for fast access, even when offline.

Procedure

To create Store objects to access a local database, supply a name for the data store.

Important: The database name must be in lowercase.

BEFORE (with `IMFData/CloudantToolkit`):

```
//Get reference to data manager
IMFDataManager *manager = [IMFDataManager sharedInstance];
NSString *name = @"automobiledb";
NSError *error = nil;

//Create local store
CDTStore *store = [manager localStore:name error:&error];
let manager = IMFDataManager.sharedInstance()
let name = "automobiledb"

var store:CDTStore?
do {
    store = try manager.localStore(name)
} catch let error as NSError {
    // Handle error
}

// Get reference to DataManager
DataManager manager = DataManager.getInstance();

// Create local store
String name = "automobiledb";

Task<Store> storeTask = manager.localStore(name);
```

```

storeTask.continueWith(new Continuation<Store, Void>() {
    @Override
    public Void then(Task<Store> task) throws Exception {
        if(task.isFaulted()){
            // Handle error
        }else{
            // Do something with Store
            Store store = task.getResult();
        }
        return null;
    }
});

```

AFTER (with Cloudant Sync):

```

// Get reference to datastore manager
CDTDatastoreManager *datastoreManager = existingDatastoreManager;
NSString *name = @"automobiledb";
NSError *error = nil;

//Create datastore
CDTDatastore *datastore = [datastoreManager datastoreNamed:name error:&error];
// Get reference to datastore manager
let datastoreManager:CDTDatastoreManager = existingDatastoreManager
let name:String = "automobiledb"

//Create local store
var datastore:CDTDatastore?
do{
    datastore = try datastoreManager.datastoreNamed(name)
}catch let error as NSError{
    // Handle error
}

// Create DatastoreManager
File path = context.getDir("databasesdir", Context.MODE_PRIVATE);
DatastoreManager manager = new DatastoreManager(path.getAbsolutePath());

// Create a Datastore
String name = "automobiledb";
Datastore datastore = manager.openDatastore(name);

```

Creating remote data stores

Procedure

To save data in the remote store, supply the data store name.

BEFORE (with IMFData/CloudantToolkit):

```

// Get reference to data manager
IMFDataManager *manager = [IMFDataManager sharedInstance];
NSString *name = @"automobiledb";

// Create remote store
[manager remoteStore:name completionHandler:^(CDTStore *createdStore, NSError *error) {
    if(error){
        // Handle error
    }else{
        CDTStore *store = createdStore;
        NSLog(@"Successfully created store: %@", store.name);
    }
}];

let manager = IMFDataManager.sharedInstance()
let name = "automobiledb"

manager.remoteStore(name, completionHandler: { (createdStore:CDTStore!, error:NSError!) -> Void in
    if nil != error {

```

```

        //Handle error
    } else {
        let store:CDTStore = createdStore
        print("Successfully created store: \(store.name)")
    }
})
// Get reference to DataManager
DataManager manager = DataManager.getInstance();

// Create remote store
String name = "automobiledb";

Task<Store> storeTask = manager.remoteStore(name);
storeTask.continueWith(new Continuation<Store, Void>() {
    @Override
    public Void then(Task<Store> task) throws Exception {
        if(task.isFaulted()){
            // Handle error
        }else{
            // Do something with Store
            Store store = task.getResult();
        }
        return null;
    }
});

```

AFTER (with Cloudant Sync):

See Cloudant REST documentation for Database Create.

Encrypting data on the device

To enable the encryption of local data stores on mobile devices, you must make updates to your application to include encryption capabilities and create encrypted data stores.

Encrypting data on iOS devices

Procedure

1. Obtain the encryption capabilities with CocoaPods.

- a. Open your Podfile and add the following line:

BEFORE (with IMFData/CloudantToolkit):

```
pod 'IMFDataLocal/SQLCipher'
```

AFTER (with Cloudant Sync):

```
pod 'CDTDatastore/SQLCipher'
```

For more information, see the CDTDatastore encryption documentation.

- b. Run the following command to add the dependencies to your application.

```
pod install
```
2. To use the encryption feature within a Swift application, add the following imports to the associated bridging header for the application: BEFORE (with IMFData/CloudantToolkit):

```

#import <CloudantSync.h>
#import <CloudantSyncEncryption.h>
#import <CloudantToolkit/CloudantToolkit.h>
#import <IMFData/IMFData.h>

```

AFTER (with Cloudant Sync):

```
#import <CloudantSync.h>
#import <CloudantSyncEncryption.h>
```

3. Initialize your local store for encryption with a key provider.

Note: If you change the password after creating the database, an error occurs because the existing database cannot be decrypted. You cannot change your password after the database has been encrypted. You must delete the database to change passwords.

BEFORE (with IMFData/CloudantToolkit):

```
//Get reference to data manager
IMFDataManager *manager = [IMFDataManager sharedInstance];
NSString *name = @"automobiledb";
NSError *error = nil;
```

```
// Initialize a key provider
```

```
id<CDTEncryptionKeyProvider> keyProvider = [CDTEncryptionKeychainProvider providerWithPassword:@
```

```
//Initialize local store
```

```
CDTStore *localStore = [manager localStore: name withEncryptionKeyProvider: keyProvider error: &
```

```
let manager = IMFDataManager.sharedInstance()
let name = "automobiledb"
```

```
let keyProvider = CDTEncryptionKeychainProvider(password: "passw0rd", forIdentifier: "identifier")
var store:CDTStore?
do {
    store = try manager.localStore(name, withEncryptionKeyProvider: keyProvider)
} catch let error as NSError {
    // Handle error
}
```

AFTER (with Cloudant Sync):

```
// Get reference to datastore manager
CDTDatastoreManager *datastoreManager = existingDatastoreManager;
NSString *name = @"automobiledb";
NSError *error = nil;
```

```
// Create KeyProvider
```

```
id<CDTEncryptionKeyProvider> keyProvider = [CDTEncryptionKeychainProvider providerWithPassword:@
```

```
//Create local store
```

```
CDTDatastore *datastore = [datastoreManager datastoreNamed:name withEncryptionKeyProvider:keyProv
```

```
// Get reference to datastore manager
```

```
let datastoreManager:CDTDatastoreManager = existingDatastoreManager
let name:String = "automobiledb"
```

```
//Create local store
```

```
var datastore:CDTDatastore?
```

```
let keyProvider = CDTEncryptionKeychainProvider(password: "passw0rd", forIdentifier: "identifier")
do{
    datastore = try datastoreManager.datastoreNamed(name, withEncryptionKeyProvider: keyProvider)
} catch let error as NSError{
    // Handle error
}
```

4. When you are replicating data with an encrypted local store, you must initialize the CDTPullReplication and CDTPushReplication methods with a key provider.

BEFORE (with IMFData/CloudantToolkit):

```
//Get reference to data manager
IMFDataManager *manager = [IMFDataManager sharedInstance];
NSString *databaseName = @"automobiledb";
```

```
// Initialize a key provider
```

```
id<CDTEncryptionKeyProvider> keyProvider = [CDTEncryptionKeychainProvider providerWithPassword:@
```

```

// pull replication
CDTPullReplication *pull = [manager pullReplicationForStore: databaseName withEncryptionKeyPro

// push replication
CDTPushReplication *push = [manager pushReplicationForStore: databaseName withEncryptionKeyPro
//Get reference to data manager
let manager = IMFDataManager.sharedInstance()
let databaseName = "automobiledb"

// Initalize a key provider
let keyProvider = CDTEncryptionKeychainProvider(password: "password", forIdentifier: "identifi

// pull replication
let pull:CDTPullReplication = manager.pullReplicationForStore(databaseName, withEncryptionKeyP

// push replication
let push:CDTPushReplication = manager.pushReplicationForStore(databaseName, withEncryptionKeyP

```

AFTER (with Cloudant Sync):

Replication with an encrypted database requires no changes from replication with an unencrypted database.

Encrypting data on Android devices

To encrypt data on an Android device, obtain encryption capabilities by including the correct libraries in your application. Then, you can initialize your local store for encryption and replicate data.

Procedure

1. Add the Cloudant Toolkit library as a dependency in your build.gradle file: BEFORE (with IMFData/CloudantToolkit):

```

repositories {
    mavenCentral()
}

dependencies {
    compile 'com.ibm.mobile.services:cloudant-toolkit-local:1.0.0'
}

```

AFTER (with Cloudant Sync):

```

repositories {
    mavenLocal()
    maven { url "http://cloudant.github.io/cloudant-sync-eap/repository/" }
    mavenCentral()
}

dependencies {
    compile group: 'com.cloudant', name: 'cloudant-sync-datastore-core', version:'0.13.2'
    compile group: 'com.cloudant', name: 'cloudant-sync-datastore-android', version:'0.13.2'
    compile group: 'com.cloudant', name: 'cloudant-sync-datastore-android-encryption', version:'0.13.2'
}

```

2. Download the SQLCipher for Android v3.2 .jar and .so binary files and include them in your application in the appropriate folders within your app structure:
 - a. Add libraries. Add the shared library files and SQLCipher archive to the jniLibs folder under your Android app directory.
 - b. Add the required ICU compressed file to the assets folder in your app.
 - c. Add sqlcipher.jar as a file dependency. From the app folder menu in Android studio, select the **Dependencies** tab under **Open Module Settings**.

3. Initialize your local store for encryption with a key provider.

Note: If you change the password after you create the database, an error occurs because the existing database cannot be decrypted. You cannot change your password after the database is encrypted. You must delete the database to change passwords.

BEFORE (with IMFData/CloudantToolkit):

```
// Get reference to DataManager
DataManager manager = DataManager.getInstance();

// Initialize a key provider
KeyProvider keyProvider = new AndroidKeyProvider(getContext(),"password","identifier");

// Create local store
String databaseName = "automobiledb";
Task<Store> storeTask = manager.localStore(databaseName, keyProvider);
storeTask.continueWith(new Continuation<Store, Void >() {
    @Override
    public Void then(Task<Store> task) throws Exception {
        if (task.isFaulted()) {
            // Handle error
        } else {
            // Do something with Store
            Store store = task.getResult();
        }
        return null;
    }
});
```

AFTER (with Cloudant Sync):

```
// Load SQLCipher libs
SQLiteDatabase.loadLibs(context);

// Create DatastoreManager
File path = context.getDir("databasesdir", Context.MODE_PRIVATE);
DatastoreManager manager = new DatastoreManager(path.getAbsolutePath());

// Create encrypted local store
String name = "automobiledb";

KeyProvider keyProvider = new AndroidKeyProvider(context,"password","identifier");
Datastore datastore = manager.openDatastore(name, keyProvider);
```

4. When you are replicating data with an encrypted local store, you must pass a KeyProvider object into the pullReplicationForStore() or pushReplicationForStore() method.

BEFORE (with IMFData/CloudantToolkit):

```
//Get reference to data manager
DataManager manager = DataManager.getInstance();
String databaseName = "automobiledb";

// Initialize a key provider
KeyProvider keyProvider = new AndroidKeyProvider(getContext(),"password","identifier");

// pull replication
Task<PushReplication> pullTask = manager.pullReplicationForStore(databaseName, keyProvider);

// push replication
Task<PushReplication> pushTask = manager.pushReplicationForStore(databaseName, keyProvider);
```

AFTER (with Cloudant Sync):

Replication with an encrypted database requires no changes from replication with an unencrypted database.

Setting user permissions

You can set user permissions on remote databases.

Procedure

Set user permissions on the remote store.

BEFORE (with IMFData/CloudantToolkit):

```
// Get reference to data manager
IMFDataManager *manager = [IMFDataManager sharedInstance];

// Set permissions for current user on a store
[manager setCurrentUserPermissions: DB_ACCESS_GROUP_MEMBERS forStoreName: @"automobiledb" completionHandler:^(BOOL success, NSError *error) {
    if(error){
        // Handle error
    }else{
        // setting permissions was successful
    }
}];

// Get reference to data manager
let manager = IMFDataManager.sharedInstance()

// Set permissions for current user on a store
manager.setCurrentUserPermissions(DB_ACCESS_GROUP_MEMBERS, forStoreName: "automobiledb") { (success:Bool, error:NSError!) -> Void in
    if nil != error {
        // Handle error
    } else {
        // setting permissions was successful
    }
}

Task<Boolean> permissionsTask = manager.setCurrentUserPermissions(DataManager.DB_ACCESS_GROUP_MEMBERS, "automobiledb");

permissionsTask.continueWith(new Continuation<Boolean, Object>() {
    @Override
    public Object then(Task<Boolean> task) throws Exception {
        if(task.isFaulted()){
            // Handle error
        }else{
            // setting permissions was successful
        }
        return null;
    }
});
```

AFTER (with Cloudant Sync): You cannot set user permissions from the mobile device. You must set permissions with the Cloudant dashboard or server-side code. For a sample of how to integrate MobileFirst OAuth tokens with Cloudant Security, see the [Bluelist sample](#).

Modeling data

Cloudant stores data as JSON documents. To store data as objects in your application, use the included data object mapper class that maps native objects to the underlying JSON document format.

About this task

Cloudant stores data as JSON documents. The CloudantToolkit framework provided an object mapper to map between native objects and JSON documents. The CDTDatastore API does not provide this feature. The snippets in the following sections demonstrate how to use CDTDatastore objects to accomplish the same operations.

Cloudant stores data as JSON documents. The CloudantToolkit API provided an object mapper to map between native objects and JSON documents. Cloudant Sync does not provide this feature. The snippets in the following sections demonstrate

how to use DocumentRevision objects to accomplish the same operations.

Performing CRUD operations

You can modify the content of a data store.

About this task

For more details on create, retrieve, update, and delete (CRUD) operations, see CDTDatastore CRUD documentation.

For create, retrieve, update, and delete (CRUD) operations on a remote store, see the Cloudant Document API

Creating data

Procedure

Save data.

BEFORE (with IMFData/CloudantToolkit):

```
// Use an existing store
CDTStore *store = existingStore;

// Create your Automobile to save
Automobile *automobile = [[Automobile alloc] initWithMake:@"Toyota" model:@"Corolla" year: 2006];

[store save:automobile completionHandler:^(id savedObject, NSError *error) {
    if (error) {
        // save was not successful, handler received an error
    } else {
        // use the result
        Automobile *savedAutomobile = savedObject;
        NSLog(@"saved revision: %@", savedAutomobile);
    }
}];

// Use an existing store
let store:CDTStore = existingStore

// Create your object to save
let automobile = Automobile(make: "Toyota", model: "Corolla", year: 2006)

store.save(automobile, completionHandler: { (savedObject:AnyObject!, error:NSError!) -> Void in
    if nil != error {
        //Save was not successful, handler received an error
    } else {
        // Use the result
        print("Saved revision: \(savedObject)")
    }
})

// Use an existing store
Store store = existingStore;

// Create your object to save
Automobile automobile = new Automobile("Toyota", "Corolla", 2006);

// Save automobile to store
Task<Object> saveTask = store.save(automobile);
saveTask.continueWith(new Continuation<Object, Void>() {
    @Override
    public Void then(Task<Object> task) throws Exception {
        if (task.isFaulted()) {
            // save was not successful, task.getError() contains the error
        } else {
```

```

        // use the result
        Automobile savedAutomobile = (Automobile) task.getResult();
    }
    return null;
}
});

```

AFTER (with Cloudant Sync):

```

// Use an existing store
CDTDatastore *datastore = existingDatastore;

// Create document body
CDTMutableDocumentRevision * revision = [CDTMutableDocumentRevision revision];
revision.body = @{@"datatype" : @"Automobile", @"make" :@"Toyota", @"model": @"Corolla", @"year" : @2006};

NSError *error = nil;
CDTDocumentRevision *createdRevision = [datastore createDocumentFromRevision:revision error:&error];

if (error) {
    // save was not successful, handler received an error
} else {
    // use the result
    NSLog(@"Revision: %@", createdRevision);
}

// Use an existing store
let datastore:CDTDatastore = existingDatastore

// Create document body
let revision = CDTMutableDocumentRevision()
revision.setBody(["make":"Toyota","model":"Corolla","year":2006])

var createdRevision:CDTDocumentRevision?
do{
    createdRevision = try datastore.createDocumentFromRevision(revision)
    NSLog("Revision: \(createdRevision)");
}catch let error as NSError{
    // Handle error
}

// Use an existing store
Datastore datastore = existingStore;

// Create document body
Map<String, Object> body = new HashMap<String, Object>();
body.put("@datatype", "Automobile");
body.put("make", "Toyota");
body.put("model", "Corolla");
body.put("year", 2006);

// Create revision and set body
MutableDocumentRevision revision = new MutableDocumentRevision();
revision.body = DocumentBodyFactory.create(body);

// Save revision to store
DocumentRevision savedRevision = datastore.createDocumentFromRevision(revision);

```

Reading data

You can fetch data.

Procedure

Read data.

BEFORE (with IMFData/CloudantToolkit):

```

CDTStore *store = existingStore;
NSString *automobileId = existingAutomobileId;

// Fetch Automobile from Store
[store fetchById:automobileId completionHandler:^(id object, NSError *error) {
    if (error) {
        // fetch was not successful, handler received an error
    } else {
        // use the result
        Automobile *savedAutomobile = object;
        NSLog(@"fetched automobile: %@", savedAutomobile);
    }
}];

// Using an existing store and Automobile
let store:CDTStore = existingStore
let automobileId:String = existingAutomobileId

// Fetch Automobile from Store
store.fetchById(automobileId, completionHandler: { (object:AnyObject!, error:NSError!) -> Void in
    if nil != error {
        // Fetch was not successful, handler received an error
    } else {
        // Use the result
        let savedAutomobile:Automobile = object as! Automobile
        print("Fetched automobile: \(savedAutomobile)")
    }
})

// Use an existing store and documentId
Store store = existingStore;
String automobileId = existingAutomobileId;

// Fetch the automobile from the store
Task<Object> fetchTask = store.fetchById(automobileId);
fetchTask.continueWith(new Continuation<Object, Void>() {
    @Override
    public Void then(Task<Object> task) throws Exception {
        if (task.isFaulted()) {
            // fetch was not successful, task.getError() contains the error
        } else {
            // use the result
            Automobile fetchedAutomobile = (Automobile) task.getResult();
        }
        return null;
    }
});

```

AFTER (with Cloudant Sync):

```

// Use an existing store and documentId
CDTDatastore *datastore = existingDatastore;
NSString *documentId = existingDocumentId;

// Fetch the CDTDocumentRevision from the store
NSError *error = nil;
CDTDocumentRevision *fetchedRevision = [datastore getDocumentWithId:documentId error:&error];

if (error) {
    // fetch was not successful, handler received an error
} else {
    // use the result
    NSLog(@"Revision: %@", fetchedRevision);
}

// Use an existing store and documentId
let datastore:CDTDatastore = existingDatastore
let documentId:String = existingDocumentId

```

```

var fetchedRevision:CDTDocumentRevision?
do{
    fetchedRevision = try datastore.getDocumentWithId(documentId)
    NSLog("Revision: \(fetchedRevision)");
}catch let error as NSError{
    // Handle error
}

// Use an existing store and documentId
Datastore datastore = existingStore;
String documentId = existingDocumentId;

// Fetch the revision from the store
DocumentRevision fetchedRevision = datastore.getDocument(documentId);

```

Updating data

To update an object, run a save on an existing object. Because the item exists, it is updated.

Procedure

Update objects.

BEFORE (with IMFData/CloudantToolkit):

```

// Use an existing store and Automobile
CDTStore *store = existingStore;
Automobile *automobile = existingAutomobile;

// Update some of the values in the Automobile
automobile.year = 2015;

// Save Automobile to the store
[store save:automobile completionHandler:^(id savedObject, NSError *error) {
    if (error) {
        // save was not successful, handler received an error
    } else {
        // use the result
        Automobile *savedAutomobile = savedObject;
        NSLog(@"saved automobile: %@", savedAutomobile);
    }
}];

// Use an existing store and Automobile
let store:CDTStore = existingStore
let automobile:Automobile = existingAutomobile

// Update some of the values in the Automobile
automobile.year = 2015

// Save Automobile to the store
store.save(automobile, completionHandler: { (savedObject:AnyObject!, error:NSError!) -> Void in
    if nil != error {
        // Update was not successful, handler received an error
    } else {
        // Use the result
        let savedAutomobile:Automobile = savedObject as! Automobile
        print("Updated automobile: \(savedAutomobile)")
    }
})

// Use an existing store and Automobile
Store store = existingStore;
Automobile automobile = existingAutomobile;

// Update some of the values in the Automobile
automobile.setYear(2015);

// Save automobile to store

```

```

Task<Object> saveTask = store.save(automobile);
saveTask.continueWith(new Continuation<Object, Void>() {
    @Override
    public Void then(Task<Object> task) throws Exception {
        if (task.isFaulted()) {
            // save was not successful, task.getError() contains the error
        } else {
            // use the result
            Automobile savedAutomobile = (Automobile) task.getResult();
        }
        return null;
    }
});

```

AFTER (with Cloudant Sync):

```

// Use an existing store and document
CDTDatastore *datastore = existingDatastore;
CDTMutableDocumentRevision *documentRevision = [existingDocumentRevision mutableCopy];

// Update some of the values in the revision
[documentRevision.body setValue:@2015 forKey:@"year"];

NSError *error = nil;
CDTDocumentRevision *updatedRevision = [datastore updateDocumentFromRevision:documentRevision error:&error];
if (error) {
    // save was not successful, handler received an error
} else {
    // use the result
    NSLog(@"Revision: %@", updatedRevision);
}

// Use an existing store and document
let datastore:CDTDatastore = existingDatastore
let documentRevision:CDTMutableDocumentRevision = existingDocumentRevision.mutableCopy()

// Update some of the values in the revision
documentRevision.body()["year"] = 2015

var updatedRevision:CDTDocumentRevision?
do{
    updatedRevision = try datastore.updateDocumentFromRevision(documentRevision)
    NSLog("Revision: \(updatedRevision)");
}catch let error as NSError{
    // Handle error
}

// Use an existing store and documentId
// Use an existing store
Datastore datastore = existingStore;

// Make a MutableDocumentRevision from the existing revision
MutableDocumentRevision revision = existingRevision.mutableCopy();

// Update some of the values in the revision
Map<String, Object> body = revision.getBody().asMap();
body.put("year", 2015);
revision.body = DocumentBodyFactory.create(body);

// Save revision to store
DocumentRevision savedRevision = datastore.updateDocumentFromRevision(revision);

```

Deleting data

To delete an object, pass the object that you want to delete to the store.

Procedure

Delete objects.

BEFORE (with IMFData/CloudantToolkit):

```
// Using an existing store and Automobile
CDTStore *store = existingStore;
Automobile *automobile = existingAutomobile;

// Delete the Automobile object from the store
[store delete:automobile completionHandler:^(NSString *deletedObjectId, NSString *deletedRevisionId, NSError *error) {
    if (error) {
        // delete was not successful, handler received an error
    } else {
        // use the result
        NSLog(@"deleted Automobile doc-%@-rev-%@", deletedObjectId, deletedRevisionId);
    }
}];

// Using an existing store and Automobile
let store:CDTStore = existingStore
let automobile:Automobile = existingAutomobile

// Delete the Automobile object
store.delete(automobile, completionHandler: { (deletedObjectId:String!, deletedRevisionId:String!, error:NSError!) -> Void
    if nil != error {
        // delete was not successful, handler received an error
    } else {
        // use the result
        print("deleted document doc-\(deletedObjectId)-rev-\(deletedRevisionId)")
    }
})

// Use an existing store and automobile
Store store = existingStore;
Automobile automobile = existingAutomobile;

// Delete the automobile from the store
Task<String> deleteTask = store.delete(automobile);
deleteTask.continueWith(new Continuation<String, Void>() {
    @Override
    public Void then(Task<String> task) throws Exception {
        if (task.isFaulted()) {
            // delete was not successful, task.getError() contains the error
        } else {
            // use the result
            String deletedAutomobileId = task.getResult();
        }
        return null;
    }
});
```

AFTER (with Cloudant Sync):

```
// Use an existing store and revision
CDTDatastore *datastore = existingDatastore;
CDTDocumentRevision *documentRevision = existingDocumentRevision;

// Delete the CDTDocumentRevision from the store
NSError *error = nil;
CDTDocumentRevision *deletedRevision = [datastore deleteDocumentFromRevision:documentRevision error:&error];
if (error) {
    // delete was not successful, handler received an error
} else {
    // use the result
    NSLog(@"deleted document: %@", deletedRevision);
}
```

```

// Use an existing store and revision
let datastore:CDTDatastore = existingDatastore
let documentRevision:CDTDocumentRevision = existingDocumentRevision

var deletedRevision:CDTDocumentRevision?
do{
    deletedRevision = try datastore.deleteDocumentFromRevision(documentRevision)
    NSLog("Revision: \(deletedRevision)");
}catch let error as NSError{
    // Handle error
}

// Use an existing store and revision
Datastore datastore = existingStore;
BasicDocumentRevision documentRevision = (BasicDocumentRevision) existingDocumentRevision;

// Delete revision from store
DocumentRevision deletedRevision = datastore.deleteDocumentFromRevision(documentRevision);

```

Creating indexes

To perform queries, you must create an index.

About this task

For more details, see [CDTDatastore Query](#) documentation. For query operations on a remote store, see the [Cloudant Query API](#).

For more details, see [Cloudant Sync Query](#) documentation. For CRUD operations on a remote store, see [Cloudant's Query API](#).

Procedure

- Create an index that includes the data type. Indexing with the data type is useful when an object mapper is set on the data store.

BEFORE (with [IMFData/CloudantToolkit](#)):

```

// Use an existing data store
CDTStore *store = existingStore;

// The data type to use for the Automobile class
NSString *dataType = [store.mapper dataTypeForClassName:NSStringFromClass([Automobile class])];

// Create the index
[store createIndexWithDataType:dataType fields:@[@"year", @"make"] completionHandler:^(NSError *error) {
    if(error){
        // Handle error
    }else{
        // Continue application flow
    }
}];

// A store that has been previously created.
let store:CDTStore = existingStore

// The data type to use for the Automobile class
let dataType:String = store.mapper.dataTypeForClassName(NSStringFromClass(Automobile.classForCoder()))

// Create the index
store.createIndexWithDataType(dataType, fields: ["year","make"]) { (error:NSError!) -> Void in
    if nil != error {
        // Handle error
    } else {
        // Continue application flow
    }
}

```

```

// Use an existing data store
Store store = existingStore;

// The data type to use for the Automobile class
String dataType = store.getMapper().getDataTypeForClassName(Automobile.class.getCanonicalName());

// The fields to index.
List<IndexField> indexFields = new ArrayList<IndexField>();
indexFields.add(new IndexField("year"));
indexFields.add(new IndexField("make"));

// Create the index
Task<Void> indexTask = store.createIndexWithDataType(dataType, indexFields);
indexTask.continueWith(new Continuation<Void, Void>() {
    @Override
    public Void then(Task<Void> task) throws Exception {
        if(task.isFaulted()){
            // Handle error
        }else{
            // Continue application flow
        }
        return null;
    }
});

```

AFTER (with Cloudant Sync):

```

// A store that has been previously created.
CDTDatastore *datastore = existingDatastore;

NSString *indexName = [datastore ensureIndexed:@"["@datatype", @"year", @"make"] withName:@"automobileindex"];
if(!indexName){
    // Handle error
}

// A store that has been previously created.
let datastore:CDTDatastore = existingDatastore

// Create the index
let indexName:String? = datastore.ensureIndexed(["@datatype","year","make"], withName: "automobileindex")
if(indexName == nil){
    // Handle error
}

// Use an existing store
Datastore datastore = existingStore;

// Create an IndexManager
IndexManager indexManager = new IndexManager(datastore);

// The fields to index.
List<Object> indexFields = new ArrayList<Object>();
indexFields.add("@datatype");
indexFields.add("year");
indexFields.add("make");

// Create the index
indexManager.ensureIndexed(indexFields, "automobile_index");

```

- Delete indexes.

BEFORE (with IMFDData/CloudantToolkit):

```

// Use an existing data store
CDTStore *store = existingStore;
NSString *indexName = existingIndexName;

// Delete the index
[store deleteIndexWithName:indexName completionHandler:^(NSError *error) {
    if(error){
        // Handle error
    }
}

```

```

        }else{
            // Continue application flow
        }
    }];
    // Use an existing store
    let store:CDTStore = existingStore

    // The data type to use for the Automobile class
    let dataType:String = store.mapper.dataTypeForClassName(NSStringFromClass(Automobile.classForCoder()))

    // Delete the index
    store.deleteIndexWithDataType(dataType, completionHandler: { (error:NSError!) -> Void in
        if nil != error {
            // Handle error
        } else {
            // Continue application flow
        }
    })
    // Use an existing data store
    Store store = existingStore;
    String indexName = existingIndexName;

    // Delete the index
    Task<Void> indexTask = store.deleteIndex(indexName);
    indexTask.continueWith(new Continuation<Void, Void>() {
        @Override
        public Void then(Task<Void> task) throws Exception {
            if(task.isFaulted()){
                // Handle error
            }else{
                // Continue application flow
            }
            return null;
        }
    });

```

AFTER (with Cloudant Sync):

```

// Use an existing store
CDTDatastore *datastore = existingDatastore;
NSString *indexName = existingIndexName;

// Delete the index
BOOL success = [datastore deleteIndexNamed:indexName];
if(!success){
    // Handle error
}

// A store that has been previously created.
let datastore:CDTDatastore = existingDatastore
let indexName:String = existingIndexName

// Delete the index
let success:Bool = datastore.deleteIndexNamed(indexName)
if(!success){
    // Handle error
}

// Use an existing store
Datastore datastore = existingStore;
String indexName = existingIndexName;
IndexManager indexManager = existingIndexManager;

// Delete the index
indexManager.deleteIndexNamed(indexName);

```

Querying data

After you create an index, you can query the data in your database.

About this task

For more details, see [CDTDatastore Query](#) documentation.

For more details, see [Cloudant Sync Query](#) documentation.

For query operations on a remote store, see the [Cloudant Query API](#).

Procedure

- Create and run a query on iOS.

BEFORE (with IMFData/CloudantToolkit):

```
// Use an existing store
CDTStore *store = existingStore;

NSPredicate *queryPredicate = [NSPredicate predicateWithFormat:@"(year = 2006)"];
CDTCloudantQuery *query = [[CDTCloudantQuery alloc]
initWithDataTypes:[store.mapper dataTypeForClassName:[NSStringFromClass([Automobile class])] withPredicate:queryPredicate];

[store performQuery:query completionHandler:^(NSArray *results, NSError *error) {
    if(error){
        // Handle error
    }else{
        // Use result of query. Result will be Automobile objects.
    }
}];

// Use an existing store
let store:CDTStore = existingStore

let queryPredicate:NSPredicate = NSPredicate(format:"(year = 2006)")
let query:CDTCloudantQuery = CDTCloudantQuery(dataType: "Automobile", withPredicate: queryPredicate)

store.performQuery(query, completionHandler: { (results:[AnyObject]!, error:NSError!) -> Void in
    if nil != error {
        // Handle error
    } else {
        // Use result of query. Result will be Automobile objects.
    }
})
```

AFTER (with Cloudant Sync):

```
// Use an existing store
CDTDatastore *datastore = existingDatastore;

CDTQResultSet *results = [datastore find:@{@"datatype" : @"Automobile", @"year" : @2006}];
if(results){
    // Use results
}

// Use an existing store
let datastore:CDTDatastore = existingDatastore

let results:CDTQResultSet? = datastore.find(["@datatype" : "Automobile", "year" : 2006])
if(results == nil){
    // Handle error
}
```

- Create and run a query for objects on Android.

To run a query for objects, create a Cloudant query with the query filters on data type. Run the query against a Store object.

BEFORE (with IMFData/CloudantToolkit):

```
// Use an existing store
Store store = existingStore;

// Create data type predicate
Map<String, Object> dataTypeEqualityOpMap = new HashMap<String, Object>();
dataTypeEqualityOpMap.put("$eq", "Automobile");

Map<String, Object> dataTypeSelectorMap = new HashMap<String, Object>();
dataTypeSelectorMap.put("@datatype", dataTypeEqualityOpMap);

// Create year predicate
Map<String, Object> yearEqualityOpMap = new HashMap<String, Object>();
yearEqualityOpMap.put("$eq", 2006);

Map<String, Object> yearSelectorMap = new HashMap<String, Object>();
yearSelectorMap.put("year", yearEqualityOpMap);

// Add predicates to AND compound predicate
List<Map<String, Object>> andPredicates = new ArrayList<Map<String, Object>>();
andPredicates.add(dataTypeSelectorMap);
andPredicates.add(yearSelectorMap);

Map<String, Object> andOpMap = new HashMap<String, Object>();
andOpMap.put("$and", andPredicates);

Map<String, Object> cloudantQueryMap = new HashMap<String, Object>();
cloudantQueryMap.put("selector", andOpMap);

// Create a Cloudant Query Object
CloudantQuery query = new CloudantQuery(cloudantQueryMap);

// Run the Cloudant Query against a Store
Task<List> queryTask = store.performQuery(query);
queryTask.continueWith(new Continuation<List, Object>() {
    @Override
    public Object then(Task<List> task) throws Exception {
        if(task.isFaulted()){
            // Handle Error
        }else{
            List queryResult = task.getResult();
            // Use queryResult to do something
        }
        return null;
    }
});
```

AFTER (with Cloudant Sync):

```
// Use an existing store
Datastore datastore = existingStore;
IndexManager indexManager = existingIndexManager;

// Create data type predicate
Map<String, Object> dataTypeEqualityOpMap = new HashMap<String, Object>();
dataTypeEqualityOpMap.put("$eq", "Automobile");

Map<String, Object> dataTypeSelectorMap = new HashMap<String, Object>();
dataTypeSelectorMap.put("@datatype", dataTypeEqualityOpMap);

// Create year predicate
Map<String, Object> yearEqualityOpMap = new HashMap<String, Object>();
yearEqualityOpMap.put("$eq", 2006);

Map<String, Object> yearSelectorMap = new HashMap<String, Object>();
yearSelectorMap.put("year", yearEqualityOpMap);

// Add predicates to AND compound predicate
```

```

List<Map<String, Object>> andPredicates = new ArrayList<Map<String, Object>>();
andPredicates.add(dataTypeSelectorMap);
andPredicates.add(yearSelectorMap);

Map<String, Object> selectorMap = new HashMap<String, Object>();
selectorMap.put("$and", andPredicates);

// Run the query against a Store
QueryResult result = indexManager.find(selectorMap);

```

Supporting offline storage and synchronization

You can synchronize the data on a mobile device with a remote database instance. You can either pull updates from a remote database to the local database on the mobile device, or push local database updates to a remote database.

Before you begin

For more details, see [CDTDatastore Replication](#) documentation.

For more details, see [Cloudant Sync Replication](#) documentation. For CRUD operations on a remote store, see the [Cloudant Replication API](#)

Running pull replication Procedure

Run pull replication.

BEFORE (with IMFData/CloudantToolkit):

```

// store is an existing CDTStore object created using IMFDataManager remoteStore
__block NSError *replicationError;
CDTPullReplication *pull = [manager pullReplicationForStore: store.name];
CDTReplicator *replicator = [manager.replicatorFactory oneWay:pull error:&replicationError];
if(replicationError){
    // Handle error
}else{
    // replicator creation was successful
}

[replicator startWithError:&replicationError];
if(replicationError){
    // Handle error
}else{
    // replicator start was successful
}

// (optionally) monitor replication via polling
while (replicator.isActive) {
    [NSThread sleepForTimeInterval:1.0f];
    NSLog(@"replicator state : %@", [CDTReplicator stringForReplicatorState:replicator.state]);
}

// Use an existing store
let store:CDTStore = existingStore

do {
    // store is an existing CDTStore object created using IMFDataManager remoteStore
    let pull:CDTPullReplication = manager.pullReplicationForStore(store.name)
    let replicator:CDTReplicator = try manager.replicatorFactory.oneWay(pull)

    // start replication
    try replicator.start()

    // (optionally) monitor replication via polling
    while replicator.isActive() {

```

```

        NSThread.sleepForTimeInterval(1.0)
        print("replicator state : \(CDTReplicator.stringForReplicatorState(replicator.state))")
    }
} catch let error as NSError {
    // Handle error
}
// Use an existing store
Store store = existingStore;

// create a pull replication task
// name is the database name of the store being replicated
Task<PullReplication> pullTask = manager.pullReplicationForStore(store.getName());
pullTask.continueWith(new Continuation<PullReplication, Object>() {
    @Override
    public Object then(Task<PullReplication> task) throws Exception {
        if(task.isFaulted()){
            // Handle error
        }else{
            // Start the replication
            PullReplication pull = task.getResult();
            Replicator replicator = ReplicatorFactory.oneway(pull);
            replicator.start();
        }
        return null;
    }
});

```

AFTER (with Cloudant Sync):

```

// Use an existing datastore
NSURL *remoteStoreUrl = existingRemoteStoreUrl;
CDTDatastoreManager *datastoreManager = existingDatastoreManager;
CDTDatastore *datastore = existingDatastore;

// Create pull replication objects
__block NSError *replicationError;
CDTReplicatorFactory *replicatorFactory = [[CDTReplicatorFactory alloc] initWithDatastoreManager:datastoreManager];
CDTPullReplication *pull = [CDTPullReplication replicationWithSource:remoteStoreUrl target:datastore];
CDTReplicator *replicator = [replicatorFactory oneway:pull error:&error];
if(replicationError){
    // Handle error
}else{
    // replicator creation was successful
}

[replicator startWithError:&replicationError];
if(replicationError){
    // Handle error
}else{
    // replicator start was successful
}

// (optionally) monitor replication via polling
while (replicator.isActive) {
    [NSThread sleepForTimeInterval:1.0f];
    NSLog(@"replicator state : %@", [CDTReplicator stringForReplicatorState:replicator.state]);
}

let remoteStoreUrl:NSURL = existingRemoteStoreUrl
let datastoreManager:CDTDatastoreManager = existingDatastoreManager
let datastore:CDTDatastore = existingDatastore

do {
    // store is an existing CDTStore object created using IMFDataManager remoteStore
    let replicatorFactory = CDTReplicatorFactory(datastoreManager: datastoreManager)
    let pull:CDTPullReplication = CDTPullReplication(source: remoteStoreUrl, target: datastore)

```

```

let replicator:CDTReplicator = try replicatorFactory.oneWay(pull)

// start replication
try replicator.start()

// (optionally) monitor replication via polling
while replicator.isActive() {
    NSThread.sleepForTimeInterval(1.0)
    print("replicator state : \(CDTReplicator.stringForReplicatorState(replicator.state))")
}

} catch let error as NSError {
    // Handle error
}

// Use an opened Datastore to replicate to
Datastore datastore = existingDatastore;
URI uri = existingURI;

// Create a replicator that replicates changes from the remote
final Replicator replicator = ReplicatorBuilder.pull().from(uri).to(datastore).build();

// Register event listener
replicator.getEventBus().register(new Object() {

    @Subscribe
    public void complete(ReplicationCompleted event) {

        // Handle ReplicationCompleted event
    }

    @Subscribe
    public void error(ReplicationErrored event) {

        // Handle ReplicationErrored event
    }
});

// Start replication
replicator.start();

```

Running push replication Procedure

Run push replication.

BEFORE (with IMFData/CloudantToolkit):

```

// store is an existing CDTStore object created using IMFDataManager localStore
__block NSError *replicationError;
CDTPushReplication *push = [manager pushReplicationForStore: store.name];
CDTReplicator *replicator = [manager.replicatorFactory oneWay:push error:&replicationError];
if(replicationError){
    // Handle error
}else{
    // replicator creation was successful
}

[replicator startWithError:&replicationError];
if(replicationError){
    // Handle error
}else{
    // replicator start was successful
}

// (optionally) monitor replication via polling

```

```

while (replicator.isActive) {
    [NSThread sleepForTimeInterval:1.0f];
    NSLog(@"replicator state : %@", [CDTReplicator stringForReplicatorState:replicator.state]);
}

// Use an existing store
let store:CDTStore = existingStore

do {
    // store is an existing CDTStore object created using IMFDataManager localStore
    let push:CDTPushReplication = manager.pushReplicationForStore(store.name)
    let replicator:CDTReplicator = try manager.replicatorFactory.oneWay(push)

    // Start replication
    try replicator.start()

    // (optionally) monitor replication via polling
    while replicator.isActive() {
        NSThread.sleepForTimeInterval(1.0)
        print("replicator state : \(CDTReplicator.stringForReplicatorState(replicator.state))")
    }
} catch let error as NSError {
    // Handle error
}

// Use an existing store
Store store = existingStore;

// create a push replication task
// name is the database name of the store being replicated
Task<PushReplication> pushTask = manager.pushReplicationForStore(store.getName());
pushTask.continueWith(new Continuation<PushReplication, Object>() {
    @Override
    public Object then(Task<PushReplication> task) throws Exception {
        if(task.isFaulted()){
            // Handle error
        }else{
            // Start the replication
            PushReplication push = task.getResult();
            Replicator replicator = ReplicatorFactory.oneway(push);
            replicator.start();
        }
        return null;
    }
});

```

AFTER (with Cloudant Sync):

```

// Use an existing datastore
NSURL *remoteStoreUrl = existingRemoteStoreUrl;
CDTDatastoreManager *datastoreManager = existingDatastoreManager;
CDTDatastore *datastore = existingDatastore;

// Create push replication objects
__block NSError *replicationError;
CDTReplicatorFactory *replicatorFactory = [[CDTReplicatorFactory alloc] initWithDatastoreManager:datastoreManager];
CDTPushReplication *push = [CDTPushReplication replicationWithSource:datastore target:remoteStoreUrl];
CDTReplicator *replicator = [replicatorFactory oneWay:push error:&error];
if(replicationError){
    // Handle error
}else{
    // replicator creation was successful
}

[replicator startWithError:&replicationError];
if(replicationError){
    // Handle error
}else{
    // replicator start was successful
}

```

```

}

// (optionally) monitor replication via polling
while (replicator.isActive) {
    [NSThread sleepForTimeInterval:1.0f];
    NSLog(@"replicator state : %@", [CDTReplicator stringForReplicatorState:replicator.state]);
}

let remoteStoreUrl:NSURL = existingRemoteStoreUrl
let dataStoreManager:CDTDataStoreManager = existingDataStoreManager
let dataStore:CDTDataStore = existingDataStore

do {
    // store is an existing CDTStore object created using IMFDataManager remoteStore
    let replicatorFactory = CDTReplicatorFactory(dataStoreManager: dataStoreManager)
    let push:CDTPushReplication = CDTPushReplication(source: dataStore, target: remoteStoreUrl)
    let replicator:CDTReplicator = try replicatorFactory.oneWay(push)

    // start replication
    try replicator.start()

    // (optionally) monitor replication via polling
    while replicator.isActive() {
        NSThread.sleepForTimeInterval(1.0)
        print("replicator state : \(CDTReplicator.stringForReplicatorState(replicator.state))")
    }

} catch let error as NSError {
    // Handle error
}

// Use an opened DataStore to replicate from
DataStore dataStore = existingStore;
URI uri = existingURI;

// Create a replicator that replicates changes from the local
// database to the remote dataStore.
final Replicator replicator = ReplicatorBuilder.push().from(dataStore).to(uri).build();

// Register event listener
replicator.getEventBus().register(new Object() {

    @Subscribe
    public void complete(ReplicationCompleted event) {

        // Handle ReplicationCompleted event
    }

    @Subscribe
    public void error(ReplicationErrored event) {

        // Handle ReplicationErrored event
    }
});

// Start replication
replicator.start();

```

Push notification

Push notification is the ability of a mobile device to receive messages that are pushed from a server. The most common form of notification is SMS (Short Message Service). Notifications are received regardless of whether the application is currently running.

Notifications can take several forms, and are platform-dependent:

- Alert: a pop-up text message
- Badge, Tile: a graphical representation that includes a short text or image
- Banner, Toast: a pop-up text message at the top of the device display that disappears after it has been read
- Audio alert

The MobileFirst unified push notification mechanism enables the sending of mobile notifications to mobile phones. Notifications are sent through the vendor infrastructure. For example, iPhone notifications are sent from the MobileFirst Server to specialized Apple servers, and from there to the relevant phones. The unified push notification mechanism in IBM MobileFirst Platform Foundation makes the entire process of communicating with the users and devices completely transparent to the developer.

The following diagram shows an example of a push notification mechanism where notifications are sent from the MobileFirst Server to specialized servers or gateways and from there to the relevant phones.

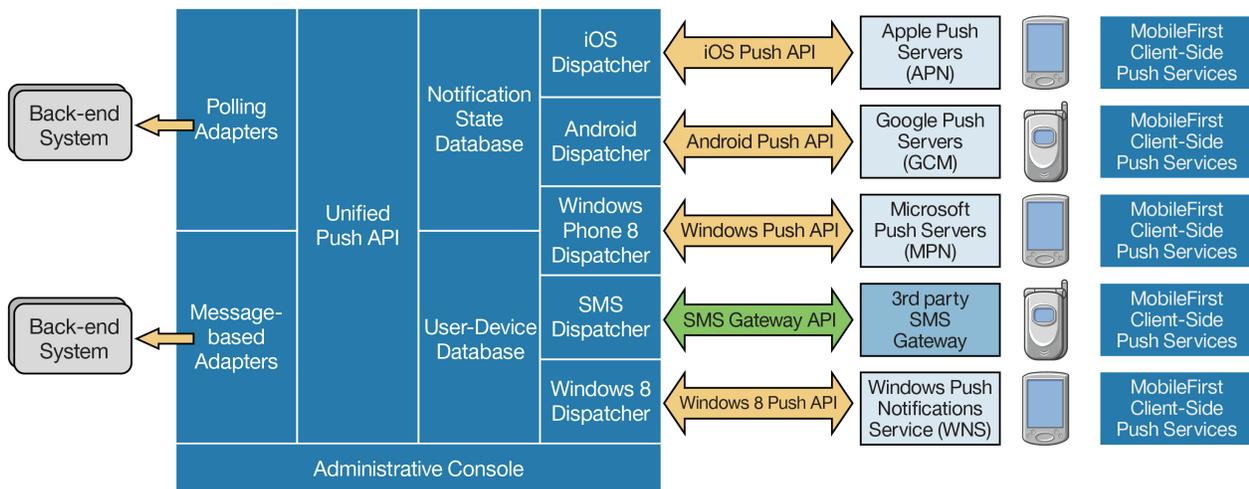

Figure 8-67. Push notification mechanism

Push notification currently works for iOS, Android, Windows 8 Universal and Windows Phone Silverlight 8. iOS apps use the Apple Push Notification Service (APNS), Android apps use Google Cloud Messaging (GCM), Windows 8 Universal apps use Windows Push Notification Service (WNS), and Windows Phone Silverlight 8 apps use the authenticated and non-authenticated Microsoft Push Notification Service (MPNS). SMS push notifications are supported on iOS, Android, Windows Phone Silverlight 8, Java ME, and BlackBerry devices that support SMS functions. For more information about setting up push notification for each platform, see “Setting up push notifications” on page 8-499.

Proxy settings

Use the proxy settings to set the optional proxy through which notifications are sent to APNS and GCM. You can set the proxy by using the **push.apns.proxy.*** and **push.gcm.proxy.*** configuration properties. For more information, see “Configuration of MobileFirst applications on the server” on page 12-50.

Architecture

Unlike other IBM MobileFirst Platform Foundation services, the push server requires outbound connections to Apple, Google, and Microsoft servers using ports that are defined by these companies.

For more information, see “Possible MobileFirst push notification architectures.”

Possible MobileFirst push notification architectures

IBM MobileFirst Platform Foundation supports two different methods of implementing push notifications, which are based on how the enterprise back end provides the messages to the MobileFirst Server.

Two common ways exist to create an IBM MobileFirst Platform Foundation push notification architecture:

- The Java Message Service (JMS) polling method, in which messages are pulled from the JMS message queue and sent by the MobileFirst Server
- The enterprise back end method, in which an enterprise back end uses a MobileFirst adapter to deliver messages to a MobileFirst Server cluster

JMS polling architecture

This architecture relies on the enterprise backend to deliver messages to a single instance of MobileFirst Server by using a JMS message queue. The developer must create an IBM MobileFirst Platform Foundation JMS adapter, which pulls messages from the queue and calls the IBM MobileFirst Platform Foundation server-side push notification API to process the messages.

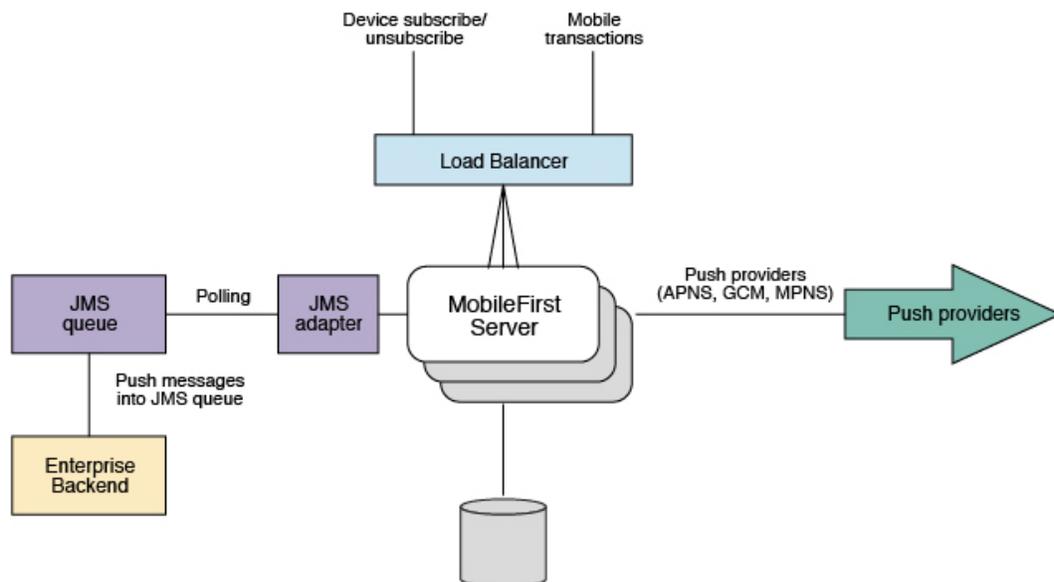

Figure 8-68. JMS polling push notification architecture

When this architecture is used, the flow is as follows:

1. Messages are put into the JMS queue by the enterprise backend.

2. The MobileFirst Server polls the JMS queue by using the JMS adapter, retrieving messages in short batches and sending them to the push providers.
3. A single MobileFirst Server instance pulls from the JMS queue and sends the push notifications. Even in a MobileFirst Server cluster, only one MobileFirst Server polls.
4. The process is implemented by using a MobileFirst JMS adapter, which functions as follows:
 - In a MobileFirst Server cluster, the single polling MobileFirst Server is selected randomly, by using the IBM MobileFirst Platform Foundation cluster-sync mechanism.
 - If the server that pulls from the JMS queue is shut down, another server takes its place.

This is the standard architecture. *Pros* of this method are that it involves an asynchronous queue, into which you can put the messages that you want to send. These messages are then processed and pulled later by the MobileFirst Server. *Cons* of this method are that only one server is sending the push notifications, so the maximum messages-per-second throughput is fixed.

Enterprise backend calling the MobileFirst Server architecture

This architecture relies on the enterprise backend to deliver messages to a MobileFirst Server cluster by calling a MobileFirst adapter procedure.

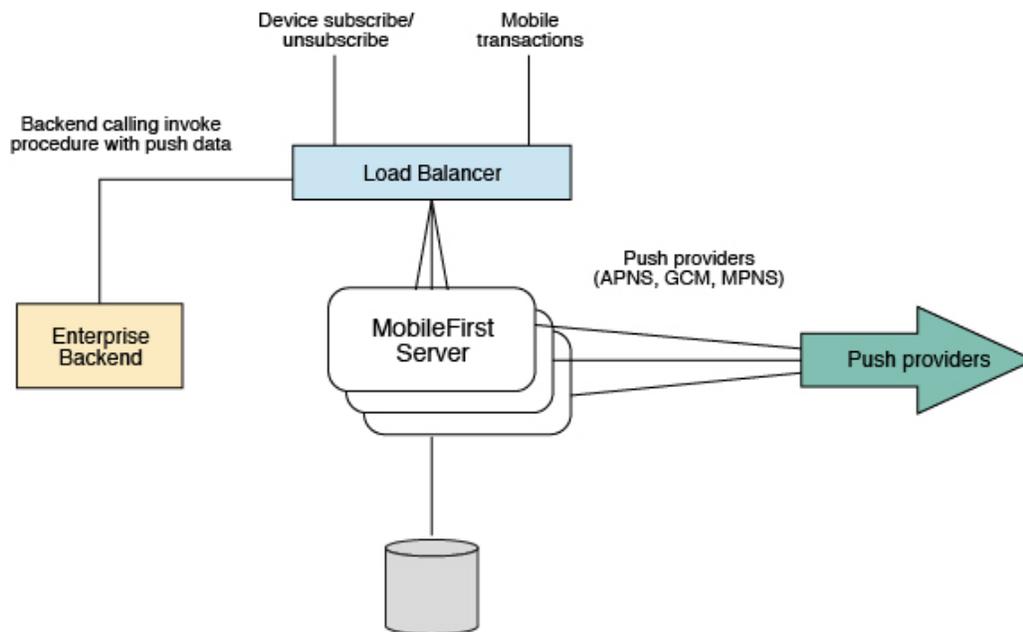

Figure 8-69. Enterprise backend push notification architecture

When this architecture is used, the flow is as follows:

1. The request is routed to one of the MobileFirst Server instances, which sends a push message to a provider.
2. In this flow, all MobileFirst Server instances can send push notifications, but for a specific request only one of the server instances performs the task.
3. The enterprise backend initiates calls to the load balancer.

Pros of this method are that all MobileFirst Server can be used to send push notifications, so you can add more servers if you must send more messages per second. *Cons* of this method are that every push message is a transaction on the MobileFirst Server. You can mitigate this overhead by sending a number of messages together or by having the MobileFirst adapter procedure that is invoked call the backend for a batch of messages rather than single messages.

Setting up push notifications

You can send push notifications to mobile devices via the MobileFirst Server. You can set up push notifications on Android, iOS, Windows 8 Universal and Windows Phone Silverlight 8.

About this task

The process for setting up push notifications varies significantly for each platform, and for Android and iOS you must refer to documentation for those products. For more information about the processes for each platform, see the following tasks:

Setting up push notifications for Android

To set up push notifications for Android devices, you must use the Google Cloud Messaging (GCM) service. In order to use GCM, you need a valid Google account.

Before you begin

Before you set up push notifications for Android in IBM MobileFirst Platform Foundation, you must have an existing Google API project in the Google Developers Console (<http://code.google.com/apis/console>). This project must have a server key credential defined.

To configure a new API project in the Google Developers Console, go to <https://developers.google.com/mobile/add>

For more information about the credentials required for GCM, review the GCM components and credentials table descriptions on the Google Cloud Messaging: Overview page at Google Developers.

Procedure

1. Gather the following information about your Google API project from Google Developers Console (<http://code.google.com/apis/console>):

Project number

Use the project number for the senderID value in the `application-descriptor.xml` file. The project number is a globally unique numerical value created when you create your Google API project. Be careful not to use either the project name or project ID as the senderID value.

You can find the project number in the Google Developers Console dashboard by expanding your project and recording the value under **Project number**.

Server key

Use the server key for the key value in the `application-descriptor.xml` file. Make sure that the server key is not restricted to any specific URL. For more information about how to create the key, see API keys.

You can get your server API from Credentials page in Google Developers Console by selecting **API Manager > Credentials**.

2. If your organization has a firewall that restricts the traffic to or from the Internet, you must do the following steps:
 - a. Configure the firewall to allow connectivity with GCM in order for your GCM client apps to receive messages. The ports to open are 5228, 5229, and 5230. GCM typically uses only 5228, but it sometimes uses 5229 and 5230. GCM does not provide specific IP, so you must allow your firewall to accept outgoing connections to all IP addresses contained in the IP blocks listed in Google's ASN of 15169. For more information, see Implementing an HTTP Connection Server.
 - b. Ensure that your firewall accepts outgoing connections from MobileFirst Server to android.googleapis.com on port 443.
3. In the application-descriptor.xml file, for **<android>** set the following attributes for the **<pushsender>** element:

Attribute	Description
key	The key value received from GCM.
senderID	The project ID received from GCM.

Note: Android OS 2.3.x devices must be synchronized with a Google account. Android OS 4.x does not impose account synchronization.

4. To set up Google Play Services in your Android project, see "Adding Google Play services to your Android project."

Results

Your push notifications setup is now complete.

Note: Only for Cordova hybrid applications can you test push notifications and set up end-to-end push notifications for Android.

Adding Google Play services to your Android project:

Google has deprecated the GCM helper library and recommends developers to move to GCM client library in Google Play services for push notifications. Adding Google Play services to your Android project can increase the size of your app.

Procedure

1. Under Extras in Android SDK Manager, install the **Google Play services** package.
2. After the installation completes successfully, import the project located in your file system at *Android_SDK_Location*\extras\google\google_play_services\libproject\google-play-services_lib into your Eclipse workspace. To do this, select **File > Import**, and then select **Android > Existing Android Code into Workspace**, and browse to the google-play-services_lib project.
3. After google-play-services_lib is successfully imported into your workspace, it needs to be marked as an Android library project. To do this, right-click *project* > **properties** > **Android** > **Select IsLibrary checkbox**.
4. Refer your project to the google-play-services_lib Android library project.

- a. Make sure that both the `google-play-services_lib` library and the application project that depends on the library are in your workspace. If one of the projects is missing, import it into your workspace.
 - b. In the Package Explorer, right-click *application project* > **properties** > **Android** > **Click Add**. The Project Selection dialog opens.
 - c. In the Project Selection dialog, select the `google-play-services_lib` project and click **OK**.
 - d. In the Properties window, click **Apply** and **OK**.
5. Add a reference to the `google-play-services` version in the application `AndroidManifest.xml` file as the first child of the `<application>` element.

```
<meta-data
    android:name="com.google.android.gms.version"
    android:value="@integer/google_play_services_version" />
```

What to do next

With Google Play services added to your project, you can enable the **sync** attribute while sending notifications. This attribute indicates that if a notification is handled on a device, it should be dismissed on other devices of the same user. For information about how to enable **sync**, see the `notifyAllDevices` and `SendMessage` APIs in the `WL.Server` class.

Adding Google Play services to a MobileFirst hybrid Android application in Android Studio:

Configure your project to work in Android Studio, add Google Play services, and troubleshoot common errors.

Procedure

1. In the Android project, open the `project.properties` file, remove the library reference to the `google-play-services` library, and save the file
2. Configure your project so that it works in Android Studio, by following the procedure “Converting a MobileFirst project to an Android Studio-based project” on page 8-74 (for project created either with the MobileFirst Platform Command Line Interface or with MobileFirst Studio), or the procedure “Converting a MobileFirst Cordova project to an Android Studio-based project” on page 8-181 (for MobileFirst Cordova projects).
3. Follow Google instructions to set up Google Play Services in Android Studio: <https://developers.google.com/android/guides/setup>.

Note: Use Google Play services V.8.3.0 when you compile with Android SDK 21 or 22. If you compile with an earlier Android SDK version, you need to use an earlier version of Google Play services.

4. Sync Gradle and run your app in Android Studio
5. Optional: Fix possible errors by adding the following three settings to the `build.gradle` file inside the `android{}` closure if they are not already present:

```
android {
    ...
    defaultConfig {
        multiDexEnabled true
    }

    dexOptions {
        javaMaxHeapSize "4g"
    }
}
```

```

        packagingOptions {
            pickFirst 'META-INF/ASL2.0'
            pickFirst 'META-INF/LICENSE'
            pickFirst 'META-INF/NOTICE'
        }
        ...
    }

```

- `com.android.dex.DexIndexOverflowException`: method ID not in [0, 0xffff]: 65536.
`multiDexEnabled` generates more than one `.dex` file to handle more than 65,000 methods. For more information, see <http://developer.android.com/tools/building/multidex.html>.
- `OutOfMemoryError`: `java.lang.OutOfMemoryError`: GC overhead limit exceeded.
 By adding `javaMaxHeapSize`, you can increase the memory allocation for compiling so many methods.
- `com.android.builder.packaging.DuplicateFileException`: Duplicate files copied in APK META-INF/ASL2.0.
`packagingOptions` handles duplicate files during the building of the APK. The example code picks the first duplicate files and ignores other duplicates. Other options can also be set instead of the `pickFirst` option.

6. Sync Gradle and run your app again.

Setting up end-to-end push notifications for Android:

To set up and test push notifications for your Android applications, that includes both legacy and Cordova apps, you need to update the `AndroidManifest.xml` and `application-descriptor.xml` files manually or you use the push plug-in.

Before you begin

- Make sure that you have a project with a MobileFirst Server instance running.
- Make sure that IBM MobileFirst Platform Command Line Interface is installed.

About this task

For Cordova hybrid applications, you can either edit the `AndroidManifest.xml` file manually or use the `cordova-plugin-mfp-push` plug-in, which will modify the manifest. For classic hybrid applications, no plug-in is available; therefore you can modify the `AndroidManifest.xml` file only manually.

Procedure

1. Update your `AndroidManifest.xml` file. You can edit the file manually, or add the push plug-in.
 - To add the push plug-in, add the following line in your `AndroidManifest.xml` file before the closing `<application/>` tag:

```
<meta-data android:name="com.google.android.gms.version" android:value="4030500" />
```
 - To edit the `AndroidManifest.xml` file manually:
 - a. Add the following code in your `AndroidManifest.xml` file before the opening `<application>` tag:

```
<uses-permission android:name="com.google.android.c2dm.permission.RECEIVE" />
<uses-permission android:name="android.permission.WAKE_LOCK" />
<uses-permission android:name="android.permission.VIBRATE" />
```

```

<uses-permission android:name="android.permission.GET_ACCOUNTS" />
<uses-permission android:name="android.permission.USE_CREDENTIALS" />
<permission android:name="$PACKAGE_NAME.permission.C2D_MESSAGE" android:protectionLevel=
<uses-permission android:name="<i>your_package_name</i>.permission.C2D_MESSAGE" />

```

- b. Add the following code before the closing `<application/>` tag:

```

<service android:name=".GCMIntentService"/>
<service android:name=".ForegroundService"/>
<receiver android:name="com.worklight.androidgap.push.WLBroadcastReceiver" android:permi
  <intent-filter>
    <action android:name="com.google.android.c2dm.intent.RECEIVE" />
    <category android:name="<i>your_package_name</i>" />
  </intent-filter>
  <intent-filter>
    <action android:name="android.intent.action.BOOT_COMPLETED" />
    <category android:name="<i>your_package_name</i>" />
  </intent-filter>
  <intent-filter>
    <action android:name="com.google.android.c2dm.intent.REGISTRATION" />
    <category android:name="<i>your_package_name</i>" />
  </intent-filter>
</receiver>
<meta-data android:name="com.google.android.gms.version" android:value="4030500" />

```

Note: To use another version of Google Play Services, change the value "4030500" in `android:value="4030500"/>` to either a different integer or to `@integer/google_play_services_version`, depending on your setup. You can add the tag by using the specific integer that is given without manually adding a Google Play Services dependency.

2. Edit the application descriptor by manually editing the `application-descriptor.xml` file, or by using the command-line interface (CLI).
 - To manually edit the `application-descriptor.xml` file, add a `<pushSender>` tag for the **key** attribute and the **senderID** attribute inside the `android` tag. The results look similar to the following example:

```

<pushSender key="YOUR_API_KEY" senderId="YOUR_SENDER_ID"/>
          
```
 - To change the file by using the CLI, you must be in your project folder.
 - a. Run **mfp config android_push_sender_key YOUR_API_KEY**
 - b. Run **mfp config android_push_sender_id YOUR_SENDER_ID**
3. Run **mfp push** from your project folder.

Testing push notifications for Android:

For a Cordova application, when a message is pushed to your application, you can have a notification or dialog box generated from the application when the message arrives. This dialog is shown if the device is unlocked and the app is on-screen, otherwise the notification is shown.

Before you begin

- Make sure that you have a project with a MobileFirst Server instance running.
- Create a Cordova application. If you are not familiar with the process, see "Developing Cordova apps" on page 8-169.
- Make sure that you set up push notifications as instructed in "Setting up push notifications for Android" on page 8-499.
- Make sure that IBM MobileFirst Platform Command Line Interface is installed.

Procedure

1. Edit the `/www/js/index.js` file.
 - a. Find the `wlCommonInit` function and add the following line of JavaScript at the end of the document:

```
WL.Client.connect({onSuccess: connectSuccess, onFailure: connectFailure});
```

2. Add the following code above the `wlCommonInit` function:

```
function connectSuccess() {
  if (WL && WL.Client.Push) {
    WL.Client.Push.onMessage = function(props, payload) {
      var msg = typeof props.alert === 'string' ? props.alert : props.alert.body;
      WL.SimpleDialog.show('Notification', msg, [{
        text: 'Close',
        handler: function() {}
      }]);
    };
  }
}
function connectFailure() {
  alert("Failed to connect to MFP Server");
}
```

3. Save the `index.js` file.
4. Run **mfp push**, then call **mfp cordova run** to run your app on a device or emulator.

For more information about these commands, see the documentation of the “**push**” on page 16-19 and “**cordova run**” on page 16-14 CLI commands.

5. Create a push adapter.
 - a. Navigate your command line to the root of your back-end MobileFirst Server project.
 - b. Run **mfp add adapter PushAdapter -t http**.
 - c. Open the `/adapters/PushAdapter/PushAdapter.xml` file and replace the two `<procedure>` tags at the end of the file with the following code.

```
<procedure name="sendPush"/>
```

- d. Open the `/adapters/PushAdapter/PushAdapter-impl.js` file and replace its contents with the following code:

```
function sendPush(pushText, payload) {
  var pushOptions = {};
  pushOptions.message = {};
  pushOptions.message.alert = pushText;
  WL.Server.sendMessage("<Your_app_id>", pushOptions);
  return {
    result: "Notification sent to all users."
  };
}
```

Note: Replace `<your_app_id>` with the value of the `id` element in the `<application>` tag from `application-descriptor.xml` file. Example: `"com_ibm_myApp"`.

- e. Save both files and run **mfp push** from the root folder of your project.
6. Run the following command from your root folder to trigger a push notification. **mfp adapter call PushAdapter/sendPush "Test Message"**

Results

If your app is displayed on your screen, a dialog is displayed with your test message. Otherwise, a notification is generated with your test message, and the dialog is shown the next time that you open the app. You can also use the servers

REST APIs to send pushes. The REST APIs refer to them as "messages".

Setting up push notifications for iOS

To set up push notifications for iOS devices, you must use the Apple Push Notification Service (APNS). To use APNS, you must be a registered Apple iOS Developer and obtain an Apple APNS certificate for your application.

Before you begin

Ensure that the following servers are accessible from MobileFirst Server:

- Sandbox servers:
 - gateway.sandbox.push.apple.com:2195
 - feedback.sandbox.push.apple.com:2196
- Production servers:
 - gateway.push.apple.com:2195
 - feedback.push.apple.com:2196

Procedure

1. Follow the required steps to obtain your APNS certificate and password. For more information, see the developerWorks article Understanding and setting up artifacts required to use iOS devices and APNS in a development environment.
2. Choose either of the following:
 - For a Hybrid app, place the Apple APNS certificate file at the root of the application folder, along with the `application-descriptor.xml` file.
 - For a Cordova app, place the `.p12` file in the root of the Cordova project, along with the `Cordova app config.xml` file.
3. Install the Entrust CA root certificate by using SSL port 443.

While you work in development mode, rename your certificate file to `apns-certificate-sandbox.p12`. When you move to production, rename your certificate file to `apns-certificate-production.p12`. In both cases, place the certificate file in the environment root folder or in the application root folder. When the hybrid application has both iPhone and iPad environments, separate certificates are necessary for push notification. In that case, place those certificates in the corresponding environment folders.

Note: The environment root folder takes the highest priority.

For more information, see the iOS Developer Library.

4. In the `application-descriptor.xml` file, for **<iPhone>** set the following attributes for the **<pushSender>** element:

Attribute	Description
password	The APNS certificate password received from Apple.

Results

Your push notification setup is now complete.

Setting up push notifications for Windows 8 Universal and Windows Phone 8 Universal

To set up push notifications for Windows 8 Universal and Windows Phone 8 Universal devices, you must use the Windows Push Notifications Service (WNS). In order to use WNS, you must have a valid Windows Store account.

Procedure

1. Create a Windows Store account at Windows Dev Center Dashboard.
2. Register your app with Windows Dev Center Dashboard and obtain the following credentials for your app.
 - Name
 - Publisher
 - Package Security Identifier (SID)
 - Client Secret

For more information, see [How to authenticate with the Windows Push Notification Service \(WNS\) \(Windows Runtime apps\)](#).

3. In the application-descriptor.xml file, for <windows8> (Windows 8 Universal) or for <windowsphoneuniversal> (Windows Phone 8 Universal), set the following attributes for the <pushSender> element.

Attribute	Setting
appIdentityName	The name of the package.
appIdentityPublisher	The subject name of the signing certificate.
packageSID	The unique identifier of your Windows Store app.
clientSecret	The secret key.

Note: If the WNS credentials are set by using REST API, then the **Name** attribute and **Publisher** attribute of the <Identity> element must be set manually in the package manifest. You can also associate your Windows 8 Universal project with the application in the Windows Store by right-clicking on the project and selecting **Store > Associate App** with the Store.

Results

Your push notifications setup is now complete.

Setting up push notifications for Windows Phone Silverlight 8

You can set up a web service to provide authenticated or unauthenticated push notification on Windows Phone Silverlight 8.

Before you begin

To use an authenticated push notification service, you must first set up a Secure Sockets Layer (SSL) certificate keystore. For more information, see [SSL certificate keystore setup](#). The keystore can contain several certificates, one of which is the certificate for authenticated push notifications to Microsoft Push Notification Service (MPNS).

You must also authenticate your web service with Microsoft, as documented in the Windows Phone Development Center at <http://dev.windowsphone.com/en-us/develop/>.

About this task

Authenticated web services have no daily limit on the number of push notifications they can send, whereas unauthenticated web services are limited to a rate of 500 push notifications per subscription per day.

For unauthenticated push, no specific setup is required, as shown in the example at the end of this procedure.

Practically, consider authenticated push notification for production, to protect your data, and non-authenticated push at development time only.

Procedure

In the `application-descriptor.xml` file, for `<windowsPhone8>`, set the following attributes for the `<pushSender>` element.

Attribute	Setting
<code>serviceName</code>	The common name (CN) found in the MPNS certificate's Subject value.
<code>keyAlias</code>	The alias that is used to access the keystore that the following properties specify in the <code>worklight.properties</code> file: <ul style="list-style-type: none">• <code>ssl.keystore.path</code>• <code>ssl.keystore.type</code>• <code>ssl.keystore.password</code>
<code>keyAliasPassword</code>	The password for your key alias.

Results

The `serviceName` attribute from the application descriptor is passed to the application's client side, and is used when a new notification channel is created. The URI token of the notification channel starts with `https`, rather than `http`. MobileFirst Server uses the `keyAlias` and `keyAliasPassword` attributes to extract the certificate from the Java™ keystore file, so that the handshake process with MPNS can use that certificate. Any push notifications that are eventually submitted to the application are authenticated and secure.

In response to push notification requests, MPNS returns a response code and a status. If the request is successful, the response code is 200, and the status is Received. For details of other response codes, go to the MSDN website at msdn.microsoft.com, and search for “push notification service response codes”.

Example

- For authenticated push notification:

```
<windowsPhone8>
  <pushSender>
    <authenticatedPush serviceName="myservice"
                      keyAlias="janedoe"
                      keyAliasPassword="a1b2c3d4"></authenticatedPush>
  </pushSender>
  ...
</windowsPhone8>
```

- For unauthenticated push notification:

```
<windowsPhone8>
  <pushSender/>
  ...
</windowsPhone8>
```

Broadcast notifications

Broadcast notifications are notification messages that are targeted to all the devices that have the MobileFirst application installed and configured for push notifications.

Broadcast notifications are enabled by default with any MobileFirst application that is enabled for push notification. For more information about configuring your application for push notifications, see “Setting up push notifications” on page 8-499.

Any MobileFirst application that is enabled for push notification has a predefined subscription to the `Push.ALL` tag, which is used by MobileFirst Server to broadcast notification messages to all the devices. To disable broadcast notification for native app, use `unsubscribeTag` method of `WLPush` class, with the tag name `Push.ALL`.

If you want to disable broadcast notification for hybrid app, use the `unsubscribeTag` method of the `WL.Client.Push` class, with the tag name `Push.ALL`.

Note: Make sure that the `WL.Client.Push.onMessage` method is defined in the application that is called when the push notification arrives.

For more information about sending broadcast notification, see “Broadcast notification” on page 8-515 section in “Sending push notifications” on page 8-515.

Event source-based notifications

Event source-based notifications are notification messages that are targeted to devices with a user subscription.

An event source can either poll notifications from the backend system, or wait for the backend system to explicitly push a new notification. The process of the event source-based notifications is as follows: :

1. Notifications are retrieved by the MobileFirst adapter event source, either by poll or by push from the backend system.
2. The adapter processes the notification and sends it to an Apple, Google, or Microsoft push service mediator.
3. The push service mediator sends a push notification to the device.
4. The device processes the received notification.

To start receiving push notifications, an application must subscribe to an event source. The event source is a push notification channel to which mobile applications can register. You can create an event source by declaring a notification event source in the MobileFirst adapter JavaScript code at a global level, outside any JavaScript function. For example,

```
WL.Server.createEventSource({
  name: 'PushEventSource',
  onDeviceSubscribe: 'deviceSubscribeFunc',
  onDeviceUnsubscribe: 'deviceUnsubscribeFunc',
  securityTest: 'PushApplication-strong-mobile-securityTest'
});
```

For more information about `createEventSource` method, see `WL.Server` class.

After the creation of the event source, you can proceed with the push notification subscriptions that is described in “Subscribing to an event source.”

For more information about sending event source-based notification, see Event source-based notification section in “Sending push notifications” on page 8-515.

Subscribing to an event source

Before a device can start receiving push notifications, it must first subscribe to a push notification event source. When the user approves the push notification subscription, the device is registered with an appropriate push server.

About this task

There are two levels of subscription: user subscription and device subscription.

- *User subscription* is an entity that contains a user ID, a device ID, and an event source ID. It represents the intent of the user to receive notification from a specific event source.
- A *device subscription* belongs to a user subscription, and exists in the scope of a specific user and event source. A user subscription can have several device subscriptions.

The user subscription for an event source is created when the user first subscribes to the event source from any device. The event source is declared in the `MobileFirst` adapter that is used by the application for push notification services.

After the user approves a push notification subscription, the device is registered with an Apple, Google, or Microsoft push server to obtain a token that is used to identify the device. The token is in the following form: Allow notifications for application X on device Y. The device then sends a subscription request to the `MobileFirst` Server.

To set up the device subscription for hybrid application, use the methods of the `WL.Client.Push` class. For native application, use the methods of `WLPush` class.

Procedure

1. When the application first connects to the `MobileFirst` Server from the device, the device registers with a push service mediator and obtains a device token. This process is done automatically by IBM `MobileFirst` Platform Foundation.
2. When the token is obtained, the `onReadyToSubscribe` callback function that is defined in the application is notified that a device is ready to subscribe to push notifications.
3. After the `onReadyToSubscribe` callback is notified, the application subscribes to a tag by using the `subscribe` API.
4. Optional: If push notifications are no longer required, you can unsubscribe. The device subscription is deleted either by an application that calls the `unsubscribe` API, or when the push mediator informs the `MobileFirst` Server that the device is permanently inaccessible.

Results

While the user subscription exists, the `MobileFirst` Server can produce push notifications for the subscribed user.

What to do next

The event source-based notifications can be delivered by the adapter code to all or some of the devices that the user subscribed from. For more information, see Event source-based notification section in “Sending push notifications” on page 8-515.

Interactive notification

With interactive notification, when a notification arrives, users can take actions without opening the application. When an interactive notification arrives, the device shows action buttons along with the notification message. Currently, interactive notifications are supported on devices with iOS version 8 onwards. If an interactive notification is sent to an iOS device with version earlier than 8, the notification actions are not displayed.

Sending interactive push notification

Prepare the notification and send notification. For more information, see “Sending push notifications” on page 8-515.

You can set a string to indicate the category of notification with the notification object. Based on the category value, the notification action buttons are displayed.

To set the category in event source notifications, you have two options:

- Create a notification JSON object and set the category in that object:
`var notification = { badge:1, category: 'poll', ...};`
- Create a notification object by using the `WL.Server.createDefaultNotification` API and set the category on the notification object:
`notification.APNS.category= 'poll';`

For more information, see the `WL.Server.createDefaultNotification` and `WL.Server.notifyAllDevices` APIs in `WL.Server` class.

In broadcast, tag-based and Uni-cast notifications, set the type while you create the notification object:

```
notification.settings.apns.category = 'poll';
```

For more information, see the `WL.Server.sendMessage` API in `WL.Server` class.

Handling interactive push notifications in hybrid iOS application

To receive interactive notifications, follow these steps:

1. In the main JavaScript, define the following method to return the registered categories for the interactive notifications.

```
WL.Client.Push.getInteractivePushCategories = function(){
  var categories = [{
    //Category identifier, this is used while sending the notification.
    id : "poll",
    //Optional array of actions to show the action buttons along with the message.
    actions: [
      {
        //Action identifier
        id : "poll_ok",

        //Action title to be displayed as part of the notification button.
        title : "OK",

        //Optional mode to run the action in foreground or background. 1-foreground. 0-background. Default is foreground.
        mode: 1,
      }
    ]
  }
];
}
```

```

//Optional property to mark the action button in red color. Default is false.
destructive: false,

//Optional property to set if authentication is required or not before running the action.(Screen lock).
//For foreground, this property is always true.
authenticationRequired: true
},
{
  id : "poll_nok",
  title : "NOK",
  mode: 1,
  destructive: false,
  authenticationRequired: true
}
],
//Optional list of actions that is needed to show in the case alert.
//If it is not specified, then the first four actions will be shown.
defaultContextActions: ['poll_ok','poll_nok'],

//Optional list of actions that is needed to show in the notification center, lock screen.
//If it is not specified, then the first two actions will be shown.
minimalContextActions: ['poll_ok','poll_nok']
});
return categories;
};

```

For more information, see `WL.Client.Push.getInteractivePushCategories` API in `WL.Client.Push` class.

- The notification callback method contains two extra properties. You can use them to take actions.
 - category:** The name of the category that you set while sending the notification.
 - action-id:** If the user clicks the action button, this represents the ID of the action.

Handling interactive push notifications in native iOS application

You must follow these steps to receive interactive notifications:

- Enable the application capability to perform background tasks on receiving the remote notifications. This step is required if some of the actions are background-enabled.
- In the `AppDelegate` (application: `didRegisterForRemoteNotificationsWithDeviceToken` application:), set the categories before you set the `deviceToken` on `WLPush` Object.

```

if([application respondsToSelector:@selector(registerUserNotificationSettings:)]) {
  UIUserNotificationType userNotificationTypes = UIUserNotificationTypeNone | UIUserNotificationTypeSound | UIUserNotifi

  NSMutableUserNotificationAction *acceptAction = [[NSMutableUserNotificationAction alloc] init];
  acceptAction.identifier = @"OK";
  acceptAction.title = @"OK";

  NSMutableUserNotificationAction *rejectionAction = [[NSMutableUserNotificationAction alloc] init];
  rejectionAction.identifier = @"NOK";
  rejectionAction.title = @"NOK";

  NSMutableUserNotificationCategory *category = [[NSMutableUserNotificationCategory alloc] init];
  category.identifier = @"poll";
  [category setActions:@[acceptAction,rejectionAction] forContext:UIUserNotificationActionContextDefault];
  [category setActions:@[acceptAction,rejectionAction] forContext:UIUserNotificationActionContextMinimal];

  NSSet *categories = [NSSet setWithObject:category];
  [application registerUserNotificationSettings:[UIUserNotificationSettings settingsForTypes:userNotificationTypes categories:categories]];
}

```

- Implement new callback method on `AppDelegate`:

```
-(void)application:(UIApplication *)application handleActionWithIdentifier:(NSString *)identifier forRemoteNotification:(NS
```

This new callback method is invoked when the user clicks the action button.

4. Implement this method mustso that it perform the action that is associated with the specified identifier and executes the block in the **completionHandler** parameter.

Silent notifications

Silent notifications are notifications that do not display alerts or otherwise disturb the user. When a silent notification arrives, the application handling code runs in background without bringing the application to foreground. Currently, the silent notifications are supported on iOS devices with version 7 onwards. If the silent notification is sent to iOS devices with version lesser than 7, the notification is ignored if the application is running in background. If the application is running in the foreground, then the notification callback method is invoked.

Sending silent push notification

Prepare the notification and send notification. For more information, see “Sending push notifications” on page 8-515.

The three types of notifications that are supported for iOS are represented by constants DEFAULT, SILENT, and MIXED. When the type is not explicitly specified, the DEFAULT type is assumed.

For MIXED type notifications, a message is displayed on the device while, in the background, the app awakens and processes a silent notification. The callback method for MIXED type notifications gets called twice - once when the silent notification reaches the device and once when the application is opened by tapping on the notification.

To set the type in event source notifications, create notification object by using the WL.Server.createDefaultNotification API and set type on the notification object:

```
notification.APNS.type = "DEFAULT" | "SILENT" | "MIXED";
```

For more information, see the WL.Server.createDefaultNotification and WL.Server.notifyAllDevices APIs in WL.Server class.

If the notification is event source-based, the silent notifications are ignored if they arrive before the application registers the callback.

In Broadcast, Tag-based and Uni-cast notifications set the type while you create the notification object:

```
notification.APNS.type = "DEFAULT" | "SILENT" | "MIXED";
```

For more information, see the WL.Server.sendMessage API in WL.Server class.

If the notification is silent, the alert, sound, and badge are ignored.

Handling silent push notifications in hybrid iOS application

In the JavaScript push notification callback method, you must do the following steps:

1. Check the notification type. For example,

```

if(props['content-available'] == 1) {
    //Silent Notification or Mixed Notification. Perform non-GUI tasks here.
}
else{
    //Normal notification
}

```

2. If the notification is silent or mixed, after you complete the background job, invoke `WL.Client.Push.backgroundJobDone` API. For more information, see `WL.Client.Push` class.

Handling silent push notifications in native iOS application

You must follow these steps to receive silent notifications:

1. Enable the application capability to perform background tasks on receiving the remote notifications.
2. Implement new callback method on `AppDelegate` (application: `didReceiveRemoteNotification:fetchCompletionHandler:`) to receive silent notifications when the application is running on background.
3. In the callback, check whether the notification is silent or not by checking that the key `content-available` is set to 1.
4. After you finish processing the notification, you must call the block in the **handler** parameter immediately. Otherwise, your app will be terminated. Your app has up to 30 seconds to process the notification and call the specified completion handler block.

Tag-based notifications

Tag notifications are notification messages that are targeted to all the devices that are subscribed to a particular tag.

Tags-based notifications allow segmentation of notifications based on subject areas or topics. Notification recipients can choose to receive notifications only if it is about a subject or topic that is of interest. Therefore, tags-based notification provides a means to segment recipients. This feature enables ability to define tags and then send and receive messages by tags. A message is targeted to only the devices that are subscribed to a tag.

You must first create the tags for the application, set up the tag subscriptions and then initiate the tag-based notifications. For more information, see “Setting up Tag-based notifications.”

For more information about sending tag-based notification, see “Tag-based notification” on page 8-516 section in “Sending push notifications” on page 8-515.

Setting up Tag-based notifications

You create tags for an application by specifying tag details in the `application-descriptor.xml` file. You can then set up tag subscriptions and initiate tag-based notifications.

Before you begin

In the `application-descriptor.xml` file, add a `<tags>` element to specify the tags that you want for the application, such as customer categories.

The `<tags>` element is supported by Android, iOS, Windows Phone Silverlight 8, and Windows 8 Universal environments. Tags represent topics of interest to the

user and provide user with an ability to receive notifications according to the chosen interest. During application deployment, the specified tags are created, updated, or deleted on the management database tables. This feature enables ability for sending and receiving messages by tags. A message is targeted to only the devices that are subscribed for a tag. In the following example, the <tags> specifies customer categories.

```
<tags>
  <tag>
    <name>Silver</name>
    <description>Silver customers</description>
  </tag>
  <tag>
    <name>Gold</name>
    <description>Gold customers</description>
  </tag>
</tags>
```

About this task

Subscriptions tie together a device registration and a tag. When a device is unregistered from a tag, all associated subscriptions are automatically unsubscribed from the device itself. In a scenario where there are multiple users of a device, subscriptions should be implemented in mobile applications based on user login criteria. For example, the subscribe call is made after a user successfully logs in to an application and the unsubscribe call is made explicitly as part of the logout action handling.

To receive notifications that are targeted to a particular tag, you subscribe the application to the tags that you defined. To set up tag subscriptions for hybrid application, you use the methods of the `WL.Client.Push` class. For native application, use the methods of `WLPush` class.

Procedure

1. When the application first connects to MobileFirst Server from the device, the device registers with a push service mediator and obtains a device token. This process is done automatically by IBM MobileFirst Platform Foundation.
2. When the token is obtained, the `onReadyToSubscribe` callback method that is defined in the application is notified that a device is ready to subscribe to push notifications.
3. After the `onReadyToSubscribe` callback is notified, the application subscribes to a tag by calling the `subscribeTag` method. Note that only successful authentications with a proper user ID will be associated.
4. Optional: You can unsubscribe the application in one of two ways:
 - The device subscription is deleted by an application that calls the `unsubscribeTag` method.
 - The push mediator informs MobileFirst Server that the device is permanently inaccessible.
5. Make sure that the `onMessage` method is defined in the application that is called when the push notification arrives. For hybrid application, see the `WL.Client.Push` class. For Android, Windows Phone Silverlight 8, and Windows 8 Universal native application, see the `WLNotificationListener` class. The implementation for iOS native application is different. The notification comes to `didReceiveRemoteNotification` method that is defined by default in your `AppDelegate.m` file.

Results

While the tag subscription exists, MobileFirst Server can produce push notifications for the subscribed tag. These notifications can be delivered by the adapter code to all the devices that subscribed to the tag.

You can view the notification tags in the MobileFirst Operations Console.

```
Last deployed at: 4/9/2014 4:35 PM
```

```
Push tag(s): OFFER10, PLATINUM, OFFER20, SILVER, GOLD, BRONZE
```

What to do next

After you have set up tag subscriptions, you can send a notification. For more information, see “Tag-based notification” on page 8-516 section in “Sending push notifications.”

Unicast notifications

Unicast notifications are notification messages that are targeted to a particular device or a **userID**.

Unicast notifications do not require any additional setup and are enabled by default when the MobileFirst application is enabled for push notifications. For more information about configuring your application for push notifications, see “Setting up push notifications” on page 8-499.

For more information about sending unicast notification, see “Unicast notification” on page 8-516 section in “Sending push notifications.”

Note: For a Unicast notification, the payload object does not contain any tag.

Sending push notifications

When you have set up push notification, whether event-source based, tag-based, or broadcast-enabled, you can send push notifications from the server.

Broadcast notification

Before you can send a broadcast notification, you must set up broadcast notifications for the required applications. For more information, see “Broadcast notifications” on page 8-508.

You can send a broadcast notification in the following way:

- Use the `sendMessage` method of the `WL.Server` class. The **applicationId** and **notificationOptions** parameters are mandatory.
- The **notificationOptions.target** object must not be specified or empty.

Event source-based notification

Before you can send event source-based notification, you must set up the subscriptions. For more information, see “Subscribing to an event source” on page 8-509.

An event source can either poll notifications from the backend system, or wait for the backend system to explicitly push a new notification. In this example, a `submitNotifications()` adapter function is called by a backend system as an external API to send notifications.

```
function submitNotification(userId, notificationText) {
  var userSubscription = WL.Server.getUserNotificationSubscription('PushAdapter.PushEventSource', userSubscription);
  if(userSubscription === null) {
    return{ result: "No subscription found for user :: "+ userId };
  }

  var badgeDigit = 1;
  var notification = WL.Server.createDefaultNotification(notificationText, badgeDigit, {custom:"data"});
  WL.Server.notifyAllDevices(userSubscription, notification);
  return{
    result: "Notification sent to user :: "+ userId
  };
}
```

For more information about the various APIs to send notifications, see `WL.Server`.

Tag-based notification

Before you can send tag-based notifications, you must set up tag subscriptions. For more information, see “Setting up Tag-based notifications” on page 8-513.

You can send a tag-based notification in the following way:

- Use the `sendMessage` method of the `WL.Server` class. The `applicationId` and `notificationOptions` parameters are mandatory.
- Specify the `tagNames` as an array in the `notificationOptions.target.tagNames` object.

Unicast notification

You can send a Unicast notification to a particular device in the following way:

- Use the `sendMessage` method of the `WL.Server` class. The `applicationId` and `notificationOptions` parameters are mandatory.
- The `deviceId(s)` as an array in the `notificationOptions.target.deviceIds` object.

You can send a Unicast notification to a particular user in the following way:

- Use the `sendMessage` method of the `WL.Server` class. The `applicationId` and `notificationOptions` parameters are mandatory.
- The `userId(s)` as an array in the `notificationOptions.target.userIds` object.

The `userId(s)` must be the user IDs that were used to subscribe to the push notification event source. The user ID in the user subscription can come from the underlying security context or be a user ID explicitly set by your mobile app. A user ID explicitly set by your mobile app is also called an application user ID (`appUserId`).

Note: For a Unicast notification, the payload object does not contain any tag.

For more information about implementing application user IDs in your mobile app, see the documentation for the following classes:

- `WLRequestOptions` class
- `WLClient` class

Note: The notification message can target multiple devices or users by specifying multiple `deviceIDs` or `userIDs` in the `notificationOptions.tager.deviceIds` or `notificationOptions.target.userIds`.

Platform or environment-based notification

You can send a platform or environment-based notification in the following way:

- Use the `sendMessage` method of the `WL.Server` class. The `applicationId` and `notificationOptions` parameters are mandatory.
- Specify the platform or platforms as an array in the `notificationOptions.target.platforms` object. The supported platforms are as follows:
 - A (Apple)
 - G (Google)
 - M (Microsoft)
 - W (Windows)

Restriction

Restriction: The `sendMessage` method does not support SMS notification. For more information, see “Sending SMS push notifications.”

REST Services APIs

You can use REST Services APIs to work with Push notifications.

Use REST API Administration Services for adapters and applications.

Use REST API Runtime Services for applications deployed outside of the MobileFirst Server.

Sending SMS push notifications

In addition to standard push notifications, you can also send Short Message Service (SMS) messages, more commonly known as text messages, to user devices. To receive SMS notifications, users must first subscribe to a push notification event source.

About this task

The SMS notification framework extends the push notification framework. SMS support is provided for Apple, Google, and Windows Phone 8 devices, and for BlackBerry devices that support SMS functions. IBM MobileFirst Platform Foundation includes the capability to send SMS notifications to all platforms that provide SMS support.

Procedure

1. An SMS notification infrastructure is set up.
A MobileFirst adapter acts as a connector to an app that is running on a mobile device.
2. The user of the mobile device sends a subscribe request from the application to the event source that is declared in the MobileFirst adapter, by using the client-side `WL.Client.Push.subscribeSMS` method.
3. The user subscription to the event source is registered at the MobileFirst Server.

4. When the back-end service must notify the user, it calls a method in the MobileFirst adapter.
5. The adapter checks whether an SMS subscription exists for that user and, if it does, sends the SMS alert message through a preconfigured SMS aggregator.
6. Optional: If SMS notifications are no longer necessary, you can unsubscribe. The subscription is deleted either by an application that calls the `WL.Client.Push.unsubscribeSMS` method, or by using the Admin console. For more information, see *Administering push notifications with the MobileFirst Operations Console*.
For a detailed scenario-based example that shows SMS messaging, see the developerWorks article *Send SMS push notifications to your mobile app using IBM MobileFirst Platform Foundation*.

Sending push notifications from WebSphere Application Server – IBM DB2

To issue push notifications from a WebSphere Application Server that uses IBM DB2 as its database, a custom property must be added.

About this task

If you use WebSphere Application Server with an IBM DB2 database, errors can arise when you try to send push notifications. To resolve this situation, you must add a custom property in WebSphere Application Server, at the data source level.

Procedure

1. Log in to the WebSphere Application Server admin console.
2. Select **Resources > JDBC > Data sources > DataSource name > Custom properties** and click **New**.
3. In the **Name** field, enter `allowNextOnExhaustedResultSet`.
4. In the **Value** field, type `1`.
5. Change the type to `java.lang.Integer`.
6. Click **OK** to save your changes.
7. Select custom property **resultSetHoldability**.
8. In the **Value** field, type `1`.
9. Click **OK** to save your changes.

Web-based SMS subscription

Subscription, and unsubscription, to SMS notifications can be performed by making HTTP GET requests to the subscribe SMS servlet. The subscribe SMS servlet can be used for SMS subscriptions without the requirement for a user to have an app installed on their device.

Enter the following URL to access the subscribe SMS servlet:

```
http://<hostname>:<port>/<context>/subscribeSMS
```

This URL can be used to subscribe and unsubscribe.

You must create an application and an event source within an adapter and deploy them on the IBM MobileFirst Platform Server before you make calls to the subscribe SMS servlet. For more information about how to create an event source, see the `createEventSource` method in the `WL.Server` class.

Table 8-55. Subscribe SMS servlet URL parameters

URL parameter	URL parameter description
option	Optional string. Subscribe or unsubscribe action to perform. The default option is subscribe. If any non-blank string other than subscribe is supplied, the unsubscribe action is performed.
eventSource	Mandatory string. The name of the event source. The event source name is in the format <i>AdapterName.EventSourceName</i> .
alias	Optional string. A short ID defining the event source during subscription. This ID is the same ID as provided in <code>WL.Client.Push.subscribeSMS</code> .
phoneNumber	Mandatory string. User phone number to which SMS notifications are sent. The phone number can contain digits (0-9), plus sign (+), minus sign (-), and space (Δ) characters only.
userName	Optional string. Name of the user. If no user name is provided during subscription, an anonymous subscription is created by using the phone number as the user name. If a user name is provided during subscription, it must also be provided during unsubscription.
appId	Mandatory string for subscribe. The ID of the application that contains the SMS gateway definition. The application ID is constructed from the application name, application environment, and application version. For example, version 1.0 of Android application <code>SMSPushApp</code> has appId = <code>SMSPushApp-android-1.0</code> .

Note: If any parameter value contains special characters, this parameter must be encoded by using URL encoding, also known as percent encoding, before the URL is constructed. Parameter values containing only the following characters do not need to be encoded:

a-z, A-Z, 0-9, period (.), plus sign (+), minus sign (-), and underscore (_)

Subscriptions that are created by using the subscribe SMS servlet are independent of subscriptions that are created by using a device. For example, it is possible to have two subscriptions for the same phone number and user name; one created by using the device and one created by using the subscribe SMS servlet. If there are two subscriptions for the same phone number and user name, unsubscription by using the subscribe SMS servlet unsubscribes only the subscription that is made through the subscribe SMS servlet. However, unsubscription by using the IBM MobileFirst Platform Operations Console unsubscribes both subscriptions.

Security

It is important to secure the subscribe SMS servlet because it is possible for entities with malicious intent to call the servlet and create spurious subscriptions. By default, IBM MobileFirst Platform Foundation protects static resources such as the subscribe SMS servlet. The `authenticationConfig.xml` file is configured to reject all requests to the subscribe SMS servlet with a rejecting login module. To allow restricted access to the subscribe SMS servlet, MobileFirst administrators must modify the `authenticationConfig.xml` file with appropriate authenticator and login modules.

For example, the following configuration in the `authenticationConfig.xml` file ensures only requests with a specific user name in the header of the HTTP request are allowed:

```

<staticResources>
  <resource id="subscribeServlet" securityTest="SubscribeServlet">
    <urlPatterns>/subscribeSMS*</urlPatterns>
  </resource>
  ...
</staticResources>

<securityTests>
  <customSecurityTest name="SubscribeServlet">
    <test realm="SubscribeServlet" isInternalUserID="true"/>
  </customSecurityTest>
  ...
</securityTests>

<realms>
  <realm name="SubscribeServlet" loginModule="headerLogin">
    <className>com.worklight.core.auth.ext.HeaderAuthenticator</className>
  </realm>
  ...
</realms>

<loginModules>
  <loginModule name="headerLogin">
    <className>com.worklight.core.auth.ext.HeaderLoginModule</className>
    <parameter name="user-name-header" value="username"/>
  </loginModule>
  ...
</loginModules>

```

Configuring a polling event source to send push notifications

Polling event sources can be used to generate notification events, such as push notifications, that the MobileFirst client framework can subscribe to.

About this task

The MobileFirst adapter framework provides the ability to implement event sources, which can be used to generate notification events such as push notifications. However, notifications must be retrieved from a back-end system before they can be sent out. Event sources can either poll notifications from the back-end system, or wait for the back-end system to explicitly push a new notification.

This task describes how to create a polling event source, and use it to send push notifications. A polling event source is a long-running task that has the following mandatory properties:

- Event source name
- Polling interval
- Polling function

Procedure

- Consider the following simple example. The diagram shows a sample for a basic polling event source:

```

1 WL.Logger.info("Creating event source");
2 WL.Server.createEventSource({
3     name: "MyPollingEventSource",
4     poll: {
5         interval: 3, // Interval in seconds
6         onPoll: "doSomething" // Function to be invoked
7     }
8 });
9
10
11 function doSomething(){
12     WL.Logger.info(new Date() + " :: Doing something");
13 }

```

The doSomething() function is invoked every three seconds. If you deploy this adapter to the MobileFirst Server, you see the following logs in the server console:

```

Worklight Development Server [worklight] (Jan 29, 2014 5:41:17 PM)
[INFO ] Creating event source [project ]
[INFO ] FWLSE0084I: Adapter 'PollingEventSourceAdapter' was deployed successfully (the adapter versi
[INFO ] Creating event source [project ]
[INFO ] Wed Jan 29 2014 17:46:31 GMT+0200 (IST) :: Doing something [project ]
[INFO ] Wed Jan 29 2014 17:46:34 GMT+0200 (IST) :: Doing something [project ]
[INFO ] Wed Jan 29 2014 17:46:37 GMT+0200 (IST) :: Doing something [project ]
[INFO ] Wed Jan 29 2014 17:46:40 GMT+0200 (IST) :: Doing something [project ]
[INFO ] Wed Jan 29 2014 17:46:43 GMT+0200 (IST) :: Doing something [project ]

[INFO ] Wed Jan 29 2014 17:46:49 GMT+0200 (IST) :: Doing something [project ]
[INFO ] Wed Jan 29 2014 17:46:52 GMT+0200 (IST) :: Doing something [project ]
[INFO ] Wed Jan 29 2014 17:46:55 GMT+0200 (IST) :: Doing something [project ]
[INFO ] Wed Jan 29 2014 17:46:58 GMT+0200 (IST) :: Doing something [project ]
[INFO ] Wed Jan 29 2014 17:47:01 GMT+0200 (IST) :: Doing something [project ]
[INFO ] Wed Jan 29 2014 17:47:04 GMT+0200 (IST) :: Doing something [project ]
[INFO ] Wed Jan 29 2014 17:47:07 GMT+0200 (IST) :: Doing something [project ]

```

The log shows that the doSomething() function is invoked at 3-second intervals.

- This second example shows a more realistic example of a polling event source:

```

1 /*
2  * Create an eventSource.
3  */
4 WL.Server.createEventSource({
5     name: "MyPollingEventSource",
6     poll: {
7         interval: 3, // Interval in seconds
8         onPoll: "sendNotifications" // Function to be invoked
9     }
10 });
11
12 /*
13  * Polling function. Gets messages from HTTP backend and sends them one by one
14  */
15 function sendNotifications() {
16     // Use adapter capabilities to retrieve messages from backend
17     var response = WL.Server.invokeHttp{/* invocation options */});
18     var messages = response.messages;
19
20     // Iterate received messages
21     for (var i = 0; i < messages.length; i++) {
22
23         // Get single message object
24         var message = messages[i];
25
26         // Retrieve userSubscription object
27         var userSubscription = WL.Server.getUserNotificationSubscription("MyAdapter.MyPollingEventSource", message.userId);
28
29         if (userSubscription) {
30             // Create default notification body and send it to all devices belonging to specific user
31             var notification = WL.Server.createDefaultNotification(message.text, message.badge, message.payload);
32             WL.Server.notifyAllDevices(userSubscription, notification);
33         } else {
34             WL.Logger.error("Subscription for userId=" + message.userId + " not found. Notification discarded.");
35         }
36     }
37 }
38 }

```

The sample includes the following key elements:

- Lines 7 - 8: The polling event source continuously invokes a sendNotifications() function with a 3-second interval.

- Lines 18 - 19: Every time the `sendNotifications()` function is invoked it requests messages data from the back-end. The sample shows an HTTP back-end, but it could be any other type of back-end that MobileFirst adapters support; for example, SQL. The code assumes that the following JSON markup is returned by the back-end. However, since the MobileFirst adapter knows how to automatically convert data to JSON, the back-end data could also be XML.

```
{
  messages: [{
    userId: "John",
    text: "New incoming transition",
    badge: 2,
    payload: {}
  }, {
    userId: "Bob",
    text: "Please approve withdrawal",
    badge: 5,
    payload: {}
  }]
}
```

- Line 22: The code iterates over the received messages array.
- Line 25: Every message contains the user ID of a user that the notification should be sent to.
- Line 28: Using this user ID, the code tries to obtain a `userSubscription` object.
- Lines 30 - 33: If a `userSubscription` object is found for the specified user ID, a new notification is created and is sent to all user devices.
- Line 35. If a `userSubscription` object is not found for the specified user ID, an error is logged.

An important feature of a polling event source is that unlike regular adapter procedures, the polling function is triggered by the MobileFirst Server itself, and not by the incoming request. Therefore any data or APIs related to request or session context are not available or functional. For example, APIs such as `WL.Server.getActiveUser()` or `WL.Server.getClientRequest()` are not functional. Also, you do not need to expose polling function in the adapter XML file.

Using two-way SMS communication

SMS two-way communication enables communication between a mobile phone and the MobileFirst Server, over an SMS channel. SMS messages that originate from the mobile device can be sent to the MobileFirst Server through an external SMS gateway. The MobileFirst Server can then send a response message back to the originating mobile device.

Before you begin

To run SMS two-way communication, the mobile device must support SMS functions.

About this task

Keywords or shortcodes should be configured with the third-party SMS gateway. The gateway should be configured to forward SMS messages to the SMS servlet of the MobileFirst Server, either directly or through a reverse proxy URL, based on the topology in your environment:

```
http://hostname:port/context/receiveSMS
```

The SMS messages that are sent from mobile phones are forwarded to an adapter procedure on the MobileFirst Server, which is configured by the developer. The adapter procedure can include the logic to process the request, or the procedure can forward the request to a back-end system for processing. The response is returned by using the MobileFirst notification framework. For more information, see Push notification.

The two-way SMS architecture is summarized in the following figure:

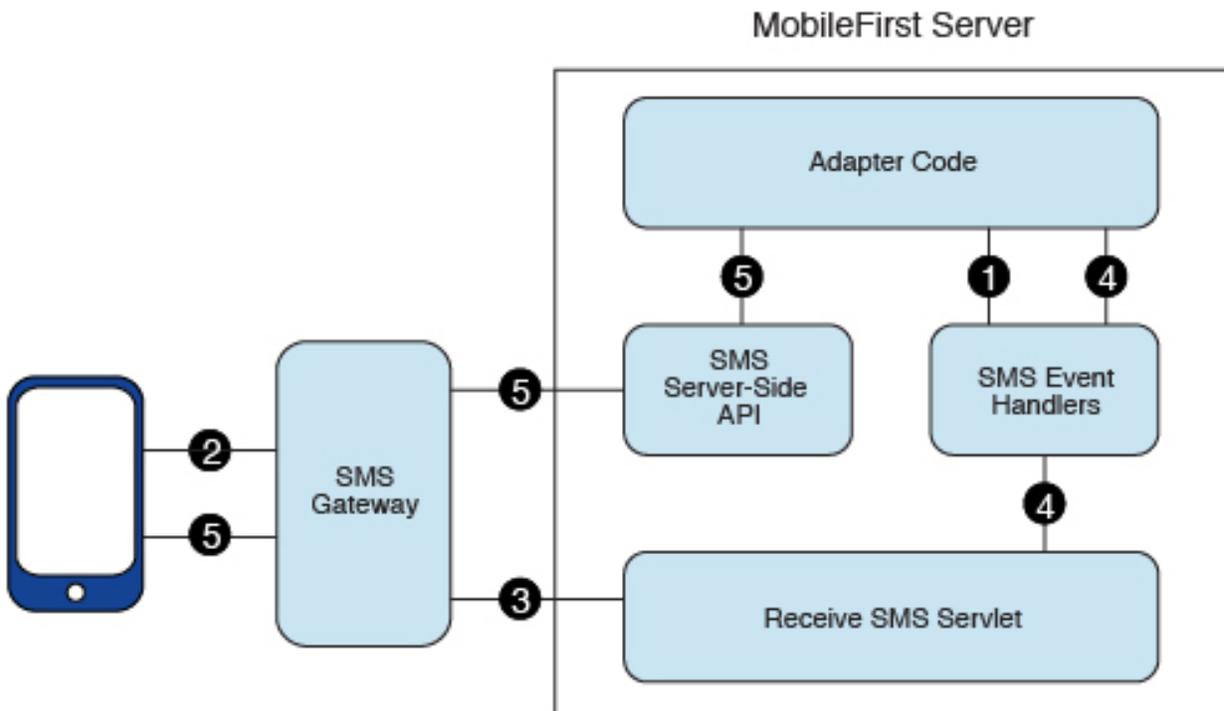

Figure 8-70. Two-way SMS architecture

1. The adapter registers SMS event handlers on the MobileFirst Server.
2. SMS messages are sent from mobile devices to the SMS gateway, which is configured with an SMS servlet of MobileFirst Server.
3. The SMS gateway forwards SMS messages to a configured MobileFirst URL.
4. An SMS servlet on MobileFirst Server matches the parameters with filters that are defined in SMS event handlers, and calls an adapter callback procedure.
5. The adapter processes SMS messages and sends an SMS message to the mobile device by using the SMS API.

You use a series of server API methods to send and receive SMS messages:

WL.Server.createSMSEventHandler

Create an SMS event handler.

WL.Server.setEventHandlers

Set event handlers to implement callbacks for received events.

WL.Server.subscribeSMS

Subscribe a phone number to the specified event source.

WL.Server.unsubscribeSMS

Unsubscribe the phone number from the specified event source.

WL.Server.getSMSSubscription

Return an SMS subscription object for a phone number.

Using native and JavaScript push APIs in the same app

You can use Native and JavaScript push APIs in the same MobileFirst app.

Overview

IBM MobileFirst Platform Foundation provides two sets of APIs to handle push notifications - native and web (JavaScript). Each of these APIs on its own allows the application to handle push notifications in its native/JavaScript environment. However, you can also use both API types in the same app, provided you follow certain restrictions:

iOS Both APIs rely on an automatic process to initialize push support, triggered when connecting to the MobileFirst Server. In case the first connection to the server is made from native code, the Native API must be used for the Push management operations throughout the app lifecycle (subscribe, unsubscribe, registerEventSourceCallback, and others). If the first connection is made from the JavaScript code, the JavaScript API must be used for these operations.

Android

In the Android Environment, there is a stronger restriction. The native Push API cannot be used in a hybrid application. The JavaScript API must be used for Push management operations (subscribe, unsubscribe, and others).

Reacting to push notifications

It is possible to react to push notifications both in native and JavaScript code in the same app. Using both provides an enhanced user experience because it allows the app to react to push notifications in the appropriate context. To achieve the use of both, follow these steps:

Using a native API for managing push operations (iOS only)

If you are coding in native iOS to handle the received push, forward the data to JavaScript using the Action Sender API.

Here is an example of JavaScript code:

```
// register an action receiver function
WL.App.addActionReceiver("myActionReceiverID", myActionReceiver);

// define action receiver function
function myActionReceiver(received)
{
  if (received.action == "handlePushFromNative")
  {
    // handle notification - do something with received.data
  }
}
```

In iOS native code, push notification is handled by the following method:

```
(void)application:(UIApplication*)application didReceiveRemoteNotification:(NSDictionary*)userInfo
```

in the implementation of the MyAppDelegate interface. For example:

```
(void)application:(UIApplication*)applicationdidReceiveRemoteNotification:(NSDictionary*)userInfo
{
    BOOL shouldHandleInNative = some applicative logic;
    if (shouldHandleInNative)
    {
        // handle notification in native code
    }
    else
    {
        // send the push data to a Javascript action receiver
        [[WL sharedInstance]sendActionToJS:@"handlePushFromNative" withData:userInfo];
    }
}
}
```

Using a JavaScript API for managing push operations

When the JavaScript API is used to handle push, the push notifications are handled by the JavaScript callback function that is registered using the API function `WL.Client.Push.registerEventSourceCallback` (alias, adapter, eventSource, callback). To handle the notifications using the native code of the app, code as follows:

In JavaScript code

Define and register a callback handler for the push notifications.
For example:

```
WL.Client.Push.registerEventSourceCallback(
    "myPush",
    "PushAdapter",
    "PushEventSource",
    pushNotificationReceived
);

function pushNotificationReceived(props, payload) {
    alert("pushNotificationReceived invoked");
    alert("props :: " + JSON.stringify(props));
    alert("payload :: " + JSON.stringify(payload));
}
```

In native Android code

1. Add a default constructor to the `GCMIntentService.java` class.
For example:

```
public GCMIntentService(){
    super();

    setBroadcastReceiver(new BroadcastReceiver() {

        @Override
        public void onReceive(Context context, Intent intent) {
            //This is Empty Broadcast Receiver, do not implement any logic here
        }
    });
}
```

2. In a custom native activity, implement the logic for handling the received push notification. Define a new broadcast receiver. For example, you can implement it in the `onStart` method of the native activity, as follows:

```
@Override
protected void onStart() {
    super.onStart();

    //Action name for inner push messages
    String action = getPackageName() + "." + getString(R.string.app_name) + ".C2DM_MESSAGE";

    //Register Custom Push Broadcast Receiver
```

```

registerReceiver(new BroadcastReceiver() {
    @Override
    public void onReceive(Context context, Intent intent) {

        if (isHandleInNative){ //Some variable controlled by applicative code
            Message message = intent.getParcelableExtra("message");

            // Custom Native Logic here using the Message class, use message.toString()
            // to receive the JSON object with push notification data.

            //Abort will prevent from sending the broadcast to hybrid part
            abortBroadcast();
        }
    }
}, new IntentFilter(action));
}

```

In native iOS code

Add the method

```
-(void)application:(UIApplication*)application didReceiveRemoteNotification:(NSDictionary*)userInfo
```

to the implementation of the MyAppDelegate interface. The method should implement the following logic:

```

- (void)application:(UIApplication*)application didReceiveRemoteNotification:(NSDictionary*)userInfo
{
    BOOL shouldHandleInNative = some applicative logic;
    if (shouldHandleInNative)
    {
        // handle notification
    }
    else
    {
        // call the worklight framework implementation - this will
        // invoke the Javascript callback handler
        [super application:application didReceiveRemoteNotification:userInfo];
    }
}

```

Troubleshooting push notification problems

To resolve iOS push notification issues, download the JCE policy file and update it for the server environment.

About this task

The push notification fails to send, and you see the following exception in the server log:

```

com.notnoop.exceptions.InvalidSSLConfig: java.io.IOException: Error in loading the keystore: Private
at com.notnoop.apns.internal.Utilities.newSSLContext(Utilities.java:88)

at com.ibm.pushworks.server.notification.apns.ApplicationConnection.createBuilderWithCertificate(App
at com.ibm.pushworks.server.notification.apns.ApplicationConnection.<init>(ApplicationConnection.java
...

```

Procedure

1. Download the unrestricted version of the JCE policy files.
 - a. Log in to Unrestricted SDK JCE policy files.
 - b. Select **Unrestricted JCE Policy files for SDK** for all later versions (Version 1.4.2 and later).

- c. Click **Continue** and finish the download process.
The .zip archive contains 3 files:
 - readme.txt
 - local_policy.jar
 - US_export_policy.jar
2. Update the JCE policy files for the server environment.
 - a. Stop the server.
 - b. Use the new local_policy.jar file and the new US_export_policy.jar file to replace the old local_policy.jar file and the US_export_policy.jar file that are in the `jdk_path/jre/lib/security` folder.

Note: The `jdk_path` might be bundled with the server.
- c. Restart the server.

MobileFirst security framework

A collection of topics that describe OAuth-based and classic security features in IBM MobileFirst Platform Foundation.

OAuth-based security model

Topics that describe OAuth-based security features in IBM MobileFirst Platform Foundation.

Overview

The OAuth 2.0 protocol is based on acquiring an access token, which encapsulates the authorization that is granted to the client. In that context, the IBM MobileFirst Platform Server serves as an authorization server and is able to generate such tokens. The client can then use these tokens to access resources on a resource server, which can be either the MobileFirst Server itself, or an external server. The resource servers perform validation on the token to make sure that the client can be granted access to the requested resource. This separation between resource server and authorization server in the new OAuth-based model allows you to enforce IBM MobileFirst Platform Foundation security on resources that are running outside the MobileFirst Server.

To support compatibility with earlier versions, the classic (pre-V7.0) security model is still in use in the flows that are based on the existing APIs (for example, `invokeProcedure` in Java). The new client APIs trigger flows that conform to the OAuth-based security model. V7.0 provides seamless integration between the two security models. The platform allows you to mix classic and new APIs in the same application, while keeping a consistent security context on the server side.

End-to-end authorization flow

The new end-to-end authorization flow is based on the OAuth specification and comprises the following phases:

1. Acquiring a token (see Figure 1): In this phase, the client obtains a token from the authorization server, following these steps:
 - a. Registration: This phase occurs once in the lifetime of a mobile app that is installed on a device. In this phase, the client registers itself with the MobileFirst Server. When application authenticity has been configured, it is activated during registration.

- b. Authorization: In this phase, the client has to undergo specific security checks, according to the scope of the authorization request. These checks are implemented using the building blocks of the classic security model: authentication realms are used on the server side, and challenge handlers are used on the client side. All the security checks supported by IBM MobileFirst Platform Foundation can be used in this phase (built-in realms such as remoteDisable and others, custom realms, and adapter-based authentication).
- c. Token generation: After successful authorization, the client is redirected to the token endpoint, where it is authenticated using the PKI trust that was established during the registration phase. The endpoint then generates two sets of tokens and sends them back to the client: an access token, which encapsulates all the security checks that the client has passed in the authorization phase and an ID token, which contains information regarding the user and device identity of the client.

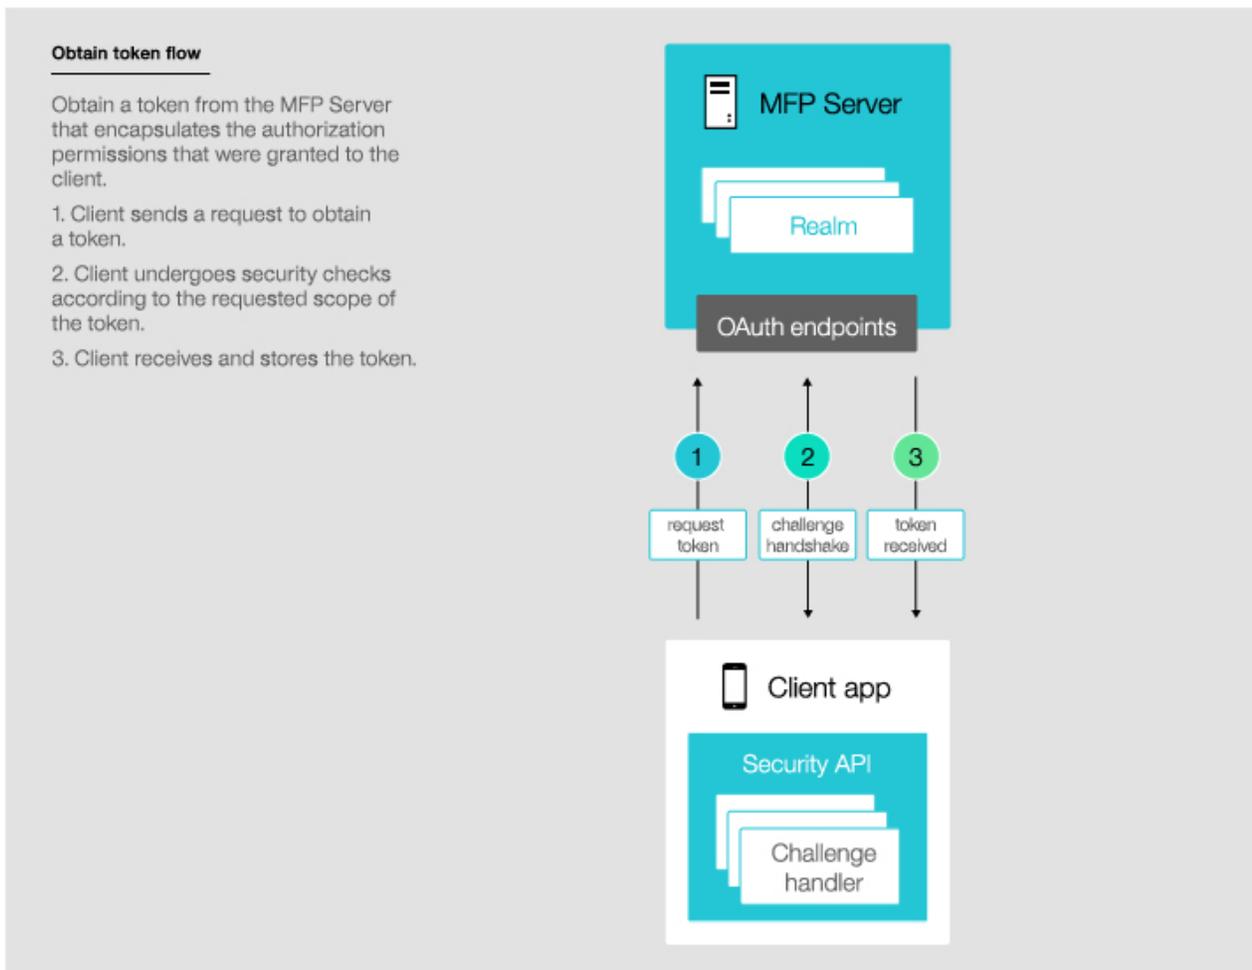

Figure 8-71. Obtain token flow

2. Using a token to access protected resources: Protected resources can run on the MobileFirst Server (see Figure 2) or on external servers (see Figure 3). Resources on external servers can be protected by using the validation modules that are provided with IBM MobileFirst Platform Foundation: the Node.js validation module for protecting Node.js resources and the Trust association

interceptor (TAI) for protecting Java resources, or by developing your own custom filter as shown in the Token validation endpoint example. These modules validate the access token and ID token in incoming requests, making sure that only authorized clients are served. To consume such protected resources, the client has to first acquire the token from the MobileFirst Server, and then add the tokens as an authorization header to outgoing requests. The new client APIs enable the client to access protected resources while transparently handling the handshake with the authorization server.

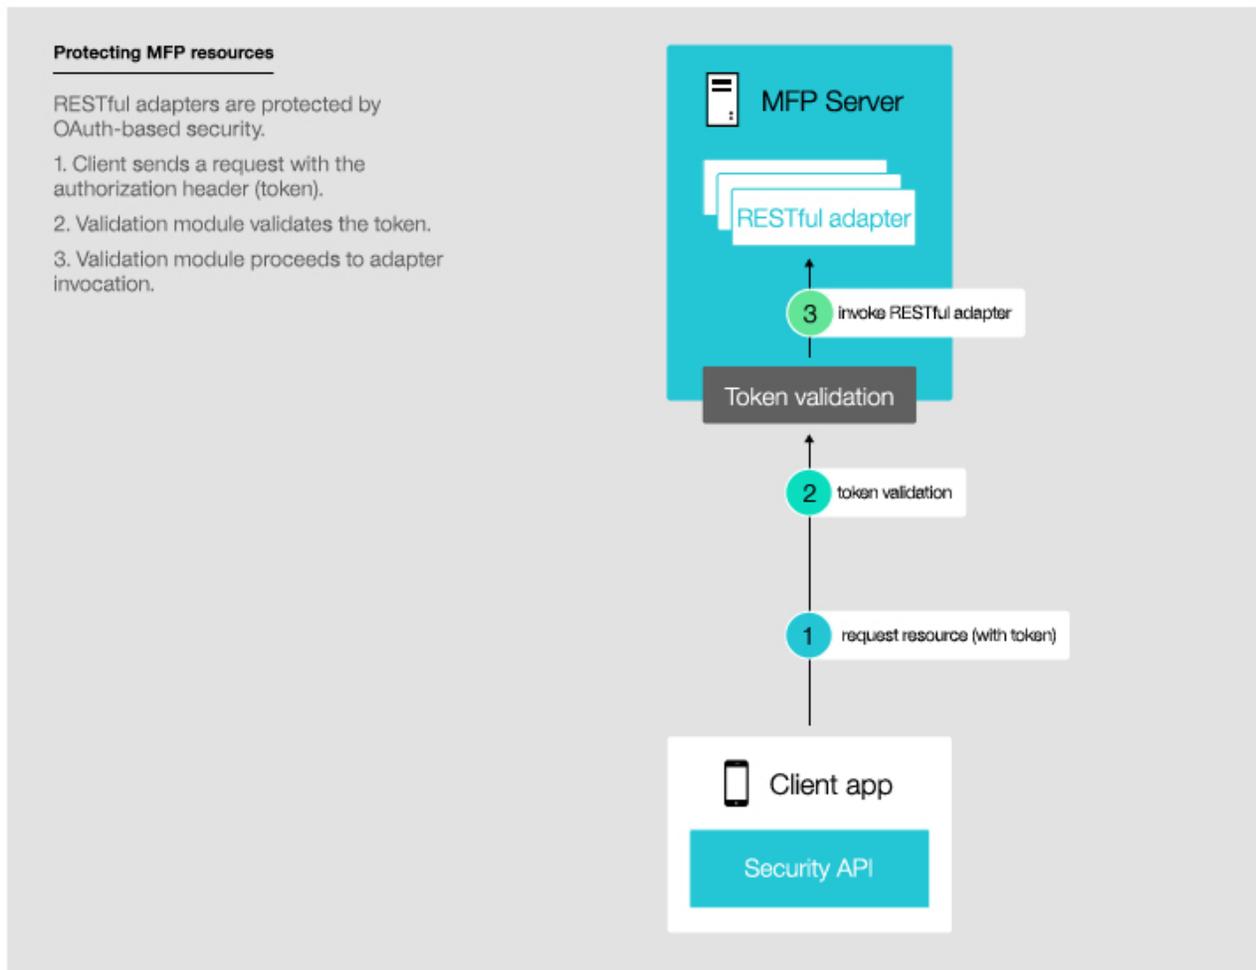

Figure 8-72. Protecting a resource on the MobileFirst Server

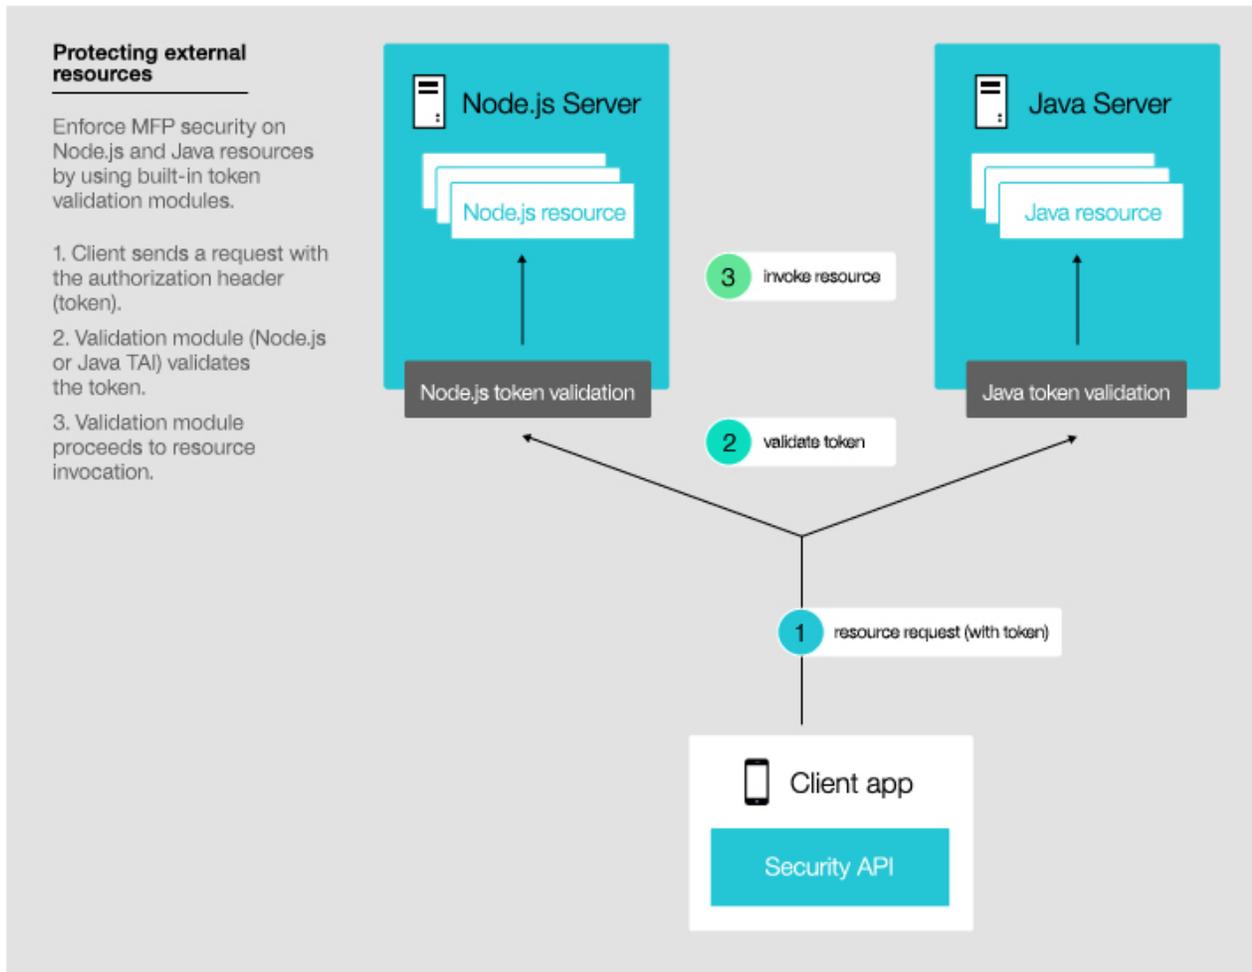

Figure 8-73. Protecting a resource on an external server

Protecting resources with OAuth-based security

It is possible to enforce IBM MobileFirst Platform Foundation security on resources running on the MobileFirst Server, as well as on resources running on any, external resource server. IBM MobileFirst Platform Foundation V7.0 provides several types of validation modules to enforce security on resources. These modules perform the following validation logic:

- Integrity: Digital signature for both ID token and access token is verified.
- Token expiration: Both tokens are tested for expiration. An expired token will fail the validation.
- Scope: Required scope for the resource is verified. The token has to contain the scope tokens (realm names) that are defined in the scope, and these scope tokens have to be valid (meaning, not expired).
- Mandatory scope: In addition to the scope defined by the resource, the access token must contain the valid scope that is required by the application. This scope contains the realms, which are defined in the security test that is protecting the application.

Note that each scope token (realm name) has its own expiration time, which can be different than the expiration time of the containing access token. To pass validation, both a scope token and its containing token must not be expired. The

expiration period of a scope token (realm name) is defined by the expiration attribute of the login module that is associated with the realm. For more information about configuring expiration of login modules, see “Configuring login modules” on page 8-617. For information about configuring access token expiration, see “The application descriptor” on page 8-50.

Consider the following example: a resource `/somePath/myResource/doSomething` is protected by the scope `{myCustomRealm myLoginRealm}`. All requests to this resource will be intercepted by the validation module, so a valid token with a scope that contains `myCustomRealm` and `myLoginRealm` must be present in the request. In case such a token exists, the request is granted, and the resource is consumed. Otherwise, the validation module rejects the request. In this case, the client (through the client API) interacts with the MobileFirst Server to obtain the token, which requires successful authentication to the specified realms. After acquiring the token, the client resends the request, which now passes the token validation, and the resource is consumed.

Protecting internal resources - RESTful adapters

IBM MobileFirst Platform Foundation V7.0 enables you to enforce security on resources that are running on the MobileFirst Server, that is, Java and JavaScript RESTful adapters. For more information, see Security configuration of a JAX-RS resource.

Protecting external resources

With IBM MobileFirst Platform Foundation V7.0, you can enforce MobileFirst security on resources running outside the MobileFirst Server. To this end, you can use the built-in Node.js and Java validation modules, or implement your own custom validation module in the technology of your choice, using the online validation endpoint:

Node filter

The `passport-mfp-token-validation` module provides a passport validation strategy for protecting apps on a Node.js server. For more information, see “Protecting resources on Node.js servers” on page 8-535.

TAI filter

You can use the IBM MobileFirst Platform Foundation OAuth trust association interceptor (TAI) to protect application resources on WebSphere Application Server or WebSphere Application Server Liberty. For more information, see “Protecting resources on WebSphere Application Server or WebSphere Application Server Liberty” on page 8-537.

Custom filter

The token validation endpoint on the MobileFirst Server validates tokens that are issued by the authorization server. For more information, see “Protecting resources with the token validation endpoint” on page 8-543.

Specifying the user identity realm in OAuth-based flows

Although user authorization may include authorization with several realms, only one of these realms is defined as the user identity realm, and that realm determines the user identity. In an OAuth-based flow, the user identity realm is set according to the `userIdentityRealms` definition in the “The application descriptor” on page 8-50. Note that in the classic (pre-V7.0) flows, the user identity realm is selected according to the definition in the security test. See `customSecurityTest`. In

OAuth-based flows, information about the user identity, which is set by the `userIdentityRealms` attribute, is part of the data contained in the "ID token" on page 8-534.

Combining classic and OAuth-based security models

MobileFirst Server V7.0 provides a smooth integration between the classic and OAuth-based security models.

Essentially, both flows share the same security context on the server side, and so any security state of a specific realm (such as expiration, or login status) is consistently shared between the flows. This allows you, the developer, to mix classic and OAuth-based security APIs, while providing a unified experience for the end user.

Consider, for example, a client application that calls an adapter procedure protected by some realm `myCustomRealm` and then retrieves a token for a scope that includes the same realm. In this case, the user will have to pass the `myCustomRealm` security check only on the first call, and will get the relevant token on the second call, without having to re-authenticate.

Some issues need to be considered when using both models in the same flow, or on the same resource:

- Device SSO:

The configuration of the Device SSO feature is based on the device and user identity realms that are defined in the security test, which is protecting the resource. However, OAuth resources are not protected by security tests and do not have a single defined user realm per resource, so the standard MobileFirst device SSO behavior does not apply to them. For more information, see "Device single sign-on (SSO)" on page 8-645..

- The login/logout API:

The `WLClientWLClient` login/logout API enables a user to log in to and log out of a specific realm, by updating the server side security state. However, in the new OAuth-based security model, security credentials are also kept in the access token on the client side. The result is that using this API will cause an inconsistent state, for example, in which the client is logged out of a realm on the server side but still holds a valid token for that realm on the client side. To solve this inconsistency, it is recommended to re-obtain the access token, by using the `obtainAuthorizationHeaderForScope` method, after successful login or logout.

For example, consider a client that passed the security checks for `Realm1` and `Realm2`, and later calls `logout(Realm2)`. In this case, the access token on the client would still contain the security credentials for both `Realm1` and `Realm2`, and the client could use this token to access protected resources. To refresh the token, that is, to obtain a token for `Realm1` only, the client calls `obtainAuthorizationHeaderForScope` without the logged out realm `Realm2`.

iOS example:

```
[[WLClient sharedInstance]logout:@"MyRealm" withDelegate:self];

-(void)onSuccess:(WLResponse *)response{
    // re-obtain the token
    [[WLAUTHORIZATIONMANAGER sharedInstance]obtainAuthorizationHeaderForScope:nil completionHandler:^(WLResponse *response, NSError *error) {
        // successful logout logic
    }];
}
```

Test token endpoint

The test token endpoint enables you to get a valid token via a REST call, without having to set up a mobile client. For more information, see “The test token endpoint” on page 8-546.

Public key endpoint

The public key endpoint gets the server's public key. The public key is used, for example, for the verification of digitally signed OAuth tokens. The path for the endpoint is as follows:

```
/authorization/v1/publickey
```

The endpoint returns the public key information using the JWK standard format. The following is an example of a result returned by this endpoint:

```
{
  "e": "AQAB",
  "n": "AM0Dd7xAdv6H-ygL7r8qCLdE-3I2kk45zgZtDd_qs8fvnYfdiqTSV4_2t60GG8CV5Ce41PMpIwmL410X9IZnvhoYiFcmSa0eIqoe-rJA0uZuw",
  "kty": "RSA"
}
```

Note: The server uses an RSA key type, and therefore the kty attribute is always RSA.

Preview mode

The new OAuth-based flows are also available in preview mode. However, in this mode, the registration phase is protected by an anti-cross site request forgery realm, wl_antiXSRFRealm, and not application authenticity.

Note: Preview mode is not available in production environments.

Exposed endpoints

You can enable white- and blacklists to the endpoints of the MobileFirst Server. For a list of endpoints for use with the OAuth-based security model, see “Endpoints of the MobileFirst Server production server” on page 6-360.

Security client APIs

IBM MobileFirst Platform Foundation V7.0 provides client APIs that conform to the new OAuth-based security model.

- There is an API for consuming protected resources, which transparently supports the interaction with the MobileFirst Server (obtaining the token requested by the resource).
 - In Objective-C: WLResourceRequest
 - In Java: WLResourceRequest
 - In JavaScript: WLResourceRequest
 - In C# for Windows 8 Universal and Windows Phone 8 Universal: WLResourceRequest
- In addition, APIs are provided to create a custom client implementation that is able to interact with the validation modules and MobileFirst Server. The following examples are provided:
 - “Custom requests to resources using Objective-C” on page 8-549

- “Custom requests to resources using Java” on page 8-550
- “Custom requests to resources using JavaScript” on page 8-551
- “Custom requests to resources using C#” on page 8-552

OAuth-based tokens

Learn about token response, MobileFirst Server authorization headers, access tokens, and ID tokens.

Access token

The access token is a digitally signed token that describes the authorization permissions of a client. The token contains the following noteworthy attributes:

- `expiration`: Expiration of the access token in seconds. An expired token is not valid.
- `scope`: Scope of the authorization permissions of this token. The scope comprises a list of scope tokens.
- `scope tokens`: Scope tokens are mapped to MobileFirst realms (a scope token is the name of a MobileFirst realm). Each such scope token represents a successful authentication that the client has undergone during the authorization phase. Each scope token has an expiration of its own (in seconds).

ID token

The ID token is a digitally signed token and implements the OIDC specification. It contains information about the device, application, and user identity. The device and application identity are defined in the registration phase and are always present in the ID token. The user identity is defined according to `userIdentityRealms`, as described in “The application descriptor” on page 8-50. In case there is no such realm defined, the ID token contains no user identity, meaning that the user is “anonymous”.

To learn more about using the data in the ID token, see [Protecting resources on WebSphere Application Server or WebSphere Application Server Liberty](#), [“Protecting resources on Node.js servers”](#) on page 8-535, [“Protecting resources with the token validation endpoint”](#) on page 8-543, and [“Implementing the JAX-RS service of the adapter”](#) on page 8-236.

MobileFirst Server authorization header

After the client has acquired an access token, it can use the token in requests to protected resources. As described in the OAuth 2.0 Bearer Token Usage specification, the client uses the “Bearer” authentication scheme to transmit the access token in the authorization HTTP header. The following is an example of the value of the authorization header:

```
Authorization: Bearer yI6ICJodHRwOi8vc2VydmVyLmV4YW1...
```

Successful token response

The access token and ID token are generated in the token endpoint after the authorization phase and sent to the client.

A successful token response from the MobileFirst authorization server looks like this:

```

HTTP/1.1 200 OK
Content-Type: application/json
Cache-Control: no-store
Pragma: no-cache
{
  "token_type": "Bearer",
  "expires_in": 3600,
  "access_token": "yI6ICJodHRwOi8vc2VydmVyLmV4YW1...",
  "id_token": "eyJhbGciOiJSUzI1NiIsImtpZCI6Ij...",
  "scope": "wl_directUpdateRealm wl_remoteDisableRealm wl_antiXSRFRealm wl_deviceNoProvisioningRealm wl_anonymousUserRealm"
}

```

Note:

- `token_type` is always "Bearer", as defined in the OAuth 2.0 Bearer Token Usage specification.
- `expires_in` is the expiration time of the access token, in seconds.
- `scope` is the list of the scope tokens (realms) that is included in the access token.

Protecting external resources

You can protect application resources that are located on WebSphere Application Server, WebSphere Application Server Liberty or Node.js servers by using OAuth security.

Protecting resources on Node.js servers:

You can protect your resources that are running on Node.js servers with OAuth-based IBM MobileFirst Platform Foundation security.

mfpStrategy

The `passport-mfp-token-validation` npm module provides a passport validation strategy and a verification function to validate access tokens and ID tokens that are issued by the MobileFirst Server .

```
passport.use (new mfpStrategy(options));
```

The **options** parameter contains one or more of the following options:

- **publicKeyServerUrl**: (Mandatory) Specifies the URL of the MobileFirst Server from which the public key is retrieved to verify the tokens.

Note: Alternatively, you can pass the public key server URL as a parameter to the `passport.authenticate` method. This method is used in the Example.)

- **scope**: Space-separated string to define the list of realm names that are required for accessing the resource. If no scope is specified, only the mandatory scope is checked in the token.

Note: Alternatively, you can pass the scope as a parameter to the `passport.authenticate` method. (See Example.)

- **cacheSize**: The maximum number of tokens allowed. The default value is 500.
- **logger**: Defines a logger instance. The default value is the IBM default logger, which outputs log messages to the console.
- **analytics.onpremise**: Use this parameter to specify where to send the analytics logs. Logs are displayed in the MobileFirst Operational Analytics console.
 - **url**: The url that specifies the location of the operational analytics server. For example, `http://localhost:10080/worklight-analytics-service/data`.
 - **username**: The user name if credentials are required.

- **password:** The password if credentials are required.

For more information about operational analytics, see “Operational analytics” on page 14-9.

For more information about npm passports, see Passport Readme. For more information about the **passport.authenticate** method, see Authenticate.

Example

The following example shows how to use **mfpStrategy** in a node application:

```
var express = require('express'),
    passport = require('passport-mfp-token-validation').Passport,
    mfpStrategy = require('passport-mfp-token-validation').Strategy;
//the configuration ('config') is optional if you wish to report
//events to the Analytics Server.
var config = {
  url : 'http://localhost:10080/worklight-analytics-service/data',
  username : 'admin',
  password : 'admin'
};

passport.use(new mfpStrategy({publicKeyServerUrl:'http://localhost:10080/WLProject',
analytics : {onpremise: config}}));

var app = express();
app.use(passport.initialize());

// protect API with mfpStrategy using scope Realm1 Realm2 Realm3
app.get('/v1/apps/:appid/service', passport.authenticate('mobilefirst-strategy',
  {session: false , scope: 'Realm1 Realm2 Realm3' })),
  function(req, res){
    res.send(200, req.securityContext);
  }
);

app.listen(3000);
```

To start the example, issue the following commands:

```
$ npm install express
$ npm install passport
$ npm install passport-mfp-token-validation
```

Token verification

The `passport-mfp-token-validation` module verifies the authorization header of the request. The authorization header consists of the following elements:

Bearer Access_token ID_token

Where

Bearer (Mandatory) Is the required string for the token type, as defined in the OAuth 2.0 specification.

Access_token

(Mandatory) Encapsulates all of the security checks that the client has passed in the authorization phase.

ID_token

(Optional) Contains information about the user and device identity of the client.

Bearer and *Access_token* are mandatory. *ID_token* is optional. The passport-mfp-token-validation module verifies the token with the public key that is retrieved from the authorization server. If the token is verified successfully, the *securityContext* and user objects are attached to the request object.

securityContext

After a successful validation, a security context object is added to the current request.

The *securityContext* object contains the following fields:

- **imf.sub**: The **sub** value of the ID token or the unique ID of the client if there is no ID token.
- **imf.user**: The **user** value that is extracted from the ID token. If there is no ID token, this field holds a blank object.
- **imf.device**: The **device** value that is extracted from the ID token. If there is no ID token, this field holds a blank object.
- **imf.application**: The **application** value that is extracted from the ID token. If there is no ID token, this field holds a blank object.

user The user object in the request is returned by the passport framework. Its value is the same as the value of `imf.user` in the *securityContext* object.

Protecting resources on WebSphere Application Server or WebSphere Application Server Liberty:

You can protect your resources that are running on WebSphere Application Server or WebSphere Application Server Liberty servers with OAuth-based IBM MobileFirst Platform Foundation security.

Overview

To enable MobileFirst OAuth security for resources on WebSphere Application Server or WebSphere Application Server Liberty servers, complete the following steps:

1. Configure OAuthTAI
2. Set the security role
3. Install and configure OAuthTAI on the server
4. Add the tokens to the authorization header
5. Use the security context to access resources

Configure OAuthTAI

You configure the OAuthTAI feature by using XML. For WebSphere Application Server Liberty, you add the XML to the `server.xml` file. For WebSphere Application Server, you save it in a separate file.

The OAuthTAI element is the root element. The following sections describe the OAuthTAI attributes and subelements:

OAuthTAI attributes

cacheSize

(Optional) Maximum number of tokens allowed. The default is 500.

id

(Mandatory) Defines a unique id of OAuthTAI.

OAuthTAI subelements

securityConstraint

(Mandatory) The value of securityConstraint must be a number 1 to *n*.

securityConstraint attributes

securedURLs

(Mandatory) If multiple URLs are specified in securedURLs, separate each URL by a space. The following types of URLs are supported:

- Exact match URL. For example, /context-root/a/xyz
- Path match URL. For example, /context-root/*
- Wild card match URL. For example, /context-root/*/xyz

httpMethods

(Optional) Default value: ALL. The httpMethods attribute is case insensitive. Its value can be one or more of the following strings: ALL, DELETE, GET, POST, PUT, HEAD, OPTIONS, TRACE, or CONNECT. If multiple methods are specified, separate the methods by a space.

scope

(Optional) If scope is not specified, the only checking that is done is to make sure that the mandatory scopes are not expired.

The following is an example:

```
<?xml version="1.0" encoding="UTF-8"?>
  <OAuthTAI>
    <securityConstraint httpMethods="GET POST" securedURLs="/mfp-oauth-java-tests/*"
      scope="Realm1 Realm2"/>
    <securityConstraint httpMethods="DELETE" securedURLs="/another-context-root/*"/>
  </OAuthTAI>
```

Set the security role

To protect the web resources used by your application, you must specify TAIUserRole as the Java Platform, Enterprise Edition (Java EE) security role. You can specify TAIUserRole as the Java EE security role in one of two ways: in the web.xml file or as an annotation.

To specify the TAIUserRole in the web.xml file, define TAIUserRole in the security-role element, and then use this role to secure the web resource in the security-constraint element. For example:

```
<security-constraint>
  <web-resource-collection>
    <web-resource-name>BaseServlet</web-resource-name>
    <url-pattern>/Test/devices</url-pattern>
  </web-resource-collection>
  <auth-constraint>
    <role-name>TAIUserRole</role-name>
  </auth-constraint>
</security-constraint>
<security-role id="SecurityRole_TAIUserRole" >
  <description>This is the role that MobileFirst OAuthTAI uses to protect the resource. It must be mapped to 'All Authenti
  <role-name>TAIUserRole</role-name>
</security-role>
```

To specify TAIUserRole with an annotation:

```
@WebServlet("/Test/devices")
@WebServletSecurity(@HttpConstraint(rolesAllowed={"TAIUserRole"}))
public class BaseServlet extends HttpServlet {
    // servlet code ...
}
```

Install and configure OAuthTAI in WebSphere Application Server or WebSphere Application Server Liberty

Installing OAuthTAI in WebSphere Application Server Liberty

1. Copy the file *product_install_dir/WorklightServer/external-server-libraries/com.ibm.worklight.oauth.tai_1.0.0.jar* to *usr/extension/lib*.

where

product_install_dir

is the installation directory for MobileFirst Server.

usr is the user directory for the WebSphere Application Server Liberty profile (default name *usr*).

2. Copy the file *OAuthTai-1.0.mf* from the directory *WorklightServer/external-server-libraries* to the directory *usr/extension/lib/features*.
3. Edit the *server.xml* file to add the OAuthTAI -1.0 feature. For example:

```
<featureManager>
  <feature>appSecurity-2.0</feature>
  <feature>usr:OAuthTai-1.0</feature>
  <!--other necessary features-->
</featureManager>
```

4. Edit the *server.xml* file to add the OAuthTAI feature. Note that the security role TAIUserRole is mapped to a special subject named ALL_AUTHENTICATED_USERS. For example:

```
<usr_OAuthTAI id="myOAuthTAI">
  <securityConstraint httpMethods="GET POST" securedURLs="/worklight-oauth-java-tests/*"
    scope="Realm1 Realm2"/>
  <securityConstraint httpMethods="DELETE" securedURLs="/another-context-root/*"/>
</usr_OAuthTAI>

  <basicRegistry id="basic" realm="BasicRealm" />

  <application type="war" id="basicauth" name="basicauth" location="${server.config.dir}/apps/basicauth.war">
  <application-bnd>
  <security-role name="TAIUserRole">
    <special-subject type="ALL_AUTHENTICATED_USERS" />
  </security-role>
  </application-bnd>
</application>
```

5. Add the URL to the authorization server into the environment variables of your deployment. One way of doing so is to add the entry into the *server.env* file, which is located in the same directory as the *server.xml* file. Add the following, where

```
publicKeyServerUrl=URL_to_authorization_server.
```

URL_to_authorization_server is the URL to the MobileFirst authorization server.

Installing OAuthTAI in WebSphere Application Server

1. Copy *project_root_dir/target/com.ibm.worklight.oauth.tai_1.0.0.jar* to *product_install_dir/lib/ext*.
2. Open the WebSphere Application Server console.

3. Click **Security > Global Security > Authentication**, and select **Enable LTPA**.
4. Click **Security > Global Security > Application security > Enable application security**.
5. Configure the trust association.
 - a. Click **Security > Global Security > Web and SIP security > Trust association**.
 - b. Click **Enable trust association**.
 - c. Under **Interceptors**, click **New**, and create a new interceptor with the following values:
 - **Interceptor class name:**com.worklight.oauth.tai.OAuthTAI
 - **Custom properties:** configFileLocation = *OAuthTAI_config_file_dir/filename.xml*
where
OAuthTAI_config_file_dir/filename.xml is the directory path and file name of the XML configuration file that you already created. See the configuration file example .
6. Create an environment entry that points to the authorization server.
 - a. In the WebSphere Application Server console, click **Servers > Server Types > WebSphere application servers > your_server_name > Server Infrastructure > Java and Process Management > Process Definition > Additional Properties > Environment Entries**.
 - b. Create the following environment variable:

```
publicKeyServerUrl=authorization_server_URL
```

 where
authorization_server_URL
is the URL to the MobileFirst authorization server.
7. Map the security role.
 - a. In the WebSphere Application Server console, click **Applications > Application Types > WebSphere enterprise applications > your_application_name > Details Properties > Security role to user/group mapping**.
 - b. Map the role that is allowed to access your application to **All Authenticated in Application's Realm**. For example: TAIUserRole as in sample above.
8. Restart WebSphere Application Server.

Add the tokens to the authorization header of your request

Add the following line to the authorization header of your request:

```
Authorization: Bearer Access_token ID_token
```

where

Bearer (Mandatory) Is the required string for the token type, as defined in the OAuth 2.0 specification.

Access_token

(Mandatory) Encapsulates all of the security checks that the client has passed in the authorization phase.

ID_token

(Optional) Contains information about the user and device identity of the client.

When the application attempts to access resources protected by OAuth TAI, the following validation checks occur:

Validation item	Result if invalid
The authorization header exists.	A 401 error is returned, with the response header <code>WWW-Authenticate: Bearer realm="imfAuthentication", scope="{required_scopes_list}"</code>
The authorization header starts with the string Bearer.	A 400 error is returned, with the response header <code>WWW-Authenticate: Bearer realm="imfAuthentication", error="invalid_request", scope="{required_scopes_list}"</code>
The signature of the access token and the ID token are valid and not expired, and they can be decoded.	A 401 error is returned, with the response header <code>WWW-Authenticate: Bearer realm="imfAuthentication", error="invalid_request", scope="{required_scopes_list}"</code>
Validation of scope. This includes the following: <ul style="list-style-type: none">• Verification of the scope in the access token.• Whether the mandatory scope is expired.• Whether the scope is expired.• Whether the access token contains all of the required realm names.	A 403 error is returned, with the response header <code>WWW-Authenticate: Bearer realm="imfAuthentication", error="insufficient_scope", error_description="{detail_information_of_error}.", scope="{required_scopes_list}"</code>

The security context object

After successful validation, a security context is available to your application. The security context is a JSON object that contains the following properties:

Subject: `securityContext.get("imf.sub");`

The subject is a string which uniquely identifies the application installation on a device and the authenticated user.

User Identity: (Optional) `securityContext.get("imf.user");`

The user identity is a JSON object which contains information about the authenticated user. For anonymous tokens, the user identity is null. The user identity contains the following properties:

- **"id"**: (Mandatory) The user identity of the authenticated user identity realm.
- **"authBy"**: (Mandatory): The name of the authenticated user identity realm.
- **"displayName"**: (Optional) The user's display name as set when authenticating the user identity realm. This property may be null.
- **"attributes"**: (Optional) Additional data that can be set when authenticating the user identity realm. This property may be null.

Application information:securityContext.get("imf.application");

Application information, including "id", "environment", and "version". For example:

```
{"id":"com.MobileFirst.TestApp","environment":"Android","version":"1.0"}
```

Device information:securityContext.get("imf.device");

Device information, including "id", "platform", "model" and "osVersion". For example:

```
{"id":"E7D426A2-214C-834C-87FF-D8E9DF93655D","platform":"Android","model":"Nexus 5","osVersion":"5.0"}
```

Example

```
JSONObject securityContext = callerWLCredential.getSecurityContext();
String subject = securityContext.get("imf.sub");
JSONObject imfUser = securityContext.get("imf.user");
JSONObject imfDevice = securityContext.get("imf.device");
JSONObject imfApplication = securityContext.get("imf.application");
```

The WSCredential and WLCredential APIs provide credential functionality.

com.ibm.websphere.security.cred.WSCredential

The WSCredential interface defines a credential that represents an authenticated principal to WebSphere Application Server or WebSphere Application Server Liberty. For example:

```
Subject callerSubject = WSSubject.getCallerSubject();
WSCredential callerCredential = callerSubject.getPublicCredentials
(WSCredential.class).iterator().next();
```

For more information about WSCredential, see the WSCredential documentation for your version of WebSphere Application Server or WebSphere Application Server Liberty. For example, see WSCredential for WebSphere Application Server Network Deployment 8.5.

com.worklight.oauth.tai.WLCredential

The WLCredential interface provides APIs to get the MobileFirst specific principal details.

```
WLCredential callerWLCredential = callerSubject.getPublicCredentials
(WLCredential.class).iterator().next();
```

IBM MobileFirst Platform Foundation OAuthTAI in development mode

In development mode, you can copy the jar and the manifest file from the following locations, depending on your development environment:

MobileFirst Studio

The root of every project contains a folder named `externalServerLibraries`. This folder contains both the TAI jar file (`com.ibm.worklight.oauth.tai_1.0.0.jar`) and the manifest file (`OAuthTai-1.0.mf`).

MobileFirst Platform Command Line Interface

The TAI jar file (`com.ibm.worklight.oauth.tai_1.0.0.jar`) and the manifest file (`OAuthTai-1.0.mf`) are located in the `CLI_install_dir/public` folder,

where

`CLI_install_dir`

is the path where MobileFirst Platform Command Line Interface is installed. Both files are also copied into the /externalServerLibraries folder in any new MobileFirst project created by the command-line interface.

Reporting analytics

The Token lib library can report analytic events to IBM MobileFirst Platform Operational Analytics. You must configure the Resource Server that contains the Token lib with your Analytics URL and credentials.

The MobileFirst Operational Analytics server is protected by basic authentication. When you installed this server, you configured the data entry point and basic authentication credentials. To configure the Resource Server, you must provide the Analytics credentials through JNDI properties, specifically the URL to the data entry point, the user name, and password. These properties are set with the following property names:

- imf.analytics.url
- imf.analytics.username
- imf.analytics.password

If your Resource Server is running on WebSphere Application Server Liberty, you must configure these properties by using JNDI by adding entries to your server.xml file. For example:

```
<jndiEntry jndiName="imf.analytics.username" value="admin"/>
```

If your Resource Server is running on WebSphere Application Server, you must configure these properties as Environment Entries. In the WebSphere Application Server Console, go to **Servers > Server Types > Websphere application servers > <your server> > Server Infrastructure > Java and Process Management > Process Definition > Additional Properties > Environment Entries > New**. This value is the location where you had to set publicKeyServerUrl when you set up OAuthTAI.

Protecting resources with the token validation endpoint:

The token validation endpoint on the IBM MobileFirst Platform Server validates tokens that are issued by the authorization server.

The token endpoint implements the OAuth 2.0 token introspection specification and validates access tokens and ID tokens. Using this endpoint, you can write a custom filter in any language to protect resources that are external to the MobileFirst Server. The filter delegates the token validation to the endpoint. An example of a custom filter in Node.js is shown at the end of this topic.

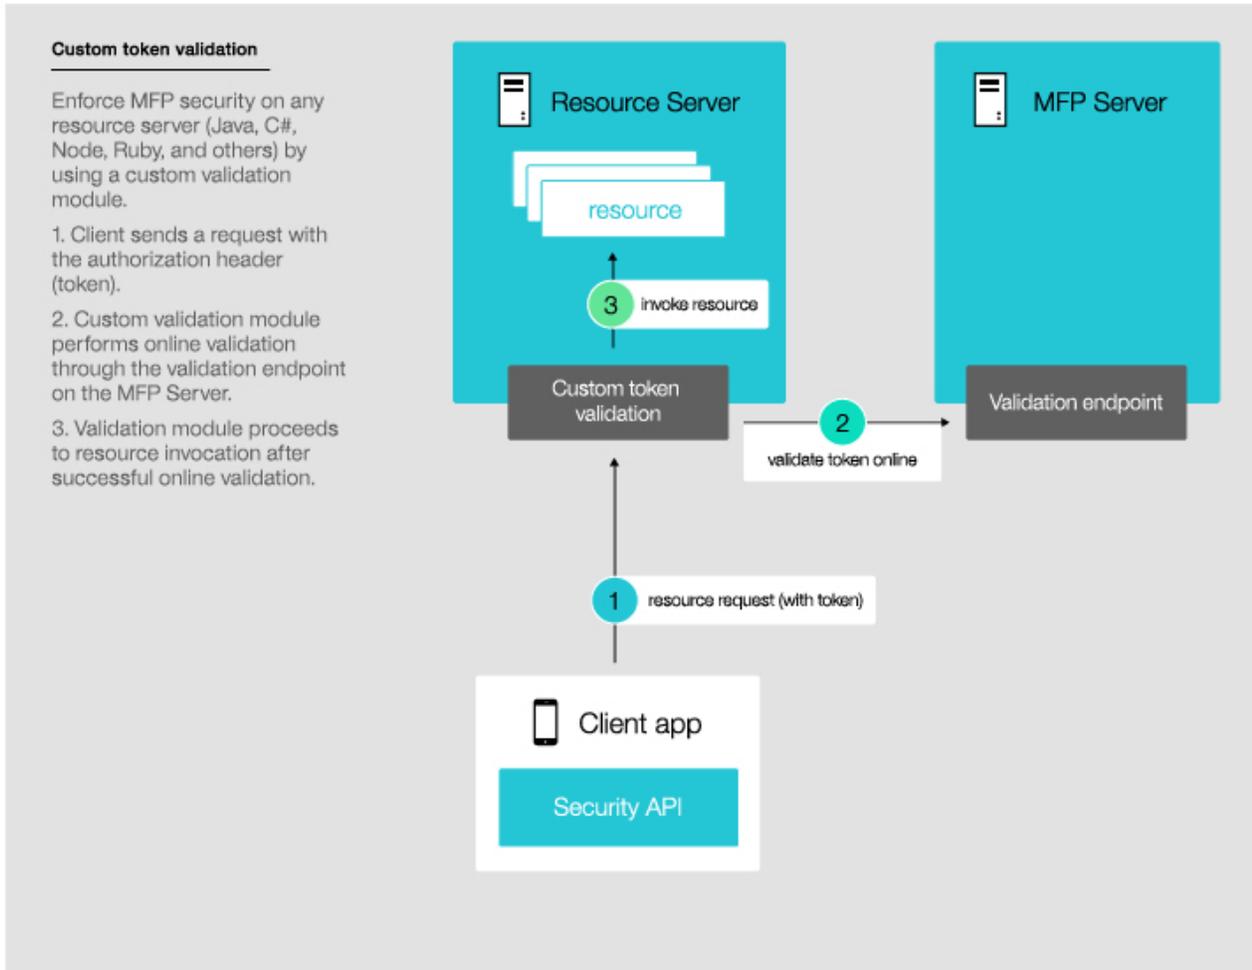

Figure 8-74. Custom token validation

The endpoint has the same processing logic as the built-in Node.js filter and TAI filter.

Usage: The URL pattern for accessing the endpoint is as follows:

`http(s)://<server_ip>:<server_port>/<project_name>/authorization/v1/token/validation`

The endpoint responds to a POST request with the following parameters:

token Mandatory. The MobileFirst access token to be checked.

id_token

Optional. The MobileFirst ID token to be checked.

required_scope

Optional. If specified, the endpoint should ensure that the access token covers that scope.

Response: If the token validates successfully, the validation endpoint responds with a JSON object that is in application/json format and that has the following top-level members:

```

{
  "active": true,
  "exp" : timestamp,

```

```

    "scope" : "scope1 scope2 scope3",
    "user_id" : userid,
    "security_context" : securityContext,
  }

```

active Indicates whether the token is valid or not.

exp Indicates the expiration time of the token.

scope Indicates the scopes of the token.

user_id

Indicates the unique identity of the token. If an ID token is provided, the value is a subfield of the ID token. If not, the value is the prn field in the access token.

security_context

Contains the decoded information from the access token and ID token. For more information, see The security context object.

In case of validation failure, the response conforms to the OAuth 2.0 specification, meaning that the status is 40* and WWW-Authenticate is added to the response header. The header looks like this:

```
WWW-Authenticate: Bearer realm="<realm name>", error="<error code>"[, error_description="<error description>"][, scope="<scope>"]
```

Example: The following example demonstrates a Node.js custom filter that uses the endpoint:

```

var express = require('express');
var http = require('http');
// For sending the data as x-www-form
var querystring = require('querystring');
var app = express();

// TokenValidationEndpoint custom filter
app.get('/resource/test0', function(req, res) {
  var authorizationHeader = req.headers["authorization"];
  var path = "/Top/authorization/v1/token/validation";
  var host = "9.148.225.200";
  var port = 10080;

  // Authorization header - Bearer <accessToken> <idToken>
  var accessToken;
  var idToken;
  var tokenType;
  if (typeof authorizationHeader != 'undefined') {
    var tokenSplit = authorizationHeader.split(" ");
    tokenType = tokenSplit[0];
    accessToken = tokenSplit[1];
    idToken = tokenSplit[2];
  }
  var form = {
    token : accessToken,
    id_Token : idToken,
    token_type_hint : tokenType
  }

  var data = querystring.stringify(form);

  var options = {
    hostname : host,
    port : port,
    path : path,
    method : 'POST',
    headers : {
      'Content-Type' : 'application/x-www-form-urlencoded',

```

```

        'Content-Length' : Buffer.byteLength(data)
    }
};

var reqToWL = http.request(options, function(resFromWL) {
    resFromWL.on('data', function(chunk) {
        var parsedData = JSON.parse(chunk);
        if (!parsedData.active) {
            console.log("Token is invalid");
            var status = resFromWL.statusCode;
            var wwwAuthenticate = resFromWL.headers["www-authenticate"];
            // Set the header and send the response we got from the WL
            // server
            res.set("WWW-Authenticate", wwwAuthenticate);
            res.status(401).send();
        } else {
            console.log("Token is valid");
            // Send the response with the payload
            res.send("hello, user");
        }
    });
});

reqToWL.on('error', function(e) {
    console.log('problem with request to WL server: ' + e.message);
});

// write data to request body
reqToWL.write(data);
reqToWL.end();
});

app.listen(3000);
console.log("app is listening at " + 3000);

```

The test token endpoint

The test token endpoint enables you to get a valid token via a REST call, without having to set up a mobile client.

The OAuth model that is used in IBM MobileFirst Platform Foundation V7.0 requires a MobileFirst client API to be running in the mobile application that interacts with the MobileFirst Server to obtain an access token. Setting up the mobile app often means unnecessary overhead, particularly in back end testing situations. Use the test token endpoint to get a valid token through a REST call (by using tools such as Postman or cURL), without a mobile client.

Note: The test token endpoint is available only in the development version of IBM MobileFirst Platform Foundation.

Usage

The endpoint provides a valid token with a default expiration of two hours and a scope that includes all the realms that are defined in your `authenticationConfig.xml` file.

The URL pattern for accessing the endpoint is as follows:

```
http(s)://<server_ip>:<server_port>/<project_name>/authorization/v1/testtoken
```

The endpoint responds to a POST request with the following parameters:

accessTokenExpiration

Number of seconds for the token expiration.

tokenFormat: Header/Token

Response format:

1. Header (default): returns a JSON object that can be copied directly to REST apps (such as Postman) as a header, for example,
{Authorization: Bearer eyJhbG...}
2. Token: returns the OAuth token as defined by the spec:

```
{  
  "scope": "SubscribeServlet wl_directUpdateRealm wl_authenticityRealm SampleAppRealm wl_remoteDisableRealm wl_antiXSRF",  
  "token_type": "bearer",  
  "expires_in": 1421262002284,  
  "id_token": "eyJhbG...",  
  "access_token": "eyJhbG..."  
}
```

Exposing mobile services to non-mobile (confidential) clients

Using IBM MobileFirst Platform Foundation you can let a confidential (or non-mobile) client connect to mobile services in a secure way. For example, you can grant a back-end service access to the Push service.

Overview

The confidential client flow is based on the client credentials flow, as defined in the OAuth specification. The client authenticates with the authorization server using a certificate. The authentication server validates the certificate, and if it is valid, issues an access token to the client. The certificate has to be signed by a trusted signer certificate that is configured at the authorization server.

Structure of the client certificate

The confidential client certificate contains three attributes that are required for the token generation:

- **Client ID:** a string that identifies the confidential client, that is, the certificate holder. The client ID is used to identify the client, for example for collecting analytics.
- **Scope:** a list of scope tokens (realm names) that can be granted to the certificate holder. Unlike realms that are used by mobile clients, the realms for certificate holders do not have to be defined in the `authenticationConfig.xml` security configuration file of the application. Built-in MobileFirst realms and realms that are defined in the security configuration file may also be included.
- **Expiration:** the expiration time (in seconds) of tokens that are generated for the certificate holder.

The Client ID attribute is stored as the common name attribute of the certificate. The Scope and Expiration attributes are stored as X.509 certificate extensions. A sample script has been provided that generates a certificate with these three attributes, and signs it with the trusted signer certificate. For more information, see [Generating the trusted signer certificate](#).

Acquiring tokens

To acquire a token, the client authenticates itself with the authorization server by providing a JSON Web Signature (JWS). The payload of the JWS contains a timestamp and is signed by the certificate of the confidential client. The signature is valid for one minute only, meaning that clients must generate a new signature with every token request.

The client posts a token request to the authorization server's token endpoint. The request includes the signature that allows the server to authenticate the client. The request might also include a Scope parameter that specifies the scope to be granted in the token. The Scope parameter has to be a subset of the scope that is defined in the certificate of the client. If no scope is included in the request, the result token is an access token that includes no realms (but this is still a valid token).

If the signature is verified correctly, the server responds with an access token. The access token is generated using the attributes that are specified in the certificate - the client ID, the token expiration, and the scope (or a subset of the scope if specified in the scope parameter of the token request). The expiration time of the individual realms is the same as the token expiration time.

The sample application, Confidential_Client_Sample can be used for constructing a signature, sending a request to the token endpoint, and extracting the access token from the response. Download Confidential_Client_Sample.

Generating a client certificate

A sample script has been provided for generating a certificate for a confidential client. The script puts the custom attributes (Client ID, Scope, and Expiration) in the certificate and signs the certificate with the trusted signer certificate. The script uses OpenSSL, so ensure that you have OpenSSL installed. The script is called `gen_cert.sh`.

The `gen_cert.sh` script requires three parameters:

- **Workdir**: the path of the working directory. The script uses two files that must be present in the working directory: `rootCA.crt`, the trusted signer certificate, and `rootCA.key`, the private key of the trusted signer certificate.
- **clientId**: the client ID attribute to be stored in the certificate.
- **password**: the password for protecting the private key of the client certificate and the resulting KeyStore.

The scope and expiration attributes to be placed in the certificate are taken from the configuration file `extensions.cnf` that is located in the directory of the script. Before running the script, edit this file and set the values for scope and expiration.

The script generates the following files:

- **certificate.crt**: the client certificate.
- **private_key.key**: the private key of the client certificate.
- **keystore.p12**: a PKCS #12 KeyStore that stores the client certificate and the private key.

Download the Certificate_Scripts sample script.

Generating the trusted signer certificate

You can generate the trusted signer certificate by creating a certificate-signing request and submitting it to a chosen certificate authority. The trusted signer certificate may also be self-signed. A sample script, `gen_root_cert.sh` generates a self-signed signer certificate. It requires a single parameter - the path of the output directory. The script generates two files: `rootCA.crt`, the signer certificate, and `rootCA.key`, the private key of the certificate. The default password is `abcdef`, but it can be changed by editing the script. The script is included in `Certificate_Scripts.zip`.

Configuring the trusted signers

The list of trusted signer certificates is configured in the property `trusted.signer.certificate.paths`. The list is space-separated. The paths may be relative to the server folder in the MobileFirst Project (for example: `conf/rootCA.crt`), or absolute paths.

Sample client project

You can download `Confidential_Client_Sample`, as a zip file. The sample project contains code for obtaining an access token by generating a JSON web signature, and submitting a request to the token endpoint. The sample project contains a KeyStore file, `keystore.p12` that was generated with the sample script `gen_cert.sh`. The KeyStore contains a client certificate that is signed with the sample signer certificate (`rootCA.crt`, located in the zip file). The scope attribute of the client certificate has the value `scope1 scope2 scope3`, and the sample code shows a request for a token with scope `scope1`, which is a subset of the scope that is defined in the certificate. To run the sample, perform the following steps:

1. Configure the authorization server to use the root certificate `rootCA.crt` as a trusted signer. Put the certificate file `rootCA.crt` inside your MobileFirst Platform project and set the value of the property `trusted.signer.certificate.paths` accordingly. For example, if you put the root certificate in the `conf` directory of your MobileFirst Platform project, the property value is `trusted.signer.certificate.paths=conf/rootCA.crt`.
2. Edit the constant `MFP_PROJECT_URL` in the source file `ConfidentialClientSample.java`, and replace the host, the protocol, and the MobileFirst Platform project name with the appropriate values. Run the `ConfidentialClientSample` Java application. The application requests an access token from the authorization server and prints it to the console.

Custom requests to resources using Objective-C

This sample illustrates how to get data from a protected resource by using a custom `NSURLRequest` and the MobileFirst `AuthorizationManager` API.

Inside the `didReceiveResponse` delegate, the `authorizationManager` determines whether this response is a MobileFirst protocol response. If so, the user gets the scope, obtains the authorization header for this scope, and requests the protected resource one more time.

```
-(IBAction)sendCustomRequestToResource:(id)sender {
    // The URL of the resource with filter
    NSString *nodeResourceString = @"http://localhost:3000/v1/apps/1234/test";

    // Create the first request to the resource - will fail due to authentication.
    NSURLRequest *request = [NSURLRequest requestWithURL:[NSURL URLWithString:nodeResourceString]];

    // Create url connection and fire request with a delegate
    NSURLConnection *conn = [[NSURLConnection alloc] initWithRequest:request delegate:self];
}

-(void) connection:(NSURLConnection *)connection didReceiveResponse:(NSURLResponse *)response{
    WLAuthorizationManager *authorizationManager = [WLAuthorizationManager sharedInstance];

    // Check that the response conforms to the MFP protocol
    if([authorizationManager isAuthorizationRequiredForResponse:response]){
        // Get required scope from response
        NSString *scope = [authorizationManager authorizationScopeForResponse:response];

        //Obtain authorization header for the scope
    }
}
```

```

[[WLAuthorizationManager sharedInstance] obtainAuthorizationHeaderForScope:scope
completionHandler:^(WLResponse *w1Response, NSError *w1Error) {
    if (!w1Error) {
        // Create the request.
        NSMutableURLRequest *mutRequest = [NSMutableURLRequest
requestWithURL:[NSURL URLWithString:@"http://localhost:3000/v1/apps/1234/test"]];

        // Add the Authorization header that was obtained
        [mutRequest addValue:authorizationManager.cachedAuthorizationHeader forHTTPHeaderField:@"authorization"];
        NSError *requestError; // Error from resource (if any) will be here

        // Create URL connection and fire request with a delegate
        NSURLConnection *conn = [[NSURLConnection alloc] initWithRequest:mutRequest delegate:self];

    } else {
        // Error obtaining Authorization header from MFP Server
        NSLog(@"%@",[w1Error localizedDescription]);
    }
}];
}
else{
//This is the applicative response from the resource
NSLog(@"Meta-data response from resource: %@",[response description]);
}
}
}

```

Custom requests to resources using Java

This sample demonstrates how to get data from a protected resource by using a custom `HttpRequest` object and the MobileFirst `AuthorizationManager` API.

After a response was first received, the `WLAuthorizationManager` class determines whether this response is a MobileFirst protocol response. If so, the user gets the scope, obtains the authorization header for this scope, and requests the protected resource one more time.

```

try {
    // Create an http client to send the request
    final DefaultHttpClient client = new DefaultHttpClient();

    // Create the request to send
    final HttpGet get = new HttpGet("http://localhost:3000/v1/apps/1234/test");

    // Send the request and get the response
    HttpResponse response = client.execute(get);

    // Check that the response conforms to the MFP protocol
    if (WLAuthorizationManager.getInstance().isAuthorizationRequired(response)){

        // Get required scope from response
        String scope = WLAuthorizationManager.getInstance().getAuthorizationScope(response);

        //Obtain authorization header for the scope
        WLAuthorizationManager.getInstance().obtainAuthorizationHeader(scope, new WLResponseListener() {

            // This method will be invoked if an authorization header was obtained successfully:
            @Override
            public void onSuccess(WLResponse w1Response) {

                // Add the obtained authorization header to the original request
                WLAuthorizationManager.getInstance().addCachedAuthorizationHeader(get);
                try {
                    // resend the request
                    HttpResponse response = client.execute(get);

                    // At this point a response from the resource was received, process it:
                    processResponse(response);
                }
            }
        });
    }
}

```

```

        } catch (Exception e) {
            Log.e("RESOURCE", "Exception during request");
        }
    }

    // This method will be invoked if an authorization header was not obtained:
    @Override
    public void onFailure(WLFailResponse response) {
        Log.e("RESOURCE", "Unable to obtain token");
    }
});

} else {
    // At this point a response from the resource was received, process it:
    processResponse(response);
}

} catch (Exception e) {
    Log.e("RESOURCE", "Exception during request");
}
}

```

Custom requests to resources using JavaScript

The sample illustrates how to get data from a protected resource by using a standard XMLHttpRequest object and the MobileFirst AuthorizationManager API.

In the code, the request is sent twice. The first request is returned with an authorization error, and then WLAuthorizationManager is called to obtain an authorization header for the required scope and the request is sent again.

```

function onSendCustomRequest() {

..onSendRequest('http://localhost:3000/v1/apps/1234/test')
    .always(
        function(response) {
            alert(response);
        }
    ));
}

function onSendRequest(url) {
    // Use JavaScript promises for asynchronous operations
    var dfd = $.Deferred();

    // Create the custom request
    var xhr = new XMLHttpRequest();
    xhr.open('GET', url, true);

    xhr.onreadystatechange = function(e) {
        if (this.readyState == 4) {
            if (this.status === 200) {
                dfd.resolve(this.responseText);
            } else {
                // 401 response the first time. Need to check whether this is an OAuth error, or not
                var authHeader = xhr.getResponseHeader('WWW-Authenticate');
                if (WLAuthorizationManager.isAuthorizationRequired(xhr.status, authHeader)) {
                    // Get the authorization scope from the authentication header
                    var scope = WLAuthorizationManager.getAuthorizationScope(authHeader);

                    // If program reaches here, the cached authorization header was missing or was not good
                    // obtain the header again and retry the request
                    WLAuthorizationManager.obtainAuthorizationHeader(scope).then (
                        function() {
                            // The auth header was received successfully
                            // The request should be constructed again, therefore this call is recursive
                            onSendRequest(url)
                                .then(
                                    function(response){

```

```

        dfd.resolve(response);
    },
    function(error) {
        dfd.reject(error);
    }
    );
},
function(error) {
    // Unable to retrieve the authorization header, fail the request;
the failure will be propagated up the chain
    dfd.reject(error);
}
);
} else {
    // Not an OAuth error, fail the request
    dfd.reject(xhr);
}
}
};

// Try to send a request with cached authorization header, which may be null
WLAuthorizationManager.addCachedAuthorizationHeader(xhr)
.always(
    // Send the request
    function() {xhr.send();}
);

return dfd.promise();
}

```

Custom requests to resources using C#

This sample demonstrates how to get data from a protected resource by using a `HttpRequest` object and the MobileFirst `WLAuthorizationManager` API for Windows 8 Universal app.

After a response was first received, the `WLAuthorizationManager` class determines whether this response is a MobileFirst protocol response. If so, the user gets the scope, obtains the authorization header for this scope, and requests the protected resource one more time.

```

class WebReqInfo {
    public HttpRequest request = null;
}

private async void externalOAuthFlow() {
    // Create a HttpRequest object to the desired URL.
    HttpRequest request = (HttpRequest)WebRequest.Create("http://localhost:3000/v1/apps/1234/test");
    request.BeginGetResponse(new AsyncCallback(responseCallback), new WebReqInfo() { request=request });
}

private void responseCallback(IAsyncResult asyncResult) {
    WebReqInfo wReqInfo = null;
    HttpResponseMessage response = null;
    try {
        /* Send the request to the server and wait for it to complete */
        wReqInfo = (WebReqInfo)asyncResult.AsyncState;

        // Get response
        response = wReqInfo.request.EndGetResponse(asyncResult) as HttpResponseMessage;

        WLResponse newResponse = new WLResponse(response);
        int sCode = newResponse.getStatus().GetHashCode();

        // Check that the response conforms to the MFP protocol
        if (WLAuthorizationManager.GetInstance().isAuthorizationRequired(response)) {

```

```

        // Get required scope from response
        String scope = WLAuthorizationManager.GetInstance().getAuthorizationScope(response);

        //Obtain authorization header for the scope
        WLAuthorizationManager.GetInstance().obtainAuthorizationHeader(scope, new MyResponseListener
    }
    else {
        // At this point a response from the resource was received, process it:
        processResponse(response)
    }
} catch (Exception e) {
    Debug.WriteLine("Exception during request");
}
}

public class MyResponseListener : WLResponseListener {
    HttpWebRequest request;
    public MyResponseListener(HttpWebRequest request) {
        this.request = request;
    }
    class WebReqInfo {
        public HttpWebRequest request = null;
    }

    // This method will be invoked if an authorization header was obtained successfully:
    public void onSuccess(WLResponse response) {

        // Add the obtained authorization header to the original request
        WLAuthorizationManager.GetInstance().addCachedAuthorizationHeader(request);
        try {
            // Resend the request
            request.BeginGetResponse(new AsyncCallback(resendRequestCallback), new WebReqInfo(){request=
        } catch (Exception e) {
            Debug.WriteLine("Unable to obtain token");
        }
    }

    // This method will be invoked if an authorization header was not obtained:
    public void onFailure(WLFailResponse response) {
        Debug.WriteLine("Unable to obtain Token");
    }

    private void resendRequestCallback(IAsyncResult asyncResult) {
        WebReqInfo wReqInfo = null;
        HttpWebResponse response = null;
        try {
            /* Send the request to the server and wait for it to complete */
            wReqInfo = (WebReqInfo)asyncResult.AsyncState;
            response = wReqInfo.request.EndGetResponse(asyncResult) as HttpWebResponse;
            processResponse(response);
        } catch (Exception e) {
            Debug.WriteLine("Exception during request");
        }
    }
}
}

```

For more information about WLAuthorizationManager, see “C# client-side API for Windows 8 Universal and Windows Phone 8 Universal apps” on page 11-7.

HTTP-based custom authentication

Custom authentication is a form of API authentication and is based on an HTTP protocol.

Overview

The custom identity provider authenticates a user by sending challenges to the client. However, custom identity providers do not communicate directly with clients. They send challenges and receive responses to the challenges by means of the IBM MobileFirst Platform Foundation authorization server. The process of authenticating a user typically involves a dialog with the client and consists of several requests and responses.

The HTTP protocol that is used in custom authentication is between IBM MobileFirst Platform Foundation authorization server and custom code. The custom code can be written in any language and can be protected or unprotected. If you choose to protect it, implement protection by using the default scope. For example, the Node.js sample on this page uses:

```
passport.authenticate('mobilefirst-strategy', {  
  session : false  
})
```

to protect the `startAuthorization` resource.

To implement custom identity provider, you must expose the following two HTTP endpoints:

- `/startAuthorization` endpoint. The headers that it receives are those which the client sends to the IBM MobileFirst Platform Foundation and which the server then adds to the request body. For example, the Node.js sample on this page gets the headers by using the following code:

```
function(req, res) {  
  var returnedJSON = startAuthorization(req.body.headers);  
  res.json(returnedJSON);  
}
```

- `/handleChallengeAnswer` endpoint. The headers that it receives are those which are received at the `/startAuthorization` endpoint, with the addition of an answer to a challenge and a state ID. This HTTP endpoint checks the challenge and returns success, challenge, or failure.

The custom identity provider may store some state related to the authentication dialog. An example use case is multi-step authentication, where the custom identity provider needs to store the result of the first authentication step when proceeding to the next step. In this case, the dialog between IBM MobileFirst Platform Foundation authorization server and the custom identity provider becomes stateful. The custom identity provider assigns a state ID, which is sent in the response. The IBM MobileFirst Platform Foundation authorization server passes the state ID in subsequent requests that belong to the client authentication process.

Headers are sent in the body because it is the header from the client request. Sending headers from the client in the body from authorization server to the custom identity provider will prevent conflicts in header names. In case you need to save state between calls to `startAuthorization` and `handleChallengeAnswer`, use the optional `stateId` property in the challenge answer. The custom identity provider and the protected resource may be implemented on the same server or on different servers.

The realm is always in the URL path, just before the endpoint API, as shown in the following examples:

- **`http://myhost:myport/custom_realm/startAuthorization`**

- http://myhost:myport/custom_realm/handleChallengeAnswer

Both HTTP endpoints can return three types of JSON response:

- **challenge**

```
{
  status: "challenge", challenge:
    { your custom JSON challenge },
  stateId : custom state id //state id is optional
}
```

- **success**

```
{
  status: "success", userIdentity:
    {userName: userName, displayName: displayName, attributes: { your optional custom JSON attr
}}
```

- **failure**

```
{ status: "failure" }
```

Samples

Let's say you want to protect an HTTP resource that is defined by the URL `/protected_resource`, with the scope "customAuthRealm_1 customAuthRealm_2". Perform the following steps:

1. Create an IBM MobileFirst Platform Foundation project.
2. In the project, define two realms and their login modules in the `authenticationConfig.xml` file.

Note: The `className` property that is shown both in the realm and login module for this example must be used **as is, in all cases**.

```
<realms>
  <realm name="customAuthRealm_1" loginModule="customAuthLoginModule_1">
    <className>com.worklight.core.auth.ext.CustomIdentityAuthenticator</className>
    <parameter name="providerUrl" value="http://localhost:3000"/>
  </realm>

  <realm name="customAuthRealm_2" loginModule="customAuthLoginModule_2">
    <className>com.worklight.core.auth.ext.CustomIdentityAuthenticator</className>
    <parameter name="providerUrl" value="http://localhost:3000"/>
  </realm>
</realms>
<loginModules>
  <loginModule name="customAuthLoginModule_1">
    <className>com.worklight.core.auth.ext.CustomIdentityLoginModule</className>
  </loginModule>

  <loginModule name="customAuthLoginModule_2">
    <className>com.worklight.core.auth.ext.CustomIdentityLoginModule</className>
  </loginModule>
</loginModules>
```

3. Configure the realm to be a user identity realm: To get the user identity in Java adapter, Node.js, or TAI resource, you must specify them in the `application-descriptor.xml` file of the application, in the user identity realms field.

Note: User identity realms are comma separated. The order of the realms dictates the selected user identity. If the list is empty, the ID token contains no identity information.

4. Now proceed to the Node.js or Java JAX-RS sample code in the next sections to see a full implementation of the solution.

Node.JS sample

The following sample code demonstrates how to implement the startAuthorization and handleChallengeAnswer endpoints in Node.js.

```
// Call the protected_nodejs_resource
app.get('/protected_nodejs_resource',
  passport.authenticate('mobilefirst-strategy', {session : false, scope: "customAuthRealm_1 customAuthRealm_2"}),
  res.status(200).send("Hello capella from node.js"));
});

//Implement custom authentication for customAuthRealm_1
app.post('/customAuthRealm_1/startAuthorization',
  passport.authenticate('mobilefirst-strategy', {
    session : false
  }),
  function(req, res) {
    var returnedJSON = startAuthorization(req.body.headers);
    res.json(returnedJSON);
  });

app.post('/customAuthRealm_1/handleChallengeAnswer',
  passport.authenticate('mobilefirst-strategy', {
    session : false
  }),
  function(req, res) {
    var returnedJSON = handleChallengeAnswer(req.body.headers, req.body.stateId, req.body.challengeAnswer);
    res.json(returnedJSON);
  });

var startAuthorization = function(headers) {
  return {
    status: "challenge",
    challenge: {
      message: "missing_credentials"
    },
    stateId : "my_custom_state_id"
  };
};

var handleChallengeAnswer = function(headers, stateId, challengeAnswer) {
  if (challengeAnswer && users[challengeAnswer.userName] && challengeAnswer.password === users[challengeAnswer.userName].password)
    return {
      status: "success",
      userIdentity: {
        userName: challengeAnswer.userName,
        displayName: users[challengeAnswer.userName].displayName,
        attributes : {"customAttr1":"customValue1", "customAttr2":"customValue2"}
      }
    };
  } else {
    return {
      status: "failure"
    }
  }
};
```

Java JAX-RS sample

The following JAX-RS sample is implemented as a Java REST adapter. The startAuthorization and handleChallengeAnswer endpoints have been implemented in Java.

```

// Call the protected_java_resource
@GET
@Path("/protected_java_resource")
@Produces("application/json")
@OAuthSecurity (scope="customAuthRealm_1 customAuthRealm_2")
public JSONObject helloCapella(){
    JSONObject hello = new JSONObject();
    hello.put("hello", "Hello Capella");
    return hello;
}

@POST
@Consumes ("application/json")
@Path("/customAuthRealm_1/startAuthorization")
@Produces(MediaType.APPLICATION_JSON)
public JSONObject startAuthorization(String payload) throws Exception{
    logger.info(payload);
    JSONObject returnJson = (JSONObject) JSON.parse(CHALLENGE_JSON);
    return returnJson;
}

@POST
@Consumes ("application/json")
@Path("/customAuthRealm_1/handleChallengeAnswer")
@Produces(MediaType.APPLICATION_JSON)
public JSONObject handleChallengeAnswer(String payload) throws Exception{
    JSONObject userStoreJson = (JSONObject) JSON.parse(USER_STORE_JSON);
    JSONObject failedResponseJson = (JSONObject) JSON.parse(FAILURE_JSON);

    if(payload == null || payload.isEmpty()) {
        return failedResponseJson;
    }
    JSONObject payloadJson = (JSONObject) JSON.parse(payload);
    JSONObject challengeAnswer = (JSONObject) payloadJson.get("challengeAnswer");

    if (challengeAnswer == null ) {
        return failedResponseJson;
    }

    String userName = (String) challengeAnswer.get("userName");
    String password = (String) challengeAnswer.get("password");

    if (userName == null || userName.isEmpty() || password == null || password.isEmpty()) {
        return failedResponseJson;
    }

    if (userStoreJson.containsKey(userName)) {
        JSONObject userInfoJson = (JSONObject) userStoreJson.get(userName);
        String userPassword = (String) userInfoJson.get("password");
        String userDisplayName = (String) userInfoJson.get("displayName");

        if (password.equals(userPassword)) {
            JSONObject returnJson = new JSONObject();
            JSONObject userIdentityJson = new JSONObject();
            userIdentityJson.put("userName", userName);
            userIdentityJson.put("displayName", userDisplayName);
            JSONObject customAttributes = new JSONObject();
            customAttributes.put("custom1Key", "custom1Value");
            customAttributes.put("custom2Key", "custom2Value");
            userIdentityJson.put("attributes", customAttributes);
            returnJson.put("status", "success");
            returnJson.put("userIdentity", userIdentityJson);
            return returnJson;
        }
    }
}

```

```

    }
    return failedResponseJson;
}

```

For more information

More techniques for implementing custom authentication

IBM MobileFirst Platform Foundation provides other custom authentication mechanisms:

- Adapter-based custom authentication. For more information, see Implementing adapter-based authenticators.
- Java-based custom authentication. For more information, see see Implementing Java-based custom authenticators.

Challenge handling in a gateway topology

Learn about special challenge-handling considerations when using a gateway between a client application and MobileFirst Server.

When access to MobileFirst Server is protected by a security gateway, a challenge is sent for any client attempt to access a server endpoint, except for pre-approved endpoints. This rule is true also for the client's initial request to register with the server. However, because the registration stage is executed entirely in the native environment, only a challenge handler that is implemented and registered in native code is called during the client's registration. A challenge handler that is implemented and registered in cross-platform JavaScript code is not called during client registration.

To allow a hybrid application to handle challenges during its registration with the server, follow these steps to register a native challenge handler from the application's native environment:

Note: The examples are for a MyHybridApp MobileFirst hybrid application with a native iPhone environment that uses the default startup process (see MobileFirst “Default startup process in iOS-based hybrid applications” on page 8-61).

1. Implement the registration challenge handler in the native-environment portion of your application.

For example, in your MyApp\iPhone\native\Classes directory, add MyChallengeHandler.h and MyChallengeHandler.m files that contain your challenge-handler class (MyChallengeHandler).

2. Register your challenge handler from the initialization method of the same native environment.

For example, in your didFinishLaunchingWithOptions method, in MyApp\iPhone\native\Classes\MyApp.m, add a call to the WL.Client registerChallengeHandler method.

Note: Call registerChallengeHandler before the call to initializeWebFrameworkWithDelegate.

```
@implementation MyAppDelegate
```

```
- (BOOL)application:(UIApplication *)application didFinishLaunchingWithOptions:
(NSDictionary *)launchOptions
{
```

```
    BOOL result = [super application:application didFinishLaunchingWithOptions:launchOptions];
```

```

// A root view controller must be created in application:didFinishLaunchingWithOptions:
self.window = [[UIWindow alloc] initWithFrame:[[UIScreen mainScreen] bounds]];
UIViewController* rootViewController = [[Compatibility50ViewController alloc] init];

[self.window setRootViewController:rootViewController];
[self.window makeKeyAndVisible];

[[WL sharedInstance] showSplashScreen];

// Register your challenge handler:
[[WLCClient sharedInstance] registerChallengeHandler:[[MyChallengeHandler alloc] init]];

[[WL sharedInstance] initializeWebFrameworkWithDelegate:self];

return result;
}

```

After completing these steps, challenges that are sent by the gateway during client registration with MobileFirst Server will be handled by the registered challenge handler (MyChallengeHandler in the example).

Classic security model

Topics that describe classic (pre-V7.0) security features in IBM MobileFirst Platform Foundation.

The following sections provide high-level information about the MobileFirst security model.

Goals and structure of MobileFirst security framework

The MobileFirst security framework serves two main goals. It controls access to the protected resources, and it propagates the user (or server) identity to the back-end systems through the adapter framework.

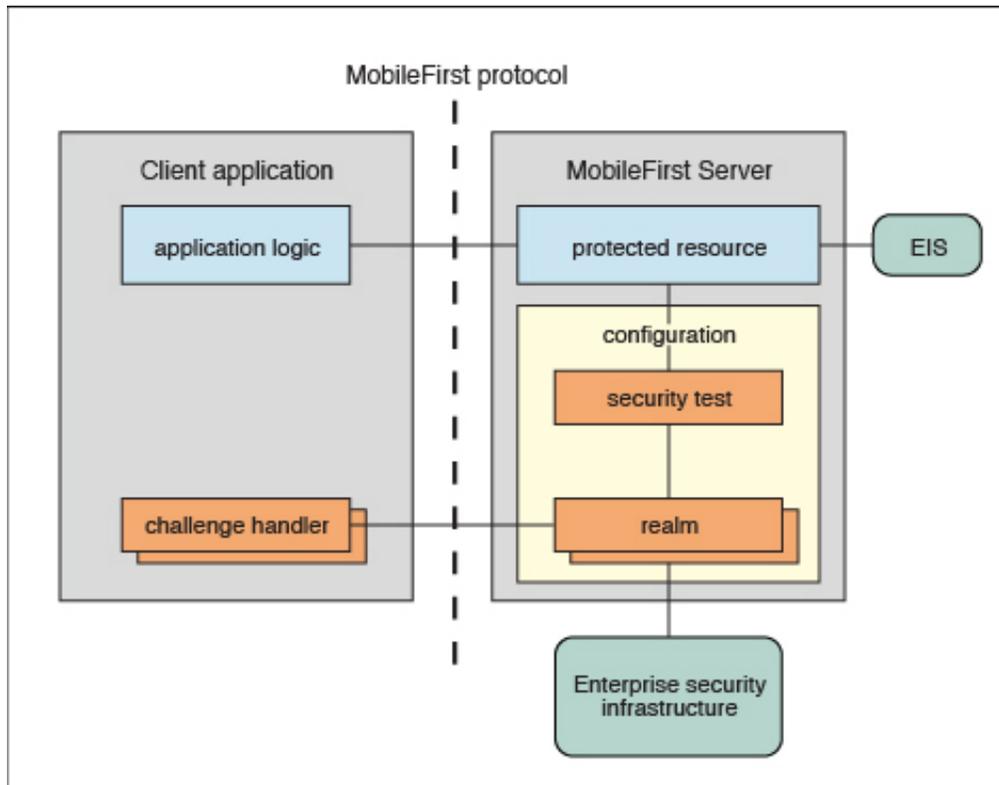

It is key to the success of the application that the MobileFirst security framework does not include its own user registry, credentials storage, or access control management. Instead, it delegates all those functions to the existing enterprise security infrastructure. This delegation allows MobileFirst Server to integrate smoothly as a presentation tier into the existing enterprise landscape. Integration with the existing security infrastructure is an important feature of the MobileFirst security framework, and supports custom extensions that allow integration with virtually any security mechanism.

Another feature of the IBM MobileFirst Platform Foundation security framework is support of multi-factor authentication. It means that any protected resource can require multiple checks to control access. A typical example of multi-factor authentication is the combination of device, application, and user authentication.

Each type of security check has its own configuration, and a configured check is called a *realm*. Multiple realms can be grouped in a named entity that is called a *security test*. Each protected resource refers to the security test. All the configuration entities are defined in a single configuration file so that the definitions can be reused across different protected resources.

An implementation of security checks usually includes a client part and a server part. The two parts interact with each other according to their private protocol. This protocol is usually a sequence of 1) challenges that are sent by the server and 2) responses that are returned by the client.

The IBM MobileFirst Platform Foundation security framework provides a *wire protocol*. This protocol allows the combination of challenges and responses of multiple security checks during a single request-and-response round trip. The protocol serves two important purposes: it allows the number of extra round trips between the client and server to be minimized, and it separates the application logic and the security checks implementation.

Protected resources and authentication context

A protected resource can be any of the following items:

- **Application**
Any request to the application requires successful authentication in all realms of the security test that is defined in the application descriptor.
- **Adapter procedure**
Procedure invocation requires successful authentication in all realms of the security test that is defined in the adapter descriptor. The user identity and credentials that are obtained during such authentication can be propagated to the enterprise information system represented by this adapter.
- **Event source**
Subscription to push notifications requires successful authentication in all realms of the security test that are defined in the event source definition (in adapter JavaScript).
- **Static resource**
Static resources are defined as URL patterns in the authentication configuration file. They allow protection of "static" web applications such as the MobileFirst Operations Console.

During the session, an application can access different resources. The results of the authentication in different realms are stored in the session authentication context. These results are then shared among all of the protected resources in the scope of the current session.

Realms and security tests

A realm represents a fully configured security check that must be completed before it can allow access to a protected resource. The semantics of the checks are not limited to the authentication, but can implement any logic that can serve as protection for the server-side application resources, for example:

- User authentication
- Device authentication and provisioning
- Application authenticity check
- Remote disable of the ability to connect to MobileFirst Server
- Direct update
- Anti-XSRF check (cross-site request forgery)

The realms are defined in the authentication configuration file on the MobileFirst project level. A realm consists of two parts: the *authenticator* and the *login module*. The authenticator obtains the credentials from the client, and the login module validates those credentials, and builds the user identity.

The realms are grouped into security tests, which are defined in the same authentication configuration files. The security test defines not only the group of realms, but also the order in which they must be checked. For example, it often makes sense not to ask for the user credentials until you make sure that the application itself is authentic.

Since some realms are relevant only to mobile or only to web environments, the configuration of a security test can be non-trivial. IBM MobileFirst Platform Foundation provides simplified security test configurations for mobile and web environments. It is also possible to create a custom security test from scratch.

MobileFirst protocol and client challenge handlers

Each security check defines its own protocol, which is a sequence of challenges that are sent by the server and responses that are sent by the client. On the server side, the component that implements this private protocol is the *authenticator*. On the client side, the corresponding component is called the *challenge handler*.

When the client request tries to access a protected resource, MobileFirst Server checks all the appropriate realms. Several realms can decide to send a challenge. Challenges from multiple realms are composed into a single response and sent back to the client.

MobileFirst client infrastructure extracts the individual challenges from the response, and routes them to the appropriate challenge handlers. When a challenge handler finishes the processing, it submits its response to the MobileFirst client infrastructure. As an example, this occurs when the challenge handler obtains the user name and password from a login user interface. When all the responses are received, the MobileFirst client infrastructure resends the original request with all the challenge responses.

MobileFirst Server extracts those responses from the request and passes them to the appropriate authenticators. If an authenticator is satisfied, it reports a success, and MobileFirst Server calls the login module. If the login module succeeds in validating all of the credentials, the realm is considered successfully authenticated. If all the realms of the security test are successfully authenticated, MobileFirst Server allows the request processing to proceed.

If a realm check fails, its authenticator sends another (or the same) challenge to the client, and the whole process repeats.

Combining multiple challenges and responses into a single response and request maximizes security efficiency by reducing the number of extra round trips. For example, the checks for device authentication, application authenticity, and direct update can be done in a single round trip.

The fact the MobileFirst client infrastructure automatically resends the original request with the challenge responses allows separation between the application logic and security aspects. Though any application request can result in a security challenge, the application logic must not include any special processing for that case. The challenge handlers are not related to the application context and can focus on the security-related logic.

Integration with container security

MobileFirst Server is technically a web application hosted by an application server (such as WebSphere Application Server). Thus, it is often desirable to reuse authentication capabilities of the application server for MobileFirst Server, and vice versa. Since this task can be non-trivial, it is important to understand the differences between IBM MobileFirst Platform Foundation and Web Container authentication models:

- The Java Platform, Enterprise Edition model allows only one authentication scheme for a web application. Multiple resource collections are defined by URL patterns, with authentication constraints defined by a white list of role names.
- The MobileFirst model, by contrast, allows protection of each resource by multiple authentication checks, and the resources are not necessarily identified by the URL pattern. In some cases, authentication can be triggered dynamically during the request processing.

As a result, the authentication integration between MobileFirst Server and the Java Platform, Enterprise Edition container is implemented as a custom IBM MobileFirst Platform Foundation realm. This realm can interact with the container and obtain and set its authenticated principal.

MobileFirst Server includes a set of login modules and authenticators for WebSphere Application Server full profile and WebSphere Application Server Liberty profile that implement this integration with LTPA tokens. The integration works as follows:

- If the caller *principal* (an entity that can be authenticated) of the servlet request is already set, the container authentication was successful, and the same principal is set as the MobileFirst user identity. This case assumes that the MobileFirst WAR file has appropriate login configuration and resource collection definitions. Including this information can be tricky because the `web.xml` file for MobileFirst project is generated automatically, and those definitions would be overwritten in every build.

- If the incoming request contains a Lightweight Third Party Authentication (LTPA) token, the login module validates it, and creates the MobileFirst user identity.
- If the request does not contain an LTPA token, the authenticator requests the user name and password from the client. The login module validates them and creates the MobileFirst user identity. In addition, it creates the LTPA token, and sends it back to the client as a cookie. In this case, the authentication capabilities of WebSphere Application Server are reused by MobileFirst realms in the form of Java utilities that implement validation and building of an LTPA token.

Integration with web gateways

Web gateways like DataPower and IBM Security Access Manager provide user authentication so that only authenticated requests can reach the internal applications. The internal applications can obtain the result of the authentication that is done by the gateway from a special header, for example, an LTPA token.

When MobileFirst Server is protected by a web gateway, it means that the client requests first encounter the gateway. The gateway sends back a login form and validates the credentials, and if the validation is successful, submits the request to the MobileFirst Server. This sequence implies the following requirements on the MobileFirst security elements:

- The client-side challenge handler must be able to present the gateway's login form, submit the credentials, and recognize the login failure and success.
- The authentication configuration must include the realm that can obtain and validate the token that is provided by the gateway.
- The security test configuration must take into account that the user authentication is always done first. For example, there is no point in using the device single sign-on (SSO) feature because the user credentials are requested by the gateway.

Further information on security, as it is implemented in IBM MobileFirst Platform Foundation, is provided in the following overview of security features. There are links to the relevant sections of the documentation, which pertain to them.

Integration with IBM Security Access Manager

IBM Security Access Manager can be integrated with IBM MobileFirst Platform Foundation to provide the following protections by using risk-based access decisions to protect MobileFirst applications and adapters as listed here:

- User authentication
- SSO
- Identity attributes
- Fine-grained authorization

SSO can be achieved to the mobile client and in adapter server connections. The context-based access policies can be defined to provide identity assurance and strong authentication with a one time password (OTP) for adapter-based transactions in IBM MobileFirst Platform Foundation and application authentication.

For more information about IBM Security Access Manager, see IBM Security Access Manager for IBM MobileFirst Platform Foundation.

MobileFirst application authenticity overview

An overview of application authenticity features and procedures within IBM MobileFirst Platform Foundation

IBM MobileFirst Platform Foundation framework provides a number of security mechanisms. One of them is a security test for application authenticity. Most IBM MobileFirst Platform Foundation security mechanisms are based on the same concept: obtaining identity through challenge handling. Just as the user authentication realm is used to obtain and validate the identity of a user, an application authenticity realm is used to obtain and validate the identity of an application. Therefore, this process is referred to as *application authenticity*.

Any entity can access HTTP services (APIs) that are available from MobileFirst Server by issuing an HTTP request. Therefore, it is suggested that you protect relevant services with a number of security tests. Application authenticity makes sure that any application that tries to connect to MobileFirst Server is authentic and was not tampered with or modified by some attacker.

Starting with IBM MobileFirst Platform Foundation V7.0, you can enable one of three levels of authentication for your app: none, basic, and extended. For more information about enabling extended app authentication, see “Configuring extended app authenticity checking” on page 12-56. Extended application-authenticity validation is not supported for iOS apps that are installed from the Apple app store. See the Extended application authenticity for iOS known limitation.

Note: This authenticity feature is not available if you use the internal MobileFirst Development Server that is embedded in MobileFirst Studio. For more information, see “Installing MobileFirst Studio” on page 6-2.

Authenticity process

Application authenticity checks use the same transport protocol as other authentication framework realms:

1. The application makes an initial request to MobileFirst Server.
2. MobileFirst Server goes through the authentication configuration and finds that this application must be protected by an application authenticity realm.
3. MobileFirst Server generates a challenge token and returns it to application.
4. The application receives the challenge token.
5. The application processes the challenge token and generates a challenge response.
6. The application submits the challenge response to MobileFirst Server.
7. If the challenge response is valid, MobileFirst Server serves the application with the required data.
8. If the challenge response is invalid, MobileFirst Server refuses to serve the application.

Authenticity considerations during migration to MobileFirst Server V7.0

In versions earlier than MobileFirst Platform Foundation V7.0, there was an option to control application authenticity from the MobileFirst Operations Console. This option is no longer available starting from V7.0. Existing applications configured with an authenticity realm and a security test in `authenticationConfig.xml` and a security test and security attributes in the `application-descriptor.xml` file are

checked for authenticity at runtime when migrated to MobileFirst Server V7.0, ignoring any previous authenticity control mode that was specified in an older version of MobileFirst Operations Console.

Enabling an application authenticity check (example)

Currently, basic application authenticity is supported only in iOS, Android, Windows Phone Silverlight 8, and Windows 8 Universal environments.

The following example shows the steps for enabling basic application authenticity on iOS, Android, Windows Phone Silverlight 8, and Windows 8 Universal:

1. Modify the `authenticationConfig.xml` file to add relevant authenticity realms to your security tests:
 - If you use `<mobileSecurityTest>`, you must add the `<testAppAuthenticity/>` child element to this file.
 - If you use `<customSecurityTest>`, you must add `<test realm="wl_authenticityRealm"/>` child element to the file.

After you have updated your `authenticationConfig.xml` file, rebuild, and redeploy the `.war` file.

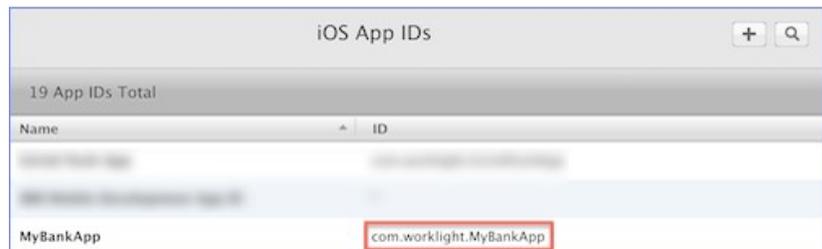

2. Modify the `application-descriptor.xml` file of your application.

Remember: In the `application-descriptor.xml` file, you must also define a security test. For more information, see “Security tests” on page 8-569.

The procedure is different for iOS, Android, Windows Phone Silverlight 8, and Windows 8 Universal environments.

For iOS

- a. Specify the **bundleId** attribute of your application exactly as you defined it in the Apple Developer portal:

For example:

```
<iphone bundleId="com.worklight.MyBankApp" version="1.0">
  <worklightSettings include="false"/>
  <security>
    <encryptWebResources enabled="false"/>
    <testWebResourcesChecksum enabled="false" ignoreFileExtensions="png, jpg, jpeg, gif, mp4, mp3"/>
  </security>
</iphone>
```

- b. Add the **applicationId** attribute to the iPhone or iPad element in the `application-descriptor.xml` file. The **applicationId** value must match the value of the **application id** property, which you can find in the `worklight.plist` file. For example:

```
<iphone bundleId="com.worklight.MyBankApp" applicationId="MyBankApp" version="1.0">
```

Note: If you decide to change the value of the application ID, ensure that you change it both in the `application-descriptor.xml` file and in the `worklight.plist` file.

- c. In addition, for a native iOS app, in your XCode project, under **Build Settings > Linking > Other Linker Flags**, add the `-ObjC` flag.

For Android

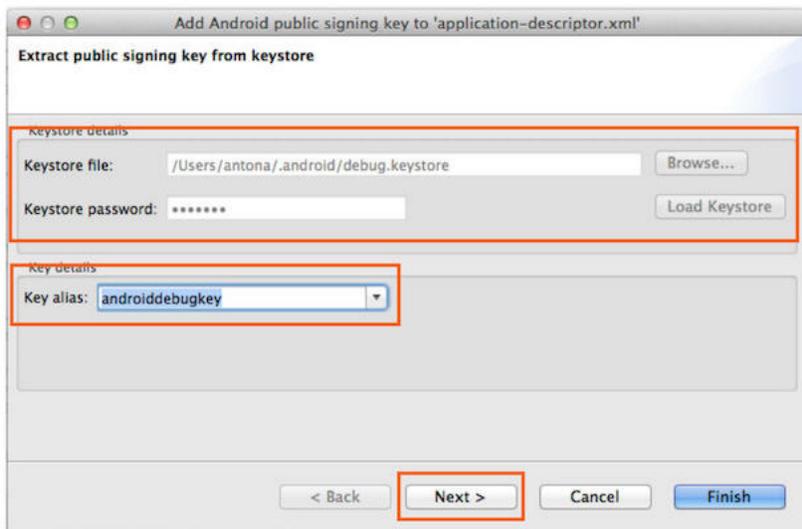

- a. Extract the public signing key of the certificate that is used to sign the application bundle (.apk file).

MobileFirst Studio provides tools to simplify this process.

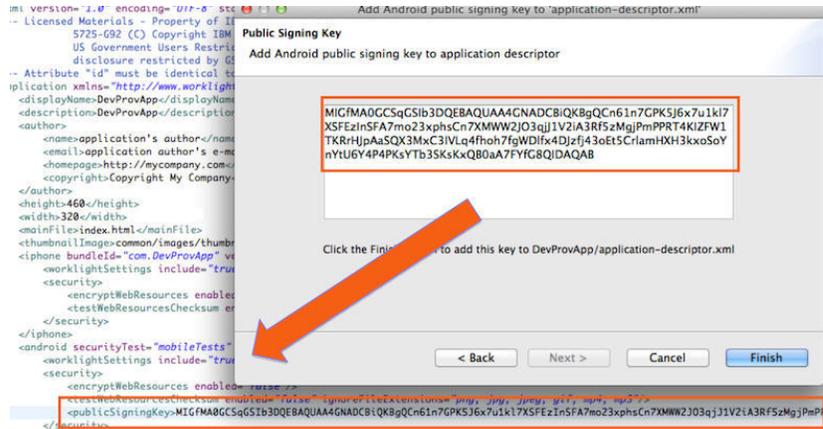

- If you are building your application for distribution (production), you must extract the public key from the certificate that you are using to sign your production-ready application.
- If you are building your application in a development environment, you can use the public key from a default development certificate that is supplied by Android. You can find the development certificate in a keystore under `{user-home}/.android/debug.keystore`.

You can either extract the public key manually or use a wizard that is provided by MobileFirst Studio. If you use the wizard, proceed as follows:

- 1) Right-click your Android environment and select **Extract public signing key**.
- 2) Specify the location and password of the keystore file and click **Load Keystore**. The default password for `debug.keystore` is **android**.
- 3) Select key alias and click **Next**.

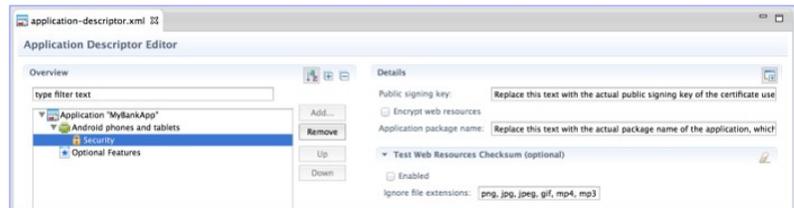

The public key is displayed on a window:

When you click **Finish**, the public key is automatically pasted into the relevant section of application-descriptor.xml.

- b. Add the application package name to the application-descriptor.xml file in either of the following ways:
 - In the Application Descriptor editor (accessible from the design view), in the **Application package name** field, add the value of the **package** attribute of the <manifest> element in the AndroidManifest.xml file.

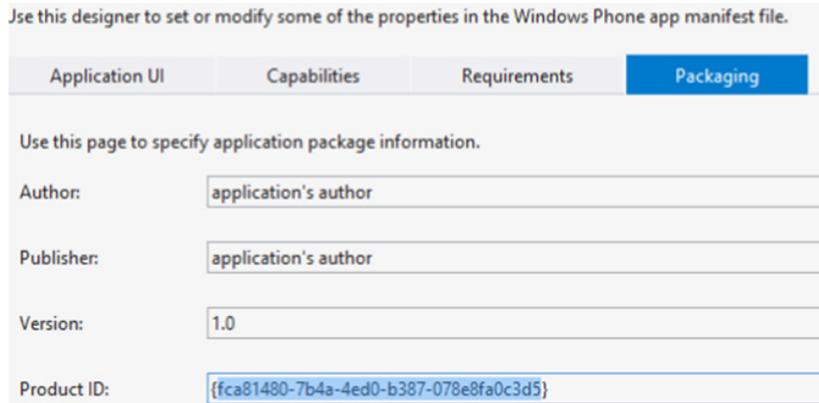

- Use your preferred text editor to edit the application-descriptor.xml file directly. For example:

```
<android securityTest="customTests" version="1.0">
  <worklightSettings include="false"/>
  <security>
    <encryptWebResources enabled="false"/>
    <testWebResourcesChecksum enabled="false" ignoreFileExtensions="png, jpg, jpeg, gif, mp4, mp3"/>
    <publicSigningKey>my-very-long-public-key</publicSigningKey>
    <packageName>com.myPackageName</packageName>
  </security>
</android>
```

Note: If you decide to change the application package name, ensure that you change it both in the application-descriptor.xml file and in the AndroidManifest.xml file.

For Windows Phone Silverlight 8

- a. Add the **productId** element to the **security** element that is defined in the application-descriptor.xml file. The **productId** value is mentioned in Properties/WMAAppManifest.xml:

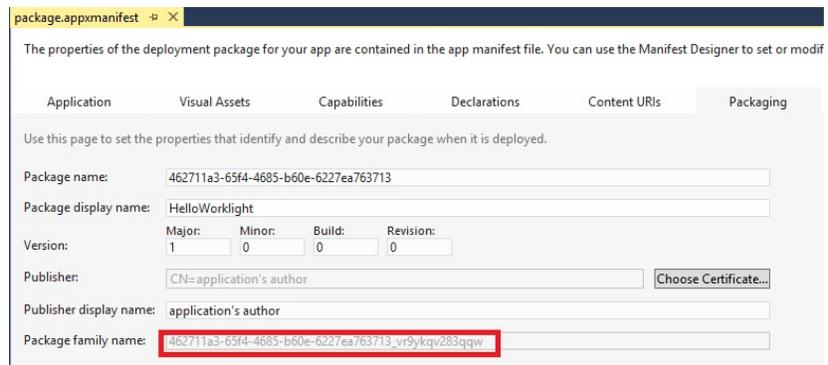

- b. Add the **applicationId** element to the **security** element that is defined in the application-descriptor.xml file. The **applicationId** value must match the value of the **wlAppId** property, which you can find in the `wlclient.properties` file. For example:

```
<windowsPhone8 version="1.0">
  <uuid>89836575-5405-4fa7-94b2-45f300201a1c</uuid>
  <security>
    <productId>fca81480-7b4a-4ed0-b387-078e8fa0c3d5</productId>
    <applicationId>HelloWorklight</applicationId>
  </security>
</windowsPhone8>
```

For more information about the **security** element, see “The application descriptor” on page 8-50.

For Windows 8 Universal

- a. Add the **packageName** element to the **security** element that is defined in the application-descriptor.xml file. The **packageName** value is mentioned in package.appxmanifest file:

- b. Add the **applicationId** element to the **security** element that is defined in the application-descriptor.xml file. The **applicationId** value must match the value of the **wlAppId** property, which you can find in the `wlclient.properties` file. For example:

```
<windows8 version="1.0">
  <uuid>89836575-5405-4fa7-94b2-45f300201a1c</uuid>
  <security>
    <packageName>462711a3-65f4-4685-b60e-6227ea763713_vr9ykqv283qqw</packageName>
    <applicationId>HelloWorklight</applicationId>
  </security>
</windows8>
```

For more information about the **security** element, see “The application descriptor” on page 8-50.

3. After you have updated the required elements, rebuild and redeploy your application to MobileFirst Server.

Security tests

A security test defines a security configuration for a protected resource. Predefined tests are supplied for standard web and mobile security requirements. You can write your own custom security tests and define the sequence in which they are implemented. In web and mobile security tests, you cannot define the sequence in which realms are processed. If you want to define the sequence, you must write your own custom security test and use the **step** property.

A security test specifies one or more authentication realms and an authentication realm can be used by any number of security tests. A protectable resource can be protected by any number of realms.

A protected resource is protected by a security test. When a client attempts to access a protected resource, IBM MobileFirst Platform Foundation checks whether the client is already authenticated according to all realms of the security test. If the client is not yet authenticated, IBM MobileFirst Platform Foundation triggers the process of authentication for all unauthenticated realms.

Before you define security tests, define the authentication realms that the tests use.

Define a security test for each environment in the `application-descriptor.xml` file, by using the property `securityTest="test_name"`. If no security test is defined for a specific environment, only a minimal set of default platform tests is run.

Note: To replace an existing security test, you should add the new security test and deploy it, after this new security test is successfully deployed you can delete the old security test that you intended to replace.

You can define three types of security test:

webSecurityTest

A test that is predefined to contain realms that are related to web security.

Use a `webSecurityTest` to protect web applications.

A `webSecurityTest` must contain one `testUser` element with a realm definition for user authentication. The identity that is obtained from this realm is considered to be a user identity.

By default, a `webSecurityTest` includes protection against cross-site request forgery (XSRF) attacks.

mobileSecurityTest

A test that is predefined to contain realms that are related to mobile security.

Use a `mobileSecurityTest` to protect mobile applications.

A `mobileSecurityTest` must contain one `testUser` element with a realm definition for user authentication. The identity that is obtained from this realm is considered to be a user identity.

A `mobileSecurityTest` must contain one `testDevice` element with a realm definition for device authentication. The identity that is obtained from this realm is considered to be a device identity.

By default, a `mobileSecurityTest` includes protection against XSRF attacks, automatic checking for Direct Updates every session, and the ability to remotely disable, from the MobileFirst Operations Console, the ability for the app to connect to MobileFirst Server.

customSecurityTest

A custom security test. No predefined realms are added. Only tests that are included are tested.

Use a `customSecurityTest` to define your own security requirements and the sequence and grouping in which they occur.

You can define any number of tests within a `customSecurityTest`. Each test specifies one realm. To define a realm as a user identity realm, add the property `isInternalUserId="true"` to the test. The `isInternalUserID` attribute means that this realm is used for user identification for reporting and push subscriptions. There must be exactly one such realm for every security configuration that is applied to a mobile or web resource.

For a device auto provisioning realm, the `isInternalDeviceID` attribute means that this realm is used for device identification for reporting, push subscriptions, and device SSO features. There must be exactly one such realm for every security configuration that is applied to a mobile resource.

Important: When you use device auto provisioning in `customSecurityTests`, an authenticity realm must also be present within the tests, otherwise provisioning cannot succeed.

To specify the order in which a client must authenticate in the different realms, add the property `step="n"` to each test, where *n* indicates the sequence. If a sequence is not specified, then all tests are done in a single step.

Note: Application authenticity and Device provisioning are not supported in Java Platform, Micro Edition (Java ME).

Sample security tests

This section describes what a `webSecurityTest` and a `mobileSecurityTest` contain.

The `webSecurityTest` contains:

- The following realms, enabled by default: `wl_anonymousUserRealm` and `wl_antiXSRFRealm`.
- The user realm that you must specify.

The `mobileSecurityTest` contains:

- The following realms, enabled by default: `wl_anonymousUserRealm`, `wl_antiXSRFRealm`, `wl_directUpdateRealm`, `wl_remotedisableRealm` and `wl_deviceNoProvisioningRealm`.
- The user and device realms that you must specify.

A `customSecurityTest` has no realms that are enabled by default. You must define all realms that you want your `customSecurityTest` to contain.

For a `webSecurityTest`:

```
<webSecurityTest name="webTest">
  <testUser realm="wl_anonymousUserRealm"/>
</webSecurityTest>
```

The equivalent as a customSecurityTest:

```
<customSecurityTest name="webTest">
  <test realm="wl_antiXSRFRealm" />
  <test realm="wl_anonymousUserRealm" isInternalUserId="true" />
</customSecurityTest>
```

For a mobileSecurityTest:

```
<mobileSecurityTest name="mobileTest">
  <testUser realm="wl_anonymousUserRealm"/>
  <testDeviceId provisioningType="none" />
</mobileSecurityTest>
```

The equivalent as a customSecurityTest:

```
<customSecurityTest name="mobileTest">
  <test realm="wl_antiXSRFRealm" />
  <test realm="wl_remoteDisableRealm" />
  <test realm="wl_anonymousUserRealm" isInternalUserID="true" />
  <test realm="wl_deviceNoProvisioningRealm" isInternalUserID="true" />
</customSecurityTest>
```

Usually, you add your own realm to your configuration to authenticate users. The following example shows a configuration where the realm named MyUserAuthRealm is the realm that the developer added.

Example with your own realm name as a realm definition for testUser:

For a webSecurityTest:

```
<webSecurityTest name="webTest">
  <testUser realm="MyUserAuthRealm"/>
</webSecurityTest>
```

The equivalent as a customSecurityTest

```
<customSecurityTest name="webTest">
  <test realm="wl_antiXSRFRealm" />
  <test realm="MyUserAuthRealm" isInternalUserId="true" />
</customSecurityTest>
```

For a mobileSecurityTest:

```
<mobileSecurityTest name="mobileTest">
  <testUser realm="MyUserAuthRealm"/>
  <testDeviceId provisioningType="none" />
</mobileSecurityTest>
```

The equivalent as a customSecurityTest:

```
<customSecurityTest name="mobileTest">
  <test realm="wl_antiXSRFRealm" />
  <test realm="wl_remoteDisableRealm" />
  <test realm="MyUserAuthRealm" isInternalUserID="true" />
  <test realm="wl_deviceNoProvisioningRealm" isInternalUserID="true" />
</customSecurityTest>
```

Security configurations of protected resources:

There is a default security configuration for every type of resource that can be protected by the MobileFirst authentication framework.

Protected resource types

The following types of resource can be protected by using the MobileFirst authentication framework:

Application environment

With IBM MobileFirst Platform Foundation, you can define a separate security test for each application environment. This capability is very useful, as different environments support different sets of security features. For example, BlackBerry and WindowsPhone environments do not support application authenticity test. In case no security test is explicitly defined, each application environment is protected by a relevant default type of security test. Mobile hybrid and native environments are protected by a default `mobileSecurityTest` and web environments are protected by a default `webSecurityTest`. If you want to protect application environments with a security test other than the default one, you must explicitly specify it in the `application-descriptor.xml` file. For example:

```
<android version="1.0" securityTest="mobileTests">
  <worklightSettings include="false"/>
  <security>
    <encryptWebResources enabled="false"/>
    <testWebResourcesChecksum enabled="false" ignoreFileExtensions="png, jpg, jpeg, gif, mp4, mp3"/>
    <publicSigningKey/>
    <packageName/>
  </security>
</android>
<mobileWebApp cacheManifest="no-use" securityTest="webTests"/>
```

Adapter procedure

With IBM MobileFirst Platform Foundation, you can protect any adapter procedure by using a security test. Doing so will ensure that the information that is provided by adapters is exposed to the client side only after successful completion of all the relevant authentication steps. Because an adapter procedure is a service that is provided by MobileFirst Server, it is protected with a default `webSecurityTest` security test. To protect adapter procedures with a security test that is different from the default one, you need to set the **securityTest** attribute of the relevant `<procedure>` element in the `adapter-descriptor XML` file. See “Structure of the adapter XML file” on page 8-247. The following example protects the `myAccounts` procedure with an `adapterProcedureSecurityTest` security test:

```
<procedure name="myAccounts" securityTest="adapterProcedureSecurityTest"/>
```

Note: This protection method of the classic security model is applicable to JavaScript adapter procedures. Java JAX-RS adapter procedures are protected by using the `@OAuthSecurity` annotation, which is part of the Java server-side `com.worklight.core.auth` package. See the annotation's API reference, as well as “Security configuration of a JAX-RS resource” on page 8-239.

EventSource

Using an event source, you can subscribe to server-generated events, for example, push notifications or SMS notifications. Subscription is based on user identity and device identity, because notifications are usually sent to either a specific device or to a specific user. So, it is important to specify security test in your event source declaration. The user and device identities that are retrieved as specified in a security test are used to subscribe to events. To define a security test for event source, add a `securityTest` property to event source declaration code.

```

WL.Server.createEventSource({
    name: 'PushEventSource',
    onDeviceSubscribe: 'deviceSubscribeFunc',
    onDeviceUnsubscribe: 'deviceUnsubscribeFunc',
    securityTest: 'eventSourceSecurityTest'
});

```

Static resource

A static resource is a URL that can be accessed on MobileFirst Server. In most cases, the URL is of the MobileFirst Console. Static resources protection can be defined in the <staticResources> section of the authenticationConfig.xml file. There is no default security test for static resources, so MobileFirst Console is not protected, by default. The developer must explicitly specify the static resource to protect in the authenticationConfig.xml file and set the desired securityTest.

```

<staticResources>
  <resource id="worklightConsole" securityTest="worklightConsole">
    <urlPatterns>/console*</urlPatterns>
  </resource>
</staticResources>

```

Authentication realms

Resources are protected by *authentication realms*. Authentication processes can be interactive or non-interactive.

An authentication realm defines the process to be used to authenticate users, and consists of the following steps:

1. Specification of how to collect user credentials, for example, by using a form, using basic HTTP authentication or using SSO.
2. Specification of how to verify the user credentials, for example, checking that the password matches the user name, or by using an LDAP server or some other authentication server.
3. Specification of how to build the user identity, that is, how to build objects that contain all the necessary user properties.

The same realm can be used in different security tests. In this case, clients must undergo the authentication process that is defined for the realm only once.

Authentication processes can be interactive or non-interactive, as demonstrated in the following authentication process examples:

- An example of interactive authentication is a login form that is displayed when a user attempts to access a protected resource. The authentication process includes verifying the user credentials.
- An example of non-interactive authentication is a user cookie that the authentication process looks for when a user attempts to access a protected resource. If there is a cookie, this cookie is used to authenticate the user. If there is no cookie, a cookie is created, and this cookie is used to authenticate the user in the future.

User certificate authentication realm:

The user certificate authentication realm authenticates the user with X.509 certificates that are generated with the MobileFirst Server together with your public key infrastructure (PKI).

For more information about this realm and how to set it up, see “User certificate authentication overview” on page 8-577.

Anti-cross site request forgery (anti-XSRF) realm:

The `wl_antiXSRFRealm` protects against cross-site request forgery attacks.

In a cross-site request forgery attack, unauthorized commands are transmitted from a web browser that is trusted by the targeted web site. To protect against this, IBM MobileFirst Platform Foundation provides an anti-cross site request forgery realm, `wl_antiXSRFRealm`. This realm is enabled by default in the `webSecurityTest` and the `mobileSecurityTest`.

The anti-XSRF realm is relevant only for web environments, when the application runs in a browser. It is not relevant for installed mobile applications. Also, the anti-XSRF realm does not protect against session hijacking.

The anti-XSRF technique is based on the same-origin constraint policy, which requires that after an initial request, all subsequent requests come from the same source as the initial one. A script that is loaded from a different origin is assumed to be an attacker script.

When a new session is initiated, the first request to MobileFirst Server receives an HTTP 401 ("Unauthorized") response that contains the `WL-Instance_Id` token. The MobileFirst framework extracts this token and uses it as a header on all subsequent requests. If this header is not present in these subsequent requests, HTTP 401 is returned again, and access to resources is denied.

The server-side realm implementation ensures that each incoming request has the correct value in the `WL-Instance_Id` header. If the header is missing or has an incorrect value, the realm again returns a 401 response with the challenge that contains the correct value for `WL-Instance_Id`. However, due to the same-origin constraint policy, the targeted web site does not allow the attacking web site to read the challenge.

The server returns a challenge and does not destroy the session in the case of a missing or incorrect token because this situation can be a result of a legitimate use case. For example, if a session is timed-out on the server side, the client might send a request with an expired token. Or, a session race condition might occur in which the client sends two or more requests simultaneously when the session is not established or is timed out. A legitimate client should be able to recover from these situations automatically, so the server sends the same challenge in the case of failure.

For more information, see [Cross-site request forgery](#).

Note: If code that uses the anti-XSRF realm attempts to access a resource that is protected by OAuth authentication, and the client has a valid token, the MobileFirst Server is not called. As a result, the server does not check whether the request contains the header. The MobileFirst Server is called when the token expires or when the anti-XSRF realm inside the token expires. When the realm expires, the anti-XSRF authenticator is invoked and the server checks whether the request contains the header. For more information about OAuth authentication, see [MobileFirst OAuth-based security model](#).

Certificate pinning

Use certificate pinning to help prevent man-in-the-middle attacks.

When communicating over public networks it is essential to send and receive information securely. The protocol widely used to secure these communications is SSL/TLS. (SSL/TLS refers to Secure Sockets Layer or to its successor, TLS, or Transport Layer Security.) SSL/TLS uses digital certificates to provide authentication and encryption. To trust that a certificate is genuine and valid, it is digitally signed by a root certificate belonging to a trusted certificate authority (CA). Operating systems and browsers maintain lists of trusted CA root certificates so that they can easily verify certificates that the CAs have issued and signed.

Protocols that rely on certificate chain verification, such as SSL/TLS, are vulnerable to a number of dangerous attacks, including man-in-the-middle attacks, which occur when an unauthorized party is able to view and modify all traffic passing between the mobile device and the backend systems.

IBM MobileFirst Platform Foundation provides an API to enable certificate pinning. It is supported in native iOS, native Android, and hybrid iOS or hybrid Android MobileFirst applications.

Certificate pinning process

Certificate pinning is the process of associating a host with its expected public key. Because you own both the server-side code and the client-side code, you can configure your client code to accept only a specific certificate for your domain name, instead of any certificate that corresponds to a trusted CA root certificate recognized by the operating system or browser.

A copy of the certificate is placed in your client application. During the SSL handshake (first request to the server), the IBM MobileFirst Platform Foundation client SDK verifies that the public key of the server certificate matches the public key of the certificate that is stored in the app.

Important:

- Some mobile operating systems might cache the certificate validation check result. Therefore, your code should call the certificate pinning API before making a secured request. Otherwise, any subsequent request might skip the certificate validation and pinning check.
- Make sure to use only MobileFirst APIs for all communications with the related host, even after the certificate pinning. Using third-party APIs to interact with the same host might lead to unexpected behavior, such as caching of a non-verified certificate by the mobile operating system.
- Calling this method a second time overrides the previous pinning operation.

If pinning is successful, the public key inside the provided certificate is used to verify the integrity of the MobileFirst Server certificate during the secured request SSL/TLS handshake. If pinning fails, all SSL/TLS requests to the server are rejected by the client application.

Certificate setup

You must use a certificate purchased from a certificate authority. Self-signed certificates are not supported. For compatibility with the supported environments, make sure to use a certificate that is encoded in DER (Distinguished Encoding Rules, as defined in the International Telecommunications Union X.690 standard) format.

You must place the certificate in both the MobileFirst Server and in your application. Place the certificate as follows:

1. In the MobileFirst Server: (WebSphere Application Server, WebSphere Application Server Liberty, or Apache Tomcat). Consult the documentation for your specific application server for information about how to configure SSL/TLS and certificates.
2. In your application:
 - Native iOS: add the certificate to the application bundle
 - Native Android: place the certificate in the assets folder
 - Hybrid: place the certificate in the project-name\apps\app-name\certificates folder

Certificate pinning API

Certificate pinning consists of a single API method, that has a parameter *certificateFilename*, where *certificateFilename* is the name of the certificate file.

Native Android

Syntax:

```
public void pinTrustedCertificatePublicKey(String certificateFilename) throws IllegalArgumentException
```

Example:

```
WLClient.getInstance().pinTrustedCertificatePublicKey("myCertificate.cer");
```

The certificate pinning method will throw an exception in two cases:

- The file does not exist
- The file is in the wrong format

Native iOS

Syntax:

```
pinTrustedCertificatePublicKeyFromFile:(NSString*) certificateFilename;
```

Example:

```
[[WLClient sharedInstance]pinTrustedCertificatePublicKeyFromFile:@"myCertificate.cer"];
```

The certificate pinning method will raise an exception in two cases:

- The file does not exist
- The file is in the wrong format

Hybrid

Syntax:

```
WLClient.pinTrustedCertificatePublicKey(certificateFilename.then(onSuccess,onFailure))
```

The certificate pinning method returns a promise:

- The certificate pinning method will call the `onSuccess` method in case of successful pinning.
- The certificate pinning method will trigger the `onFailure` callback in two cases:
 - The file does not exist
 - The file is in the wrong format

Example:

```
WLClient.pinTrustedCertificatePublicKey('myCertificate.cer').then(onSuccess,onFailure)
```

Later, if a secured request is made to a server whose certificate is not pinned, the `onFailure` callback of the specific request (for example, `WL.Client.connect` or `WLResourceRequest`) is called.

Note: Certificate pinning is not supported for Cordova applications.

For more details on the certificate pinning API, see the following reference sections:

- Native Android: Java client-side API `WLClient` class.
- Native iOS: Objective-C client-side API `WLClient` class.
- Hybrid: JavaScript client-side API `WL.Client` class.

User certificate authentication

Enterprises can now use X.509 client-side certificates to authenticate users, by applying a new user authentication realm to their existing security tests. This new realm is called `UserCertificateAuthRealm`. This feature allows enterprises to enroll users to their enterprise certificate authority (CA) directly from their mobile devices. The traffic between the MobileFirst application on the device and the MobileFirst Server in the enterprise can be secured over HTTPS with client-side certificates that are issued to the users as part of the initial enrollment process.

This feature is available on iOS and Android (hybrid and native) environments.

This feature is not supported with the FIPS 140-2 feature.

User certificate authentication overview

The User Certificate Authentication feature is a newly introduced user authentication realm in IBM Worklight V6.1 that establishes user identity with an X.509 client certificate.

With the User Certificate Authentication feature, IBM MobileFirst Platform Foundation provides a mechanism for enterprises to easily integrate their mobile infrastructure and existing public key infrastructure (PKI). With this new added function, enterprises can now authenticate users that are trying to access sensitive backend systems through mobile devices with X.509 client side certificates. Mobile clients can now present an X.509 certificate to establish a secure client identity over the transport layer security (TLS) protocol.

This feature allows enterprises to use their existing PKI to obtain full control of the user authentication and user enrollment process. An embedded PKI implementation is provided, which allows enterprises without their own PKI to quickly set it up. With the embedded PKI option, IBM MobileFirst Platform Foundation internally signs certificates and manages the validation and enrollment process.

More specifically, mobile clients are now able to present an X.509 client certificate to establish a secure connection over the transport layer security (TLS) protocol. Users are enrolled to the enterprise certificate authority (CA) directly from their device. The client certificate is then used to authenticate and establish a user identity on subsequent requests.

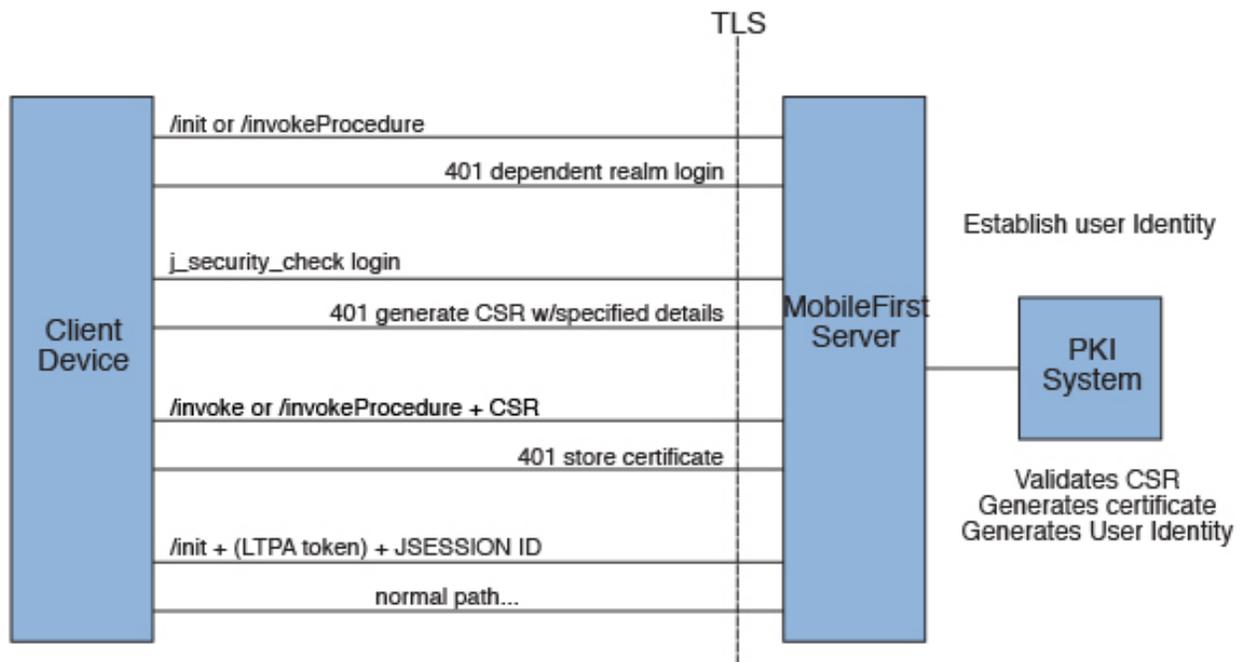

This feature is available on iOS and Android (hybrid and native) environments.

How it works

The MobileFirst Server can be configured to protect an application or adapter with the user certificate authentication user realm (UserCertificateAuthRealm). This realm requires the use of a PKI for managing X.509 client certificates. An existing PKI can be used by implementing the PKI bridge interface that is provided for you. The PKI bridge interface serves as the bridge between IBM MobileFirst Platform Foundation and your PKI. Another option is to use the embedded PKI that is provided with this feature for testing and development purposes.

The first time a user accesses a protected application or adapter procedure from a device, the server initiates the applicable challenges and starts the user enrollment process. The user enrollment process consists of having the user enroll into the configured PKI and then provisioning the device with an X.509 certificate for future use. Users enroll into existing PKIs through the help of a dependent user authentication realm. After the user is authenticated through the dependent realm, IBM MobileFirst Platform Foundation, through the PKI, generates the client certificate and provisions the device with the certificate that is issued to the user. The server enrolls the user after successfully establishing the user identity by using one of the pre-existing login modules. This process results in an X.509 certificate that is issued to the user and installed securely on the device.

The following figure shows the user enrollment flow:

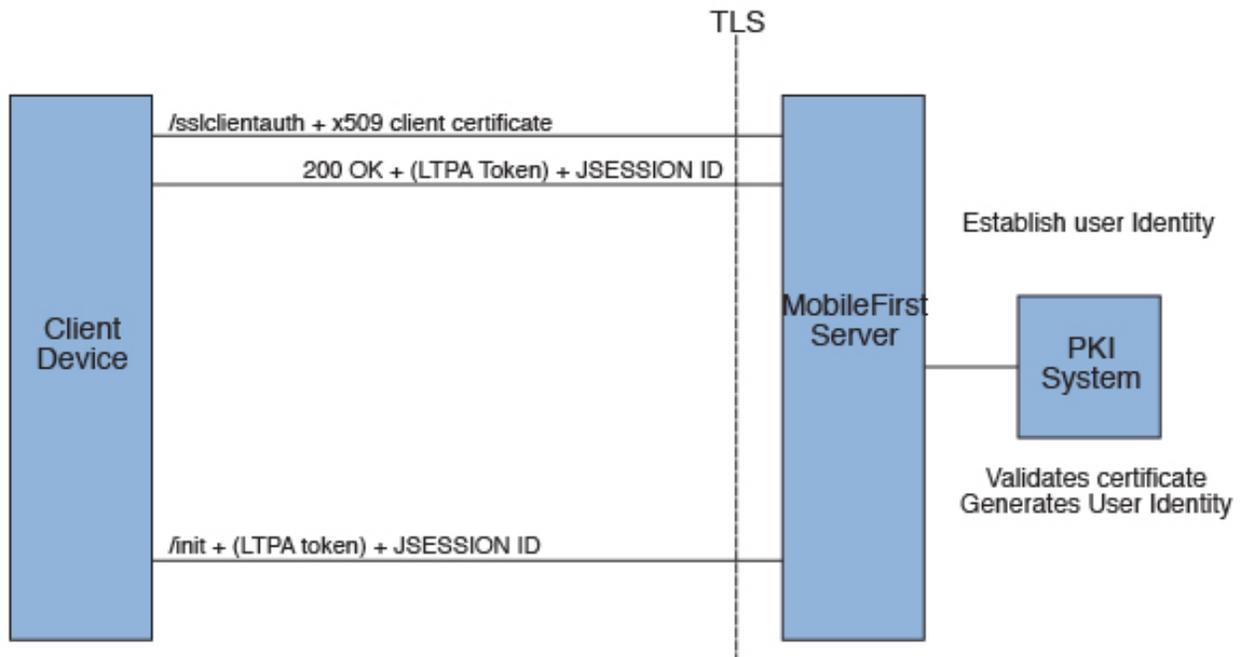

Subsequent calls from that MobileFirst application use this X.509 certificate to establish a secure connection over HTTPS, authenticate the user, and establish the user identity on the server. Users need to log in only once for the life of the certificate. When the certificate expires or is revoked by the PKI, the enrollment process is initiated again. You can allow user enrollment to continue, ban the user, or allow the user to log in only through the dependent realm.

Both the client and the server runtimes enforce certificate verification, ensuring that the client certificate is valid and is issued to a known user. The client certificate is

valid if it is issued by a trusted CA, is not expired and is not revoked, and its validity period is current. The server also verifies the client certificate's subject against a user registry to ensure that the client certificate was issued to a known user. Support for certificate revocation lists (CRL) is provided by the underlying Java Platform, Enterprise Edition server, and JVM. For more information about how to enable CRL support in WebSphere Application Server, see SSL configurations.

Note: Not all JVMs provide CRL support.

The following figure shows the client certificate authentication flow:

Protecting resources with user certificate authentication

You can protect your application or adapter procedures with the user certificate authentication user realm.

About this task

Follow the steps to configure the user certificate authentication user realm to protect your application or adapter procedure.

Procedure

1. Create a MobileFirst project.
2. Create a new hybrid MobileFirst application.
3. Configure the challenge handlers for your dependent realm. These challenge handlers help establish the identity of the user as part of the enrollment process. For more information, see “User certificate authentication on the client” on page 8-589.
4. Configure the server.
 - a. Configure your WebSphere Application Server Liberty profile server. For more information, see “Configuring the Liberty profile” on page 8-588.

- b. Configure the server for HTTPS. For more information, see “SSL configuration.”
 - c. Configure an embedded public key infrastructure (PKI) or external PKI. For more information, see “PKI bridge configuration” on page 8-581.
 - d. Uncomment out the `wl_UserCertificateAuthRealm` realm elements in the authentication configuration and update it as needed. For more information, see “Updating the server authentication configuration” on page 8-588.
5. Edit the application descriptor to specify the security test that enforces certificate authentication of the user. You can protect the application or the adapter.
 6. Install the root certificate authority (CA). For more information, see “Configuring SSL by using untrusted certificates” on page 6-193.
 7. Complete the deployment to the server.
 8. Install the application on the client.

What to do next

For a more comprehensive sample, see the Client X.509 Certificate Authentication and User Enrollment tutorial on the Getting Started page of the Developer Center.

User certificate authentication on the server

Both the MobileFirst Server and its hosting application server must be configured to use the User Certificate Authentication feature. The application server must be configured for client-side SSL. The MobileFirst Server must be configured with a PKI bridge and an appropriate security test to use the feature.

SSL configuration

The User Certificate Authentication feature depends on the use of the Secure Sockets Layer (SSL) for authentication purposes. You can host your application only on HTTPS, unless a reverse proxy is being used.

For more information about how to configure SSL, see “WebSphere Application Server and Liberty profile requirements” on page 8-587.

The User Certificate Authentication feature requires integration with a public key infrastructure (PKI). For the embedded PKI option, you must provide a certificate authority (CA) that can be used to generate the client X.509 certificates.

Certificates and CAs

Client certificates that are issued to the user by the User Certificate Authentication feature can be signed by a custom CA or a well-trusted CA through your PKI. Server-side certificates can be signed by either type of CA.

If you encounter errors with certificates that are not signed by well-trusted CAs, see “Configuring SSL by using untrusted certificates” on page 6-193.

Restriction: Self-signed certificates are not supported.

For more information about how to use and create an intermediate CA to sign both the server and client certificates, see the tutorials on the Getting Started page.

Certificate chains, keystore, and truststore

You must set the server certificate as the MobileFirst Server keystore. Also, set the client's certificate-signing CA as part of the truststore so that the server can trust the client certificates. For more information about setting up the server with these certificates, see "WebSphere Application Server and Liberty profile requirements" on page 8-587.

Note: If you use intermediate custom CAs, ensure that you concatenate the server certificate with the certificate chain. When you create the server certificate, use the following order:

Server certificate -> intermediate(s) in order -> trust anchor

The following example works in Mac OS X and Linux, and concatenates the server certificate with one intermediate CA and the trust anchor (root CA):

```
cat server/server.crt signingca/signing_ca.crt rootca/root_ca.crt > server_chain.crt
```

PKI bridge configuration

The PKI bridge is an interface between the MobileFirst Server and a business' public key infrastructure (PKI). Each realm definition that uses the `WorklightCertificateAuthenticator` must have a PKI bridge that is defined in its configuration.

User certificate identity versus standard MobileFirst user identity

The standard MobileFirst user identity contains basic user details and is built after a user realm is authenticated. The identity contains user name, display name, and extra attributes. The identity can be requested for each realm in a security test by authenticated resources, such as an adapter. For user certificate authentication, more details might be required, such as device ID and application name. These details are provided in the user certificate identity object that is sent to the PKI bridge.

A user certificate identity instance contains the following elements:

- Standard MobileFirst user identity
 - User name
 - Display name
 - Attributes
- Device ID
- Application name

Embedded PKI bridge:

The embedded PKI bridge is an included PKI bridge that can be used with user certificate authentication. The embedded PKI bridge is available with the `com.worklight.core.auth.ext.UserCertificateEmbeddedPKI` class name and is configured by adding parameters to the realm definition.

The embedded PKI bridge is useful for developers without direct access to the business' PKI during testing. Administrators that are interested in testing the user certificate authentication feature without implementing their own PKI bridge can also use the embedded PKI bridge. The embedded PKI bridge is not recommended or supported for production environments.

Requirements for use

For the embedded PKI bridge, a certificate authority (CA) certificate and private key must be available. The certificate and private key must be added to a keystore manually. The keystore must be in the PKCS #12 file format, such as a .p12 file. A password to access the keystore can be supplied optionally in plaintext form. If the .p12 file does not exist, cannot be read, or is supplied an invalid password, an error is thrown in the server trace. The following example shows a realm definition for `wl_userCertificateAuthRealm` with the embedded PKI:

```
<realm name="wl_userCertificateAuthRealm"
  loginModule="UserCertificateLoginModule">
  <className>com.worklight.core.auth.ext.UserCertificateAuthenticator</className>
  <parameter name="dependent-user-auth-realm"
    value="WASLTPARealm" />
  <parameter name="pki-bridge-class"
    value="com.worklight.core.auth.ext.UserCertificateEmbeddedPKI" />
  <parameter name="embedded-pki-bridge-ca-p12-password"
    value="capassword" />
  <parameter name="embedded-pki-bridge-ca-p12-file-path"
    value="/opt/ssl_ca/ca.p12" />
  <parameter name="embedded-pki-bridge-organization"
    value="IBM Worklight" />
  <parameter name="embedded-pki-bridge-add-cert-extensions"
    value="true" />
</realm>
```

Configuration parameters

The following embedded PKI bridge parameters are available.

embedded-pki-bridge-ca-p12-file-path

Required

Full file path of the .p12 file for the CA that signs user certificate requests.

embedded-pki-bridge-ca-p12-password

Optional

Password in plaintext that is used to decode the CA .p12 file that is specified. No password is used if not specified.

embedded-pki-bridge-organization

Optional

Organization name that is added to the distinguished name (DN) inside a signed certificate (O=<organization name specified>). If not specified, no organization is added to the DN.

embedded-pki-bridge-add-cert-extensions

Optional

Add non-critical MobileFirst custom certificate extensions to the user certificate before it is signed. This parameter provides more details to user identity attributes on subsequent runs. These details include device ID, group ID, and application name that is stored in the certificate. By default, this parameter is false. You can enable the parameter by using the true value. This parameter is not always supported and may not work for your configured server configuration. You must test this option first on your infrastructure to ensure that a certificate is not marked invalid if extensions are enabled. When this parameter is enabled, the device ID is added with the OID 1.3.6.1.4.1.2.6.256.1 and the app name is added with the OID 1.3.6.1.4.1.2.6.256.2. These OIDs are not formally registered and may change.

embedded-pki-bridge-days-before-expire

Optional

Configure the length of time the generated certificate is valid. This setting defaults to one year (365 days).

embedded-pki-bridge-crl-uri

Optional

Configure an optional CRL for your certificate authority. If the certificate that is generated exists on a client's device and is revoked in the CRL, the client is required to generate a certificate.

External/adapter-based PKI bridge:

The adapter-based PKI bridge is an included PKI bridge that can be used with user certificate authentication. The adapter-based PKI bridge is available with the `com.worklight.core.auth.ext.UserCertificateAdapterBasedPKI` class name, and is configured by adding parameters to the realm definition. An adapter is required for this PKI bridge to work, and must be uploaded before any user connects with this configuration. The adapter-based PKI bridge is useful if your PKI can be accessed with an adapter (such as a REST API).

Requirements for use

For the adapter-based PKI bridge, an adapter must be added in the console and the parameters for the bridge must be configured in the realm definition. The following example shows a realm definition for `wl_userCertificateAuthRealm` with the adapter-based PKI that uses an adapter that is called `PKIAdapter`:

```
<realm name="wl_userCertificateAuthRealm"
  loginModule="UserCertificateLoginModule">
  <className>com.worklight.core.auth.ext.UserCertificateAuthenticator</className>
  <parameter name="dependent-user-auth-realm"
    value="WASLTPARealm" />
  <parameter name="pki-bridge-class"
    value="com.worklight.core.auth.ext.UserCertificateAdapterBasedPKI" />
  <parameter name="adapter-pki-bridge-init-procedure"
    value="PKIAdapter.init" />
  <parameter name="adapter-pki-bridge-identity-validation-procedure"
    value="PKIAdapter.validateIdentity" />
  <parameter name="adapter-pki-bridge-csr-requirements-procedure"
    value="PKIAdapter.getCSRRequirements" />
  <parameter name="adapter-pki-bridge-csr-validation-procedure"
    value="PKIAdapter.validateCSR" />
  <parameter name="adapter-pki-bridge-certificate-generation-procedure"
    value="PKIAdapter.generateCertificate" />
  <parameter name="adapter-pki-bridge-identity-from-certificate-procedure"
    value="PKIAdapter.getIdentityFromCertificate" />
  <parameter name="adapter-pki-bridge-certificate-validation-procedure"
    value="PKIAdapter.validateCertificate" />
</realm>
```

Configuration parameters

The following adapter-based PKI bridge parameters are available.

adapter-pki-bridge-init-procedure

Required

An adapter procedure that is called to initialize the PKI bridge on each call. Requires a single parameter for the configuration that is available in the realm definition. The following example shows a sample value of this parameter:

```

{"adapter-pki-bridge-csr-validationprocedure":
PKIBridgeAdapter.validateCSR", "adapter-pki-bridge-identity-fromcertificate-
procedure": "PKIBridgeAdapter.identityFromCertificate", "pkibridgetclass":
com.worklight.core.auth.ext.UserCertificateAdapterBasedPKI", "adapterpki-
bridge-identity-validationprocedure":
PKIBridgeAdapter.identityVerify", "adapter-pki-bridge-csrrequirements-
procedure": "PKIBridgeAdapter.csrRequirements", "adapter-pkibridget-
certificate-generationprocedure":
PKIBridgeAdapter.generateCertificate", "adapter-pki-bridgertificate-
validationprocedure":
PKIBridgeAdapter.certificateVerify", "adapter-pki-bridge-initprocedure":
PKIBridgeAdapter.init", "dependent-user-authrealm":
WASLTPARealm"}

```

adapter-pki-bridge-identity-validation-procedure

Optional

An adapter procedure that is called that allows the adapter to determine whether the user identity from the dependent realm is allowed to generate a certificate. This procedure is optional. By default, the PKI bridge always returns YES. Requires a single `userIdentity` parameter. The following example shows a sample value of this parameter:

```

{"deviceId": "C146B473-DA25-46A7-8A79-E8CE5E9270EE", "userIdentity":
{"userName": "user@ibm.com", "attributes":
{"LtpaToken": "dHwRqHp61ukJcKfEBMRd6g63uV1bDg0rmGBU2cuBrinFp+7L7BVb
+40ebyIRMOoKLhH1dLxj9JIPiWH4s16tHtNjddBxxbd9rdjZUgnicVY8+6GM8uTEw1eRW
+1VzzwJX0Htvfa2iOQD9KAWLXkNHgneiELIANjAUxGsMzJGGg2K8LYYWeBhE0JGqJcb8WFFLYH4T5
Cgb9C+qXpre/KF/MNTrv2WQF9kWjPmM1PuT1Lh1tY9oSSqN20DNNZ8VcQ8p26po5yBMvtDMtn4/
EzfdhKYeTNFzQEmQpR66caQJ1RV++m/
Oq4EiZBBzk0Y6zpBVtmUzcH3D2xh5PYVvcF08g="}, "displayName": "", "appId": "UserCert"}

```

The procedure must return an object with the following format:

```
{valid: "YES"}
```

Options for `valid`:

- YES - The user is allowed to generate a certificate.
- NO_USE_DEPENDENT_REALM_ONLY - The user is allowed to log in to the dependent realm, but is not allowed to generate a certificate.
- NO - The user is not allowed to log in at all, and is not allowed to generate a certificate.

adapter-pki-bridge-csr-requirements-procedure

Optional

Build a set of requirements that must be in a CSR that the client generates. This procedure is optional. By default, the CSR requirements include the `commonName` that is equal to the user name from the dependent realm user identity. The procedure has a single parameter that is called `userIdentity` with the following format:

```

{"deviceId": "C146B473-DA25-46A7-8A79-E8CE5E9270EE", "userIdentity":
{"userName": "user@ibm.com", "attributes":
{"LtpaToken": "dHwRqHp61ukJcKfEBMRd6g63uV1bDg0rmGBU2cuBrinFp+7L7BVb
+40ebyIRMOoKLhH1dLxj9JIPiWH4s16tHtNjddBxxbd9rdjZUgnicVY8+6GM8uTEw1eRW

EzfdhKYeTNFzQEmQpR66caQJ1RV++m/
Oq4EiZBBzk0Y6zpBVtmUzcH3D2xh5PYVvcF08g="}, "displayName": "", "appId": "UserCert"}

```

This procedure must return a JSON object in the following format:

```
{ commonName: "user@ibm.com", additionalSubject: { "0": "IBM" }, additionalAttributes: {} }
```

- `commonName` - This attribute is a required entry that is used as the CN attribute in the CSR. This value must match a user in the user registry of the application server.

- additionalSubject - This attribute is a required JSON object that contains key/value pairs for each additional attribute that must be in the subject of the CSR, such as 0 for organization. If no additional attributes are required, use an empty JSON object.
- additionalAttributes - This attribute is a required JSON object that contains key/value pairs for each additional attribute that must be included in the CSR. If no additional attributes are required, use an empty JSON object.

adapter-pki-bridge-csr-validation-procedure

Optional

This procedure is called after a client sends a CSR that follows a request. It is responsible for ensuring that all of the CSR attributes that were requested in the requirements exist in the CSR. This procedure is optional. By default, the PKI bridge always returns YES. The procedure has a single parameter csr that contains a JSON object with the following format:

```
{ "csr": "MIICXzCCAUCADAbMRkwFwYDVQQDFBBSaXpldEB1cy5pYm0uY29tMIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAt9A8WLa0NqAji zn9ccZFUPBLCCGEBUCUAgNPZKcf3wW2LhQ75MEMfLyahZvqSBF7IMMstRrpKio bx6PTGiMCKNB710zNa88tCHv81+wHaTIu2QggqpBMFPhvBdTbS93pafEQ7kXEGbk+uU7vwa1UIHQyQT1+9ZaiH4ssf8Ybi+qYmGr0H4Cjv07h9310sAy00WqcGBnOCcb1+YJP9F/EyHLNfdr1FTDAAp0ERtUqVMDeJIRxscFnqZ1GG0rXCEJqA13IHvrn6BiLrmQ0xA5oE+Lk4ry6cizw1yxYY1mWZq9eTCQqBMGBS/Aa+4KB0G3NCCL+e4YKN2RJ0m2bcHRswIDAQABoAAwDQYJKoZIhvcNAQEFBQADggEBAHhOJbrGBCZCiDi3hXzVzji71euKMf8IUjGe+sfr+Sy5sfx9k+icvKixImHCxSy0PeKp4QICSgfZxk2xQzHhYVgdeB0Uv2WT7FjPngRjAgLL1jxu7LIkEMKwgiGiJMPg54g0x8kWuj5uE9vqpWGRK0dGuPN1nQxh50pSgZi4PhRGz2nCBF6WdQFNmHDqssijk//CUHwBnVMTIWyuHhXEhtwkp1c0dAp1b3hHBywYM9Vae9fUmfpbHDb0yvjBjCHvceRjwkoQG6ABfh99ucE1NW051Rc03XqGnHKsnk16B1qSH0YpM/sVWYrmio/F9h75aNX+Sz5EhkB7t/n4301aP0o="}
```

Note: csr is the CSR in DER format and is represented in base64.

The procedure must return a JSON object with the following format:

```
{valid: "YES"}
```

or

```
{valid: "NO"}
```

Options for valid:

- YES - The CSR meets the requirements from the PKI.
- NO - The CSR does not meet the requirements from the PKI. Authentication fails.

adapter-pki-bridge-certificate-generation-procedure

Required

This procedure is responsible for requesting a certificate from the PKI and returning a certificate. This procedure is required and has one required parameter csr, which has the following format:

```
{ "deviceId": "C146B473-DA25-46A7-8A79-E8CE5E9270EE", "csr": "MIICXzCCAUCADAbMRkwFwYDVQQDFBBSaXpldEB1cy5pYm0uY29tMIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAt9A8WLa0NqAji zn9ccZFUPBLCCGEBUCUAgNPZKcf3wW2LhQ75MEMfLyahZvqSBF7IMMstRrpKio bx6PTGiMCKNB710zNa88tCHv81+wHaTIu2QggqpBMFPhvBdTbS93pafEQ7kXEGbk+uU7vwa1UIHQyQT1+9ZaiH4ssf8Ybi+qYmGr0H4Cjv07h9310sAy00WqcGBnOCcb1+YJP9F/EyHLNfdr1FTDAAp0ERtUqVMDeJIRxscFnqZ1GG0rXCEJqA13IHvrn6BiLrmQ0xA5oE+Lk4ry6cizw1yxYY1mWZq9eTCQqBMGBS/Aa+4KB0G3NCCL+e4YKN2RJ0m2bcHRswIDAQABoAAwDQYJKoZIhvcNAQEFBQADggEBAHhOJbrGBCZCiDi3hXzVzji71euKMf8IUjGe+sfr+Sy5sfx9k+icvKixImHCxSy0PeKp4QICSgfZxk2xQzHhYVgdeB0Uv2WT7FjPngRjAgLL1jxu7LIkEMKwgiGiJMPg54g0x8kWuj5uE9vqpWGRK0dGuPN1nQxh50pSgZi4PhRGz2nCBF6WdQFNmHDqssijk//"
```

0q4EiZBBzk0Y6zpbVtmUzcH3D2xh5PYVvcF08g="}, "displayName": "", "appId": "UserCert"}
```

Note: csr is the CSR in DER format and is represented in base64.

The procedure must return a base64 string of the X.509 certificate in DER format in a JSON object with the following format:

```
{ certificateBase64: "<BASE64 STRING OF THE X.509 CERTIFICATE>" }
```

adapter-pki-bridge-certificate-validation-procedure

Optional

This procedure is responsible for validating a user's certificate when it is first received. This procedure is optional. If it is not used, the PKI bridge always returns YES. The procedure has one parameter certificate that is in the same format as the procedure in the adapter-pki-bridge-identity-from-certificate-procedure parameter.

The procedure is required to return a JSON object that states the validity of the certificate:

```
{valid: "YES"}
```

or

```
{valid: "NO"}
```

Options for valid:

- YES - The certificate is considered valid by the PKI.
- NO - The certificate is not considered valid by the PKI, and the client is required to start the enrollment process over.

adapter-pki-bridge-identity-from-certificate-procedure

Required

This procedure is responsible for creating a user certificate identity from a certificate that is passed by the user. The procedure must have one parameter certificate with the following format:

```
{ "publicKey":
{ "base64": "MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAt9A8WLa0NqAjizn9ccZFUPBLC

configuration. If you want to protect the MobileFirst Server with the WebSphere Application Server Liberty Profile security mechanisms, you must install a fix for APAR PI10103 for Liberty Versions 8.5.5.0 and 8.5.5.1. For more information, see PI10103: Support certificate authentication to fail over to a form-based login.

Configuring the Liberty profile:

You must enable an HTTPS endpoint in WebSphere Application Server Liberty profile that uses the server's certificate, and trusts the client certificates.

Before you begin

Ensure that you understand the documentation at Enabling SSL communication for the Liberty profile. To set up the MobileFirst Server, see the WebSphere Application Server Liberty profile documentation about setting up SSL for the server at Liberty profile: SSL configuration attributes.

About this task

The application server requirements can be configured on the WebSphere Application Server Liberty profile in the `server.xml` file.

Procedure

1. Install a server certificate for use by the SSL channel, and configure the SSL channel.
2. Add a truststore to the configuration that contains a keystore with the CA certificate that is used to sign user certificates. Add the following element to the `server.xml` file:

```
<keyStore id="defaultTrustStore" location="trust.jks" type="JKS" password="defaultPWD" />
```
3. Enable the client authentication support by adding the `clientAuthenticationSupported="true"` attribute to the SSL element in the `server.xml` file.
4. Access the MobileFirst Operations Console over SSL. You are presented with a trusted website that asks for an optional user certificate.

Updating the server authentication configuration

A requirement to enable the User Certificate Authentication feature is to configure the authentication configuration on the MobileFirst Server.

About this task

You must update the `authenticationConfig.xml` file to configure your server to use the User Certificate Authentication feature. User certificate authentication uses standard MobileFirst authentication mechanisms: authenticator and login modules. The `com.worklight.core.auth.ext.UserCertificateAuthenticator` and the `com.worklight.core.auth.ext.UserCertificateLoginModule` modules are bundled with the core MobileFirst Server library.

Procedure

1. From within your server configuration, open the `authenticationConfig.xml` file for editing.
2. Add a realm definition inside the `<realms>` attribute in your `authenticationConfig.xml` file.

```

<realm name="wl_userCertificateAuthRealm"
  loginModule="UserCertificateLoginModule">
  <className>com.worklight.core.auth.ext.UserCertificateAuthenticator</className>
  <parameter name="dependent-user-auth-realm"
    value="<DEPENDENT REALM NAME HERE>" />
  <parameter name="pki-bridge-class"
    value="<PKI BRIDGE CLASS>" />
</realm>

```

3. Modify this realm definition by supplying your own dependent realm by specifying its name for the dependent-user-auth-realm parameter and a PKI bridge implementation (full Java class path) for the pki-bridge-class parameter. You can use the included PKI bridge classes such as embedded (“Embedded PKI bridge” on page 8-581) or adapter-based (“External/adapter-based PKI bridge” on page 8-583) or supply your own custom PKI bridge implementation (“Custom PKI bridge” on page 8-587).
4. Add your custom parameters to this realm definition based on your PKI bridge implementation. Bundled PKI bridge implementations such as Embedded (“Embedded PKI bridge” on page 8-581) or Adapter-Based (“External/adapter-based PKI bridge” on page 8-583) have extra required parameters that must be added.
5. Add the following login module definition, as-is, to your <loginModules> element in the authenticationConfig.xml file.

```

<loginModule name="UserCertificateLoginModule">
  <className>com.worklight.core.auth.ext.UserCertificateLoginModule</className>
</loginModule>

```

6. Add the wl_userCertificateAuthRealm realm as a test in the security test that you want to use for your application or environment.
7. Add the security test to the resource you want to protect. To protect an adapter procedure, add the securityTest attribute for the procedure. For more information, see “Structure of the adapter XML file” on page 8-247 and “Security tests” on page 8-569. To protect an application environment, define a security test for each environment in the application-descriptor.xml file, by using the securityTest="your_test_name" property. If no security test is defined for a specific environment, only a minimal set of default platform tests are run.

```

<securityTest name="your_test_name">
  <testUser realm="wl_userCertificateAuthRealm" />
  <testDeviceId provisioningType="none" />
</securityTest>

```

Note: To protect your application or adapter procedure, reference your security test in your application descriptor file.

```

<iphone bundleId="com.UserCertApp" version="1.0" securityTest="your_test_name">

```

User certificate authentication on the client

The User Certificate Authentication feature requires little configuration on the client side. The MobileFirst client run time takes care of most of the heavy lifting on your behalf. There are however, a few things you need to be aware of to ensure successful and secure communication with your server.

Establishing trust

Because the User Certificate Authentication feature requires communication over HTTPS, the first thing you must ensure is that your client device trusts the server's credentials that are sent on the SSL handshake.

Each mobile platform comes with a predefined set of trusted certificate authorities (CAs) that are deemed trustworthy by the platform. Trust is easily established if your server uses a server certificate that is signed by one of these trusted CAs.

However, if your server uses a CA that is unknown to your device, you must do some extra work on the client side to establish appropriate trust. To establish trust, you must install the trust anchor certificate on the client device. The trust anchor is either the root CA, or the root certificate if you are using a self-signed certificate. For more information, see “Configuring SSL by using untrusted certificates” on page 6-193.

Dependent user realm

The first time a user attempts to connect to the server, IBM MobileFirst Platform Foundation tries to enroll the user into the PKI and provision the device with the user certificate. To enroll the user, IBM MobileFirst Platform Foundation requires the help of a dependent user authentication realm. This behavior is all configured on the server. But you must ensure that your application has the appropriate challenge handlers that are required to handle the challenges that come from the server. The dependent realm challenge handlers do not require any additional configuration. For more information, see the appropriate section of this user documentation or getting started modules for instructions on how to write the respective challenge handlers for your dependent user realm.

Group support

User certificates are issued by default to a user on a specific application and device. Group support allows a certificate to be issued to the user on a specific device and to a group of applications. The same user certificate can be shared among a group of applications that are installed on the device, allowing the user to only authenticate through a dependent realm once, and not for every application.

In this case, the user enrollment process that requires the user to log in to a dependent realm happens the first time that the user attempts to log in to the server on a particular device. After the device is provisioned with the necessary certificate, all subsequent authentications to the server from any of the MobileFirst applications that are designated by you use the same certificate to authenticate to the server.

To configure the sharing of user certificates among a group of applications, see “Configuring user certificate authentication for a group of applications” on page 8-591.

Clearing certificates on the chain

Certificates on the client are managed by the MobileFirst client run time. They are installed and removed from the device as needed. However, there might be situations when you want the ability to clear the certificates that are installed on the device. For this reason, a JavaScript API is provided. The API allows the application to remove the certificates at more convenient times, like during test and development, or when the device is transferred to a new user.

The following API removes the certificate on the device for the specific application in use:

```
WL.UserAuth.deleteCertificate();
```

On iOS only, if you would like to delete the certificate that is associated with a specific group of applications, use the following API:

```
WL.UserAuth.deleteCertificate("yourGroupNameHere");
```

Security considerations

This new feature introduces a powerful and ITU-T X.509 standards-based way to authenticate users. It also introduces a password-less login mechanism. The identity is established by the MobileFirst client run time as part of the application that presents the certificate as part of the server-side connection. Although this behavior greatly simplifies the user experience, the following precautions must be taken by the enterprise. These precautions ensure that there is adequate protection on the device to ensure cases where the user loses the device or when the device is stolen.

1. Single user is required. The device is owned and used only by a single user and not accessible to others.
2. Device must be maintained under a device passcode lock or PIN to ensure that only the designated user can access the device and applications.

Configuring user certificate authentication for a group of applications

You can configure the User Certificate Authentication feature to issue a certificate to a user on a device for a group or family of applications that are protected by the user certificate authentication realm. This configuration allows a user to authenticate once and be automatically authenticated to a set of applications on the device (single sign-on). This single sign-on option among a family of applications can be achieved with the Simple Data Sharing feature. The Simple Data Sharing feature allows the User Certificate Authentication feature to provision a device with a user certificate that applies to, and is used by, all applications in the same specified MobileFirst family.

About this task

You can configure the User Certificate Authentication feature to provision the device with a user certificate that is shared among a group of applications. This configuration allows a group of applications to authenticate with the same X.509 client certificate.

Note: The iOS `x509AccessGroup` property is deprecated since IBM MobileFirst Platform Foundation V7.1.0. Use the Simple Data Sharing feature instead.

Procedure

1. Enable the Simple Data Sharing feature.
 - a. For hybrid applications, follow the steps in “Enabling the Simple Data Sharing feature for hybrid applications” on page 8-595.
 - b. For native Android applications, follow the steps in “Enabling the Simple Data Sharing feature for Android native applications” on page 8-596.
 - c. For native iOS applications, follow the steps in “Enabling the Simple Data Sharing feature for iOS native applications” on page 8-596.
2. Ensure that you select the user certificate authentication group support option in the application descriptor file.

✓ Enable User Client Certificate Authentication Group Support

When you use the User Certificate Authentication feature, enable this option to provision the device with a user certificate that is shared by all applications in the same family.

Troubleshooting the User Certificate Authentication feature

Find solutions to problems with the User Certificate Authentication feature.

Table 8-56. User Certificate Authentication troubleshooting guidelines. This table lists possible problems and actions to take to troubleshoot the User Certificate Authentication feature.

Problem	Actions to take
The server is not responding even though it is accessible through the browser when it uses a certificate that is signed by a private CA.	Make sure that you can reach the MobileFirst Server on your device. For example, go to the MobileFirst Operations Console on the device's internet browser. If you can reach it, then the most likely error is that the client is not trusting the server's certificate. The server's certificate is most likely a certificate that is signed by a private CA. To fix this problem, you must install the root CA on the device so that it is trusted. For more information, see "Establishing trust" on page 8-589.
Certificates that are signed by a private CA work on Android but not on iOS.	When Android is in debuggable mode, some SSL errors are ignored. This behavior gives the impression that SSL is working. Android is in debuggable mode when the APK is unsigned, or when you explicitly set it in the manifest. . Verify that the debuggable flag is set to false (debuggable:false) in the Android manifest file, or sign the APK. Make sure that there is no explicit declaration in the manifest that sets it to debuggable mode. For more information about how to trust certificates that are signed by your private CA, see "Configuring SSL by using untrusted certificates" on page 6-193.
javax.net.ssl.SSLPeerUnverifiedException on Android or WLSecureRequest:sendRequestToServerWithURL A connection failure occurred: SSL Problem (Possible causes may include a bad/expired/self-signed certificate, clock set to the wrong date) on iOS.	One of the certificates was not trusted. Usually it is because the server did not send the server certificate with the whole certificate chain in the right order, when it uses an intermediate CA. For more information, see "SSL configuration" on page 8-580. Another explanation can be that the certificate was revoked by the certificate revocation list (CRL), and the PKI did not allow the device to renew the certificate.

Table 8-56. User Certificate Authentication troubleshooting guidelines (continued). This table lists possible problems and actions to take to troubleshoot the User Certificate Authentication feature.

Problem	Actions to take
Authentication fails with an exception in the PKI.	There was an exception somewhere in the PKI bridge. To see more information about the exception, make sure that the MobileFirst Server has trace that is enabled for <code>com.worklight.*=all</code> , and search for <code>UserCertificate*</code> in the trace file. Possible reasons include a syntax or runtime error in the adapter when you use the adapter-based PKI bridge, or a configuration error in the embedded PKI.
The client certificate is expired or not yet valid.	If the certificate is expired or not yet valid, the client logs this information in the client's logs. The client then proceeds with the authentication as if it did not have a certificate. The PKI then decides whether it allows the user to renew the certificate or not. In the 'certificate not yet valid' scenario, verify that the device and the server clocks are set correctly.

Simple data sharing

Learn about the Simple Data Sharing feature.

Simple data sharing overview

Learn about the Simple Data Sharing feature.

The Simple Data Sharing feature makes it possible to securely share lightweight information among a family of applications on a single device. This feature uses native APIs that are already present in the different mobile SDKs to provide one unified developer API. This MobileFirst API abstracts the different platform complexities, making it easier for developers to quickly implement code that allows for inter-application communication.

This feature is supported on iOS and Android for both hybrid and native applications.

After you enable the Simple Data Sharing feature, you can use the provided hybrid and native APIs to exchange simple string tokens among a family of applications on a device.

When used with other features like the MobileFirst device single sign-on (SSO) or User Certificate Authentication features, the Simple Data Sharing feature enhances the ability of these features to share security credentials among applications in the same family. For example, you can share user authentication cookies among a family of applications to allow device SSO to work when a reverse proxy is used. It also enables the User Certificate Authentication feature to provision an X.509 user certificate to a family of applications on a device.

For more information about device SSO with a reverse proxy, see "Configuring device single sign-on with a reverse proxy" on page 8-650.

For more information about user certificate group support, see “Configuring user certificate authentication for a group of applications” on page 8-591.

Simple data sharing general terminology

Learn about simple data sharing general terminology.

MobileFirst application family

An application family is a way to associate a group of applications which share the same level of trust. Applications in the same family can securely and safely share information with each other.

To be considered part of the same MobileFirst application family, all applications in the same family must comply with the following requirements:

- Specify the same value for the application family in the application descriptor.
 - For iOS applications, this requirement is synonymous to the access group entitlements value and the `wlAppFamily` value in the `worklight.plist` file.
 - For Android applications, this requirement is synonymous to the `sharedUserId` value in the Android manifest file.
 - For Android, the name must be in the `x.y` format.
 -

Note: Enabling or changing the MobileFirst application family settings require earlier Android applications to be uninstalled. Upgrading an application that modified its `sharedUserId` is not allowed by the Android operating system for security reasons.

- Applications must be signed by the same signing identity. This requirement means that only applications from the same organization can use this feature.
 - For iOS applications, this requirement means the same Application ID prefix, provisioning profile, and signing identity is used to sign the application.
 - For Android applications, this requirement means the same signing certificate and key.

Aside from the IBM MobileFirst Platform Foundation provided APIs, applications in the same MobileFirst application family can also use the data sharing APIs that are available through their respective native mobile SDK APIs.

String tokens

Sharing string tokens across applications of the same MobileFirst application family can now be accomplished in hybrid or native iOS and Android applications through the Simple Data Sharing feature.

String tokens are considered simple strings, such as passwords or cookies. Using large strings results in considerable performance degradation.

Consider encrypting tokens when you use the APIs for added security. For more information, see “JSONStore security utilities” on page 8-467.

Enabling the Simple Data Sharing feature

Learn how to enable the Simple Data Sharing feature.

Enabling the Simple Data Sharing feature for hybrid applications

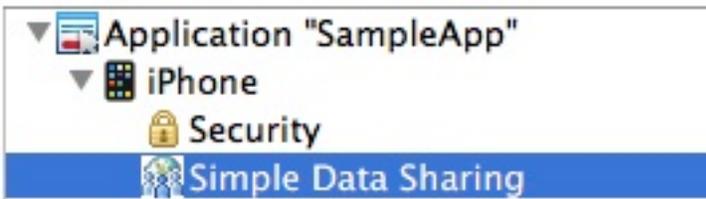

Update the application descriptor to enable the Simple Data Sharing feature on hybrid applications.

About this task

To enable simple data sharing, you must modify the application descriptor.

Procedure

1. Add an Android or iOS environment.
2. Add the **Simple Data Sharing** option.

3. Enable the Simple Data Sharing option and specify an application family name.

Enable Simple Data Sharing among an application family.

Application family*:

Note: For Android, the application family name must be in the form of `com.xx.yy`.

Note: Enabling or changing the MobileFirst application family settings require earlier Android applications to be uninstalled. Upgrading an application that modified its `sharedUserId` is not allowed by the Android operating system for security reasons.

4. Save.
5. Build all environments.
6. Ensure that applications that are part of the same family are signed by the same signing credentials.
7. For Android environments, follow these steps.
 - a. Before you install the newly built application on the device, uninstall any earlier applications from the device that were using a different family name value.
 - b. Install the newly built application on the device.
8. For iOS environments, follow these steps.
 - a. Ensure that applications that are part of the same family share the same Application ID prefix. For more information, see [Managing Multiple App ID Prefixes in the iOS Developer Library](#).
9. Repeat the steps for all applications that you want to make part of the same application family.

Results

You can now use the Simple Data Sharing JavaScript APIs to share simple strings among the group of applications in the same family. For more information, see the Simple Data Sharing JavaScript APIs in the `WL.Client` class.

Enabling the Simple Data Sharing feature for iOS native applications

Update iOS native applications to enable the Simple Data Sharing feature.

Before you begin

For more information about how to develop iOS native applications, see “Developing native applications for iOS” on page 8-185.

Note: Only applications from the same organization can use this feature.

About this task

To enable simple data sharing, you must modify your iOS native application.

Procedure

1. Enable the Simple Data Sharing option by specifying the application family name in the `worklight.plist` file with the `wlAppFamily` property.
2. In Xcode, add a Keychain Access Group with the same name as your `wlAppFamily`.

The application-identifier entitlement must be the same for all applications in your family.

Note: By default, MobileFirst applications are part of the `worklight.group` access group that is defined in the entitlement property file. Ensure that this group continues to be the first group in the list.

3. Ensure that applications that are part of the same family share the same Application ID prefix. For more information, see Managing Multiple App ID Prefixes in the iOS Developer Library.
4. Save and sign applications. Ensure that all applications in this group are signed by the same iOS certificate and provisioning profiles.
5. Repeat the steps for all applications that you want to make part of the same application family.

Results

You can now use the native Simple Data Sharing APIs to share simple strings among the group of applications in the same family. For more information, see the Simple Data Sharing Objective-C APIs in the `WLSimpleDataSharing` class.

Enabling the Simple Data Sharing feature for Android native applications

Update Android native applications to enable the Simple Data Sharing feature.

Before you begin

For more information about how to develop Android native applications, see “Developing native applications for Android” on page 8-200.

About this task

To enable simple data sharing, you must modify your Android native application.

Procedure

1. Enable the Simple Data Sharing option by specifying the application family name as the `android:sharedUserId` element in the manifest tag of your Android manifest file.

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.myApp1"
    android:versionCode="1"
    android:versionName="1.0"
    android:sharedUserId="com.myGroup1">
```

The `sharedUserId` is equivalent to your `WlAppFamily` name.

Note: Enabling or changing the MobileFirst application family settings require earlier Android applications to be uninstalled. Upgrading an application that modified its `sharedUserId` is not allowed by the Android operating system for security reasons.

2. Ensure that applications that are part of the same family are signed by the same signing credentials.
3. Uninstall any earlier versions of the applications that did not specify a `sharedUserId` or that used a different `sharedUserId`.
4. Install the application on the device.
5. Repeat the steps for all applications that you want to make part of the same application family.

Results

You can now use the native Simple Data Sharing APIs that are provided to share simple strings among the group of applications in the same family. For more information, see the Simple Data Sharing Java APIs in the `WLSimpleDataSharing` class.

Simple data sharing API concepts

Learn about simple data sharing API concepts.

Sharing string tokens across applications of the same MobileFirst application family can be accomplished in iOS and Android for both hybrid and native applications. This API is meant for sharing simple strings securely.

The Simple Data Sharing APIs allow any application in the same family to set, get, and clear key-value pairs from a common place. The Simple Data Sharing APIs are similar for every platform, and provide an abstraction layer, hiding the complexities that exist with each native SDK's APIs, making it easy to use.

The following examples show how you can set, get, and delete tokens from the shared credential storage for the different environments.

Hybrid applications

```
WL.Client.setSharedToken({key: myName, value: myValue})
WL.Client.getSharedToken({key: myName})
WL.Client.clearSharedToken({key: myName})
```

For more information about the hybrid APIs, see the `getSharedToken`, `setSharedToken`, and `clearSharedToken` functions in the `WL.Client` class.

iOS native applications

```
[WLSimpleDataSharing setSharedToken: myName value: myValue];
NSString* token = [WLSimpleDataSharing getSharedToken: myName]];
[WLSimpleDataSharing clearSharedToken: myName];
```

For more information about the native iOS APIs, see `WLSimpleDataSharing Class Reference`.

Android native applications

```
WLSimpleSharedData.setSharedToken(myName, myValue);
String token = WLSimpleSharedData.getSharedToken(myName);
WLSimpleSharedData.clearSharedToken(myName);
```

For more information about the native Android APIs, see `Class WLSimpleDataSharing`.

Troubleshooting simple data sharing

Find information to help resolve issues that you might encounter when you use the Simple Data Sharing feature.

Table 8-57. Troubleshooting the Simple Data Sharing feature. This table lists possible problems and actions to take to troubleshoot the Simple Data Sharing feature.

Problem	Actions to take
Unable to access shared data when you use the Simple Data Sharing APIs.	Ensure that all applications in the same family are all redeployed under the same MobileFirst application family name. For more information, see “Enabling the Simple Data Sharing feature” on page 8-594.
Android: Application fails to install.	<ol style="list-style-type: none"> 1. Ensure that all applications that are part of the same MobileFirst application family name, are also signed by the same signing identity. 2. Uninstall previous versions of applications that have a different MobileFirst application family or <code>wlSharedUserID</code>, or are signed by a different signing identity.
Unable to get MobileFirst device SSO to work with a reverse proxy.	<ol style="list-style-type: none"> 1. Ensure that you enabled the Simple Data Sharing feature. For more information, see “Enabling the Simple Data Sharing feature” on page 8-594. 2. Ensure that all applications in the same family specified the necessary reverse proxy authentication cookie. <p>For more information, see “Configuring device single sign-on with a reverse proxy” on page 8-650.</p>

Table 8-57. Troubleshooting the Simple Data Sharing feature (continued). This table lists possible problems and actions to take to troubleshoot the Simple Data Sharing feature.

Problem	Actions to take
Unable to specify cookie or user certificate sharing.	You must first enable the MobileFirst Simple Data Sharing feature and specify a MobileFirst application family before you can enable device SSO or user certificate authentication sharing options. For more information, see “Enabling the Simple Data Sharing feature” on page 8-594.

Simple data sharing limitations and special considerations

Learn about the limitations and special considerations of the Simple Data Sharing feature.

Security considerations

Because this feature allows for data access among a group of applications, special care must be taken to protect access to the device from unauthorized users. Consider the following security aspects:

Device Lock

For added security, ensure that devices are secured by a device password, passcode, or pin, so that access to the device is secured if the device is lost or stolen.

Jailbreak Detection

Consider using a mobile device management solution to ensure that devices in your enterprise are not jailbroken or rooted.

Encryption

Consider encrypting any tokens before you share them for added security. For more information, see “JSONStore security utilities” on page 8-467.

Size limit

This feature is meant for sharing of small strings, such as passwords or cookies. Be cognizant not to abuse this feature, as there are performance implications with such attempts to encrypt and decrypt or read and write any large values of data.

Maintenance challenges

Android developers must be aware that enabling this feature, or changing the application family value, results in their inability to upgrade existing applications that were installed under a different family name. For security reasons, Android requires earlier applications to be uninstalled before applications under a new family name can be installed.

Mobile device authentication

You can require mobile devices to authenticate themselves. Device identity is used in several places within IBM MobileFirst Platform Foundation. You can use provisioning, which is the process of obtaining a security certificate. There are three modes of the provisioning process.

Unique device ID

The unique device ID is used by IBM MobileFirst Platform Foundation for device ID-related features, such as security, device SSO, reports, and push notifications.

On iOS

- To calculate the unique device ID, a globally unique ID (GUID) is used that is generated during device authentication process.
- The unique device ID can be unique either to the application or to all applications from the same vendor.
- The unique device ID is stored in the device keychain.

On Android

- To calculate the unique device ID, device properties are used, such as the WiFi Mac address. This mechanism guarantees the uniqueness of the device ID, and make the process more secure by generating the device ID at the start of each application.
- The unique device ID can be unique either to the application or to all applications from the same vendor.
- The unique device ID is stored in the application keystore, which is a file in the application sandbox folder.

On BlackBerry

- To calculate the unique device ID, the ID that is provided by the operating system is used.
- The unique device ID is global to the device.

On Windows Phone Silverlight 8

- The publisher host ID is used as a unique device ID. The host ID is unique per device and per publisher, which means that no two publishers will receive the same value for the same device.

On Windows 8 Universal

- The MAC address is used as a unique device ID.

Note: The availability of the unique device ID depends on the operating system of the device, and on the application vendor. A vendor who provides multiple applications that can be installed on the same device might then choose whether to require provisioning for each individual application or for a group of applications. If several applications are from the same vendor, they can have the same unique device ID. If these applications are from different vendors, they have different unique device IDs.

To access the unique device ID on the device and on the MobileFirst back-end server, some security controls are performed. The device ID is not a secret data and can be passed to the server in one of the two following ways:

- As is, for a non-secure device authentication.
- Accompanied with credentials, for a secure device authentication. In that case, the device ID is digitally signed with a X509 certificate. This certificate results of the provisioning process that takes place the first time the application runs on the device.

The unique device ID is sent along with various event types to MobileFirst Operational Analytics (see “Operational analytics” on page 14-9). For more information on these event types, see “Event types” on page 14-14.

The unique device ID is also stored in the raw data reports (deprecated) that are generated by IBM MobileFirst Platform Foundation. There are no special access controls available on these reports, as the unique device ID is not considered sensitive data. For more information about raw data reports, see "Using raw data reports" on page 14-103.

For more information about mobile device provisioning, see the Device provisioning concepts tutorial on the Getting Started page of the Developer Center.

Scope of mobile device authentication

In addition to requiring users to authenticate before they access certain resources, you can also require mobile devices to authenticate before apps installed on them can access the MobileFirst Server.

Device and application authentication is a process that allows making claims of type "this is application A installed on device D".

Device and application authentication is relevant only for applications that are installed on mobile devices.

Mobile device provisioning

When a MobileFirst application first runs on a mobile device, it creates a pair of PKI-based keys. It then uses the keys to sign the public characteristics of the device and application, and sends them to the MobileFirst Server for authentication purposes.

A key pair alone is not sufficient to sign these public characteristics because any app can create a key pair. In order for a key pair to be trusted, it must be signed by an external trusted authority to create a certificate. The process of obtaining such a certificate is called *provisioning*.

When a certificate is obtained, the app can then store the key pair in the device keystore, access to which is protected by the operating system.

The provisioning process has three modes:

No provisioning

In this mode, the provisioning process does not happen. This mode is usually suitable during the development cycle, to temporarily disable the provisioning for the application. Technically, the client application does not trigger the provisioning process, and the server does not verify the client certificate.

Auto-provisioning

In this mode, the MobileFirst Server automatically issues a certificate for the device and application data that is provided by the client application. Use this option only when the MobileFirst application authenticity features are enabled.

Custom provisioning

In this mode, the MobileFirst Server is augmented with custom logic that controls the device and application provisioning process. This logic can involve integration with an external system, such as a mobile device

manager (MDM). The external system can issue the client certificate based on an activation code that is obtained from the app, or can instruct the MobileFirst Server to do so.

Note: Auto-provisioning and custom provisioning are supported only on Android, iOS, Windows 8 Universal, and Windows Phone Silverlight 8.

Device auto-provisioning

Device auto-provisioning has three aspects:

- Provisioning granularity: the scope of the provisioned entity.
- Pre required login: the realms that a client must be authenticated with before it can get permission to perform provisioning.
- CA Certificate: the parent certificate, which issues device certificates for the provisioning process.

The default behavior is as follows:

- Provisioning granularity: a single application.
- Pre required login: a login is required to the authentication realm, if any, defined for the current security test.
- CA Certificate: a MobileFirst CA Certificate, which is embedded into the platform.

Whether it is obtained by an auto-provisioning or custom provisioning process, the certificate is stored by the client app on the device, and used for signing the payload sent to the MobileFirst Server. The MobileFirst Server validates the client certificate, regardless of how it is obtained.

The server sends a request for ID, which the client responds to with a certificate-signed payload. If the client does not have the certificate, then a request is sent to the MobileFirst Server automatically to get a certificate, and after that is done, the client automatically sends the signed payload.

After the server sends the ok response, the original request is sent automatically.

Granularity of provisioning

The key pair that is used to sign the device and app properties can represent a single application, a group of applications, or an entire device. Windows 8 Universal and Windows Phone Silverlight 8 support only single application level granularity. For example:

Single application

A company's provisioning process requires separate activation for each application that is installed on the device. In this case, the application is the provisionable entity, and each application must generate its own key pair.

Group of applications

A company develops different groups of applications to employees in different geographical regions. If the activation is required per region, the key pair would represent the group of applications that belong to that region. All applications from the same group use the same key pair for their signatures.

Entire device

In this case, the key pair represents the whole device. All the applications from the same vendor that are installed on that device use the same key pair.

Authenticators and login modules

An authenticator collects client credentials. A login module validates them.

An *authenticator* is a server component that is used to collect credentials from the client. The authenticator passes the credentials to a *login module*, which validates them and builds a client identity object. Both authenticators and login modules are components of the application's *realm*.

An authenticator can, for example, collect any type of information accessible from an HTTP request object, such as cookies or any data in headers or the body of the request.

A login module can validate the credentials that are passed to it in various ways. For example:

- Using a web service
- Looking up the client ID in a database
- Using an LTPA token

A number of predefined authenticators and login modules are supplied. If these do not meet your needs, you can write your own in Java.

The authentication configuration file

All types of authentication component are configured in the authentication configuration file.

Authentication components, security tests, realms, login modules, and authenticators are all configured in the `authenticationConfig.xml` authentication configuration file, which is in the `/server/conf` directory of your MobileFirst project. A web security test or mobile security test must contain a `<testUser>` element that specifies the realm name. The definition of a realm includes the class name of an authenticator, and a reference to a login module, and refers to a collection of resource managers that recognizes a common set of user credentials and authorizations. Authenticators are the entities that authenticate clients. Authenticators collect client information, and then use login modules to verify this information.

Table 8-58. Predefined realms: properties of the <test realm> element.

Realm reference	Login module reference	Description
wl_anonymousUserRealm	WeakDummy	<p>This realm is the default user realm. As having a user identity is mandatory for a user to use IBM MobileFirst Platform Foundation properly, use this realm if you do not require any special identification of users. This realm gives the user a random unique user ID to be used for various features in the server, such as reports and audit, identification of access to back-end systems, and push notification. This realm is transparent, that is, it does not require any user interaction.</p> <p>The wl_anonymousUserRealm realm is a persistent cookie and is used by MobileFirst Server to differentiate between different application instances. MobileFirst Server looks for a WL_PERSISTENT_COOKIE cookie in each request. In case none is found, it will generate a GUID and send it back to the client in a Set-Cookie header with a one-year expiration date.</p>
wl_antiXSRFRealm	WLANtiXSRFLoginModule	<p>This realm is used to avoid cross-site request forgery attacks. When a new session is initiated, the first request to MobileFirst Server gets an HTTP 401 response that contains the WL-Instance-Id token. The MobileFirst framework extracts this token and uses it as a header on all subsequent requests. If this header is not present in these subsequent requests, HTTP 401 is returned again. This security mechanism makes sure that all subsequent requests are coming from the same source as the initial one.</p>

Table 8-58. Predefined realms: properties of the <test realm> element. (continued)

Realm reference	Login module reference	Description
w1_authenticityRealm	w1_authenticityLoginModule	This realm is used to verify that application is authentic and it was not modified by a third party. The realm is applicable to Android, iOS, Windows Phone Silverlight 8, and Windows 8 Universal. The basic authenticity check is based on certificates that are used to sign applications. Extended application authenticity is based on the application binary file. This functionality is only available on the IBM-supported editions of IBM MobileFirst Platform Foundation, and is supported by Android, iOS, Windows 8 Universal, and Windows Phone Silverlight 8 only. You cannot enable extended authenticity if you use the internal MobileFirst Development Server that is embedded in MobileFirst Studio.
w1_deviceAutoProvisioningRealm	w1_deviceAutoProvisioningLoginModule	Description of this parameter is the same as for w1_deviceNoProvisioningRealm , but the obtained device identity is automatically provisioned by the MobileFirst Server. This realm must be used with w1_authenticityRealm .
w1_deviceNoProvisioningRealm	w1_deviceNoProvisioningLoginModule	Default <i>device identity</i> realm. Device identity is similar to user identity, but it is provided by the device itself. Device identity is relevant for hybrid and native smartphone environments only. The device identity is a must for functionality such as push notifications, and reports. This parameter means that the obtained device identity is used as is, without provisioning.

Table 8-58. Predefined realms: properties of the <test realm> element. (continued)

Realm reference	Login module reference	Description
w1_directUpdateRealm	WLDirectUpdateNullLoginModule	<p>This realm is used to enable the direct update feature. The direct update feature allows for updating of application web resources (not native code) on client devices without the need for users to explicitly download and install the new version. This realm is useful when a fix or an enhancement is done to the web resources of the application and you do not want to start a full release cycle for it. It can be configured to test for updates once per session, per each request, or disabled. For more information about direct update, see “Configuring and customizing direct update” on page 8-378.</p>

Table 8-58. Predefined realms: properties of the <test realm> element. (continued)

Realm reference	Login module reference	Description
wl_remoteDisableRealm	WLRemoteDisableNullLoginModule	This realm is used to block applications with specific application environments or versions from accessing resources on the server, or to notify clients with some mandatory message that is related to the server. This realm is typically used when a new application version is released and you no longer want the applications with the older versions to connect to the server. In this case, for example, you want to give directions to the clients on how to obtain the new version of the application with a link to its market download page. Another typical use of this realm is when you find a problem with an application security and you want to immediately block access from this application to sensitive data until the problem is fixed. You can configure the contents of the block or notification message and give a link to more information or the new version. For more information about remote disable, see “Remotely disabling application connectivity” on page 13-3.

MobileFirst static resources (other than Application Center) such as the MobileFirst Operations Console are also configured in the authentication configuration file, in the <resource> element.

The configuration file has the following structure:

```
<?xml version="1.0" encoding="UTF-8"?>
<tns:loginConfiguration xmlns:tns="http://www.worklight.com/auth/config" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <staticResources>
    <resource>...</resource>
    <resource>...</resource>
  </staticResources>
  <securityTests>
    <customSecurityTest>...</customSecurityTest>
    <customSecurityTest>...</customSecurityTest>
  </securityTests>
  <realms>
    <realm>...</realm>
    <realm>...</realm>
  </realms>
</loginModules>
```

```

<loginModule>...</loginModule>
<loginModule>...</loginModule>
</loginModules>
</tns:loginConfiguration>

```

Configuring device auto provisioning

You can change the default behavior of device auto provisioning with regards to granularity of the provisioning, and pre-required realms for provisioning. You can also change the CA certificate (root certificate) that is used to issue certificates for provisioned devices.

Procedure

- To change the default behavior of provisioning granularity and pre-required realms, define a new realm for device provisioning and add the following `<realm>` element to the `<realms>` element in the `authenticationConfig.xml` file. Then, use it in your security test of choice:

```

<realm name="wl_myProvisioningRealm"
  loginModule="WLDeviceAutoProvisioningLoginModule">
  <className>com.worklight.core.auth.ext.DeviceAutoProvisioningAuthenticator</className>
  <parameter name="provisioned-entity" value="application" />
  <parameter name="pre-required-realms" value="wl_authenticityRealm" />
</realm>

```

where *provisioned-entity* can have one of the following values:

- application
- device
- group:<group-name>, where *group-name* is the name of the provisioning application group

and *pre-required-realms* is a comma-separated list of realm names that are required to be successfully logged in to before provisioning is allowed to begin.

Note: All applications that are part of the same group must be signed by the same signing credentials and (on iOS) share the same `bundleID` prefix.

- To use a CA certificate other than the default MobileFirst CA certificate, configure the following properties.

wl.ca.keystore.path

The path to the keystore, relative to the server folder in the MobileFirst Project, for example: `conf/default.keystore`.

wl.ca.keystore.type

The type of the keystore file. Valid values are `jks` or `pkcs12`.

wl.ca.keystore.password

The password to the keystore file, for example: `worklight`.

wl.ca.key.alias

The alias of the entry where the private key and certificate are stored, in the keystore, for example: `keypair1`.

wl.ca.key.alias.password

The password to the alias in the keystore for example: `worklight`.

For information about how to specify MobileFirst configuration properties, see “Configuration of MobileFirst applications on the server” on page 12-50

- To enable multiple applications to share the same certificate, define a **sharedUserId** attribute (for Android) or a **bundleId** attribute (for iOS) in the

application descriptor. For further information about defining these attributes, see “The application descriptor” on page 8-50.

Configuring and implementing custom device provisioning

Custom device provisioning is an extension of auto device provisioning. The main difference between auto and custom provisioning is that you can perform custom validation of the certificate signing request (CSR) during the provisioning process and custom validation of the certificate during each device authentication process.

The custom device provisioning must be implemented in the JavaScript code of an adapter. Specify the names of the `validate-csr` and `validate-certificate` functions in the `authenticationConfig.xml` file as realm and login module parameters:

```
<securityTests>
  <mobileSecurityTest name="CustomDeviceProvisioningSecurityTest">
    <testAppAuthenticity/>
    <testDeviceId provisioningType="custom" realm="CustomDeviceProvisioningRealm"/>
  </mobileSecurityTest>
</securityTests>

<realms>
  <realm name="CustomDeviceProvisioningRealm" loginModule="CustomDeviceProvisioningLoginModule">
    <className>com.worklight.core.auth.ext.DeviceAutoProvisioningAuthenticator</className>
    <parameter name="validate-csr-function" value="ProvisioningAdapter.validateCSR"/>
  </realm>
</realms>

<loginModules>
  <loginModule name="CustomDeviceProvisioningLoginModule">
    <className>com.worklight.core.auth.ext.DeviceAutoProvisioningLoginModule</className>
    <parameter name="validate-certificate-function" value="ProvisioningAdapter.validateCertificate"/>
  </loginModule>
</loginModules>
```

The `validate-csr-function` checks that the certificate signing request (CSR) sent by the client is complete and contains the correct information that is needed for the certification of the device. This logic might also validate some properties of CSR against internal or external services / directories.

The `validate-certificate-function` verifies that the certificate was issued with the correct certificate authority (CA). The logic might also verify that the certificate contains all the necessary data about the device for this custom device authentication realm.

For more information about how to implement these functions, see the Custom device provisioning tutorial on the Getting Started page.

It is important to understand the concept of mobile device authentication and auto provisioning. For more information about mobile device authentication, see “Mobile device authentication” on page 8-599.

With custom device provisioning, you can also implement custom variations of the CSR during the initial provisioning flow and of the certificate at each application start.

You must configure the server and the client for custom device provisioning.

Implementing server-side components for custom device provisioning:

You can implement server-side components for custom device provisioning.

About this task

To implement server-side components for custom device provisioning, complete the following steps.

Procedure

1. Create an adapter and name it ProvisioningAdapter.
2. Add two functions with the following signatures to the adapter's JavaScript file:
 - The `validateCSR(clientDN, csrContent)` function is called only during initial device provisioning. The function is used to check whether the device is authorized to be provisioned. After the device is provisioned, this function is not called again.
 - The `validateCertificate(certificate, customAttributes)` function is called each time that the mobile application establishes a new session with the MobileFirst Server. The function is used to validate that the certificate that the application or device possesses is still valid and that the application or device is allowed to communicate with the MobileFirst Server.

Note: These functions are called internally by the MobileFirst authentication framework. Do not declare them in the adapter's XML file.

3. Configure the `authenticationConfig.xml` file.
 - a. Add a realm and name it `CustomDeviceProvisioningRealm` to the `authenticationConfig.xml` file.
 - Use `CustomDeviceProvisioningLoginModule` for the `loginModule`.
 - Use the auto provisioning authenticator `className` parameter.
 - Add a `validate-csr-function` parameter.
 - The value of this parameter points to an adapter function that validates the certificate signing request (CSR).

```
<realms>
  <realm name="CustomDeviceProvisioningRealm"
    loginModule="CustomDeviceProvisioningLoginModule">
    <className>com.worklight.core.auth.ext.DeviceAutoProvisioningAuthenticator</className>
    <parameter name="validate-csr-function"
      value="ProvisioningAdapter.validateCSR" />
  </realm>
</realms>
```

- b. Add the `loginModule` named `CustomDeviceProvisioningLoginModule`.
 - Use the auto provisioning login module `className` parameter.
 - Add a `validate-certificate-function` parameter.
 - The value of this parameter points to an adapter function that validates the certificate.

```
<loginModules>
  <loginModule name="CustomDeviceProvisioningModule">
    <className>com.worklight.core.auth.ext.DeviceAutoProvisioningLoginModule</classname>
    <parameter name="validate-certificate-function"
      value="ProvisioningAdapter.validateCertificate" />
  </loginModule>
</loginModules>
```

- c. Create a `securityTest` named `mobileSecurityTest`.
 - Add a mandatory `<testAppAuthenticity />` test.

- Add a mandatory <testDeviceId /> test.
- Specify provisioningType="custom".
- Specify realm="CustomDeviceProvisioningRealm".

```
<securityTests>
  <mobileSecurityTest name="CustomDeviceProvisioningSecurityTest">
    <testAppAuthenticity />
    <testDeviceId provisioningType="custom" realm="CustomDeviceProvisioningRealm" />
  </mobileSecurityTest>
</securityTests>
```

Results

You implemented server-side components for custom device provisioning.

Example

validateCSR function

The following example shows the validateCSR function:

```
function validateCSR(clientDN, csrContent) {
  WL.Logger.log("validateCSR :: clientDN :: " + JSON.stringify(clientDN));
  WL.Logger.log("validateCSR :: csrContent :: " + JSON.stringify(csrContent));

  var activationCode = csrContent.activationCode;

  // This is a place to perform validation of csrContent and update clientDN if required.
  // You can do it using adapter backend connectivity
  if (activationCode == "worklight") {
    response = {
      isSuccessful: true,
      clientDN: clientDN + ",CN=someCustomData",
      attributes: {
        customAttribute: "some-custom-attribute"
      }
    };
  } else {
    response = {
      isSuccessful: false,
      errors: ["Invalid activation code"]
    };
  }

  return response;
}
```

validateCertificate function

The following example shows the validateCertificate function:

```
function validateCertificate(certificate, customAttributes) {
  WL.Logger.log("validateCertificate :: certificate :: " + JSON.stringify(certificate));
  WL.Logger.log("validateCertificate :: customAttributes :: " + JSON.stringify(customAttributes));

  // Additional custom certificate validations can be performed here.

  return {
    isSuccessful: true
  };
}
```

What to do next

You can implement client-side components for custom device provisioning. For more information about implementing client-side components, see “Implementing client-side components for custom device provisioning” on page 8-612. For more information about custom device provisioning, see tutorial on the Getting Started page.

Implementing client-side components for custom device provisioning:

You can implement client-side components for custom device provisioning.

The following prerequisites are required for device provisioning:

- MobileFirst Studio and MobileFirst Server from IBM MobileFirst Platform Foundation.
- Android applications must be built for production and signed by a certificate other than the included debugging certificate.
- In the Application Center console, application authentication must be set to enabled, blocking.

The included MobileFirst Development Server can be used for device provisioning.

The following sections describe the implementation of the client-side components in hybrid, native Android, and native iOS applications.

Implementing client-side components for hybrid applications:

You can implement client-side components for custom device provisioning in the hybrid applications.

Before you begin

For more information about the prerequisites, see “Implementing client-side components for custom device provisioning.”

About this task

To implement client-side components for custom device provisioning, complete the following steps.

Procedure

1. Create an application.
2. Add an iPhone, iPad, Android, or Windows Phone Silverlight 8 environment to the application.
3. Configure the application for the Application Authenticity test.

Note: The authenticity test does not work if you use the internal MobileFirst Development Server that is embedded in MobileFirst Studio. For more information about application authenticity, see “MobileFirst application authenticity overview” on page 8-564.

4. Update the application HTML file.

```
<body id="content" style="display: none;">
  <div id="AppBody">
    <div class="header">
      <h1>CustomProvisioningApp</h1>
    </div>
    <div id="wrapper">
      Device authentication with custom device provisioning was not complete
    </div>
    <button id="connectToServerButton">
      Connect to MobileFirst Server
    </button>
  </div>
  <div id="ProvBody" style="display: none;">
    <div id="provisioningError"></div>
```

```

        <input id="submitProvCodeButton">Send</button>
    </div>
    ...
</body>

```

5. Add a listener to connectToServerButton.
6. Optional: Use the WL.Client.connect API to connect to the MobileFirst Server.

```

function wlCommonInit() {
    $("#connectToServerButton").click(function(){
        WL.Client.connect();
    });
}

```

7. For the WL.Client.connect function to trigger authentication, specify the MobileFirst Server instance as the protected resource by adding a custom security test or mobile security test in the application descriptor.

```
<iphone securityTest="ADPSecurityTest" version="1.0">
```

or

```
<ipad securityTest="ADPSecurityTest" version="1.0">
```

or

```
<android securityTest="ADPSecurityTest" version="1.0">
```

or

```
<windowsPhone8 securityTest="ADPSecurityTest" version="1.0">
```

8. Add a CustomDeviceProvisioningRealmChallengeHandler.js file and reference it from the main HTML file.
9. Implement the following methods that are required by the device provisioning challenge handler:

- The handler.createCustomCsr(challenge) method is responsible for returning custom properties that are added to the certificate signing request (CSR) . Add a custom **activationCode** property, which is used in the adapter's validateCSR function.

Note: This method is asynchronous to allow collecting custom properties through native code or separate flow.

- The handler.processSuccess(identity) method is called when certificate validation is successfully completed by the validateCertificate adapter function.
- The handler.handleFailure() method is called when certificate validation fails.

10. Implement the device provisioning challenge handler.

```

var customDevProvChallengeHandler =
    WL.Client.createProvisioningChallengeHandler("CustomDeviceProvisioningRealm");

customDevProvChallengeHandler.createCustomCsr = function(challenge) {
    WL.Logger.debug("createCustomCsr :: " + JSON.stringify(challenge));

    $("#AppBody").hide();
    $("#ProvBody").show();
    $("#provisioningCode").val("");

    if (challenge.error) {
        $("#provisioningError").html(new Date() + " " + challenge.error);
    } else {
        $("#provisioningError").html(new Date() + " Enter activation code.");
    }
}

$("#submitProvCodeButton").click(function() {

```

```

        var customCsrProperties = {
            activationCode: $("#provisioningCode").val()
        };
        customDevProvChallengeHandler.submitCustomCsr(customCsrProperties, challenge);
    });
};

customDevProvChallengeHandler.processSuccess = function(identity) {
    WL.Logger.debug("processSuccess :: " + JSON.stringify(identity));
    $("#connectToServerButton").hide();
    $("#AppBody").show();
    $("#ProvBody").hide();
    $("#wrapper").text("Device authentication with custom device provisioning " +
        "was successfully completed");
};

customDevProvChallengeHandler.handleFailure = function() {
    WL.Logger.debug("handleFailure");
    $("#AppBody").show();
    $("#ProvBody").hide();
    $("#wrapper").text("Server has rejected your device. You must reinstall the
        application and perform device provisioning again.");
};
};

```

Results

You implemented client-side components for custom device provisioning.

What to do next

You can implement server-side components for custom device provisioning. For more information about implementing server-side components, see “Implementing server-side components for custom device provisioning” on page 8-610. For more information about custom device provisioning, see the tutorials on the Getting Started page.

Implementing client-side components for native Android:

You can implement client-side components for custom device provisioning in native Android.

Before you begin

For more information about the prerequisites, see “Implementing client-side components for custom device provisioning” on page 8-612.

About this task

To implement client-side components for custom device provisioning, complete the following steps.

Procedure

1. Create a MobileFirst native API application for Android.
2. Configure the application for the Application Authenticity test.

Note: The authenticity test does not work if you use the internal MobileFirst Development Server that is embedded in MobileFirst Studio. For more information about application authenticity, see “MobileFirst application authenticity overview” on page 8-564.

3. Create an Android native application and use `WLClient.getInstance().connect()` to connect to server.

4. For the `WLClient.getInstance().connect()` function to trigger authentication, specify the MobileFirst native API application as a protected resource by adding a custom security test or mobile security test in the application descriptor.

```
<nativeAndroidApp securityTest="MySecurityTest" version="1.0">
```
5. Add a new class `CustomDeviceProvisioningRealmChallengeHandler`, and register it in the main activity class by using `WLClient.getInstance().registerChallengeHandler(new CustomDeviceProvisioningRealmChallengeHandler('CustomDeviceProvisioningRealm'))`.
6. Implement the following methods that are required by the device provisioning challenge handler:
 - The `createCustomCsr(challenge)` method is responsible for returning custom properties that are added to the certificate signing request (CSR). Add a custom **activationCode** property, which is used in the adapter's `validateCSR` function.
 - The `handleSuccess(identity)` method is called when certificate validation is successfully completed by the `validateCertificate` adapter function.
 - The `handleFailure()` method is called when certificate validation fails. You must call `clearDeviceProvisioningCertificate()` from this method to delete the stored certificate on the device.

Results

You implemented client-side components for custom device provisioning in native Android.

Example

The following sample shows the implementation of the challenge handler for custom device provisioning.

```
public class CustomDeviceProvisioningRealmChallengeHandler extends BaseProvisioningChallengeHandler {
    public CustomDeviceProvisioningRealmChallengeHandler(String realm) {
        super(realm);
    }

    @Override
    protected void createCustomCsr(JSONObject challenge) {
        JSONObject customCsrProperties= new JSONObject();
        try {
            customCsrProperties.put(activationCode, activationCode.getText());
        } catch (JSONException e) {
        }
    }

    submitCustomCsr(customCsrProperties, challenge);
}

@Override
public void handleSuccess(JSONObject identity) {
    System.out.println("Device authentication with custom device provisioning was successfully completed");
}

@Override
public void handleFailure(JSONObject identity) {
    clearDeviceProvisioningCertificate();
    System.out.println("Server has rejected your device. You must reinstall the application
and perform device provisioning again.");
}
}
```

What to do next

You can implement server-side components for custom device provisioning. For more information about implementing server-side components, see “Implementing server-side components for custom device provisioning” on page 8-610. For more information about custom device provisioning, see the tutorials on the Getting Started page.

Implementing client-side components for native iOS:

You can implement client-side components for custom device provisioning in native iOS.

Before you begin

For more information about the prerequisites, see “Implementing client-side components for custom device provisioning” on page 8-612.

About this task

To implement client-side components for custom device provisioning, complete the following steps.

Procedure

1. Create a MobileFirst native API application for iOS.
2. Configure the application for the Application Authenticity test.

Note: The authenticity test does not work if you use the internal MobileFirst Development Server that is embedded in MobileFirst Studio. For more information about application authenticity, see “MobileFirst application authenticity overview” on page 8-564.

3. Create an iOS native application and use the `wlConnectWithDelegate` function to connect to the server.
4. For the `wlConnectWithDelegate` function to trigger authentication, specify the MobileFirst native API application as a protected resource by adding a custom security test or mobile security test in the application descriptor.

```
<nativeIOSApp securityTest="MySecurityTest" version="1.0">
```
5. Add a new class `CustomChallengeHandler` and register it in the main by using `[[WLCClient sharedInstance] registerChallengeHandler:[customChallengeHandler initWithRealm:@"wl_myCustomProvisioningRealm"]]`.
6. Implement the following methods, which are required by the challenge handler for device provisioning.

createCustomCsr(challenge)

This method is responsible for returning custom properties that are added to the certificate signing request (CSR). Add a custom **activationCode** property, which is used in the adapter’s `validateCSR` function.

handleSuccess(identity)

This method is called when certificate validation is successfully completed by the `validateCertificate` adapter function.

handleFailure()

This method is called when certificate validation fails. You must call `clearDeviceProvisioningCertificate()` from this method to delete the stored certificate on the device.

Here is a sample implementation of a challenge handler for custom device provisioning:

```
@interface CustomChallengeHandler : BaseProvisioningChallengeHandler <WLDelegate>{
@private
    ViewController *vc;
}
- (id)initWithController: (ViewController *)mainView;
- (void) createCustomCsr : (NSDictionary *) challenge;
@property (nonatomic, strong)NSString *passcode;
@end

@implementation CustomChallengeHandler
- (id)initWithController: (ViewController *) mainView{
    if ( self = [super init] )
    {
        vc = mainView;
    }
    return self;
}
-(void) createCustomCsr : (NSDictionary *) challenge {
    [vc updateMessage:@"\nCreating custom Csrâ€¦"];
    [vc updateMessage:[NSString stringWithFormat:@"\t Passcode :: %@", self.passcode]

    NSMutableDictionary* answer =[[NSMutableDictionary alloc] init];
    [answer setValue:self.passcode forKey:@"activationCode"];
    [self submitCsr:answer :challenge];
}
-(void)onSuccess:(WLResponse *)response {
    [vc updateMessage:@"Device authentication with custom device provisioning was successfully completed"];
    [vc updateMessage:response.description];
}
-(void)onFailure:(WLFailResponse *)response{
    [vc updateMessage:@"Server has rejected your device. You must reinstall the application and perform device provisioning again."];
    [vc updateMessage:response.description];
}
@end
```

Results

You have implemented client-side components for custom device provisioning in native iOS.

What to do next

You can implement server-side components for custom device provisioning. For more information, see “Implementing server-side components for custom device provisioning” on page 8-610. For more information about custom device provisioning, see the tutorial on the Getting Started page.

Configuring login modules

Login modules are defined in `<loginModule>` elements in the `authenticationConfig.xml` file.

The <loginModules> element contains a separate <loginModule> subelement for each login module.

The <loginModule> element has the following attributes:

Attribute	Description
expirationInSeconds	<p>Optional. Defines the expiration period of realms that use this login module. If not set, the server will use a default expiration period of 3600 seconds (one hour).</p> <p>Note that if the server is not running in session-independent mode, authentication to a login module is only valid within the same client session. In session-dependent mode only, you can use the special value "-1" that indicates that there is no set expiration period and the login remains valid until the end of the client session.</p> <p>For more information about session-independent mode, see "Session-independent mode" on page 8-324.</p>
name	Mandatory. The unique name by which realms reference the login module.
audit	<p>Optional. Defines whether login attempts that use the login module are logged in the audit log. The log file is <i>Worklight Project Name/server/log/audit/audit.log</i>.</p> <p>Valid values are:</p> <p>true Login and logout attempts are logged in the audit log.</p> <p>false Default. Login and logout attempts are not logged in the audit log.</p>

The MobileFirst security framework provides several built-in realms (for example, directUpdate and remoteDisable). In order to modify the default expiration period of these realms, open the `worklight.properties` file, uncomment the line corresponding to the realm, and change the expiration value. The following shows the relevant sections in `worklight.properties`:

```
#####
#   Expiration time for built-in realms
#####
# Use these properties to configure the expiration time (in seconds) for MobileFirst's built-in realms.
# When mfp.session.independent is false, a value of -1 means that a realm will remain authenticated
# until the session times out
wl.realm.expiration.directUpdate=3600
wl.realm.expiration.remoteDisable=300
wl.realm.expiration.deviceAutoProvisioning=3600
wl.realm.expiration.deviceNoProvisioning=3600
wl.realm.expiration antiXSRF=3600
wl.realm.expiration.authenticity=3600
wl.realm.expiration.anonymousUser=3600
```

Note: To avoid application-authenticity validation failures, use the same expiration periods for the application-authenticity and device-provisioning realms. The default expiration periods are identical, but if you customize the default period of the authenticity, deviceAutoProvisioning, or deviceNoProvisioning realms, set the same period also for the other two realms.

The <loginModule> element has the following subelements:

Element	Description
<className>	Mandatory. The class name of the login module. For details of the supported login modules, see the following topics.
<parameter>	Optional. An initialization property of the login module. The supported properties and their semantics depend on the login module class. This element can occur multiple times.

Important: Changes to realm configuration and login module configuration (excluding changes to the expiration period) are not applied immediately to clients that authenticated within the realm before the change. The changes will be applied only when the realm expires or when the client has logged out of the realm explicitly. Consider this behavior if you plan to use a long expiration period: in addition to the security implications, a long expiration period also limits the flexibility of making changes to the realm configuration.

Non-validating login module

The non-validating login module accepts any user name and password passed by the authenticator.

Class Name

com.worklight.core.auth.ext.NonValidatingLoginModule

Parameters

None

```
<loginModule name="dummy">
  <className> com.worklight.core.auth.ext.NonValidatingLoginModule </className>
</loginModule>
```

Single identity login module

The single identity login module is used to grant access to a protected resource to a single user, the identity of which is defined in the worklight.properties file. Use this module only for test purposes.

Class Name

com.worklight.core.auth.ext.SingleIdentityLoginModule

Parameters

None

Configuration

.The worklight.properties file must contain the following properties:

Key	Description
console.username	Name of the user who can access the protected resource.
console.password	Password of the user who can access the protected resource. The password can be encrypted as indicated in "Storing properties in encrypted format" on page 12-62.

Header login module

The Header login module is always used with the Header authenticator. It validates the request by looking for specific headers.

Class Name

com.worklight.core.auth.ext.HeaderLoginModule

Parameters

The Header login module has the following parameters:

Parameter	Description
user-name-header	Mandatory. The name of the header that contains the user name. If the request does not contain this header, the authentication fails.
display-name-header	Optional. The name of the header that contains the display name. If this parameter is not specified, the user name is used as the display name.

```
<loginModule name="HeaderLoginModule" audit="true">
  <className>com.worklight.core.auth.ext.HeaderLoginModule</className>
  <parameter name="user-name-header" value="userid"/>
  <parameter name="display-name-header" value="username"/>
</loginModule>
```

WASLTPAModule login module

The WASLTPAModule login module enables integration with WebSphere Application Server LTPA mechanisms.

Note: This login module is only supported on WebSphere Application Server. To avoid unnecessary errors when IBM MobileFirst Platform Foundation is run on other application servers, the login module is commented out in the default authenticationConfig.xml file that is created with an empty MobileFirst project. To use it, remove the comments first.

Class Name

com.worklight.core.auth.ext.WebSphereLoginModule

Parameters

The login module class has the following parameters:

Parameter	Description
cookie-domain	Optional. A String such as <code>example.com</code> , which specifies the domain in which the LTPA SSO cookie applies. If this parameter is not set, no domain attribute is set on the cookie. The single sign-on is then restricted to the application server host name and does not work with other hosts in the same domain.
httponly-cookie	Optional. A String with a value of either <code>true</code> or <code>false</code> , which specifies whether the cookie has the <code>HttpOnly</code> attribute set. This attribute helps to prevent cross-site scripting attacks.
cookie-name	Optional. A String that specifies the name of the LTPA SSO cookie. If this parameter is not set, the default cookie name is <code>LtpaToken</code> .
role	Optional. A String that specifies the Java EE role that the authenticated user must belong to for the login to be successful. If the parameter is not specified, no role checking is performed.

Note: When you specify a role parameter, the role must be defined in the MobileFirst web application deployment descriptor (`web.xml`). A set of users or groups must be mapped to that role by using the usual WebSphere Application Server mechanisms.

```
<loginModule name="WASLTPAModule">
  <className>com.worklight.core.auth.ext.WebSphereLoginModule</className>
  <parameter name="role" value="w1user"/>
  <parameter name="cookie-domain" value="example.com"/>
  <parameter name="httponly-cookie" value="true"/>
  <parameter name="cookie-name" value="LtpaToken2"/>
</loginModule>
```

LDAP login module

You can use the LDAP login module to authenticate users against lightweight directory access protocol (LDAP) servers such as Active Directory or OpenLDAP.

The class of the LDAP login module is `LdapLoginModule`.

Note: The LDAP login module implements a `UserNamePasswordLoginModule` interface. Therefore, you must use this module with an authenticator that implements a `UsernamePasswordAuthenticator` interface.

Class Name

`com.worklight.core.auth.ext.LdapLoginModule`

Validation methods

The value of the **validationType** configuration parameter of the LDAP login module determines the method that is used to validate the credentials that are received from the client, and authorize the client:

exists This method checks whether the provided client credentials exist in the LDAP server: the login module attempts to bind to the LDAP server with the provided credentials. If the binding is successful, the credentials validation succeeds. Otherwise, the validation fails.

searchPattern

This method performs a specified search in the LDAP server, as a condition for the credentials validation: the login module first attempts to bind to the LDAP server with the provided client credentials, as done in the `exists` validation method. If the binding succeeds, the login module searches the LDAP server using the search criteria that are set in the **ldapSearchFilterPattern** and **ldapSearchBase** parameters. If the search returns one or more entries, the credentials validation succeeds. Otherwise, the validation fails.

The following `LdapLoginModule` configuration parameters are mandatory when using the `searchPattern` validation method:

- **ldapSearchFilterPattern** - The search filter to use in the LDAP search. Use `{username}` in the pattern as a placeholder for the client-credentials user name.

Example

```
(&!(objectClass=user)(sAMAccountName={username}))(memberof=CN=goodgroup,OU=Groups,OU=Workgroups)
```

- **ldapSearchBase** - The search base for the LDAP search.

Example

```
dc=myserver,dc=com
```

searchUniqueUser

This method consists of two parts: search the LDAP server using the credentials of a system user; then validate the client credentials by binding to the server with a unique user name that is derived from the search result. The login module performs the following steps; each step depends on the success of the previous step:

1. Bind to the LDAP server with the system-user credentials that are provided in the **ldapSearchUserName** and **ldapSearchPassword** parameters.
2. Perform an LDAP search using the search criteria that are provided in the **ldapSearchFilterPattern** and **ldapSearchBase** parameters.
3. Verify that the LDAP search returns a single user entry. If the search returns no match or more than one match, the validation fails.
4. Bind to the LDAP server with the password that is provided in the client credentials, and the user name that is derived from the search result according to the provided parameters:
 - When the value of the **ldapUseAttributeToExtract** parameter is `false`, the user name is the name of the user entry that is returned by the LDAP search.
 - When the value of the **ldapUseAttributeToExtract** parameter is `true`, the user name is the value of the attribute that is defined in the **ldapAttributeToExtract** parameter, which the login module extracts from the user entry that is returned by the LDAP search.
5. Verify that the binding succeeds.

The following `LdapLoginModule` configuration parameters are mandatory when using the `searchUniqueUser` validation method:

- **ldapSearchUserName** - The user name that is used for searching the LDAP server.

Example

```
dc=worklight,dc=lan
```

- **ldapSearchPassword** - The password that is used for searching the LDAP server.

Example

abcd!234

- **ldapSearchFilterPattern** - The search filter to use in the LDAP search. Use {username} in the pattern as a placeholder for the client-credentials user name.

Example

```
(&!(objectClass=user)(SAMAccountName={username})(memberof=CN=goodgroup,OU=Groups,OU=...))
```

- **ldapSearchBase** - The search base for the LDAP search.

Example

```
dc=myserver,dc=com
```

- **ldapUseAttributeToExtract** - Indicates whether to use the **ldapAttributeToExtract** parameter. This parameter determines the user name that the login module uses to bind to the LDAP server:
 - false - Do not use the **ldapAttributeToExtract** parameter. When set, the login module binds to the server using the name of the user entry that is returned by the LDAP search.
 - true - Use the **ldapAttributeToExtract** parameter. When set, the login module binds to the server using the value of the **ldapAttributeToExtract** attribute, which it extracts from the user entry that is returned by the LDAP search.

The following LdapLoginModule configuration parameter is mandatory when the **ldapUseAttributeToExtract** parameter is set to true:

- **ldapAttributeToExtract** - The name of the attribute whose value should be extracted from the user entry that is returned by the LDAP search. The login module uses the extracted attribute value as the user name for binding to the LDAP server.

Example

```
distinguishedname
```

custom This method executes custom credentials-validation logic: the login module first attempts to bind to the LDAP server with the provided client credentials, as done in the exist validation method. If successful, the login module calls the doCustomValidation method of the doCustomValidationLdapLoginModule class, which performs custom validation.

Parameters

The LDAP login module has the following configuration parameters:

Parameter	Description	Sample values
ldapProviderUrl	Mandatory. The URL or IP address of the LDAP server.	ldap://10.0.1.2 ldaps://10.0.1.3
ldapTimeoutMs	Mandatory. The connection timeout for processing LDAP-server requests, in milliseconds.	2000
ldapSecurityAuthentication	The authentication method that is used by the LDAP server. Contact your LDAP administrator to obtain the correct value for your LDAP server. In most cases, the value is simple.	none simple strong

Parameter	Description	Sample values
validationType	<p>Mandatory. The method that is used by the login module to validate the credentials that are received from the client, and authorize the client. This parameter can be set to one of the following values; see “Validation methods” on page 8-621:</p> <ul style="list-style-type: none"> exists - Verifies that the provided client credentials exist in the server. See the exists validation method. searchPattern - Searches the LDAP server using the specified search filter. See the searchPattern validation method. searchUniqueUser - Searches the LDAP server with the specified system-user credentials, and binds to the server with a unique user name. See the searchUniqueUser validation method. custom - Executes custom credentials-validation logic. See the custom validation method. 	<p>exists</p> <p>searchPattern</p> <p>searchUniqueUser</p> <p>custom</p>
ldapSecurityPrincipalPattern	<p>Mandatory. A pattern that defines the LDAP security principal to send to the LDAP server. The pattern depends on the syntax that is required by the LDAP server. Use username in the pattern as a placeholder for the user name that is provided in the client credentials.</p>	<p>{username}</p> <p>{username}@myserver.com</p> <p>CN={username},DC=myserver,DC=com</p>
ldapSearchFilter	<p>Mandatory for the searchPattern and searchUniqueUser validation methods, and not applicable to the other validation methods. See the documentation of the applicable validation methods.</p>	<p>(sAMAccountName={username})</p> <p>(&(objectClass=user)(sAMAccountName=OU=MyCompany,DC=myserver,DC=com))</p>
ldapSearchBase	<p>Mandatory for the searchPattern and searchUniqueUser validation methods, and not applicable to the other validation methods. See the documentation of the applicable validation methods.</p>	<p>dc=myserver,dc=com</p>
ldapSearchUserName	<p>Mandatory for the searchUniqueUser validation method, and not applicable to the other validation methods. See the documentation of the searchUniqueUser method.</p>	<p>@code</p> <p>dc=worklight,dc=lan</p>
ldapSearchPassword	<p>Mandatory for the searchUniqueUser validation method, and not applicable to the other validation methods. See the documentation of the searchUniqueUser method.</p>	<p>abcd!234</p>
ldapUseAttributeExtract	<p>Mandatory for the searchUniqueUser validation method, and not applicable to the other validation methods. See the documentation of the searchUniqueUser method.</p>	<p>false</p>

Parameter	Description	Sample values
LdapAttributeToExtract	Directory for the searchUniqueUser validation method when LdapUseAttributeToExtract is true; not applicable to the other validation methods or when LdapUseAttributeToExtract is false. See the documentation of the searchUniqueUser method.	distinguishedname
LdapReferral	Optional. The referral-handling method to be used by the LDAP server. This parameter can be set to one of the following values: <ul style="list-style-type: none"> ignore - Ignore referrals. follow - Automatically follow referrals. throw - Throw a referral exception (ReferralException) for every referral. When no value is set for this parameter, the login module does not instruct the LDAP server on how to handle referrals.	ignore

Sample LDAP login module definition

```
<loginModule name="LDAPLoginModule">
  <className>com.worklight.core.auth.ext.LdapLoginModule</className>
  <parameter name="ldapProviderUrl" value="ldap://10.0.1.2"/>
  <parameter name="ldapTimeoutMs" value="2000"/>
  <parameter name="ldapSecurityAuthentication" value="simple"/>
  <parameter name="validationType" value="searchPattern"/>
  <parameter name="ldapSecurityPrincipalPattern" value="{username}@myserver.com"/>
  <parameter name="ldapSearchFilterPattern" value="(&!(objectClass=user)(sAMAccountName={username}))"/>
  <parameter name="ldapSearchBase" value="dc=myserver,dc=com"/>
  <parameter name="ldapReferral" value="ignore"/>
</loginModule>
```

Sample custom validation implementation

```
package mycode;
import javax.naming.ldap.LdapContext;
import com.worklight.core.auth.ext;

public class MyCustomLdapLoginModule extends LdapLoginModule {

  @Override
  public boolean doCustomValidation(LdapContext ldapCtx, String username, String password) {

    boolean success = true;

    // Do some custom validations here using ldapCtx, validationProperties, and username.
    // Return true in case of validation success, and false otherwise.

    return success;
  }
}
```

Note:

After you implement your custom extension of LdapLoginModule, use the name of your extension class as the <class> name in <loginModule> elements in your AuthenticationConfig.xml file. The following sample definition uses the custom mycode.MyCustomLdapLoginModule class:

```

<loginModule name="LDAPLoginModule">
  <className>myCode.MyCustomLdapLoginModule</className>
  <parameter name="ldapProviderUrl" value="ldap://10.0.1.2"/>
  <parameter name="ldapTimeoutMs" value="2000"/>
  <parameter name="ldapSecurityAuthentication" value="simple"/>
  <parameter name="validationType" value="custom"/>
  <parameter name="ldapSecurityPrincipalPattern" value="{username}@myserver.com"/>
  <parameter name="ldapReferral" value="ignore"/>
</loginModule>

```

Configuring authenticators and realms

Authenticators are defined within the realm that uses them.

Realms are defined in <realm> elements in the authenticationConfig.xml file. The <realms> element contains a separate <realm> subelement for each realm.

Modify realms by using the authentication configuration editor.

The <realm> element has the following attributes:

Table 8-59. The <realm> element attributes

Attribute	Description
name	Mandatory. The unique name by which the realm is referenced by the protected resources.
loginModule	Mandatory. The name of the login module that is used by the realm.

The <realm> element has the following subelements:

Table 8-60. The <realm> element subelements

Element	Description
<className>	Mandatory. The class name of the authenticator. For details of the supported authenticators, see the following topics.
<parameter>	Optional. Represents the name-value pairs that are passed to the authenticator upon instantiation. This element might be displayed multiple times.
<onLoginUrl>	Optional. Defines the path to which the client is forwarded upon successful login. If this element is not specified, then depending on the authenticator type, either the current request processing is continued, or a saved request is restored.

Implementing basic authenticators

You can implement basic authentication in mobile applications.

About this task

The basic authenticator implements basic HTTP authentication. Basic authentication is an industry-standard method that is used to collect user name and password information.

In accordance with standard basic authentication, MobileFirst Server sends an HTTP Not Authorized (401) response to the client, with the header:

WWW-Authenticate: Basic realm="realmName". When MobileFirst Server receives the response from the client, it extracts the base64-encoded credentials from the Authorization header of the request and decodes them. A login module validates the credentials that have been received.

Note: You can use basic authentication for web applications only, not for mobile applications.

The fully qualified Java class name for the basic authenticator is:
`com.worklight.core.auth.ext.BasicAuthenticator`

Parameters

The basic authenticator has the following parameter:

Parameter	Description
<code><basic-realm-name></code>	Mandatory. A string that is sent to the client as a realm name, and presented by the browser in the login dialog.

Flow

The following diagram illustrates the flow in the basic authentication process:

Figure 8-75. Basic authentication process

Procedure

1. Configure the `authenticationConfig.xml` file. For more information, see “The authentication configuration file” on page 8-603.
2. Code the server side.

Note: If you want to protect an adapter procedure with basic authentication, you must declare it in the adapter XML file. See the example in this page.

3. Associate the basic authenticator with a login module. MobileFirst Studio provides several predefined login modules. For an example, see Non-validating login module.
4. Code the client side, if necessary.

Example

The following example demonstrates how to implement a simple basic authentication mechanism. An adapter procedure is protected by a basic authenticator, and when the user attempts to invoke the procedure from the application, the browser displays a login dialog and the authentication process starts.

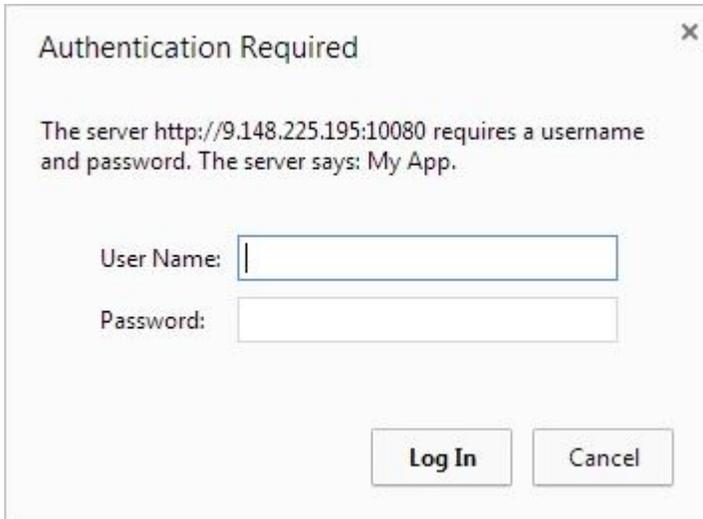

Figure 8-76. Login dialog for authentication

Configuration of the authenticationConfig.xml file

```

<securityTests>
  <customSecurityTest name="DummyAdapter-securityTest">
    <test isInternalUserID="true" realm="MyAppRealm"/>
  </customSecurityTest>
</securityTests>

<realms>
  <realm name="MyAppRealm" loginModule="StrongDummy">
    <className>com.worklight.core.auth.ext.BasicAuthenticator</className>
    <parameter name="basic-realm-name" value="My App"/>
  </realm>
</realms>

<loginModules>
  <loginModule name="StrongDummy">
    <className>com.worklight.core.auth.ext.NonValidatingLoginModule
    </className>
  </loginModule>
</loginModules>

```

Note:

The realm uses the StrongDummy login module, which is implemented by the class NonValidatingLoginModule (see Non-validating login module). "Non-validating" means that the user credentials are not checked against any list of user names and passwords. In other words: any combination of user name and password is valid.

Coding the server side

1. Create a MobileFirst adapter.
2. Add a procedure and protect it with the custom security test that you created earlier. This procedure's implementation can return some hard-coded value, for example:

```
<procedure name="getSecretData" securityTest="DummyAdapter-securityTest"/>
```

Coding the client side

1. Create a MobileFirst application.
2. Write a call to the adapter procedure that you added on the server side, for example:

```

var invocationData = {
    adapter: <adapterName>,
    procedure: "getSecretData",
    parameters: []
};

WL.Client.invokeProcedure(invocationData, {
    onSuccess : successCallback,
    onFailure : failCallback
});

```

Implementing form-based authenticators

You can authenticate users of mobile applications by using a login form.

About this task

In form-based authentication, if an application tries to access a protected resource, the server returns the HTML code of a login form. Even though a form of this kind is most suited to desktop and web environments (where you display the returned login form), you can also use form-based authentication in mobile applications.

The fully qualified Java class name of the form-based authenticator is: `com.worklight.core.auth.ext.FormBasedAuthenticator`.

This authenticator type presents a login form to the user. The login form must contain `j_username` and `j_password` fields, the `j_security_check` submit action, and the `POST` submit method.

A login module validates the credentials that are provided. If the login fails, the user is redirected to an error page.

Parameters

The form-based authenticator has the following parameters:

Parameter	Description
login-page	<p>Path to a user-defined login page template, relative to the web application context under the <code>conf</code> directory. A sample <code>login.html</code> template file is provided under this directory when you create a MobileFirst project.</p> <p>The authenticator renders the login page template with the error messages. To display the error message, use the placeholder <code>\${errorMessage}</code> in the login page template.</p>
auth-redirect	<p>Path to a user-defined login page (<code>html/jsp</code>) relative to the web application context. IBM MobileFirst Platform Foundation redirects to the page when the user credentials are needed.</p>

Both the **login-page** and **auth-redirect** parameters are optional, but if you decide to use them, use either one or the other. You cannot use them together. You can also use neither. In this case, IBM MobileFirst Platform Foundation uses its default login page template.

Flow

The following diagram illustrates the flow in the form-based authentication process:

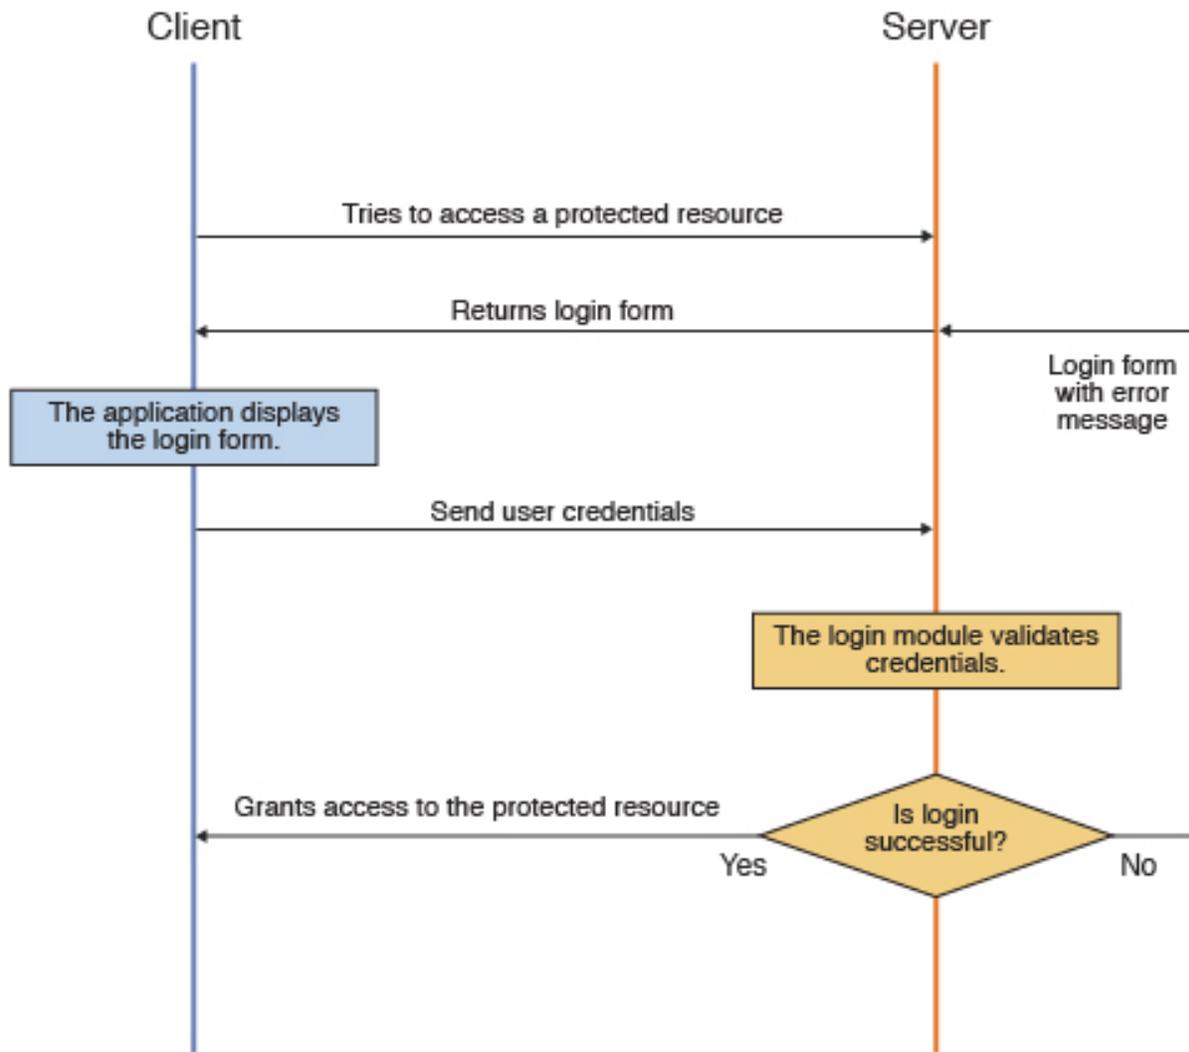

Figure 8-77. Form-based authentication process

Procedure

1. Configure the authenticationConfig.xml file. For more information, see "The authentication configuration file" on page 8-603.
2. Code the server side. To work, the form-based authenticator must be associated with a login module. MobileFirst Studio provides several predefined login modules. For an example, see Non-validating login module.

Note: If you want to protect an adapter procedure with form-based authentication, you must declare it in the adapter XML file. See the example in this page.

3. Code the client side.

You must declare a challenge handler in the application to handle challenges from the form-based configured realm. The following sample shows one way to implement a challenge handler class:

```
var sampleAppRealmChallengeHandler = WL.Client.createChallengeHandler("SampleAppRealm");
```

The challenge handler must implement the following functions:

- `isCustomResponse`: this function is called each time that a response is received from the server. It is used to detect whether the response contains data that is related to this challenge handler. It must return either `true` or `false`. Here is a simple example:

```
sampleAppRealmChallengeHandler.isCustomResponse = function(response) {
    return false;
};
```

- `handleChallenge`: this function is used to perform required actions, such as hide application screen and show login screen. `handleChallenge` is called by the framework, if `isCustomResponse` returns `true`. Here is a simple implementation, as an example:

```
sampleAppRealmChallengeHandler.handleChallenge = function(response) {
};
```

The challenge handler can also optionally implement the following, additional functions:

- `submitLoginForm`: this function sends the collected credentials to a specific URL. You can also specify request parameters, headers, and callback.
- `submitSuccess`: this function notifies the MobileFirst framework that the authentication finished successfully. The MobileFirst framework then automatically issues the original request that triggered the authentication.
- `submitFailure`: this function notifies the MobileFirst framework that the authentication process failed to finish. The MobileFirst framework then disposes of the original request that triggered the authentication.

Example

The following example demonstrates how to implement a simple form-based authentication mechanism that is based on a user name and a password. In the example, an adapter procedure is protected by a form-based authenticator, and when the user attempts to call the procedure from the application, the login form is displayed and the authentication process starts.

Configuration of the `authenticationConfig.xml` file

```
<securityTests>
    <customSecurityTest name="DummyAdapter-securityTest">
        <test isInternalUserID="true" realm="SampleAppRealm"/>
    </customSecurityTest>
</securityTests>

<realms>
    <realm name="SampleAppRealm" loginModule="StrongDummy">
        <className>com.worklight.core.auth.ext.FormBasedAuthenticator</className>
        <parameter name="login-page" value="login.html"/>
    </realm>
</realms>

<loginModules>
    <loginModule name="StrongDummy">
        <className>com.worklight.core.auth.ext.NonValidatingLoginModule</className>
    </loginModule>
</loginModules>
```

Coding the server side

Perform the following steps:

1. Create a MobileFirst adapter.
2. Add a procedure and protect it with the custom security test that you created earlier. The implementation can return some hard-coded value, for example:

```
<procedure name="getSecretData" securityTest="DummyAdapter-securityTest"/>
```

Coding the client side

Perform the following steps:

1. Create a MobileFirst application.
2. Create a challenge handler in the application, to handle challenges from the SampleAppRealm realm, for example:

```
var sampleAppRealmChallengeHandler = WL.Client.createChallengeHandler("SampleAppRealm");
```

3. Implement the mandatory `isCustomResponse` and `handleChallenge` functions (and other, optional functions) of the challenge handler, as described previously.

What to do next

For a more extensive example of implementing form-based authentication, see the Form-based authentication tutorials on the Developer Center website.

Implementing Java-based custom authenticators

You can use default MobileFirst login modules and authenticators, or customize your own.

About this task

You can write custom login modules and authenticators when those that IBM MobileFirst Platform Foundation supplies do not match your requirements.

Procedure

1. Configure the `authenticationConfig.xml` file.

For more information, see “The authentication configuration file” on page 8-603.

2. Code the server side.

You create custom login modules and authenticators as instances of Java classes, which you must place in the `server/java` folder of the project. They are server-side entities and they are packed inside the WAR file of the project. The authenticator, login module, and user identity instances are stored in a session scope, so that they exist while the session is active.

Important: To correctly support session-independent mode, observe the following guidelines. For a detailed overview of session-independent mode, refer to “Session-independent mode” on page 8-324.

- Ensure that you do not save any applicative data in the HTTP session.
- In your custom authenticator implementation, do not send (“flush”) the prepared server-authentication response to the client. Sending the response while running in session-independent mode might lead to incorrect behavior if the client receives the response before the authentication context is saved to the attribute store. If the authenticator does not send the response to the client, MobileFirst Server does so automatically after all authentication-context information is saved to the attribute store.

Authenticator interface and methods

Your custom authenticator class must implement the `com.worklight.server.auth.api.WorkLightAuthenticator` interface. The `WorkLightAuthenticator` interface extends the `java.io.Serializable` interface, so as a result, your custom authenticator implements

`java.io.Serializable`. This means that your custom authenticator must have no non-serializable members and also declare a `serialVersionUID` version number, as recommended in the `Serializable` Interface Java documentation.

The custom authenticator must implement the following methods:

- `init`: This method is called when the authenticator instance is created. It receives the options that are specified in the realm definition in the `authenticationConfig.xml` file.
- `processRequest`: This method is called for each request from an unauthenticated session. The method must return an `AuthenticationResult` status. While the request is processed, the method might retrieve data from the request and write data to the response.

The `AuthenticationResult` status can return the following values:

- `SUCCESS`: The credentials were successfully collected and the login module can now validate them.
- `CLIENT_INTERACTION_REQUIRED`: The client must still supply authentication data.
- `REQUEST_NOT_RECOGNIZED`: The authenticator is not handled.
- `processAuthenticationFailure`: This method is called if the login module returns a failure for the validation of credentials.
- `processRequestAlreadyAuthenticated`: This method is called for each request from a session that has already been authenticated. It returns an `AuthenticationResult` value for authenticated requests.
- `getAuthenticationData`: Login modules use this method to retrieve the credentials that are collected by an authenticator.
- `changeResponseOnSuccess`: This method is called after the login module successfully validates credentials. Use this method to notify a client application of the success of the authentication, for example to modify the response before it is returned to the client. This method must return `true` if the response was modified or `false` otherwise.
- `clone`: This method creates a deep copy of the object members.

Login module interface and methods

Your custom login module class must implement the `com.worklight.server.auth.api.WorkLightAuthLoginModule` interface. The `WorkLightAuthLoginModule` interface extends the `java.io.Serializable` interface, so as a result, your custom login module implements `java.io.Serializable`. This means that your login module must have no non-serializable fields and also declare a `serialVersionUID` version number, as recommended in the `Serializable` Interface Java documentation.

The login module must implement the following methods:

- `init`: This method is called when the login module instance is created. This method receives the options that are specified in the login module definition of the `authenticationConfig.xml` file.
- `login`: This method is called after the authenticator returns `SUCCESS` status. It receives an `authenticationData` object from the authenticator and validates the credentials that are collected by the authenticator. If the credentials are valid, the method returns `true`. If the credential validation fails, the method returns `false` or raises a

runtime exception. In this case, the exception string that is returned to the authenticator as an **errorMessage** parameter.

- **createIdentity**: This method is called after the credentials are successfully validated. The method creates and returns a **UserIdentity** object, which contains information about the authenticated user, such as unique user name, display name, Java security roles, and custom user attributes.
- **logout**: Use this method to clean up cached data and class members after the user logs out.
- **abort**: Use this method to clean up cached data and class members after the user stops the authentication flow.
- **clone**: This method creates a deep copy of the object members.

3. Code the client side.

You must declare a challenge handler in the application to handle challenges from the custom authenticator realm. The following sample shows one way to implement a challenge handler class:

```
var myChallengeHandler = WL.Client.createChallengeHandler("CustomAuthenticatorRealm");
```

The challenge handler must implement the following methods:

- **isCustomResponse**: This method is called each time that a response is received from the server. It detects whether the response contains data that is related to this challenge handler. It must return true or false. Here is a simple example:

```
sampleAppRealmChallengeHandler.isCustomResponse = method(response) {  
    return false;  
};
```

- **handleChallenge**: Use this method for such actions as hide application screen and show login screen. If the **isCustomResponse** method returns true, the **handleChallenge** method is called by the framework. Here is a simple implementation, as an example:

```
sampleAppRealmChallengeHandler.handleChallenge = method(response) {  
};
```

Optionally, the challenge handler can also implement the following methods:

- **submitLoginForm**: This method sends the collected credentials to a specific URL. You can also specify request parameters, headers, and callback.
- **submitSuccess**: This method notifies the MobileFirst framework that the authentication finished successfully. The MobileFirst framework then automatically issues the original request that triggered the authentication.
- **submitFailure**: This method notifies the MobileFirst framework that the authentication process failed. The MobileFirst framework then disposes of the original request that triggered the authentication.

Example

The following example shows how to implement a custom authenticator and login module. In the example, an adapter procedure is protected by a custom authenticator. When the user attempts to call the procedure from the application, the application requests the user's credentials and the authentication process starts.

Configuration of the authenticationConfig.xml file

```
<securityTests>  
  <customSecurityTest name="DummyAdapter-securityTest">  
    <test isInternalUserID="true" realm="CustomAuthenticatorRealm"/>  
  </customSecurityTest>  
</securityTests>
```

```

<realms>
  <realm name="CustomAuthenticatorRealm" loginModule="CustomLoginModule">
    <className>com.mypackage.MyCustomAuthenticator</className>
  </realm>
</realms>

<loginModules>
  <loginModule name="CustomLoginModule">
    <className>com.mypackage.MyCustomLoginModule</className>
  </loginModule>
</loginModules>

```

Coding the server side

Code the following elements on the server side: adapter, authenticator, and login module.

- Adapter:
 1. Create a MobileFirst adapter.
 2. Add a procedure and protect it with the custom security test that you created earlier. The implementation can return some hardcoded value. For example:

```
<procedure name="getSecretData" securityTest="DummyAdapter-securityTest"/>
```

- Authenticator:
 1. Create a MyCustomAuthenticator.java class in the server/java/com/mypackage folder. This class must implement the com.worklight.server.auth.api.WorkLightAuthenticator interface, as follows:

```
public class MyCustomAuthenticator implements WorkLightAuthenticator{
```

2. Add the generated serialVersionUID constant to the class.

3. Implement the mandatory methods of the class.

- processRequest: This method retrieves the user name and password credentials that are passed as request parameters. Check the credentials for basic validity, collect the credentials, and return SUCCESS. If a problem occurs with the received credentials, add an errorMessage to the response and return the CLIENT_INTERACTION_REQUIRED status message. If the request does not contain authentication data, add the authStatus:required property to the response and again, return a CLIENT_INTERACTION_REQUIRED status message.

```

public AuthenticationResult processRequest(HttpServletRequest request, HttpServletResponse response,
boolean isAccessToProtectedResource) throws IOException, ServletException {
    if (request.getRequestURI().contains("my_custom_auth_request_url")){
        String username = request.getParameter("username");
        String password = request.getParameter("password");

        if (null != username && null != password && username.length() > 0 && password.length() > 0){
            this.username = request.getParameter("username");
            this.password = request.getParameter("password");
            return AuthenticationResult.createFrom(AuthenticationStatus.SUCCESS);
        } else {
            response.setContentType("application/json; charset=UTF-8");
            response.setHeader("Cache-Control", "no-cache, must-revalidate");
            response.getWriter().print("{\"authStatus\":\"required\",
\\errorMessage\":\"Please enter username and password\"}");
            return AuthenticationResult.createFrom(AuthenticationStatus.CLIENT_INTERACTION_REQUIRED);
        }
    }

    if (!isAccessToProtectedResource)
        return AuthenticationResult.createFrom(AuthenticationStatus.REQUEST_NOT_RECOGNIZED);
}

```

```

response.setContentType("application/json; charset=UTF-8");
response.setHeader("Cache-Control", "no-cache, must-revalidate");
response.getWriter().print("{\"authStatus\":\"required\"}");
return AuthenticationResult.createFrom(AuthenticationStatus.CLIENT_INTERACTION_REQUIRED);
}

```

- processAuthenticationFailure: This method writes an error message to a response body and returns the CLIENT_INTERACTION_REQUIRED status message.

```

public AuthenticationResult processAuthenticationFailure(HttpServletRequest request, HttpServletResponse response, String errorMessage) throws IOException, ServletException {
    response.setContentType("application/json; charset=UTF-8");
    response.setHeader("Cache-Control", "no-cache, must-revalidate");
    response.getWriter().print("{\"authStatus\":\"required\", \"errorMessage\":\"\" + errorMessage + "\"}");
    return AuthenticationResult.createFrom(AuthenticationStatus.CLIENT_INTERACTION_REQUIRED);
}

```

- Login module:

1. Create a MyCustomLoginModule.java class in the server/java/com/mypackage folder. This class must implement the com.worklight.server.auth.api.WorkLightAuthLoginModule interface.

```
public class MyCustomLoginModule implements WorkLightAuthLoginModule{
```

2. Implement the mandatory methods of the class.

- login: This method retrieves the user name and password credentials that the authenticator stored previously. In this example, the login module validates the credentials against hardcoded values. You can implement your own validation rules. If the credentials are valid, the login method returns true. For example:

```

public boolean login(Map<String> authenticationData) {
    USERNAME = (String) authenticationData.get("username");
    PASSWORD = (String) authenticationData.get("password");
    if (USERNAME.equals("w1user") && PASSWORD.equals("12345"))
        return true;
    else throw new RuntimeException("Invalid credentials"); }
</String>

```

- createIdentity: This method is called when the login method returns true. It is used to create a UserIdentity object. In that object, you can store your own custom attributes and use them later in Java or adapter code. The UserIdentity object contains user information. Its constructor is as follows:

```
public UserIdentity(String loginModule, String name, String displayName, Set<String> roles, Map<String, Object> attributes, Object credentials)
```

Here is an example of how to implement this method:

```

public UserIdentity createIdentity(String loginModule) {
    HashMap<String, Object> customAttributes = new HashMap<String, Object>();
    customAttributes.put("AuthenticationDate", new Date());

    UserIdentity identity = new UserIdentity(loginModule, USERNAME, null, null, customAttributes, PASSWORD);
    return identity;
}

```

Coding the client side

Follow these steps:

1. Create a MobileFirst application.
2. Create a challenge handler in the application to handle challenges from the custom authenticator realm. For example:

```
var myAppRealmChallengeHandler =  
WL.Client.createChallengeHandler ("CustomAuthenticatorRealm");
```

3. Implement the mandatory `isCustomResponse` and `isCustomResponse` methods, and optional methods of the challenge handler, as described in Step 3.

What to do next

For a more extensive example of implementing custom authentication and login, see the Custom authentication in hybrid applications tutorial.

IBM MobileFirst Platform Foundation provides other custom authentication mechanisms:

- Adapter-based custom authentication. For more information, see [Implementing adapter-based authenticators](#).
- HTTP-based custom authentication. For more information, see [HTTP-based authentication](#).

Header authenticator

Description and syntax of the header authenticator.

Description

The header authenticator is not interactive. The header authenticator must be used with the Header login module.

Class Name

```
com.worklight.core.auth.ext.HeaderAuthenticator
```

Parameters

None.

```
<realm name="RealmHeader" loginModule="HeaderLoginModule">  
<className> com.worklight.core.auth.ext.HeaderAuthenticator </className>  
</realm>
```

Persistent cookie authenticator

Description and syntax of the persistent cookie authenticator.

Description

The persistent cookie authenticator looks for a specific cookie in any request that is sent to it. If the request does not contain the cookie, the authenticator creates a cookie, and sends it in the response. This authenticator is not interactive, that is, it does not ask the user for credentials, and is mainly used in environment realms.

Class Name

```
com.worklight.core.auth.ext.PersistentCookieAuthenticator
```

Parameters

The persistent cookie authenticator class has the following parameter:

Parameter	Description
<cookie-name>	Optional. The name of the persistent cookie. If this parameter is not specified, the default name, WL_PERSISTENT_COOKIE, is used.

```
<realm name="PersistentCookie" loginModule="dummy">  
<className> com.worklight.core.auth.ext.PersistentCookieAuthenticator </className>  
</realm>
```

Implementing adapter-based authenticators

You can authenticate users of mobile applications by using an adapter-based authenticator.

About this task

Adapter-based authentication enables you to develop custom authentication logic by using a JavaScript function within a MobileFirst adapter.

Adapter-based authentication is flexible and customizable. The following diagram illustrates one possible implementation. The process is illustrated and described as follows.

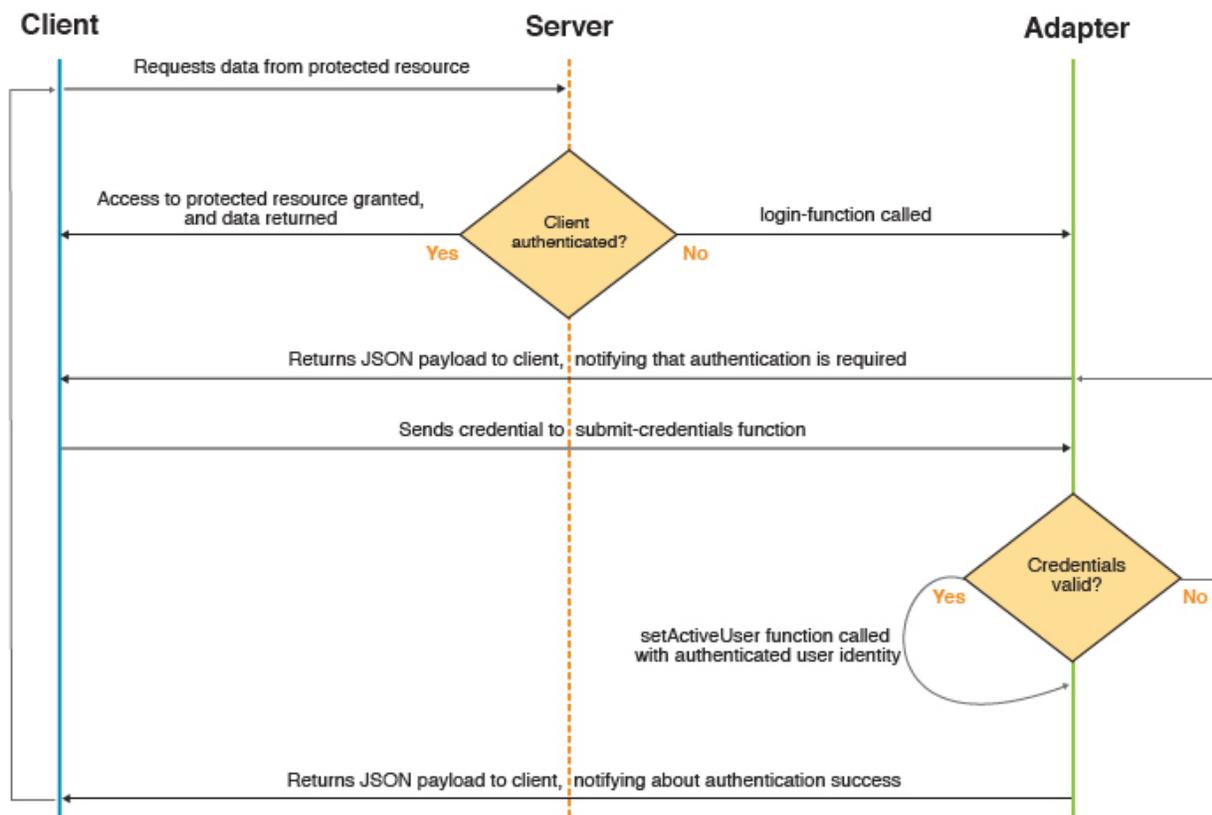

Figure 8-78. Adapter-based authentication process

1. The client makes a request to the resource that is protected by adapter authentication.
2. MobileFirst Server checks whether the client is already authenticated.
 - a. If it is, the requested data is returned.
 - b. Otherwise, authentication continues.
3. The adapter procedure that is defined in `authenticationConfig.xml` as a login-function is called.
4. The login-function procedure is used to return a custom JSON payload to the client.
5. The client processes the custom JSON payload and sends its credentials to the adapter procedure used for authentication.
6. The adapter procedure that is used for authentication receives credentials and validates them.
 - a. If validation fails, the flow returns to step 4.
 - b. Otherwise, authentication continues.
7. The adapter procedure that is used for authentication creates a user identity and returns a success status to the client.
8. The client receives the success status and issues the original request.
9. The flow returns to step 2.

For more information, see “The authentication configuration file” on page 8-603.

Procedure

1. Configure the `authenticationConfig.xml` file.
 - Add security tests to the `<securityTest>` section of the file. Because the security test that you are using is protecting an adapter procedure, you use the `<customSecurityTest>` parameter.
 - Add authentication realms to the `<realms>` section. For the `className` parameter, use the `com.worklight.integration.auth.AdapterAuthenticator` to indicate that the server-side part of the authenticator is defined in the adapter. Define two parameter-value pairs for login and logout:
 - `login-function`: whenever the MobileFirst authentication framework detects an attempt to access a protected resource, the login-function is called automatically.
 - `logout-function`: when logout is detected (explicit or session timeout), the logout-function is called automatically.

In both cases, the value syntax is `adapterName.functionName`.

- Add a login module to the `<loginModules>` section. All of the validation logic that is done in a login module is performed in the adapter's JavaScript code and you need no further validation. For that reason, adapter-based authentication must be used with a `NonValidatingLoginModule` only. No additional validation is performed by the IBM MobileFirst Platform, and the developer takes responsibility for the validation of credentials within the adapter. For more information, see `Non-validating login module`.
2. Code the server side.

The fully qualified name of the Java class for adapter authenticators is `com.worklight.integration.auth.AdapterAuthenticator`. It takes the mandatory **login-function** parameter and the optional **logout-function** parameters. Both parameters specify adapter function names. The syntax is: `adapter-name.function-name`, for example, `myAuthAdapter.onAuthRequired`. You

need to implement the login-function and logout-function in your adapter.js source file. In the example, these parameters are implemented as AuthAdapter.onAuthRequired and AuthAdapter.onLogout.

Note:

- Both login-function and logout-function should only be used internally by a MobileFirst Server. For this reason, it is important that you do not expose them as procedures in the adapter XML file.
- In contrast, the function that receives credentials is directly called by a client. Therefore, you must expose the function in the adapter XML file. When the challenge handler invokes the submit call, the handler is responsible for handling all the possible responses. In particular, if the submit call returns a challenge, the challenge is passed to the invocation callback, and is not processed by the security framework. To prevent a situation in which the invocation callback cannot handle the challenge, disable the authentication requirement for the submit procedure by using the wl_unprotected security test.
- Alternatively, you can define a more sophisticated security test for this function. Just make sure that the security context on the client side is sufficient to answer the challenge. One way to do this is to enrich the client security context by a call to WL.Client.connect before the adapter is called.
- If your MobileFirst Server runs on WebSphere Application Server, version 7 (any release) or releases of WebSphere Application Server Liberty 8.5 Before Fix Pack 2, the application server's Web container custom flag `com.ibm.ws.webcontainer.suppressLoggingServiceRuntimeExcep`

must be set to true. The default is false. If this flag is not changed, then the adapter will fail to authenticate and an exception will occur. For more information, see APAR PM74090 for WebSphere Application Server or APAR PM79934 for WebSphere Application Server Liberty.

In addition to implementing login-function and logout-function, you also need to implement an adapter function that receives credentials from the client, validate them, and create a user identity, for example, function `submitCredentials (user, password)`.

- **The login function**

The login-function parameter specifies the name of the JavaScript function to be invoked once the login process is triggered. The triggering can happen either when the client application explicitly invokes the WL.Client.login API, or when an unauthenticated attempt to access a resource protected by the adapter authentication realm is made. Use this function to return a payload to the client to notify it about the required authentication. The login-function receives original request headers that are converted to JSON as a first function argument so that they can be used to decide on the kind of authentication that is needed, for example. Then it is the login-function that returns the response to the client, instead of the original function

- **The logout function**

The logout-function parameter specifies the name of the JavaScript function to be invoked once logout from the realm has occurred. The logout can be triggered by having the client application call the WL.Client.logout API, or when the MobileFirst Server decides to invalidate the session (for example, a session timeout). The logout-function receives no arguments.

- **The submit credentials function**

This is the function that actually performs the authentication. The client should call this function with arguments containing user credentials or authentication data. It should then validate the credentials and once validated, this function should use `WL.Server.setActiveUser(realm, identity)` to register the authenticated identity. The function can include a flag or message in the response to let the application know if the login was successful or not. If not, it is advised to programatically limit the number of login trials in your application.

3. Code the client side.
 - a. Create a MobileFirst application, with an element for displaying the application content and an element for authentication. For example, when authentication is required, the application hides the applicative element and shows the authentication element. When authentication is complete, it does the opposite.
 - b. Create a challenge handler, by using the `WL.Client.createChallengeHandler` method to create a challenge handler object. You must *implement* the following mandatory methods: `isCustomResponse`, `handleChallenge`. In addition, the following mandatory methods are available in every challenge handler that you must *use*: `submitAdapterAuthentication`, `submitSuccess`, `submitFailure`. For more information, see APAR PM79934.

Note:

You must attach each of these mandatory challenge handler functions to its object. For example: `myChallengeHandler.submitSuccess`.

Example

The following example demonstrates how to implement an adapter-based authentication mechanism that relies on a user name and a password.

Configuration of the authenticationConfig.xml file

```
<securityTests>
  <customSecurityTest name="SingleStepAuthAdapter-securityTest">
    <test isInternalUserID="true" realm="SingleStepAuthRealm"/>
  </customSecurityTest>
</securityTests>

<realms>
  <realm loginModule="AuthLoginModule" name="SingleStepAuthRealm">
    <className>com.worklight.integration.auth.AdapterAuthenticator</className>
    <parameter name="login-function"
      value="SingleStepAuthAdapter.onAuthRequired"/>
    <parameter name="logout-function"
      value="SingleStepAuthAdapter.onLogout"/>
  </realm>
</realms>

<loginModules>
  <loginModule name="AuthLoginModule">
    <className>com.worklight.core.auth.ext.NonValidatingLoginModule
    </className>
  </loginModule>
</loginModules>
```

Code the server side authentication

Perform the following steps:

1. Create an adapter that takes care of the authentication process. In this example, it is `SingleStepAuthAdapter`.

2. SingleStepAuthAdapter could include the following two procedures, for example:

```
<procedure name="submitAuthentication" securityTest="wl_unprotected"/>
<procedure name="getSecretData" securityTest="SingleStepAuthAdapter-securityTest"/>
```

- The submitAuthentication procedure takes care of the authentication process and authentication is not required to call it.
- The getSecretData procedure is available to authenticated users only.

3. Define the onAuthRequired function:

```
function onAuthRequired(headers, errorMessage) {
    errorMessage = errorMessage ? errorMessage : null;

    return {
        authRequired: true,
        errorMessage: errorMessage
    };
}
```

- This function receives the response headers and an optional errorMessage parameter. The object that is returned by this function is sent to the client application. The authRequired:true and errorMessage:errorMessage pairs define a custom challenge object that is sent to the application.
- The authRequired:true property is used in a challenge handler to detect that the server is requesting authentication.
- Whenever the MobileFirst framework detects an unauthenticated attempt to access a protected resource, the onAuthRequired function is called, as you defined in the authenticationConfig.xml file.

4. Define the submitAuthentication function. The function is called by the client app to validate the user name and password.

```
/* In this sample, the credentials are validated against some
 * hardcoded values, but any other validation mode is valid,
 * for example by using SQL or web services. */
if (username=="worklight" && password === "worklight"){

/* If the validation passed successfully, the WL.Server.setActiveUser method
 * is called to create an authenticated session for the SingleStepAuthRealm,
 * with user data stored in a userIdentity object. You can add your own custom
 * properties to the user identity attributes. */
var userIdentity = {
    userId: username,
    displayName: username,
    attributes: {
        foo: "bar"
    }
};

WL.Server.setActiveUser("SingleStepAuthRealm", userIdentity);

/* An object is sent to the application, stating that the authentication
 * screen is no longer required. */
return {
    authRequired: false
};
}

/* If the credentials validation fails, an object that is built
 * by the onAuthRequired function is returned to the application
 * with a suitable error message. */
return onAuthRequired(null, "Invalid login credentials");
}
```

5. Define the `getSecretData` function. For the purposes of demonstration, at the conclusion of successful authentication, you could return a hard-coded value:

```
function getSecretData() {
  return {
    secretData: "Very very secret data"
  };
}
```

6. Define the `onLogout` function, to be called automatically on logout. It can perform a cleanup, for example.

```
function onLogout(){
  WL.Logger.debug("Logged out");
}
```

Code the client side authentication

Perform the following steps:

1. Create a MobileFirst application.
2. You might create some HTML code, for example, to display application content only after authentication is complete.
3. Create the challenge handler. Use the `WL.Client.createChallengeHandler` method to create a challenge handler object; supply a realm name as a parameter. For example:

```
var singleStepAuthRealmChallengeHandler =
  WL.Client.createChallengeHandler("SingleStepAuthRealm");

/* The isCustomResponse function of the challenge handler
 * is called each time a response is received from the server.
 * That function is used to detect whether the response contains
 * data that is related to this challenge handler. The function returns true or false.
 */

singleStepAuthRealmChallengeHandler.isCustomResponse = function(response) {
  if (!response||!response.responseJSON||response.responseText === null) {
    return false;
  }
  if (typeof(response.responseJSON.authRequired) !== 'undefined'){
    return true;
  } else {
    return false;
  }
};
```

4. Define a `handleChallenge` function. That function behaves differently according to the result of the `authRequired` function in the previous step.

```
/* If the isCustomResponse function returns true, the
 * framework calls the handleChallenge function. This function
 * is used to perform required actions, such as to hide the
 * application screen or show the login screen. */
singleStepAuthRealmChallengeHandler.handleChallenge =
  function(response){
    var authRequired = response.responseJSON.authRequired;

    if (authRequired == true){
      $("#AppDiv").hide();
      $("#AuthDiv").show();
      $("#AuthPassword").empty();
      $("#AuthInfo").empty();

      if (response.responseJSON.errorMessage)
        $("#AuthInfo").html(response.responseJSON.errorMessage);
    }
  }
```

```

    } else if (authRequired == false){
      $("#AppDiv").show();
      $("#AuthDiv").hide();
      singleStepAuthRealmChallengeHandler.submitSuccess();
    }
  };
  $("#authCancelButton").click(function(){
    singleStepAuthRealmChallengeHandler.submitFailure();
  });

```

The code in this step demonstrates two of three additional challenge handler functions that you need to use:

- The `submitSuccess` function notifies the MobileFirst framework that the authentication process completed successfully. The MobileFirst framework then automatically issues the original request that triggered authentication.
 - The `submitFailure` function notifies the MobileFirst framework that the authentication process completed with failure. The MobileFirst framework then disposes of the original request that triggered authentication.
5. The third challenge handler function you must use is `submitAdapterAuthentication`. It sends collected credentials to a specific adapter procedure. It has the same signature as the `WL.Client.invokeProcedure` function. Here is an example:

```

$("#AuthSubmitButton").bind('click', function () {
  var username = $("#AuthUsername").val();
  var password = $("#AuthPassword").val();

  var invocationData = {
    adapter : "SingleStepAuthAdapter",
    procedure : "submitAuthentication",
    parameters : [ username, password ]
  };

  singleStepAuthRealmChallengeHandler.submitAdapterAuthentication(invocationData, {});
});

```

What to do next

For a more extensive example of implementing adapter-based authentication, see the tutorials on the Getting Started page.

IBM MobileFirst Platform Foundation provides other custom authentication mechanisms:

- Java-based custom authentication. For more information, see [Implementing Java-based authenticators](#).
- HTTP-based custom authentication. For more information, see [HTTP-based custom authentication](#).

LTPA authenticator

Description and syntax for the LTPA authenticator.

Description

Use the Lightweight Third-Party Authentication authenticator to integrate with the WebSphere Application Server LTPA mechanisms.

Note: This authenticator is supported only on WebSphere Application Server. To avoid unnecessary errors on other application servers, the authenticator is commented out in the default authenticationConfig.xml file that is created with an empty MobileFirst project. To use it, remove the comments first.

This authenticator can be used with the WASLTPAModule login module.

Class Name

com.worklight.core.auth.ext.WebSphereFormBasedAuthenticator

Parameters

The adapter authenticator class has the following parameters:

Parameter	Description
login-page	Mandatory. The login page URL relative to the web application context.
error-page	Optional. The error page URL relative to the web application context. If this parameter is not set, the URL from the login-page is also used for the error-page.
cookie-domain	Optional. A String such as example.com, which specifies the domain in which the LTPA SSO cookie applies. If this parameter is not set, no domain attribute is set on the cookie. The single sign-on is then restricted to the application server host name and does not work with other hosts in the same domain. Note: This parameter is deprecated. Define this parameter in the <loginModule> entry for the WebSphereLoginModule instead. If the parameter is defined in both places, the value in the <loginModule> entry takes precedence.
httponly-cookie	Optional. A String with a value of either true or false, which specifies whether the cookie has the HttpOnly attribute set. This attribute helps to prevent cross-site scripting attacks. Note: This parameter is deprecated. Define this parameter in the <loginModule> entry for the WebSphereLoginModule instead. If the parameter is defined in both places, the value in the <loginModule> entry takes precedence.
cookie-name	Optional. A String that specifies the name of the LTPA SSO cookie. If this parameter is not set, the default cookie name is LtpaToken. Note: This parameter is deprecated. Define this parameter in the <loginModule> entry for the WebSphereLoginModule instead. If the parameter is defined in both places, the value in the <loginModule> entry takes precedence.

Example

```
<realm name="WASLTPARealm" loginModule="WASLTPAModule">
  <className>com.worklight.core.auth.ext.WebSphereFormBasedAuthenticator</className>
  <parameter name="login-page" value="/login.html"/>
  <parameter name="error-page" value="/loginError.html"/>
</realm>
```

Device single sign-on (SSO)

Single sign-on (SSO) enables users to access multiple resources (that is, applications and adapter procedures) by authenticating only once.

When a user successfully logs in through an SSO-enabled login module, the user gains access to all resources that are using the same login module, without having

to authenticate again for each of them. The authenticated state remains alive as long as requests to resources protected by the login module are being issued within the timeout period, which is identical to the session timeout period.

Device authentication

The SSO feature requires the use of device authentication. This means that for a protected resource that needs to be protected with SSO, there must also be a device authentication realm in the securityTest protecting the resource in the authenticationConfig.xml file. Device authentication should take place before the SSO-enabled user authentication.

Supported devices

SSO is supported on Android, iOS, Windows 8 Universal, and Windows Phone Silverlight 8 devices.

Performance

When you use the single sign-on feature, the load on the database might increase, and you might have to adjust the database configuration.

Implementing a custom authentication to support SSO

To allow SSO to operate on your custom authentication classes (authenticator and loginModule) you must:

1. Make all fields in your class transient except for those fields that are being used by the following methods:
 - `WorklightAuthenticator.processRequestAlreadyAuthenticated(HttpServletRequest, HttpServletResponse)`
 - `WorklightAuthLoginModule.logout()`
2. Mark the authenticator and loginModule classes (and any class referred to by those classes that is not transient after you perform step 1) with the class annotation `@DeviceSSO(supported = true)` .

Device SSO in the OAuth-based security model

OAuth resources are not protected by security tests and do not have a single defined user realm per resource, therefore the standard MobileFirst device SSO behavior does not apply for them.

However, in order to obtain an access token in the MobileFirst OAuth-based security model, the client is also required to pass the application's security test. If SSO is configured for this security test, it will function for the MobileFirst OAuth-based security model as it does for the classical MobileFirst security model.

Configuring device single sign-on

Single sign-on (SSO) is a property of a login module. You can enable single sign-on for custom security tests and for mobile security tests.

About this task

You can enable single sign-on from a `<mobileSecurityTest>` element or from a `<loginModule>` element of the `authenticationConfig.xml` configuration file. For

custom security tests, you enable single sign-on on the <loginModule> element. For mobile security tests, you enable single sign-on on the testUser realm of the <mobileSecurityTest> element.

Basically, you configure SSO in the same way for native IOS applications as for hybrid applications. However, for native SSO to work on iOS, this additional step is mandatory: In Xcode, add a Keychain Access Group with the same name for all apps that participate in device SSO.

Procedure

Take the following points into consideration, depending on how you choose to configure device single sign-on:

- When you configure <mobileSecurityTest> elements, enable single sign-on from the <securityTest> element by setting the value of the **sso** attribute to true. You can enable SSO for user realms only. If the **sso** attribute is not specified, it is assumed to be set to false. For example:

```
<mobileSecurityTest name="mst">
  <testDeviceId provisioningType="none"/>
  <testUser realm="myUserRealm" sso="true"/>
</mobileSecurityTest>
```

- When you configure <customSecurityTest> elements, enable single sign-on by configuring an **ssoDeviceLoginModule** property on the user login module in the authentication configuration file, where **ssoDeviceLoginModule** is the name of the login module that is used for the device authentication realm. For example:

```
<loginModule name="MySSO" ssoDeviceLoginModule="WLDeviceNoProvisioningLoginModule">
  <className>com.worklight.core.auth.ext.NonValidatingLoginModule</className>
</loginModule>
```

In this example, "MySSO" is the name of the user login module for which single sign-on is being enabled so that its login can be shared.

"WLDeviceNoProvisioningLoginModule" is the name of the login module that handles device authentication; in this case, with no provisioning. To use auto-provisioning as the device login module, set the **ssoDeviceLoginModule** property to the value "WLDeviceAutoProvisioningLoginModule". With custom provisioning, you define the name when you create the custom provisioning login module.

- When you configure <customSecurityTest> elements, you must configure the user realm at least one step later than the device realm. This is necessary to ensure that the SSO feature operates correctly. When you configure SSO on <mobileSecurityTest>, the platform takes care of this prioritization automatically. The following example illustrates a correct <customSecurityTest> configuration:

```
<customSecurityTest name="adapter">
  <test realm="wl_deviceNoProvisioningRealm" isInternalDeviceID="true" step="1"/>
  <test realm="MySSO" isInternalUserID="true" step="2"/>
</customSecurityTest>
```

- For Windows Phone 8, the following items must be implemented:
 - The Publisher ID specified in the WMAppManifest.xml file must be the same for all applications that participate in the single sign-on.
 - The following line must be added to the WMAppManifest.xml file:

```
<Capability Name='ID_CAP_IDENTITY_DEVICE' />
```

- A cleanup task cleans the database of orphaned and expired single-sign-on login contexts. To configure the cleanup task interval, use the **sso.cleanup.taskFrequencyInSeconds** server property and assign the required task interval value, expressed in seconds. For information about how to specify

MobileFirst configuration properties, see “Configuration of MobileFirst applications on the server” on page 12-50.

Results

Device single sign-on implementations are successful if they conform to any of the following valid configurations. Avoid inconsistent states that result from configurations with built-in conflicts. Inconsistent states can result in the MobileFirst project failing to start.

Valid configurations:

- The `<loginModule>` element does not specify the **ssoDeviceLoginModule** attribute, and all mobile security tests that use this login module for their user realms have `sso="false"`. In this case, SSO is disabled for all applications that are protected by security tests (mobile or custom) with this login module for a user realm. For example:

```
<securityTests>
  <mobileSecurityTest name="FormTest">
    <testDeviceId provisioningType="none"/>
    <testUser realm="SampleAppRealm" sso="false"/>
  </mobileSecurityTest>
  <mobileSecurityTest name="AnotherFormTest">
    <testDeviceId provisioningType="none"/>
    <testUser realm="SampleAppRealm" sso="false"/>
  </mobileSecurityTest>
</securityTests>
<realms>
  <realm name="SampleAppRealm" loginModule="StrongDummy">
    <className>com.worklight.core.auth.ext.FormBasedAuthenticator</className>
  </realm>
</realms>
<loginModules>
  <loginModule name="StrongDummy">
    <className>com.worklight.core.auth.ext.NonValidatingLoginModule</className>
  </loginModule>
</loginModules>
```

- The `<loginModule>` element does not specify the **ssoDeviceLoginModule** attribute, and all mobile security tests that use this login module for their user realms have `sso="true"`. In this case, SSO is enabled for all applications that are protected by security tests (mobile or custom) with this login module for a user realm. For example:

```
<securityTests>
  <mobileSecurityTest name="FormTest">
    <testDeviceId provisioningType="none"/>
    <testUser realm="SampleAppRealm" sso="true"/>
  </mobileSecurityTest>
  <mobileSecurityTest name="AnotherFormTest">
    <testDeviceId provisioningType="none"/>
    <testUser realm="SampleAppRealm" sso="true"/>
  </mobileSecurityTest>
</securityTests>
<realms>
  <realm name="SampleAppRealm" loginModule="StrongDummy">
    <className>com.worklight.core.auth.ext.FormBasedAuthenticator</className>
  </realm>
</realms>
<loginModules>
  <loginModule name="StrongDummy">
    <className>com.worklight.core.auth.ext.NonValidatingLoginModule</className>
  </loginModule>
</loginModules>
```

- The `<loginModule>` element specifies the **ssoDeviceLoginModule** attribute, and all mobile security tests that use this login module for their user realms have `sso="true"`. In this case, SSO is enabled for all applications that are protected by security tests (mobile or custom) with this login module for a user realm. For example:

```
<securityTests>
  <mobileSecurityTest name="FormTest">
    <testDeviceId provisioningType="none"/>
    <testUser realm="SampleAppRealm" sso="true"/>
  </mobileSecurityTest>
  <mobileSecurityTest name="AnotherFormTest">
    <testDeviceId provisioningType="none"/>
    <testUser realm="SampleAppRealm" sso="true"/>
  </mobileSecurityTest>
</securityTests>
<realms>
  <realm name="SampleAppRealm" loginModule="StrongDummy">
    <className>com.worklight.core.auth.ext.FormBasedAuthenticator</className>
  </realm>
</realms>
<loginModules>
  <loginModule name="StrongDummy" ssoDeviceLoginModule="WLDeviceAutoProvisioningLoginModule">
    <className>com.worklight.core.auth.ext.NonValidatingLoginModule</className>
  </loginModule>
</loginModules>
```

Single sign-on inconsistent state

Avoid conflicts in the single sign-on configuration of a login module. Such conflicts cause inconsistency in the single sign-on state of the login module, and can lead to unexpected results.

A conflict can exist between the configuration of a `<loginModule>` element and the configuration of a `<mobileSecurityTest>` element. Such conflict can happen when you enable single sign-on of a login module in the `<loginModule>` element and then disable single sign-on for the same login module, by using it in a `<mobileSecurityTest>` without specifying `sso="true"` for the realm of this `<loginModule>`. For example:

```
<securityTests>
  <mobileSecurityTest name="FormTest">
    <testDeviceId provisioningType="none"/>
    <testUser realm="SampleAppRealm"/>
  </mobileSecurityTest>
</securityTests>
<realms>
  <realm name="SampleAppRealm" loginModule="StrongDummy">
    <className>com.worklight.core.auth.ext.FormBasedAuthenticator</className>
  </realm>
</realms>
<loginModules>
  <loginModule name="StrongDummy" ssoDeviceLoginModule="WLDeviceAutoProvisioningLoginModule">
    <className>com.worklight.core.auth.ext.NonValidatingLoginModule</className>
  </loginModule>
</loginModules>
```

Another case of conflict can happen between different `<mobileSecurityTest>` elements, when two `<mobileSecurityTest>` elements use the same login module, with conflicting values for the **sso** attribute. In this example, the same realm contains conflicting **sso** enablement states in two `<mobileSecurityTest>` elements.

```
<securityTests>
  <mobileSecurityTest name="FormTest">
    <testDeviceId provisioningType="none"/>
```

```

    <testUser realm="SampleAppRealm"/>
  </mobileSecurityTest>
  <mobileSecurityTest name="FormTestWithSso">
    <testDeviceId provisioningType="none"/>
    <testUser realm="SampleAppRealm" sso="true"/>
  </mobileSecurityTest>
</securityTests>

```

Here is another example, in which the same login module is used for different realms with conflicting SSO enablement states in two <mobileSecurityTest> elements:

```

<securityTests>
  <mobileSecurityTest name="FormTest">
    <testDeviceId provisioningType="none"/>
    <testUser realm="SampleAppRealm"/>
  </mobileSecurityTest>
  <mobileSecurityTest name="FormTestWithSso">
    <testDeviceId provisioningType="none"/>
    <testUser realm="SampleAppRealmWithSso" sso="true"/>
  </mobileSecurityTest>
</securityTests>
<realms>
  <realm name="SampleAppRealm" loginModule="StrongDummy">
    <className>com.worklight.core.auth.ext.FormBasedAuthenticator</className>
  </realm>
  <realm name="SampleAppRealmWithSso" loginModule="StrongDummy">
    <className>com.worklight.core.auth.ext.FormBasedAuthenticator</className>
  </realm>
</realms>

```

What to do next

When you use a reverse proxy, more configuration and settings are necessary. Either of the following options allow device SSO to work with a reverse proxy.

Device single sign-on with the IBM Security Access Manager Web reverse proxy:

Additional configuration and settings are required when you use the IBM Security Access Manager Web reverse proxy.

You can configure the IBM Security Access Manager Web reverse proxy or IBM Security Access Manager WebSEAL when you enable device SSO to delegate user authentication to the MobileFirst Device SSO realm. For more information about the required configurations and samples, see IBM Security Access Manager for IBM MobileFirst Platform Foundation.

This option is supported on all mobile platforms and you can use the IBM Security Access Manager features such as Risk-Based Access (RBA), Context-Based Access (CBA), Strong Authentication (One-time password), and Identity aware applications (OAuth) to further enhance security.

Configuring device single sign-on with a reverse proxy:

Additional configuration and settings are required when you use a reverse proxy.

Before you begin

Ensure that you configured device single sign-on as explained in “Configuring device single sign-on” on page 8-646.

About this task

Device SSO and reverse proxies

Device single sign-on with a reverse proxy can also be achieved with the “Simple data sharing” on page 8-593 feature. The Simple Data Sharing feature allows a set of applications to share authentication cookies that allow access through the reverse proxy and delegate authentication to the MobileFirst Server Device SSO realm.

The Simple Data Sharing feature is supported only on iOS and Android devices.

With the Simple Data Sharing feature, you can tell the MobileFirst client runtime environment to share credentials among applications in the same MobileFirst application family. Because you are working with security tokens, you must ensure that access to the applications is protected by other mechanisms. For example, ensure that the device is not jailbroken, and that the device is password-protected. For more information, see “Simple data sharing limitations and special considerations” on page 8-599.

The following steps show how to configure device single sign-on with a reverse proxy.

Procedure

1. Enable the Simple Data Sharing feature as explained in “Enabling the Simple Data Sharing feature” on page 8-594.
2. For hybrid applications, follow these steps.
 - a. Ensure that you select the MobileFirst device SSO option.
 - b. Specify a comma-separated list of cookie names that you want IBM MobileFirst Platform Foundation to remember and share among the applications in your specified family.

Enable MobileFirst Device SSO - Reverse Proxy

Enable this option when you use a device single sign-on (SSO) enabled security realm and a reverse proxy. Specify the reverse proxy user authentication cookie(s) to share among members of the same application family.

Cookies:

3. For native applications, follow these steps.
 - a. Add the `wlShareCookies` property in the MobileFirst properties file.
 - b. Specify a comma-separated list of cookie names that you want IBM MobileFirst Platform Foundation to remember and share among the applications in your specified family.

```
wlShareCookies = PD-S-SESSION-ID
```

Each application in the MobileFirst family must be enabled for simple data sharing, and must also specify the cookie, which it agrees to share and reuse. For example, you can specify any one of the `PD-*SESSION-ID` cookies for IBM Security Access Manager or the `Ltpatoken` or `Ltpatoken2` cookies for IBM WebSphere DataPower.

Results

You have configured device single sign-on with a reverse proxy.

Configuring MobileFirst web application authorization

Configure authentication to the MobileFirst Operations Console, usage reports, and the Application Center console.

The MobileFirst web applications that require authentication are the MobileFirst Operations Console, the MobileFirst usage reports, and the Application Center console. The MobileFirst Operations Console and MobileFirst usage reports are configured by using <resource> elements in the authenticationConfig.xml file.

The Application Center console is not subject to the authentication model described here. For information about setting up authentication for the Application Center console, see “Configuring user authentication for Application Center” on page 6-270.

Location services

Location services in IBM MobileFirst Platform Foundation provide you with the opportunity to create differentiated services that are based on a user location, by collecting geolocational and WiFi data, and by feeding the location data and triggers to business processes, decision management systems, and analytics systems.

Geolocation is a powerful differentiator of mobile apps. Yet because geolocation coordinates must be constantly polled to understand where a mobile device is located, the resulting stream of geographic information can be difficult to manage without exhausting resources such as battery and network. IBM MobileFirst Platform Foundation includes location services that handle multiple geo modalities such as GPS, WiFi sampling, and interpolation. You can set policies for acquiring geolocation data and transmitting it to the server in order to optimize battery and network usage.

With location services in IBM MobileFirst Platform Foundation, you can use data that is acquired by a mobile device to trigger events that benefit both the owner of the device and the enterprise that has received the data. For example:

- A fast food outlet could start preparing food for a customer, based on data collected regarding his geographical location, so that the food is ready just as the customer arrives to collect.
- A warehouse could improve the efficiency of its processes by using locational data from its delivery vehicles to ensure that goods are removed from storage and made ready for collection.
- Shopping outlets could respond more readily to the needs of regular customers by using geo-locational data.

Location services can also be used to improve internal efficiency within an organization, for example, by understanding behavior and trends in application usage, and thus driving ongoing improvement.

Location services are currently supported on hybrid Android, iOS, and Windows Phone Silverlight 8.

The following figure shows how the location services feature works:

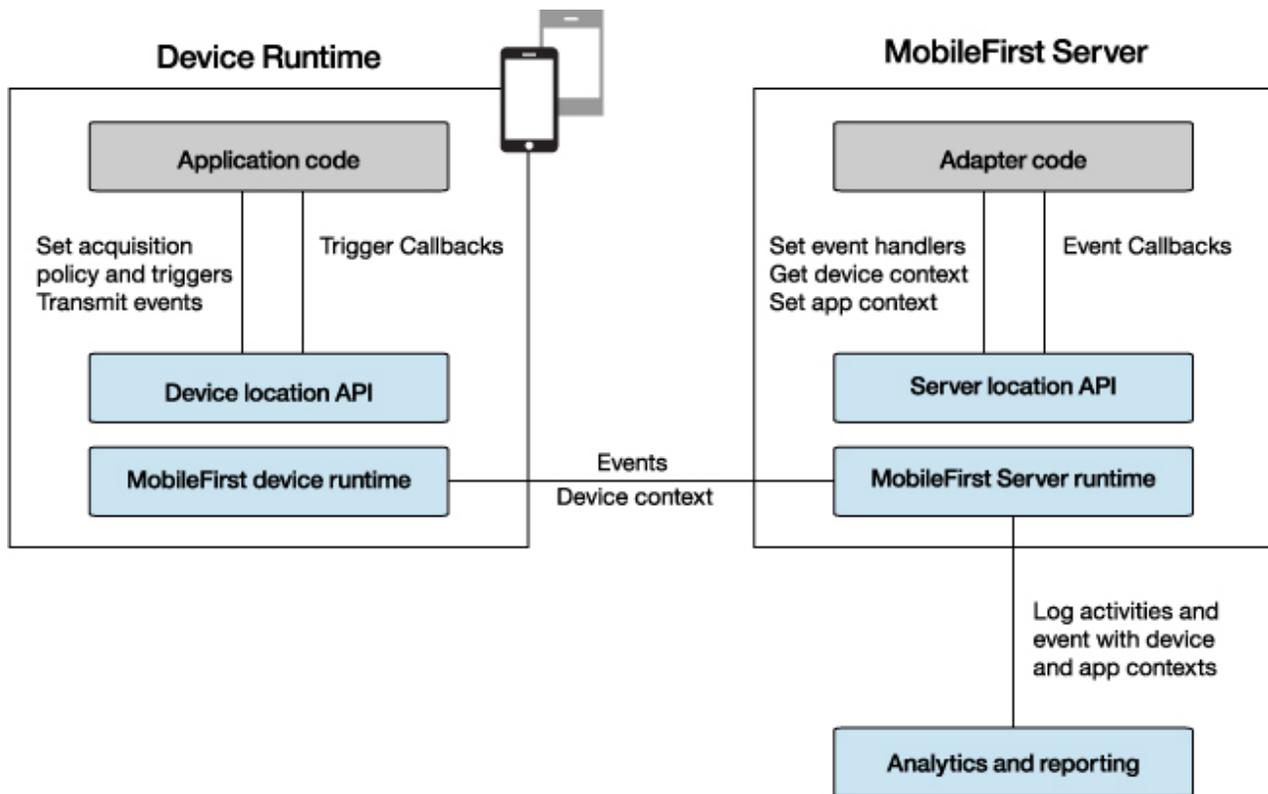

Figure 8-79. Location services architecture

Application code on the mobile device, in the form of an *acquisition policy*, controls the collection of data from device sensors. The collected data is referred to as the *device context*. When a change occurs in the device context, such as a change in the geolocation of the device, or the fact that it has just entered a WiFi zone, triggers can be activated. The triggers specify that an action should occur: either a callback function is called, or an event is sent to the server, based on the device context.

Events are created by triggers and application code, and include a snapshot of the device context at the time of their creation. Events are buffered on the client, and are transmitted to the server periodically. The server might process the event much later. During the event transmission process, the device context is synchronized transparently to the server.

To handle the events, the server uses adapter application code. This code sets up event handlers on the server, which filter event data and pass matching events to a callback function. The code also accesses the client's device context (its location and WiFi network information) and sets an application context. Server activities and received events are logged, together with the device and application contexts, for future reporting and analytics.

Related concepts:

Testing hybrid location service applications

You can use the Mobile Browser Simulator to test applications within a browser, and preview MobileFirst applications on Android, iOS, and Windows Phone 8. Location services only support these platforms, other platforms must be removed. With the Geolocation, Network and Scenario widgets, you can test applications in Mobile Browser Simulator that use the JavaScript location service APIs.

Platform support for location services

Location services are supported for hybrid applications on iOS, Android, and Windows Phone Silverlight 8. However, the level of support for each platform is slightly different.

The following table lists the features of location services where support differs for iOS, Android, and Windows Phone Silverlight 8:

Feature	iOS	Android	Windows Phone Silverlight 8
Geo acquisition policy	minChangeTime is not supported.	highAccuracyOptions: iOSBestAccuracy is not supported.	highAccuracyOptions: iOSBestAccuracy is not supported.
WiFi visible access points	Not supported. Only the Connect and Disconnect triggers are supported for iOS WiFi.		Not supported. Only the Connect and Disconnect triggers are supported for Windows Phone 8 Universal WiFi.
Connected WiFi signal strength	Not supported.		Not supported.
Connected WiFi MAC address			Not supported.
KeepAliveInBackground	Not supported. Use standard iOS options for acquiring location data while in the background.		Not supported. Use standard Windows Phone Silverlight 8 options for acquiring location data while in the background.

For information about iOS, Android, and Windows Phone Silverlight 8 permissions, see "Location services permissions."

Location services permissions

To use MobileFirst location services, you must define the correct permissions.

Location services are supported for hybrid applications on Android, iOS, and Windows Phone Silverlight 8.

Location services permissions in Android

To enable MobileFirst location services for Android, you must define the proper permissions.

The permissions that you require differ for versions earlier than Android 6.0 Marshmallow and versions starting from Android 6.0 Marshmallow onwards.

Before Android 6.0 Marshmallow

In versions of Android earlier than Android 6.0 Marshmallow, the following permissions are required:

For Geo acquisition:

- ACCESS_COARSE_LOCATION
- ACCESS_FINE_LOCATION (when **enableHighAccuracy=true**)

For WiFi acquisition:

- ACCESS_WIFI_STATE
- CHANGE_WIFI_STATE

For Android 6.0 Marshmallow and later

In Android 6.0 Marshmallow and later, geo acquisition (location) permissions require additional runtime permissions.

Overview of runtime permissions

According to the Android 6.0 Marshmallow permissions model, in addition to defining permissions at installation, users must also allow or deny access to different features at runtime. Before an app accesses location services, it must check whether permission has already been granted and, if needed, request permission. Developers are responsible to perform the check before accessing any of the following methods in the `WLDevice` interface:

- `startAcquisition`
- `acquireGeoPosition`
- `stopAcquisition`

If permissions have not been requested or not granted, the MobileFirst API does not get a provider and returns an error, `WLGeoErrorCodes.PERMISSION_DENIED`, along with a message about the requested accuracy level.

Checking and requesting permissions from the Android 6.0 Marshmallow API

Checking if permissions have been granted

Two levels of access permission are available from `android.Manifest.permission`:

- `android.Manifest.permission.ACCESS_FINE_LOCATION`
- `android.Manifest.permission.ACCESS_COARSE_LOCATION`

In the examples that follow and in the sample that is provided, these methods are inherited by the `MainActivity` from the `android.app.Activity` class. To check the status of the permissions, call `checkSelfPermission` with the appropriate access level, as follows:

```
getContext().checkSelfPermission(android.Manifest.permission.ACCESS_FINE_LOCATION)
```

If permission has already been granted, the method returns the value `PackageManager.PERMISSION_GRANTED`.

Requesting permissions

To ask the user for permission for the appropriate level of access, use the inherited `requestPermissions` method, as follows:

```
requestPermissions(new String[]{Manifest.permission.ACCESS_FINE_LOCATION}, 0);
```

Calling this Android method displays a dialog box that prompts the app to grant permission and invokes `onRequestPermissionsResult` when the choice is made. Once this permission has been granted to the system, `startAcquisition`, `stopAcquisition`, and `acquireGeoPosition` are granted access to the location services. If the user denies access, these methods return the `WLGeoErrorCodes.PERMISSION_DENIED` error. See the sample at <https://developer.ibm.com/mobilefirstplatform/documentation/>

getting-started-7-1/foundation/advanced-client-side-development/location-services-hybrid-applications/ for a full demonstration of how to handle the new Android 6.0 Marshmallow permissions model.

Using Android location services in a hybrid Android application environment

Android 6.0 Marshmallow requires user permissions to be granted at runtime. Because runtime JavaScript code in the web framework of the hybrid app does not have access to the Android API, these permissions must be requested and checked by the native code before launching Apache Cordova. The file `<application name>.java` in the native folder is responsible for loading the web resources. The code for requesting and checking permissions for location services can be called within the `onInitWebFrameworkComplete` API or within any other startup API in the class.

```
public void onInitWebFrameworkComplete(WLInitWebFrameworkResult result){
    if (result.getStatusCode() == WLInitWebFrameworkResult.SUCCESS) {
        super.loadUrl(WL.getInstance().getMainHtmlFilePath());
    } else {
        handleWebFrameworkInitFailure(result);
    }
}

if (!(WLClient.getInstance().getContext().checkSelfPermission
    (android.Manifest.permission.ACCESS_FINE_LOCATION) == PackageManager.PERMISSION_GRANTED))
{
    requestPermissions(new String[]{android.Manifest.permission.ACCESS_FINE_LOCATION}, 0);
}
}
```

This code requests permission if the permission has not already been granted. If the permission is still not granted, all requests for location services from the web framework fail.

Location services permissions in iOS

To enable MobileFirst location services for iOS, you must update `info.plist`

Location services are supported for hybrid applications on Android, iOS, and Windows Phone Silverlight 8.

iOS

For iOS, you must update `info.plist` with the following information.

```
Geo:
UIRequiredDeviceCapabilities:
    location-services
    gps (when enableHighAccuracy=true)
Wifi:
UIRequiredDeviceCapabilities: wifi
```

When location services are running in the background on iOS:

```
UIBackgroundModes key: location (when enableHighAccuracy=true)
```

Location services permissions in Windows Phone Silverlight 8

To enable MobileFirst location services for Windows Phone Silverlight 8, you must add the `ID_CAP_LOCATION` capability in the `WMAppManifest.xml` file.

When location services are running in the background on Windows Phone Silverlight 8, replace the DefaultTask details in the WMAppManifest.xml file with the following information:

```
<DefaultTask Name="_default" NavigationPage="MainPage.xml">  
  <BackgroundExecution> <ExecutionType Name="LocationTracking" />  
  <BackgroundExecution> </DefaultTask>
```

See the Windows Phone Development Center web page [http://msdn.microsoft.com/en-us/library/windowsphone/develop/jj662935\(v=vs.105\).aspx](http://msdn.microsoft.com/en-us/library/windowsphone/develop/jj662935(v=vs.105).aspx) for details on running location-tracking apps in the background.

Triggers

A trigger is a mechanism that detects an occurrence, and can cause additional processing in response. Triggers are activated when a change occurs in the device context.

Triggers can be activated for changes in Geo or WiFi data.

Geo triggers

For Geo data, two types of regions, also known as *geofences*, are considered: circles and polygons. The following trigger types are available for Geo data.

Trigger type	Description
PositionChange	The trigger is activated when the position of the device changes by at least a specified distance.
Enter	The trigger is activated when the device enters a region.
Exit	The trigger is activated when the device leaves a region.
DwellInside	The trigger is activated when the device remains inside a region for a given time period.
DwellOutside	The trigger is activated when the device remains outside a region for a given time period.

For Enter, Exit, DwellInside, and DwellOutside, you can increase or decrease the size of the region by altering the buffer zone width. Sensor accuracy is measured by using GPS coordinates and network accuracy.

You can control trigger activation based on confidence levels. For example, if you choose a confidence level of low, accuracy is not taken into account when you are determining whether a geo-locational coordinate acquired from a device is inside or outside a region. If you choose a confidence level of medium, accuracy is taken into account, and you can be sure that the coordinate lies within, or outside of, the region at approximately a 70% confidence level. If you choose a confidence level of high, accuracy is taken into account, and you can be sure that the coordinate lies within, or outside of, the region at approximately a 95% confidence level.

WiFi triggers

For WiFi data, triggers are activated based on a change in visible access points. Access points are defined by using SSIDs (service set identifiers) and MACs (media access control addresses). The following trigger types are available for WiFi data.

Trigger type	Description
VisibleAccessPointsChange	The trigger is activated when the visible access points that define a WiFi area change by a specified amount.
Enter	The trigger is activated when the device enters a WiFi area.
Exit	The trigger is activated when the device leaves a WiFi area.
DwellInside	The trigger is activated when the device remains inside a WiFi area for a given time period.
DwellOutside	The trigger is activated when the device remains outside a WiFi area for a given time period.
Connect	The trigger is activated when the device connects to a WiFi access point.
Disconnect	The trigger is activated when the device gets disconnected from a WiFi access point.

You can control trigger activation based on confidence levels. A low confidence level is used to indicate that the WiFi acquisition policy **signalStrengthThreshold** value is used when determining whether an access point is visible. A medium confidence level is used to indicate that a signal strength of at least 50% is necessary for an access point to be visible. A high confidence level is used to indicate that a signal strength of at least 80% is necessary for an access point to be visible.

When you use the confidence level to determine whether an access point is visible, each specified access point in the area must be at least as strong as that indicated by the confidence level. If the area access point is for an SSID without a MAC address, then the highest signal strength for that SSID must be at least as strong as that indicated by the confidence level. In order to exit the area, the signal strength level for at least one access point must be below the WiFi acquisition policy **signalStrengthThreshold** value.

Note: For WiFi triggers, the **confidenceLevel** parameter is not supported by **DwellOutside**.

For detailed information about the parameters for the trigger types, see the **startAcquisition** method as defined in the **WL.Device** class.

Setting an acquisition policy

You can set up a location services acquisition policy that is based on your requirements. For example, your policy could be set up to maximize positional accuracy, but with the capability of reducing accuracy if the device is known to be low on charge, to conserve battery usage.

About this task

An acquisition policy controls how data is collected from a sensor of a mobile device, using GPS positions and WiFi access points. To manage battery life appropriately, you should match the policy used to your needs. For example, while you might want to have a very accurate position for a geofence trigger, you may be able to save power by using a different policy when the device is far away from the area of interest.

You set up an acquisition policy by using the `WL.Device.startAcquisition` API.

You can specify a preset geo policy to use in the `WL.Device.startAcquisition` API. You do this by using the `WL.Device.Geo.Profiles` API, in which you can specify one of the following functions, based on your requirements:

- `LiveTracking`. Use to get the most accurate and timely position information, but with heavy battery use.
- `RoughTracking`. Use to track devices, but when you do not need the most accurate or timely information. Use of power is less than for `LiveTracking`.
- `PowerSaving`. Use to get infrequent positional data at low accuracy levels, but with very good power conservation.

For information about the preset values for each function, see `WL.Device.Geo.Profiles`.

In addition to these three functions, you can specify many other configuration options as part of the `WL.Device.startAcquisition` API. At the most basic level, you can decide whether you want to allow for GPS use. This option is controlled by the `enableHighAccuracy` parameter. If you want to use GPS, set your permissions appropriately. For information about permissions, see “Location services permissions” on page 8-654. If you decide not to use GPS, then a low-power and less accurate position provider is used.

When the device for which you are acquiring data is plugged in, you might want to use the `LiveTracking` profile. Then, at different battery levels, switch to other options that save power. You might want similar behavior when the application goes to the background, or resumes. To fulfill these requirements, you can use Apache Cordova, and register for the appropriate event. Apache Cordova events provide you with the ability to monitor battery status, and respond appropriately based on the status. For more information, see the Apache Cordova documentation at <http://cordova.apache.org/docs/en/2.6.0/index.html>, and search for “events”.

Procedure

1. Decide on the requirements for your application policy.
2. Optional: Call the `WL.Device.Geo.Profiles` API, specifying the required function.
3. Optional: Use Apache Cordova to monitor your battery status.
4. Call the `WL.Device.startAcquisition` API.

Example

In the code, *triggers* is a variable that stores the currently defined triggers, and *failureFunctions* is a variable that stores the functions to be called when acquisition fails.

For hybrid Android, iOS, or Windows Phone Silverlight 8

```

window.addEventListener("batterylow", goToPowerSaveMode, false);

function goToPowerSaveMode() {
    WL.Device.startAcquisition(
        { Geo: WL.Device.Geo.Profiles.PowerSaving() },
        triggers,
        failureFunctions
    );
}

```

For native Android

```

WLDevice wLDevice = WLClient.getInstance().getWLDevice();
wLDevice.startAcquisition(
    new WLLocationServicesConfiguration()
        .setPolicy(new WLAcquisitionPolicy()
            .setGeoPolicy(WLGeoAcquisitionPolicy.getPowerSavingProfile()))
        .setTriggers(triggers)
        .setFailureCallbacks(failureFunctions)
);

```

For native iOS

```

id<WLDevice> wLDevice = [[WLClient sharedInstance] getWLDevice];
[ wLDevice startAcquisition:
 [
 [
 [
 [[WLLocationServicesConfiguration alloc] init]
 setPolicy:
 [
 [[WLAcquisitionPolicy alloc] init]
 setGeoPolicy: [WLGeoAcquisitionPolicy getPowerSavingProfile]
 ]
 ]
 ]
 setTriggers: triggers
 ]
 setFailureCallbacks: failureFunctions
 ];

```

Working with geofences and triggers

You can use geofences and triggers to identify users who enter, exit, or stay inside or outside a geographical area. You can initiate actions, such as improving responsiveness for privileged guests at a hotel chain, based on geofence-related data.

Before you begin

Acquisition of geolocation data must be started before you can receive triggers related to geofences. For more information, see “Setting an acquisition policy” on page 8-658.

About this task

A geofence is a geographical area, which is defined in the form of a circle or polygon. You can increase or decrease the size of the area by changing the value of the **bufferZoneWidth** parameter in the `WL.Device.startAcquisition` method.

Triggers are used to identify users who enter, exit, or stay inside or outside a geofence. For the entering and exiting triggers, the user must have been previously outside or inside the area, including the buffer zone, for the trigger to occur.

Confidence levels are used to help determine whether the trigger condition is met. You can also use them to trade off sensitivity, correctness, and battery usage. A confidence level of *low*, which is the default, uses the acquired position and does not take into account the accuracy of the measurement. The *medium* and *high* confidence levels do take accuracy into account. The *medium* confidence level indicates that the system is approximately 70% confident that the condition is met. The *high* confidence level corresponds to a level of approximately 95%.

A *low* confidence level indicates that the condition is met more often, although there is a higher likelihood of it being mistaken. A *high* confidence level indicates that the condition is met less often, however it is less likely to be mistaken.

Note: After an Enter trigger is activated, it will not activate again until the user leaves the “activated” area, which includes the buffer zone. For the entering and dwelling-inside triggers, this means that the user must exit the area. For the exiting and dwelling outside triggers, this means that the user must enter the area.

Procedure

1. Start acquiring geolocation data, by using the `WL.Device.startAcquisition` method.
2. Include trigger definitions for geofence triggers: Enter, Exit, DwellInside, and DwellOutside.
3. Set confidence levels for the triggers.
4. Set events to be transmitted when triggers are activated.

Example

For hybrid Android, iOS, or Windows Phone 8

```
function wlCommonInit(){
  /*
   * Use of WL.Client.connect() API before any connectivity to a MobileFirst Server is required.
   * This API should be called only once, before any other WL.Client methods that communicate
   with the MobileFirst Server.
   * Don't forget to specify and implement onSuccess and onFailure callback functions
   for WL.Client.connect(), e.g:
   *
   *   WL.Client.connect({
   *     onSuccess: onConnectSuccess,
   *     onFailure: onConnectFailure
   *   });
   *
   */

  // Common initialization code goes here

  WL.App.hideSplashScreen();
}

// Common initialization code goes here
}

var triggers = {
  Geo: {
    centralPark: {
      type: "DwellInside",
      polygon: [
        {longitude: -73.95824432373092, latitude: 40.80062106285157},
        {longitude: -73.94948959350631, latitude: 40.79691751000037},
```

```

        {longitude: -73.97309303283704, latitude: 40.764486356929645},
        {longitude: -73.98167610168441, latitude: 40.76799670467469}
    ],
    dwellingTime: 600000, // 10 minutes
    bufferZoneWidth: -100, // at least 100 meters within the park
    callback: after10MinsInCentralPark
},
statueOfLiberty: {
    type: "Enter",
    circle: {
        longitude: -74.044444,
        latitude: 40.689167,
        radius: 5000 // 5km
    },
    confidenceLevel: "high", // ~95% confidence that you are in the circle
    eventToTransmit: {
        event: {
            nearAttraction: "statue_of_liberty"
        },
        transmitImmediately: true
    }
}
}
};

```

For native Android

```

WLTriggersConfiguration triggers = new WLTriggersConfiguration();
triggers.getGeoTriggers().put("centralPark",
    new WLGeoDwellInsideTrigger()
        .setArea(new WLPolygon(Arrays.asList(
            new WLCoordinate(40.80062106285157, -73.95824432373092),
            new WLCoordinate(40.79691751000037, -73.94948959350631),
            new WLCoordinate(40.764486356929645, -73.97309303283704),
            new WLCoordinate(40.76799670467469, -73.98167610168441))))
        .setDwellingTime(600000) // 10 minutes
        .setBufferZoneWidth(-100) // at least 100 meters within the park
        .setCallback(after10MinsInCentralPark));
triggers.getGeoTriggers().put("statueOfLiberty",
    new WLGeoEnterTrigger()
        .setArea(new WLCircle(new WLCoordinate(40.689167, -74.044444), 5000)) // 5 km
        .setConfidenceLevel(WLConfidenceLevel.HIGH) // ~95% confidence that we are in the circle
        .setEvent(new JSONObject("{\"nearAttraction: 'statue_of_liberty'"}))
        .setTransmitImmediately(true));

```

For native iOS

```

WLTriggersConfiguration* triggers = [[WLTriggersConfiguration alloc] init];

[[triggers getGeoTriggers] setObject:
    [[[
        [[WLGeoDwellInsideTrigger alloc] init]
        setArea: [[WLPolygon alloc] initWithLatitude:40.80062106285157 longitude:-73.95824432373092],
        [[WLCoordinate alloc] initWithLatitude:40.79691751000037 longitude:-73.94948959350631],
        [[WLCoordinate alloc] initWithLatitude:40.764486356929645 longitude:-73.97309303283704],
        [[WLCoordinate alloc] initWithLatitude:40.76799670467469 longitude:-73.98167610168441],
        nil]]]
        setDwellingTime: 600000 // 10 minutes
        setBufferZoneWidth: -100 // at least 100 meters within the park
        setCallback: after10MinsInCentralPark]
    forKey:@"centralPark"];

[[triggers getGeoTriggers] setObject:
    [[[
        [[WLGeoEnterTrigger alloc] init]
        setArea: [[WLCircle alloc] initWithCenter:[[WLCoordinate alloc] initWithLatitude:40.689167
        longitude:-74.044444] radius:5000]]

```

```
setConfidenceLevel: HIGH] // △95% confidence that we are in the circle
setEvent: [NSDictionary dictionaryWithObject: @"statue_of_liberty" forKey:@"nearAttraction"]]
setTransmitImmediately: true]
forKey:@"statueOfLiberty"];
```

Differentiating between indoor areas

You can use visible access points to identify areas in an indoor location such as a shopping mall. After transmitting this data to a server, together with the device context, you can use it for auditing, reporting, and analysis.

About this task

The process of acquiring data that identifies discrete areas in an indoor location, where the GPS signal might be poor or non-existent, involves acquiring WiFi data, and using WiFi triggers to initiate events.

Procedure

1. Scan the area to determine which access points are visible from each area that you are interested in, and then record the access points.

To scan the area, create a small application that has the following elements:

- A WiFi acquisition policy for appropriate SSIDs. In the policy, specify MAC: "*" to see each access point.
 - A data entry function, for specifying the various indoor areas of interest, and submitting the data. This data entry function calls `WLClient.transmitEvent` to send the location, together with the device context, to the server for logging and subsequent analysis.
2. Analyze the data, and use the analysis to determine which access points are visible in each of the regions.
 3. In the application, use the **accessPointFilters** parameter to define the same visible access points that were used previously.
 4. Define WiFi-fence triggers for each region.

Example

This example shows the use of two small applications.

The first defines which networks are to be scanned, and lets the user define named regions as the client device moves around the indoor area. For example, when the user enters the food court, they could specify that the region is called "FoodCourt". Upon leaving it, they could either clear the current region, or enter the name of the adjacent region they are entering, such as "MallEntrance5". In order to implement this process, adapter logic is implemented on the server side. It updates the application context with the region information and handles all received events. In this way, all the information is written out to the raw reports database, where each row includes the region name in the APP_CONTEXT column, and the visible access points under WIFI_APS.

The data can then be gathered to define triggers to implement the required application logic. For example, in the triggers that are defined at the end of the example, the two specific access points are identified, which should be visible when the device is in the food court. The example shows the identification of a global trigger for entering the mall; instead, a trigger could have been defined for each of the mall entrances based on the access points visible at each location.

Application to set up acquisition policy, including triggers - hybrid Android, iOS, and Windows Phone Silverlight 8

```
function wlCommonInit(){
  /*
   * Use of WL.Client.connect() API before any connectivity to a MobileFirst Server is required.
   * This API should be called once, before any other WL.Client methods that communicate with the MobileFirst Server.
   * Do not forget to specify and implement the onSuccess and onFailure callback functions for WL.Client.connect():
   *
   *   WL.Client.connect({
   *     onSuccess: onConnectSuccess,
   *     onFailure: onConnectFailure
   *   });
   *
   */

  // Common initialization code goes here.

  WL.App.hideSplashScreen();
}

var SSIDs = [];

function addNetworkToBeScanned(ssid) {
  if (SSIDs.indexOf(ssid) < 0)

        nil]]
    setCallback: showFoodCoupons]
 forKey:@"foodCourt"];

```

Securing server resources based on location

Device context data can tell you whether a user's device is connected to a secure network. If it is not connected, the device context can tell you whether the device is within a required geofence. This data can be used to restrict access to sensitive information or to prevent running specific program logic. It can also be used to require that additional authentication mechanisms, such as one-time pads, be used.

About this task

In many environments it is important to ensure that sensitive resources are secure, but can be easily accessed by authorized users who are on site. You can use the `WL.Server.getClientDeviceContext` API to obtain a device context from an authorized user. You can then validate the device context by checking whether a user's device is connected to a secure network, or is within a designated required geofence.

For example, in a hospital, patient records must be secure and confidential, but must be accessible by authorized personnel such as doctors and nurses.

Procedure

1. While the acquisition is running, the device context reflects the most up-to-date information regarding the user's location. The user's device context is transparently synchronized to the server, so that `WL.Device.getContext` and `WL.Server.getClientDeviceContext` return the same result.

Note: The developer must call `WL.Device.startAcquisition` to benefit from the synchronization and validation. Until the developer calls `WL.Device.startAcquisition`, the result is null.

2. Based on the information in the device context, the adapter logic can check whether the user is connected to a specific network. Additionally, by using the WL.Geo functions, the adapter logic can validate whether the user is in a specific, required geographical location.

Example

This example performs the following tasks:

1. An attempt is made to verify the location. The device context information is acquired, by using both Geo and WiFi data. A check is made to ensure that the data is current (acquired within the last 5 minutes), and that the device is within the area that is defined by the *legalPolygon* variable. Time calculations are done by using UTC time.
2. If the location cannot be verified, the message not in an authorized location is thrown.
3. If the location is verified, further processing takes place.

```

var legalPolygon = loadFromDB();
var secureNetworks = ['Secure1', 'Secure2'];

function loadFromDB() {
    // invoke Cast Iron or load from a database, etc.
    // for this example: showing a triangle
    return [{longitude: 0, latitude: 1}, {longitude: 1, latitude: 0}, {longitude: -1, latitude: 0}];
}

function verifyLocation() {
    // get the server's copy of the client's device context
    var deviceContext = WL.Server.getClientDeviceContext();
    if (deviceContext == null)
        throw 'acquisition not started';

    // is the device connected to a WiFi access point?
    if (deviceContext.Wifi && deviceContext.Wifi.connectedAccessPoint) {
        // is the connected access point a secure one?
        if (secureNetworks.indexOf(deviceContext.Wifi.connectedAccessPoint.SSID) >= 0)
            return;
    }

    // has a geolocation been acquired?
    if (deviceContext.Geo && deviceContext.Geo.coords) {
        // verify the information:
        var timestamp = deviceContext.Geo.timestamp;
        var offset = deviceContext.timezoneOffset;
        var utcTime = timestamp + offset;

        var now = new Date();
        var nowTime = now.getTime() + now.getTimezoneOffset();

        if (nowTime - utcTime <= 5*60000) { // time is within last 5 minutes
            if (WL.Geo.isInsidePolygon(deviceContext.Geo.coords, legalPolygon))
                return;
        }
    }

    throw 'not in an authorized location';
}

function aProcedure() {
    verifyLocation();

    // rest of logic:
    // ...
}

```

Tracking the current location of devices

You can track the location of devices by ensuring that ongoing acquisition of geo-locational data is taking place. When the position of the device changes, a trigger is activated.

About this task

You acquire geo-locational data from a device by using the `WL.Device.startAcquisition` API. The `PositionChange` trigger is activated if the position of the device changes significantly, and events can then be sent to the server. The server handles these events by setting up an event handler.

For example, a warehouse could improve the efficiency of its processes by using locational data from its delivery vehicles to guide the vehicles to the correct docks, and notify warehouse personnel so that they can be prepared for the arrival of the vehicles.

Procedure

1. The acquisition of geo-locational data is initiated by the `WL.Device.startAcquisition` API.
2. The `PositionChange` trigger in the API is used to emit events that are then transmitted to the server. For "live" views, either the transmission interval that is set in the `WL.Client.setEventTransmissionPolicy` API should be small, or the `transmitImmediately` parameter must be set to true.
3. An event handler is set up on the server by using the `WL.Server.createEventHandler(filter,handlerFunction)` API. The filter is a literal object that is used to match only the events that you want the handler function to handle.
4. The events that are transmitted to the server contain the client's device context at the time the trigger was activated. The handler can pass this, or other information, to external systems where, for example, the data could be displayed on a map.

Example

Adapter code

```
function handleDeviceLocationChange(event) {
    // do something with event
}

function handleDeliveryTruckMoved(event) {
    // do something with event
}

function handleRefrigeratedDeliveryTruckMoved(event) {
    // do something with event
}

var deviceMoveHandler = WL.Server.createEventHandler(
    {},
    handleDeviceLocationChange
);

var deliveryTruckMovedHandler = WL.Server.createEventHandler(
    {vehicle: "DeliveryTruck"},
    handleDeliveryTruckMoved
);
```

```

var coolTruckMovedHandler = WL.Server.createEventHandler(
    {
        vehicle: "DeliveryTruck",
        refrigeration: true
    },
    handleRefrigeratedDeliveryTruckMoved
);

WL.Server.setEventHandlers(
    [
        deviceMoveHandler,
        deliveryTruckMovedHandler,
        coolTruckMovedHandler
    ]
);

```

Mobile application logic -hybrid Android, iOS, and Windows Phone Silverlight

8

```

function wlCommonInit(){

    // Common initialization code goes here.
    // get truck id (for example from the user) -- for this example, using a hard-coded value
    var truckId = 123;
    var driverName = "John Smith";

    var policy = {
        Geo: {
            enableHighAccuracy: true,
            timeout: 10000
        }
    };

    var triggers = {
        Geo: {
            tracking: {
                type: "PositionChange",
                minChangeDistance: 100, // 100 meters
                eventToTransmit: {
                    event: {
                        vehicle: "DeliveryTruck",
                        id: truckId,
                        driverName: driverName
                    }
                }
            }
        }
    };

    WL.Device.startAcquisition(policy, triggers);
}

```

Mobile application logic - native Android

```

// get truck id (for example from the user) -- for this example, using a hard-coded value.
long truckId = 123;
String driverName = "John Smith";

WLAcquisitionPolicy policy = new WLAcquisitionPolicy()
    .setGeoPolicy(new WLGeoAcquisitionPolicy()
        .setEnableHighAccuracy(true)
        .setTimeout(10000));

WLTriggersConfiguration triggers = new WLTriggersConfiguration();
triggers.getGeoTriggers().put(
    "tracking",
    new WLGeoPositionChangeTrigger()

```

```

        .setMinChangeDistance(100)
        .setEvent(new JSONObject()
            .put("vehicle", "DeliveryTruck")
            .put("id", truckId)
            .put("driverName", driverName));

WLClient.getInstance().getWLDevice().startAcquisition
    new WLLocationServicesConfiguration()
        .setPolicy(policy)
        .setTriggers(triggers));

```

Mobile application logic - native iOS

```

// get truck id (for example from the user) -- for this example, using a hard-coded value.
long long truckId = 123;
NSString* driverName = @"John Smith";

WLAcquisitionPolicy* policy =
    [[WLAcquisitionPolicy alloc] init]
    [
        setGeoPolicy:
            [
                [[WLGeoAcquisitionPolicy alloc] init]
                setEnableHighAccuracy: true]
                setTimeout: 10000]];

        [
            [[WLGeoPositionChangeTrigger alloc] init]
            setMinChangeDistance: 100]
            setEvent: [NSDictionary dictionaryWithObjectsAndKeys:
                @"DeliveryTruck", @"vehicle",
                truckId, @"id",
                driverName, @"driverName",
                nil]]
        forKey:@"tracking"];

[[[WLClient sharedInstance] getWLDevice] startAcquisition:
    [
        [[WLLocationServicesConfiguration alloc] init]
        setPolicy: policy]
        setTriggers: triggers]];

```

Keeping the application running in the background

When you are tracking a device by acquiring geolocation data, it is important to keep an application running in the background so that data can continue to be acquired.

About this task

If you are using Android, iOS, or Windows Phone Silverlight 8, you can keep an application running in the background, even when the device owner is using another application, such as checking email.

The process for each platform is described in the following procedure.

Procedure

- For Android devices and hybrid applications, to ensure that the application will continue to run in the background use `WL.App.setKeepAliveInBackground(true, options)`. Using this API binds the application to a foreground service. By default, if no options are specified, the application's name and icon are displayed. Tapping on the notification takes the user back to the last activity that

made the call to `WL.App.setKeepAliveInBackground(true)`. The notification is present until the app exits, or `WL.App.setKeepAliveInBackground(false)` is called. For details on using the options to change the text, the icon, or which activity gets called when the user presses on the notification, see the method `setKeepAliveInBackground` as defined in the `WL.App` class.

- For Android devices and native applications, you should access the location APIs through a service. For more information about Android services, see the “Services” section on the Android development site at <http://developer.android.com/guide/components/services.html>.
- For iOS devices, you must set up your `info.plist` file to indicate that you want to use background location services when `enableHighAccuracy=true`. To do this, you must set the location string on the `UIBackgroundModes` key in the `info.plist` file.
- For Windows Phone Silverlight 8 devices, replace the `DefaultTask` details in the `WMAppManifest.xml` file with: `<DefaultTask Name="_default" NavigationPage="MainPage.xml"> <BackgroundExecution> <ExecutionType Name="LocationTracking" /> </BackgroundExecution> </DefaultTask>`. See the Windows Phone Development Center web page [http://msdn.microsoft.com/en-us/library/windowsphone/develop/jj662935\(v=vs.105\).aspx](http://msdn.microsoft.com/en-us/library/windowsphone/develop/jj662935(v=vs.105).aspx) for details on running location-tracking apps in the background.

Client-side log capture

Applications in the field occasionally experience problems that require a developer's attention to fix. It is often difficult to reproduce problems in the field. Developers who worked on the code for the problem application often do not have the environment or exact device with which to test. In these situations, it is helpful to be able to retrieve debug logs from the client devices as the problems occur in the environment in which they happen.

Starting in IBM Worklight V6.2.0, developers that use MobileFirst client-side APIs who want to capture both platform (IBM MobileFirst Platform Foundation) and application (your code) logs for debug and problem determination should use the appropriate client-side APIs. By doing so, debug log data is made available for capture and sending to the server.

Introduction to client-side logging

The APIs that are available with MobileFirst client libraries include a logger in JavaScript, Android native, and iOS native code base. The logger API is similar to commonly used logger APIs, such as `console.log` (JavaScript), `java.util.logging` (Java), and `NSLog` (Objective-C). The MobileFirst logger API has the additional capability of persistently capturing logged data for sending to the server to be used for analytics gathering and developer inspection. Use the logger APIs to report log data at appropriate levels so that developers who inspect logs can triage and fix problems without having to reproduce problems in their labs.

There are seven levels. From least verbose to most verbose, they are FATAL, ERROR, WARN, INFO, LOG, DEBUG, TRACE.

Example usage of level-appropriate messages:

- Use TRACE for method entry and exit points.
- Use DEBUG for method result output.
- Use LOG for class instantiation.

- Use INFO for initialization reporting.
- Use WARN to log deprecated usage warnings.
- Use ERROR for unexpected exceptions or unexpected network protocol errors.
- Use FATAL for unrecoverable crashes or hangs.

Default log feature behavior

- Log capture is ON.
- During development, the default log level is DEBUG.
 - On iOS, development mode means that the DEBUG macros is defined.
 - On Android, development mode means that the app is signed with the default Android certificate.
- In production, the default log level is FATAL.
 - On iOS, production mode means that the DEBUG macros is not defined.
 - On Android, production mode means that the app is signed with the customer's generated certificate.
- Log persistent client-side buffer maximum size is 100k bytes.
 - Log entries are treated as a first in, first out (FIFO) queue; oldest log entries are deleted to make room for more recent log entries.
- Log configuration set at the server by the MobileFirst administrator is piggybacked on responses to explicit WLClient connect and invokeProcedure API calls, and is applied automatically.
- All captured log data, if any, is sent to the MobileFirst Server during each successful client network init sequence and invokeProcedure response, with a 60 second minimum interval between sends.
 - Turn this automatic behavior on or off by using one or more of the following options:
 - `Logger.setAutoSendLogs(boolean)`
 - `OCLogger.setAutoSendLogs(boolean)`
 - `WL.Logger.config({autoSendLogs: boolean})`
 - After automatic behavior is turned off, you must explicitly call the send method (in both the Logger and Analytics classes) in your application to send any persistently captured client logs to the MobileFirst Server.
- (Android) Native Logger API is not active, and not capturing logs or data about unrecoverable errors, unless and until the `Logger.setContext(Context)` method is called.
 - This API call is made automatically under the `WL.Client.init()` method call.

Note: For example, when capture is ON and the logger level is configured to FATAL, the logger captures uncaught exceptions and only logs at the FATAL level. It would not capture logs at ERROR, WARN, or INFO that may lead up to that failure. Alternatively, a more verbose logger level would also capture non-FATAL level logs leading up to the FATAL entry.

During development

- Developers should make liberal and reasonable use of the client-side logger APIs.
- Client-side logs that are uploaded to the embedded Liberty server in IBM MobileFirst Platform Foundation are written to files under the `clientlogs` folder. This folder is a peer to the `logs` folder of the embedded server.

- Verifying this behavior is a good way to confirm the expected behavior of your usage of the API.

In production

- Logger configuration is controllable from the MobileFirst Operations Console. Configuration that is retrieved from the server is used as an override of the locally set configuration. Clients revert to the pre-override configuration when the MobileFirst administrator removes the logger configuration and the client retrieves the instruction from the server.

Things to consider

During application development, consider the following questions.

Should capture be always on or always off?

The default setting of capture is ON. When capture is on, all logs at the specified level or filter are captured in a persisted rotating log buffer. You can change the default of the capture setting by using the logger API.

Consider that turning capture on at a verbose logger level has an impact to resource consumption:

- CPU
- File system space
- frequency of network usage when captured log data is also being sent to the server
- size of network payload when captured log data is also being sent to the server

At what level should you set the logger?

There are seven levels. From least verbose to most verbose, they are FATAL, ERROR, WARN, INFO, LOG, DEBUG, TRACE.

For example, when capture is ON and the logger level is configured to FATAL, the logger captures uncaught exceptions and only logs at the FATAL level. It will not capture logs at ERROR, WARN, or INFO that may lead up to that failure. Alternatively, a more verbose logger level will also capture non-FATAL level logs leading up to the FATAL entry.

Consider that verbose logger levels, when capture is ON, can affect:

- frequency of network usage
- size of the payload that is sent to the server
- application performance, and therefore user experience

How frequently should clients check with the server for logger configuration changes?

By default, client applications check for updated logger configuration during the MobileFirst client network `init` sequence, which is not necessarily application startup or application foreground events.

The `init` sequence can be infrequent, depending on the design of your application. For example, the `init` sequence might happen only at check-out in a retail shopping application. In this example, the application can check for new configuration on every `onForeground` event to ensure that it retrieves and applies the configuration soon after the MobileFirst administrator sets in the **Catalog** tab of the MobileFirst Operations Console.

For example, to retrieve and apply configuration overrides from the server when the client comes to the foreground, you can place the WLClient `updateConfigFromServer` function call:

- `onResume` (Android, in each Activity, if necessary)
- `applicationDidBecomeActive` (iOS)
- an `onForeground` event listener (JavaScript)

How can you guarantee that all captured log data on the client gets to the server?

The short answer is that there is no way to guarantee preservation of all captured data. Clients might be running the application offline and simultaneously accumulating captured log data. Because the client is offline with limited file system space, older log data must be purged in favor of preserving more recent log data, which is the behavior of the log capture feature.

You can make a best effort at ensuring that all captured data gets to the server by applying one or more of the following strategies:

- Call the `send` function on a time interval.
- Trigger a call to the `send` function on application lifecycle events, like `pause` and `resume` events.
- Batch the `send` call with other application network activity, like `invokeProcedure`. This approach allows the device radio to sleep and preserve battery.
- Increase the capacity of the persistent log buffer on the client by calling the `setMaxFileSize` function.

How can you capture logs from your application only, and exclude logger entries from MobileFirst code?

If your application code is making good use of the MobileFirst logger API, and you want to capture logs from your application only, you can use a consistent package name or consistent set of package names for your logger instances. For example:

```
• // JavaScript
  var logger = WL.Logger.create({pkg: 'MyAppPkg'});
• // Android
  Logger logger = Logger.getInstance(MyClass.class.getName());

  or

  // Android
  Logger logger = Logger.getLogger(MyClass.class.getName());
• // iOS
  OCLoggerDebugWithPackage(@"MyPackage", @"this is a debug message");
  // or Info, Log, Warn, and so on

  or

  // iOS
  OCLogger* logger = [OCLogger getInstanceWithPackage:@"MyPkg"];
  [logger debug:@"this is a debug message"];
  // or Info, Log, Warn, and so on
```

Then, set the filters on the logger to allow logging only for your package or packages:

- // JavaScript
WL.Logger.config({pkg : 'MyAppPkg', filters : {'MyAppPkg' : 'debug'}});
-

```

// Android
HashMap filters = new HashMap();
filters.put("MyAppPkg", Logger.LEVEL.DEBUG);
Logger.setFilters(filters);
• // iOS
[OCLogger setFilters:@{@"MyAppPkg": @(OCLogger_DEBUG)}];

```

How can you never collect or send logs from deployed apps in the field?

Call `setCapture(false)` as early as possible in your application lifecycle code to set the default behavior. Avoid the **Client Log Profiles** tab of the MobileFirst Operations Console.

Configuring the MobileFirst Logger

You can configure how the MobileFirst Logger runs on a range of client operating systems by modifying `WL.Logger` methods.

For more information on Logger and how to configure it, see Client-side log capture.

Set log level after IBM MobileFirst Platform Foundation starts

Logger is always on, but you can set the log level after IBM MobileFirst Platform Foundation starts.

```

WL.Client.init({
  onSuccess : function() {
    WL.Logger.config({'level' : 'fatal'});
  },
  onFailure : function(err){
    WL.Logger.error('Caught an exception', err);
  }
});

```

Select log levels

You can select from among various log levels.

Debug

Add a debug message.

```

WL.Logger.debug('Loop finished');
// Loop finished.

```

Log

Add a log message.

```

WL.Logger.log('Got', response.statusCode, 'from server. ');
// Got 200 from the server.

```

Info

Add an informative message.

```

WL.Logger.info('Public IP address is', getIpAddress());
// Public IP address is 192.168.1.102.

```

Warn

Add a warning message.

```

if (!window.indexedDB) {
  WL.Logger.warn('IndexedDB not supported, falling back to LocalStorage. ');
  // IndexedDB not supported, falling back to LocalStorage.
}

```

Error

Add an error message.

```

try {
  // Code that may throw new Error('Something failed here.').
} catch (e) {
  WL.Logger.error('Caught an exception', e);
  // Caught an exception Error: Something failed here.
}

```

Log different data types

You can log a range of data types including numbers, strings, and arrays

Strings

```

WL.Logger.info('Hello', 'world.');
```

//Hello World.

Booleans

```

WL.Logger.info(true, false);
```

//true false

Numbers

```

WL.Logger.info(1,2,3.14,4,5,6,7);
```

//1 2 3.14 4 5 6 7

Arrays

```

WL.Logger.info([1,2,3], [[1,2,3], [1,2,3]])
```

//[1,2,3] [[1,2,3], [1,2,3]]

Objects

```

WL.Logger.info({hello: 'world'}, {hey: {test: [1,2,3, {hello: 'world'}]}});
```

//{"hello": "world"} {"hey": {"test": [1,2,3, {"hello": "world"}]}}

Exceptions

```

var e = new Error('Something failed');
var te = new TypeError('Wrong type');
WL.Logger.info(e, te);
```

//Error: Something failed TypeError: Wrong type

undefined

```

var undef;
WL.Logger.info(undefined, undef);
```

//undefined undefined

null

```

var n = null;
WL.Logger.info(null, n);
```

//null null

Any Combination

```

WL.Logger.info('Hey', 1, 2, true, false, [1,2,3], {hey: 'world'}, new Error('Uh oh'), undefined, null);
```

//Hey 1 2 true false [1,2,3] {"hey": "world"} Error: Uh oh undefined null

Filter log levels

You can filter logs to display only logs of equal or lower priority, set by the level property.

For example, to show only warn, error, and fatal logs:

```

WL.Logger.config({level: ['warn']});
```

To show only error and fatal logs:

```

WL.Logger.config({level: ['error']});
```

To show all logs:

```
WL.Logger.config({level : []});
```

To set Logger priority, you can specify a string or int value:

```
WL.Logger.config({level: 'trace'});  
WL.Logger.config({level: 600});
```

Possible string values:

```
'trace',  
'debug',  
'log',  
'info',  
'warn',  
'error',  
'fatal'  
'analytics'
```

Note: These values are not case-sensitive, for example LOG and Log are also possible values.

Possible int values:

```
25 (analytics)  
50 (fatal)  
100 (error)  
200 (warn)  
300 (info)  
400 (log)  
500 (debug)  
600 (trace)
```

Log package whitelist and blacklist

You can associate a set of log messages with a specific part of the application.

Add packages to the whitelist to include the packages in logging:

```
WL.Logger.config({filters : {'wl.jsonstore' : 'info'}});
```

Associate a log message with a package, and log a message. To exclude packages from logging (blacklist), exclude them from the filter object:

```
var JSONSTORE_PKG = 'wl.jsonstore';
```

```
WL.Logger.info('Hey!'); // Ignored.
```

```
WL.Logger.ctx({pkg: JSONSTORE_PKG}).info('JSONStore started');  
// JSONStore started.
```

```
WL.Logger.ctx({pkg: JSONSTORE_PKG}).warn('JSONStore finished executing find.');
```

```
// JSONStore finished executing find.
```

```
WL.Logger.ctx({pkg: 'wl.analytics'}).warn('Hello.');
```

You can list the packages that are on the whitelist or the blacklist:

```
WL.Logger.status();  
//{ enabled : true, stringify: true, whitelist : [], blacklist : [], level : [], pkg : '',  
tag: {level: false, pkg: true}, android: false }
```

The list of keys returned match the options that you can pass to **WL.Logger.config**.

Create log for package

You can create a logger for a specific package.

To avoid writing a package name every time a log message is written, you can create a logger for a specific package.

```
var JSONStoreLogger = new WL.Logger.create({pkg: 'wl.jsonstore'});

JSONStoreLogger.info('Hello', 'world.');//Hello world.

JSONStoreLogger.warn(1,2,3,4);
//1 2 3 4

var AnalyticsLogger = new WL.Logger.create({pkg: 'wl.analytics'});

AnalyticsLogger.error(new Error('BOOM.'));
//Error: BOOM.
```

Stringify

You can convert arguments to strings using the **stringify** function.

Some environments, for example the Xcode console, can print the arguments passed to the logger only if the arguments are converted to strings and concatenated first. Other environments, for example Google Chrome, can provide better visualization of arguments if the arguments are not turned into strings and concatenated.

By default, all logs are stringified. To disable this feature:

```
WL.Logger.config({stringify: false});
```

```
> WL.Logger.log(obj);
Object {name: "carlos", age: 100}
```

To re-enable this feature:

```
WL.Logger.config({stringify: true});
```

```
> WL.Logger.log(obj);
{"name":"carlos","age":100}
```

Callback

You can pass a callback function to `WL.Logger.config` that is called after every log message.

The callback function takes the following arguments:

- message (string or array)
- priority (string)
- package (string)

If `stringify : true` is set, the message is a string. Otherwise it is an array. If the package is not defined, the message is an empty string.

Send all log messages to a backend by using `jQuery.ajax`:

```
var ajaxSender = function (message, priority, pkg) {

    $.ajax({
        url: 'http://localhost:3000/logs'
        type: 'POST',
```

```

        data: {
            message: message,
            priority: priority,
            pkg: pkg
        }
    });

});

WL.Logger.config({callback: ajaxSender});

```

Send all log messages to a backend by using an `invokeProcedure` method as defined in the `WL.Client` class.

```

var adapterSender = function (message, priority, pkg) {

    var invocationData = {
        adapter: 'Logger',
        procedure: 'sendLogs',
        parameters: [message, priority, pkg]
    }

    WL.Client.invokeProcedure(invocationData);
};

WL.Logger.config({callback: adapterSender});

```

Log message tags

You can add context to a log message by appending the level tag, the package tag, or both.

Add level and error tags to a defined package:

```

WL.Logger.config({tag: {level: true, pkg: true} });

WL.Logger.info('Hello');
// [INFO] Hello

WL.Logger.ctx({pkg: 'wl.jsonstore'}).error('Hey');
// [ERROR] [wl.jsonstore] Hey

```

Turn off the tags:

```

WL.Logger.config({tag: {level: false, pkg: false} });

WL.Logger.info('Hello');
// Hello

WL.Logger.ctx({pkg: 'MYPKG'}).error('Hey');
// Hey

```

Note: Tags only show in web applications and not in hybrid applications.

Method chaining

You can invoke multiple method calls by chaining logger methods.

You can chain these logger methods:

```

WL.Logger.ctx
WL.Logger.create

```

This example carries out these steps:

- Sets the package context to `com.my.app`
- Logs Hello.

```
WL.Logger.ctx({pkg: 'com.my.app'}).log('Hello');  
// '[com.my.app] Hello'
```

Pretty-print JSON objects

You can format JSON objects by enabling stringify.

By enabling (pretty: true) you can display JSON objects in a more readable format.

```
var obj = {name: 'carlos', age: 100};  
WL.Logger.config({stringify: true, pretty: true});
```

```
> WL.Logger.debug(obj)  
Q {  
  "name": "carlos",  
  "age": 100  
}
```

```
WL.Logger.config({pretty: false});
```

```
> WL.Logger.debug(obj)  
Q {"name":"carlos","age":100}
```

Print stack traces

You can print stack traces for certain objects.

You can print stack traces for an object if the object is an instance of Error (if (object instanceof Error) evaluates true).

```
WL.Logger.config({stringify: true, stacktrace : true});  
WL.Logger.error("BOOM");
```

```
✖ ▶ Error: Boom  
  at Object.<anonymous> (http://localhost:10080/wlp  
  at Object.Test.run (http://localhost:10080/wlproj  
  at Test.queue.bad (http://localhost:10080/wlproj/  
  at process (http://localhost:10080/wlproj/apps/se
```

```
WL.Logger.config({stacktrace: false});  
WL.Logger.error(object);
```

```
WL.Logger.error(object);  
▶ Error: BOOM
```

Logger Android check and override

Logger checks the operating system on which it is running to determine whether to use the Android logger. You can override this behavior.

By default, WL.Logger checks the operating system at run time, and if it is running on Android it attempts to use the cordova plug-in. If the plug-in fails, it falls back to console.log. There are several differences between the cordova plug-in logger and console log:

Cordova plugin logger

Asynchronous

Provides better output in LogCat

Requires that the deviceready event previously fired.

Console log

Synchronous

Native logger + LogCat:

```
com.wlapp    wlapp    hey1
com.wlapp    wlapp    hey2
com.wlapp    wlapp    hey3
com.wlapp    wlapp    hey4
com.wlapp    wlapp    hey5
```

console.log + LogCat:

```
com.wlapp CordovaLog hey1
com.wlapp CordovaLog hey2
com.wlapp CordovaLog hey3
com.wlapp CordovaLog hey4
com.wlapp CordovaLog hey5
```

To override the Android check, do one of these:

- Pass `android: false` to `WL.Logger.config`

Note: Logs with `WL.Logger.log` are treated as verbose by LogCat.

Environment-specific settings

You can specify that logger options are selected according to the client environment.

Use `initOptions.js` to select options for each environment:

```
//General logger options
wlInitOptions.logger = {enabled: true, stringify: false};

//Environment specific logger options
if (WL.Client.getEnvironment() === WL.Environment.IPHONE) {

    wlInitOptions.logger.stringify = true;
}

WL.Client.init(wlInitOptions);
```

As examples, you can use environment-specific settings to specify no logs in production and default logging for non-production:

```
//Change accordingly
var CURRENT_ENV = 'production';

//General init options
var wlInitOptions = {};

//General logger options
wlInitOptions.logger = {enabled: true};
```

```
//Give your application a small speed boost by not logging in production
if (CURRENT_ENV === 'production') {
    wlInitOptions.logger.enabled = false;
}
```

```
WL.Client.init(wlInitOptions);
```

JavaScript module example

View an example of how to use WL.Logger to add log messages to a JavaScript module.

This example demonstrates how to use WL.Logger to add log messages to a JavaScript module by using these methods:

- `myApp.Greeter.start()` Initializes the module.
- `myApp.Greeter.sayHello(name)` Alerts a greeting to the name that is passed.

The example uses the default `initOptions.js` file for IBM Worklight V6.0. This list contains some of the principles that are demonstrated by the example:

- The module, **myApp.Greeter.js**, uses the JavaScript Revealing Module Pattern, however the concepts in the example apply no matter how you structure your JavaScript code.
- By using `WL.Logger.create({pkg: '[package-name]'})` you can create a `LogInstance` linked to a package.
- Using a short variable name such as `l` for the `LogInstance` makes it easier to write logs, for example: `(l.log(msg), l.info(msg))`
- You can log errors by using the JavaScript try/catch block (synchronous code) and failure callbacks (asynchronous code).
- You can avoid problems by using correct log levels, precise package names, and by filtering as necessary.

myApp.Greeter.js

```
var myApp = myApp || {};
myApp.Greeter = (function (WL) {

    //ECMAScript 5 strict mode
    'use strict';

    //Dependencies
    var WL_LOGGER = WL.Logger;
    //... other dependencies

    //Constants
    var PKG_NAME = 'myApp.Greeter';
    var DEFAULT_NAME = 'Stranger';
    //... other constants

    //LogInstance local to this module
    var l = WL_LOGGER.create({pkg: PKG_NAME});

    //Private function to the module that does validation and alerts a name
    var __alertName = function (name) {

        l.debug('Calling __alertName with name =', name);

        if (typeof name !== 'string' || name.length < 1) {
            l.warn('Name was not a string or empty string, setting name to', DEFAULT_NAME);
            name = DEFAULT_NAME;
        }
    }
}
```

```

        else if (name === '*') {
            throw new Error('Name can not be *');
        }

        //Assume 'alert' is always a global function that exists
        alert('Hello ' + name);

        l.debug('Done calling __alertName');
    };

    //Public API function that does initialization
    var _start = function () {

        l.info('Started', PKG_NAME , 'module');

        //... init code
    };

    //Public API function that alerts 'Hello [name]'
    var _sayHello = function (name) {

        l.debug('Starting _sayHello');

        try {
            __alertName(name);
        } catch (e) {
            //Log any errors
            l.error(e);
        }

        l.debug('End _sayHello');
    };

    //Public API
    return {
        start : _start,
        sayHello: _sayHello
    };

}(WL); //Pass global variables to the module

```

main.js

```

function wlCommonInit () {
    myApp.Greeter.start(); //Start our application's greeter module
    myApp.Greeter.sayHello('Carlos'); //should alert 'Hello Carlos'
    myApp.Greeter.sayHello(); //should alert 'Hello Stranger'
    myApp.Greeter.sayHello('*'); //should log an error
}

```

index.html

```

<!-- ... other html tags -->
<body id="content" style="display: none;">

❌ ▶ [myApp.Greeter] Error: Name can not be *

```

Figure 8-80. Log output

Server preparation for uploaded log data

You must prepare your server to receive uploaded client log data.

Upon receiving uploaded client logs, the MobileFirst production server passes the uploaded data to the Operational Analytics component feature and to an adapter that you create and deploy. Neither of these options are present in a production MobileFirst Server; you must install and configure them. To receive and persist uploaded client logs at the MobileFirst Server, you must take at least one of the following two actions:

1. Install the IBM MobileFirst Platform Operational Analytics as described in “Installing the IBM MobileFirst Platform Operational Analytics” on page 6-216.
2. Deploy an adapter that is named `WLCClientLogReceiver` or the name that corresponds to the value of the `wl.clientlogs.adapter.name` JNDI property.

If you deploy an adapter to receive uploaded client logs, the adapter must be an HTTP adapter that is named `WLCClientLogReceiver` or the value of the `wl.clientlogs.adapter.name` JNDI property. The adapter must have at least one procedure that must be named `log`. The `log` procedure is passed two parameters: `deviceInfo` (a JSON object) and `logMessages` (a JSON array). For more information about implementing adapter procedures, see “Implementing adapter procedures” on page 8-305.

The following example shows an implementation of the `log` procedure in the `WLCClientLogReceiver-impl.js` file:

```

function log(deviceInfo, logMessages) {
    /* The adapter can choose to process the parameters,
    for example to forward them to a backend server for
    safekeeping and further analysis.

    The deviceInfo object may look like this:
    {
      "appName":      "wlapp",
      "appVersion":   "1.0",
      "deviceId":     "66eed0c9-ecf7-355f-914a-3cedac70ebcc",
      "model":        "Galaxy Nexus - 4.2.2 - API 17 - 720x1280",
      "systemName":   "Android",
      "systemVersion": "4.2.2",
      "os.arch":      "i686",           // Android only
      "os.version":   "3.4.0-qemu"     // Android only
    }
    The logMessages parameter is a JSON array
    that contains JSON object elements, and might look like this:
    [
      {
        "timestamp" : "17-02-2013 13:54:23:745", // "dd-MM-yyyy hh:mm:ss:S"
        "level"     : "ERROR",                  // ERROR || WARN || INFO || LOG || DEBUG
        "package"   : "your_tag",              // typically a class name, app name, or JavaScript object name
        "msg"       : "the message",           // a helpful log message
        "threadid"  : 42,                       // (Android only) id of the current thread
        "metadata"  : { "$src" : "js" }         // additional metadata placed on the log call
      }
    ]
    */
}

```

```

    }}
    */
    return true;
}

```

The procedure element in the `WLCClientLogReceiver.xml` file for log:

```
<procedure name="log" />
```

The implementation of the adapter determines the destination of the uploaded log content.

One convenient way to persistently record uploaded client logs is to place the `audit="true"` attribute in the adapter's procedure element. This flag instructs the MobileFirst Server to report all adapter invocations and parameter arguments inline to the server log file:

```
<procedure name="log" audit="true" />
```

Alternatively, you process the parameters that are passed into the log procedure explicitly.

Server security

By default, there is no security that protects the `loguploader` servlet that receives uploaded client logs and analytics at the MobileFirst Server. You can configure the security tests that protect the servlet in the `authenticationConfig.xml` file. But to avoid unexpectedly prompting the user for authentication credentials when you send logs, you have two choices:

1. Use a security test that requires no custom challenge handler code and no user interaction, and freely call the logger send function.
2. Ensure that the security test in front of the servlet remains the same as the security test of the application, and be careful about placement of extra logger send function calls.

If you choose to change the security test, and you choose option one, an explicit call to the logger send function does not result in an unexpected authentication challenge prompt or other authentication failure. The logger send function is safe to place throughout your application.

If you choose to change the security test, and you choose option two, a carelessly placed call to the logger send function might result in an unexpected authentication challenge prompt or other authentication failure. In this case, explicit calls to the logger send function in your application must be placed carefully. If your client applications call the logger send function explicitly, ensure that they do so after authentication succeeds. For example, call the logger send function in the `invokeProcedure onSuccess` callback of an adapter invocation that is protected by the same security test as the log receiver servlet.

Logging sensitive data

The logger library does not automatically protect against logging sensitive data. Data is stored in plain text, but is only readable within the context of the application that is using the logger API. Avoid logging sensitive data

Uploaded client logs

In the embedded Liberty development server, the uploaded client logs are written to a file that corresponds with that client's unique attributes. The uploaded client log file is written, or appended, at the following path, which is a peer to the logs folder:

```
clientlogs/[os]/[os_version]/[app_id]/[app_version]/[device_id].log
```

Uploaded logs are not written to the file system in MobileFirst production servers.

Client-side log capture configuration from MobileFirst Operations Console

In the redesigned MobileFirst Operations Console, administrators can use the Client Log Profile link of a runtime environment to adjust client logger configuration.

Administrators can adjust the log level and log package filters for any combination of operating system, operating system version, application, application version, and device model.

When the MobileFirst administrator creates a configuration profile, the log configuration is concatenated with responses to explicit WLClient connect and invokeProcedure API calls, and is applied automatically.

When the MobileFirst administrator removes a configuration profile, on the next client application WLClient connect and invokeProcedure API calls, the client reverts to its configuration before the server configuration profile override.

What is provided on the client side

Android

```
com.worklight.common.Logger
```

Note: Native Android code that calls the `android.util.Log.*` API is not captured in the client-side logs. Developers must use `com.worklight.common.Logger` to capture client-side logs. For more information about the `com.worklight.common.Logger` API, see the `Logger` class.

Alternatively, developers can use standard `java.util.logging.Logger` in their code with the understanding that levels, filtering, and capturing are still controlled in the `com.worklight.common.Logger` class. No `java.util.logging.Logger` method calls are captured until the `com.worklight.common.Logger.setContext(Context)` method is called.

iOS

```
OCLogger
```

Note: Native iOS code that calls `nslog` directly is not captured in the client-side logs. Developers must use `OCLogger` to capture client-side logs. For more information about the `OCLogger` API, see “Objective-C client-side API for iOS apps” on page 11-5.

JavaScript

```
WL.Logger
```

Note: JavaScript code that calls `console.log` directly is not captured in the client-side logs. Developers must use `WL.Logger` to capture client-side logs. For more information about the `WL.Logger` API, see the `WL.Logger` API.

Migrating applications created on IBM Bluemix to IBM MobileFirst Platform Foundation

You can migrate native applications that were developed on Bluemix Mobile Services to IBM MobileFirst Platform Foundation.

The existing Bluemix Mobile Services app must use a custom identity provider. To provide this security for the app when it is running on IBM MobileFirst Platform Foundation, you must modify some server-side components.

To migrate the application to IBM MobileFirst Platform Foundation, you must complete the following tasks:

- Adapt the server-side authentication code, by using one of the following HTTP-based custom authentication methods:
 - Security realm within a Java adapter
 - Oauth TAI
 - A protected Node.js resource
- Migrate the client application. Migrating the client application includes the following steps:
 - Installing the IBM MobileFirst Platform Foundation SDK, including its associated framework. For iOS applications, you also install a compatibility framework.
 - Making configuration changes to your Xcode project
 - Modifying the application code to remove references that are specific to the Bluemix Mobile Services environment, replacing them with references required in the IBM MobileFirst Platform Foundation environment

For iOS applications, an API, called the compatibility API, translates Bluemix Mobile Services calls to IBM MobileFirst Platform Foundation calls. The compatibility framework communicates with the MobileFirst iOS client framework, which in turn communicates with the MobileFirst Server.

Migration scenario

To illustrate how to migrate an existing Bluemix Mobile Services app to IBM MobileFirst Platform Foundation, this documentation uses an existing Bluemix application that is written in Java. It runs on the Liberty for Java runtime and uses Oauth TAI for security. The Oauth TAI security is implemented as a custom identity provider through the Bluemix Mobile Client Access service.

The following code is the JAX-RS Java class that is deployed to the Liberty for Java server runtime on Bluemix. The class has one service (/hello) and a custom identity provider that is defined by the following HTTP APIs:

```
• /startAuthorization
• /handleChallengeAnswer
package com.mycompany;

import javax.ws.rs.Consumes;
import javax.ws.rs.GET;
import javax.ws.rs.POST;
import javax.ws.rs.Path;
import javax.ws.rs.PathParam;
```

```

import javax.ws.rs.Produces;
import javax.ws.rs.core.MediaType;
import com.ibm.json.java.JSON;
import com.ibm.json.java.JSONObject;

@Path("/")
public class CustomAuthResource {

    // local user repository
    private final static String USER_STORE_JSON = "{\"leonard\": {\"password\": \"1234\", \"displayName\"}}";

    // failure JSON
    private final static String FAILURE_JSON = "{\"status\": \"failure\"}";

    // challenge JSON
    private final static String CHALLENGE_JSON = "{\"status\": \"challenge\", \"challenge\": {\"message\"}}";

    @POST
    @Consumes("application/json")
    @Path("/{tenantId}/customAuthRealm_3/startAuthorization")
    @Produces(MediaType.APPLICATION_JSON)
    public JSONObject startAuthorization(String payload,
    @PathParam("tenantId") String deviceId,
    @PathParam("realmName") String realmName) throws Exception {

        JSONObject returnJson = (JSONObject) JSON.parse(CHALLENGE_JSON);
        return returnJson;
    }

    @POST
    @Consumes("application/json")
    @Path("/{tenantId}/customAuthRealm_3/handleChallengeAnswer")
    @Produces(MediaType.APPLICATION_JSON)
    public JSONObject handleChallengeAnswer(String payload,
    @PathParam("tenantId") String deviceId,
    @PathParam("realmName") String realmName) throws Exception {

        JSONObject userStoreJson = (JSONObject) JSON.parse(USER_STORE_JSON);
        JSONObject failedResponseJson = (JSONObject) JSON.parse(FAILURE_JSON);

        if (payload == null || payload.isEmpty()) {
            return failedResponseJson;
        }

        JSONObject payloadJson = (JSONObject) JSON.parse(payload);
        JSONObject challengeAnswer = (JSONObject) payloadJson.get("challengeAnswer");

        if (challengeAnswer == null) {
            return failedResponseJson;
        }

        String userName = (String) challengeAnswer.get("userName");
        String password = (String) challengeAnswer.get("password");

        if (userName == null || userName.isEmpty() || password == null
            || password.isEmpty()) {
            return failedResponseJson;
        }

        if (userStoreJson.containsKey(userName)) {
            JSONObject userInfoJson = (JSONObject) userStoreJson.get(userName);
            String userPassword = (String) userInfoJson.get("password");
            String userDisplayName = (String) userInfoJson.get("displayName");

            if (password.equals(userPassword)) {
                JSONObject returnJson = new JSONObject();
            }
        }
    }
}

```

```

        JSONObject userIdentityJson = new JSONObject();
        userIdentityJson.put("userName", userName);
        userIdentityJson.put("displayName", userDisplayName);
        returnJson.put("status", "success");
        returnJson.put("userIdentity", userIdentityJson);

        return returnJson;
    }
}
return failedResponseJson;
}

@GET
@Path("/{tenantId}/hello")
public String hello() {
    return "Hello from JAX-RS";
}
}

```

Adapting the server-side code

For an existing Bluemix Mobile Services application to run on premises, on IBM MobileFirst Platform Foundation, you must modify parts of the MobileFirst Server runtime.

Migrating a Bluemix app that uses HTTP-based custom authentication to on-premises MobileFirst Server

If your application runs on Liberty for Java on Bluemix, you can implement a Java adapter on the on-premises MobileFirst Server to provide HTTP-based custom authentication for your migrated application.

Before you begin

- You must have the MobileFirst Server installed.
- You must have either MobileFirst Studio or the IBM MobileFirst Platform Command Line Interface installed.
- You must have created a native application for iOS project on your on-premises MobileFirst Server. For more information, see “Creating MobileFirst projects with MobileFirst Studio” on page 8-6 and “Developing native applications for iOS” on page 8-185.

Procedure

1. Configure a realm name and a login module in the authenticationConfig.xml file. The authenticationConfig.xml file is in the /server/conf directory of your new MobileFirst project. Use the same realm name that was used on Bluemix . For example:

```

<!-- Under realms node -->
<realm name="customAuthRealm_3" loginModule="customAuthLoginModule_3">
  <className>com.worklight.core.auth.ext.CustomIdentityAuthenticator</className>
  <parameter name="providerUrl" value="http://localhost:10080/CustomAuthProject/adapters/customAuthAdapter">
</realm>

<!-- Under loginModules node -->
<loginModule name="customAuthLoginModule_3">
  <className>com.worklight.core.auth.ext.CustomIdentityLoginModule</className>
</loginModule>

```

2. Optional: If you want your application to authenticate with the accessing mobile device by using the user identity, edit the application-descriptor.xml

file and set the user identity realm to one of the realm names that is defined in the authenticationConfig.xml file. You can also specify the user identity realm by using MobileFirst Studio. With MobileFirst Studio, specify one of the realm names that is in the application-descriptor.xml file in the **user identity realms** field.

3. Implement the Java adapter. For more information about Java adapters, see “MobileFirst Java adapters” on page 8-233. For client-side examples of implementing the challenge handler for an app with a Java adapter, see Adapter-based authentication.
 - a. Copy the code of the JAX-RS class that is deployed to the Liberty for Java runtime on IBM Bluemix and paste it into the file that implements the Java adapter.
 - b. Modify the code of the newly created Java adapter's JAX-RS Resource class:
 - 1) Remove the variable `{tenantId}` from the resource PATH.
 - 2) Remove strings that contain `@PathParam`. For example, you would remove the strings `@PathParam("tenantId") String deviceId` and `@PathParam("realmName") String realmName` from the following code:

```
@POST

@Consumes ("application/json")
@Path("/{tenantId}/customAuthRealm_3/startAuthorization")
@Produces(MediaType.APPLICATION_JSON)
public JSONObject startAuthorization(String payload,
    @PathParam("tenantId") String deviceId,
    @PathParam("realmName") String realmName) throws Exception {
    JSONObject returnJson = (JSONObject) JSON.parse(CHALLENGE_JSON);
    return returnJson;
}
```
 - 3) Add a scope. In the following example, the scope `@OAuthSecurity (scope="customAuthRealm_3")`, is added just before the `hello()` method.

The following example shows a JAX-RS Resource class after modification:

```
@Path("/")
public class CustomAuthResource {
    //local user repository
    private final static String USER_STORE_JSON = "{\"leonard\": {\"password\": \"1234\", \"dis

//failure JSON
    private final static String FAILURE_JSON = \"{\"status\": \"failure\"}\";

//challenge JSON
    private final static String CHALLENGE_JSON = \"{\"status\": \"challenge\", \"challenge\": {\

@POST
@Consumes ("application/json")
@Path("/customAuthRealm_3/startAuthorization")
@Produces(MediaType.APPLICATION_JSON)

public JSONObject startAuthorization(String payload) throws Exception {
    JSONObject returnJson = (JSONObject) JSON.parse(CHALLENGE_JSON);
    return returnJson;
}

@POST
@Consumes ("application/json")
@Path("/customAuthRealm_3/handleChallengeAnswer")
@Produces(MediaType.APPLICATION_JSON)
public JSONObject handleChallengeAnswer(String payload) throws Exception {
    JSONObject userStoreJson = (JSONObject) JSON.parse(USER_STORE_JSON);
    JSONObject failedResponseJson = (JSONObject) JSON.parse(FAILURE_JSON);
```

```

        if(payload == null || payload.isEmpty()) {
            return failedResponseJson;
        }

        JSONObject payloadJson = (JSONObject) JSON.parse(payload);
        JSONObject challengeAnswer = (JSONObject) payloadJson.get("challengeAnswer");
        if (challengeAnswer == null ) {
            return failedResponseJson;
        }

        String userName = (String) challengeAnswer.get("userName");
        String password = (String) challengeAnswer.get("password");

        if (userName == null || userName.isEmpty() || password == null || password.isEmpty()) {
            return failedResponseJson;
        }

        if (userStoreJson.containsKey(userName)) {
            JSONObject userInfoJson = (JSONObject) userStoreJson.get(userName);
            String userPassword = (String) userInfoJson.get("password");
            String userDisplayName = (String) userInfoJson.get("displayName");

            if (password.equals(userPassword)) {
                JSONObject returnJson = new JSONObject();
                JSONObject userIdentityJson = new JSONObject();
                userIdentityJson.put("userName", userName);
                userIdentityJson.put("displayName", userDisplayName);
                returnJson.put("status", "success");
                returnJson.put("userIdentity", userIdentityJson);

                return returnJson;
            }
        }
        return failedResponseJson;
    }

    @GET
    @OAuthSecurity (scope="customAuthRealm_3")
    @Path("/hello")
    public String hello(){
        return "Hello from JAX-RS";
    }
}

```

What to do next

1. Deploy the adapter to the MobileFirst Server. For more information, see “Deploying adapters” on page 8-321.
2. Migrate the client application. For more information, see “Adapting the iOS client application” on page 9-11.

Migrating a Bluemix app that uses an OAuth TAI filter to on-premises MobileFirst Server

If your application runs on Liberty for Java on Bluemix, you can run it on the on-premises MobileFirst Server and protect resources by adding the built-in OAuth TAI (Trust Association Interceptor) filter.

Before you begin

- You must have the MobileFirst Server installed. The underlying application server must be WebSphere Application Server Liberty. For step-by-step instructions for installing WebSphere Application Server Liberty, see “Tutorial for a basic installation of MobileFirst Server” on page 6-35.

Important:

- To use the OAuth TAI authentication method, your underlying application server can also be WebSphere Application Server. However, the following instructions assume that the application server is WebSphere Application Server Liberty unless otherwise stated. For instructions on installing WebSphere Application Server, see the installation instructions for your version of WebSphere Application Server in the IBM Knowledge Center.
- In the server.xml file in your WebSphere Application Server Liberty, make sure you have added a <feature>appSecurity-2.0</feature> element, and make sure the <basicRegistry> element exists.
- You must have either MobileFirst Studio or the IBM MobileFirst Platform Command Line Interface installed.
- You must have created a native application for iOS project on your on-premises MobileFirst Server. For more information, see “Creating MobileFirst projects with MobileFirst Studio” on page 8-6 and “Developing native applications for iOS” on page 8-185.

About this task

For more information about OAuth TAI configuration, see “Protecting resources on WebSphere Application Server or WebSphere Application Server Liberty” on page 8-537.

Procedure

1. Configure a realm name and a login module in the authenticationConfig.xml file. The authenticationConfig.xml file is in the /server/conf directory of your new MobileFirst project. Use the same realm name that was used on Bluemix . For example:

```
<!-- Under realms node -->
<realm name="customAuthRealm_3" loginModule="customAuthLoginModule_3">

    <className>com.worklight.core.auth.ext.CustomIdentityAuthenticator</className>

    <parameter name="providerUrl" value="http://localhost:9080/CustomAuthProject/adapters/customAuth
</realm>

<!-- Under loginModules node -->
<loginModule name="customAuthLoginModule_3">
    <className>com.worklight.core.auth.ext.CustomIdentityLoginModule</className>
</loginModule>
```

2. Change the path for the following endpoint protocols that must be exposed: /startAuthorization and /handleChallengeAnswer. Change the path from what it was on Bluemix:

```
/apps/${tenant_id}/${realm_name}/${endpoint_api}
```

to what is required for IBM MobileFirst Platform Foundation:

```
/${realm_name}/${endpoint_api}
```

For example:

```
/apps/{tenantId}/customAuthRealm_3/startAuthorization
```

changes to

```
/customAuthRealm_3/startAuthorization
```

and

```
/apps/{tenantId}/customAuthRealm_3/handleChallengeAnswer
```

changes to

```
/customAuthRealm_3/handleChallengeAnswer
```

3. Optional: If you want your application to authenticate with the accessing mobile device by using the user identity, edit the `application-descriptor.xml` file and set the user identity realm to one of the realm names that is defined in the `authenticationConfig.xml` file. You can also specify the user identity realm by using MobileFirst Studio. With MobileFirst Studio, specify one of the realm names that is in the `application-descriptor.xml` file in the **user identity realms** field.

4. Modify the JAX-RS Resource class code for the application:

- a. Remove the variable `{tenantId}` from the resource PATH.

- b. Remove strings that contain `@PathParam`. For example, you would remove the strings `@PathParam("tenantId") String deviceId` and `@PathParam("realmName") String realmName` from the following code:

```
@POST
@Consumes ("application/json")
@Path("/{tenantId}/customAuthRealm_3/startAuthorization")
@Produces(MediaType.APPLICATION_JSON)
public JSONObject startAuthorization(String payload,
    @PathParam("tenantId") String deviceId,
    @PathParam("realmName") String realmName) throws Exception {
    JSONObject returnJson = (JSONObject) JSON.parse(CHALLENGE_JSON);
    return returnJson;
}
```

5. Export the updated application as a WAR file.

6. Place the WAR file in the `usr/servers/serverName/apps` folder to deploy it to WebSphere Application Server Liberty.

7. Configure WebSphere Application Server Liberty for OAuth TAI. For more information about configuring WebSphere Application Server Liberty for OAuth TAI, see *Installing OAuthTAI in WebSphere Application Server Liberty* in “Protecting resources on WebSphere Application Server or WebSphere Application Server Liberty” on page 8-537.

- a. Edit the `server.xml` file to add the OAuth TAI feature. Note that the security role `TAIUserRole` is mapped to a special subject named `ALL_AUTHENTICATED_USERS`. For example:

```
<usr_OAuthTAI id="myOAuthTAI">
  <securityConstraint httpMethods="GET POST" securedURLs="/worklight-oauth-java-tests/*"
    scope="wl:Realm1 wl:Realm2"/>
  <securityConstraint httpMethods="DELETE" securedURLs="/another-context-root/*"/>
</usr_OAuthTAI>

  <basicRegistry id="basic" realm="BasicRealm" />

  <application type="war" id="basicauth" name="basicauth" location="${server.config.dir}/
<application-bnd>
  <security-role name="TAIUserRole">
    <special-subject type="ALL_AUTHENTICATED_USERS" />
  </security-role>
</application-bnd>
</application>
```

- b. Modify the server environment variable. In the `server.env` file, change the existing URL:

```
imfServiceUrl=http://imf-authserver.ng.bluemix.net/imf-authserver
```

to
publicKeyServerUrl=authorization_server_URL

where

authorization_server_URL

is the URL to the MobileFirst authorization server.

8. Modify the server.xml file.

- a. Remove realmName="imfRealm".
- b. Replace the separator "," with a space if it exists in the values of the **httpMethods** or the **securedURLs** attributes. The following code snippet shows an example of code before modification:

```
<usr_OAuthTAI id="myOAuthTAI" realmName="imfRealm">  
  <securityConstraint httpMethods="GET, POST" securedURLs="/custom-oauth-java/*"/>  
</usr_OAuthTAI>
```

The following code snippet shows the code after modification is complete:

```
<usr_OAuthTAI id="myOAuthTAI">  
  <securityConstraint httpMethods="GET POST" securedURLs="/custom-oauth-java/*"/>  
</usr_OAuthTAI>
```

- c. Modify the **id**, **location**, and **name** attributes of the application element in the server.xml file based on the values for these attributes that are in your application.

Example

Here is an example of the revised code for the JAX-RS Resource class:

```
//local user repository  
private final static String USER_STORE_JSON = "{\"leonard\": {\"password\": \"1234\", \"displayName\": \"Lisa\": {\"password\": \"1234\", \"displayName\": \"Lisa G.\"}}}\"";  
  
//failure JSON  
private final static String FAILURE_JSON = "{\"status\": \"failure\"}";  
  
//challenge JSON  
private final static String CHALLENGE_JSON = "{\"status\": \"challenge\", \"challenge\": {\"message\": \"missing_credentials\", \"stateId\": \"myStateId\"}}\"";  
  
@POST  
@Consumes ("application/json")  
@Path("/customAuthRealm_3/startAuthorization")  
@Produces(MediaType.APPLICATION_JSON)  
public JSONObject startAuthorization(String payload) throws Exception {  
  JSONObject returnJson = (JSONObject) JSON.parse(CHALLENGE_JSON);  
  return returnJson;  
}  
  
@POST  
@Consumes ("application/json")  
@Path("/customAuthRealm_3/handleChallengeAnswer")  
@Produces(MediaType.APPLICATION_JSON)  
public JSONObject handleChallengeAnswer(String payload) throws Exception {  
  
  JSONObject userStoreJson = (JSONObject) JSON.parse(USER_STORE_JSON);  
  JSONObject failedResponseJson = (JSONObject) JSON.parse(FAILURE_JSON);  
  
  if(payload == null || payload.isEmpty()) {  
    return failedResponseJson;  
  }  
  JSONObject payloadJson = (JSONObject) JSON.parse(payload);  
  JSONObject challengeAnswer = (JSONObject) payloadJson.get("challengeAnswer");
```

```

if (challengeAnswer == null ) {
    return failedResponseJson;
}

String userName = (String) challengeAnswer.get("userName");
String password = (String) challengeAnswer.get("password");

if (userName == null || userName.isEmpty() || password == null || password.isEmpty()) {
    return failedResponseJson;
}

if (userStoreJson.containsKey(userName)) {
    JSONObject userInfoJson = (JSONObject) userStoreJson.get(userName);
    String userPassword = (String) userInfoJson.get("password");
    String userDisplayName = (String) userInfoJson.get("displayName");

    if (password.equals(userPassword)) {
        JSONObject returnJson = new JSONObject();
        JSONObject userIdentityJson = new JSONObject();
        userIdentityJson.put("userName", userName);
        userIdentityJson.put("displayName", userDisplayName);

        returnJson.put("status", "success");
        returnJson.put("userIdentity", userIdentityJson);
        return returnJson;
    }
}

return failedResponseJson;
}

```

What to do next

1. Restart the application server.
2. Migrate the client application. For more information, see “Adapting the iOS client application” on page 9-11.

Migrating a Bluemix app that uses a Node.js filter to on-premises MobileFirst Server

If your Bluemix app uses a Node.js filter, you can run it on the on-premises MobileFirst Server and protect Node.js resources by adding the built-in Node.js filter.

Before you begin

- You must have the MobileFirst Server installed.
- You must have either MobileFirst Studio or the IBM MobileFirst Platform Command Line Interface installed.
- You must have created a native application for iOS project on your on-premises MobileFirst Server. For more information, see “Creating MobileFirst projects with MobileFirst Studio” on page 8-6 and “Developing native applications for iOS” on page 8-185.

Procedure

1. Configure a realm name and a login module in the authenticationConfig.xml file. The authenticationConfig.xml file is in the /server/conf directory of your new MobileFirst project. Use the same realm name that was used on Bluemix . For example:

```

<!-- Under realms node -->
<realm name="customAuthRealm_3" loginModule="customAuthLoginModule_3">
  <className>com.worklight.core.auth.ext.CustomIdentityAuthenticator</className>

```

```
<parameter name="providerUrl" value="http://localhost:3000/CustomAuthProject/adapters/customAuthProject" />
</realm>
```

```
<!-- Under loginModules node -->
<loginModule name="customAuthLoginModule_3">
  <className>com.worklight.core.auth.ext.CustomIdentityLoginModule</className>
</loginModule>
```

- Optional: If you want your application to authenticate with the accessing mobile device by using the user identity, edit the `application-descriptor.xml` file and set the user identity realm to one of the realm names that is defined in the `authenticationConfig.xml` file. You can also specify the user identity realm by using MobileFirst Studio. With MobileFirst Studio, specify one of the realm names that is in the `application-descriptor.xml` file in the **user identity realms** field.
- Change the path for the following endpoint protocols that must be exposed: `/startAuthorization` and `/handleChallengeAnswer`. Change the path from what it was on Bluemix:

```
/apps/${tenant_id}/${realm_name}/${endpoint_api}
```

to what is required for IBM MobileFirst Platform Foundation:

```
/${realm_name}/${endpoint_api}
```

For example:

```
/apps/{tenantId}/customAuthRealm_3/startAuthorization
```

changes to

```
/customAuthRealm_3/startAuthorization
```

and

```
/apps/{tenantId}/customAuthRealm_3/handleChallengeAnswer
```

changes to

```
/customAuthRealm_3/handleChallengeAnswer
```

- Replace the `require` declaration. Change this declaration from what it was on Bluemix:

```
require('passport-imf-token-validation').$(any strategy)
```

to what is required for IBM MobileFirst Platform Foundation:

```
require('passport-mfp-token-validation').Strategy
```

- Replace the protection part of each function with the following code:

```
passport.authenticate('mobilefirst-strategy', {
  session : false
}),
```

Example

Here is an example of the code:

```
mfpStrategy = require('passport-mfp-token-validation').Strategy;
```

```
...
```

```
app.post('/customAuthRealm/startAuthorization',
```

```
  passport.authenticate('mobilefirst-strategy', {
```

```

        session : false
    }},    function(req, res) {
        var returnedJSON = startAuthorization(req.body.headers);
        res.json(returnedJSON);
    });

app.post('/customAuthRealm/handleChallengeAnswer',
    passport.authenticate('mobilefirst-strategy', {
        session : false
    }},    function(req, res) {
        var returnJSON = handleChallengeAnswer(req.body.headers, req.body.stateId, req.body.challengeAnswer);
        res.json(returnJSON);
    });var startAuthorization = function(headers) {
return {
    status: "challenge",
    challenge: {
        message: "missing_credentials"
    },
    stateId : "my_custom_state_id"
};
};

var handleChallengeAnswer = function(headers, stateId, challengeAnswer) {
    console.log('State id ' + stateId);
    if (challengeAnswer && users[challengeAnswer.userName] && challengeAnswer.password === users[challengeAnswer.userName].password) {
        return {
            status: "success",
            userIdentity: {
                userName: challengeAnswer.userName,
                displayName: users[challengeAnswer.userName].displayName
            }
        };
    } else {
        return {
            status: "failure"
        }
    }
};
};

```

What to do next

1. Deploy the Node.js service.
2. Migrate the client application. For more information, see “Adapting the iOS client application.”

Adapting the iOS client application

To adapt the client application, you must install new components, configure the Xcode project, and then modify the application code.

Installing required components

To prepare for migrating the client application, you must install the required MobileFirst SDK and iOS frameworks.

Before you begin

Your application must use CocoaPods for dependency management. Specifically,

- You must have CocoaPods, the dependency manager for Xcode projects, installed in your development environment. For more information, see the "Getting Started" guide for CocoaPods installation.
- Your application must be set up to use CocoaPods. For more information, see Using CocoaPods.
- You must have an existing Podfile. If one does not exist, create one by using the **pod init** command. For more information, see Using CocoaPods.

Procedure

1. Edit the Podfile file:
 - a. Create a folder in your environment and copy your original Xcode project to it. Use this copied project for the migration.
 - b. Open the Podfile file that is in the root directory of the copied project with a text editor.
 - c. Comment out or remove references to dependencies that are associated with the IBM MobileFirst Platform for iOS SDK. For example:

```
#pod 'IMFGoogleAuthentication'  
#pod 'IMFFacebookAuthentication'  
#pod 'IMFPush'  
#pod 'IMFData'  
#pod 'IMFURLProtocol'  
#pod 'IMFCore'
```

For a list of all the possible dependencies, see the Installing the IBM MobileFirst Platform for iOS Client SDK using CocoaPods documentation on Bluemix.

- d. Add the following lines and save the changes:

```
source 'https://github.com/CocoaPods/Specs.git'  
pod 'IMFCompatibility'
```
2. Open **Terminal** and navigate to the location of the Podfile file.
 3. Verify that the Xcode project is closed.
 4. Type `pod install` to run the **pod install** command. This command installs the following components and integrates them with the mobile application Xcode project:
 - the IBM MobileFirst Platform for iOS compatibility framework, called `IMFCompatibility.framework`
 - the MobileFirst SDK, called the `IBMMobileFirstPlatformFoundation.framework`

What to do next

Configure the Xcode project. See "Configuring the Xcode project" on page 9-13.

Configuring the Xcode project

You must change some settings and add a file to your Xcode project as part of the migration process.

Procedure

1. Open your *ProjectName.xcworkspace* file in Xcode by typing `open ProjectName.xcworkspace` from a command prompt. This file is located in the same directory as the *ProjectName.xcodeproj* file.
2. In Xcode, select **Build Settings**. In the **Other Linker Flags** field, enter `${inherited}`.
3. Add a `worklight.plist` file to the project. All IBM MobileFirst Platform Foundation applications require a `worklight.plist` file to be present in the application resources. A `.plist` template is supplied in the `IBMMobileFirstPlatformFoundation` pod. Add the `worklight.plist` file to your copied application by completing the following steps:
 - a. In the `Pods` subdirectory of your project, click **Pods > IBMMobileFirstPlatformFoundation > Resources**. Locate the `sample.worklight.plist` file in the `Resources` directory.
 - b. Copy the `sample.worklight.plist` file to the top-level directory of the project. For example, if the project name is `MyProject`, the original `sample.worklight.plist` file is in the directory `MyProject/Pods/IBMMobileFirstPlatformFoundation/Resources`. Create a copy of `sample.worklight.plist` and move the copy to the directory `MyProject`.
 - c. Rename the copy of file `sample.worklight.plist` to `worklight.plist` and add it to the project.
4. Edit the `worklight.plist` file and set the **application id** key to the name of your application that is to be deployed to the IBM MobileFirst Platform Foundation server.

Note: Make sure to use the same application name that you defined when you created the IBM MobileFirst Platform Foundation project.

What to do next

Modify the application code. See “Modifying the application code.”

Modifying the application code

You must modify the code in your existing IBM MobileFirst Platform for iOS application on Bluemix as part of the migration process.

Before you begin

Complete the configuration steps that are described in “Installing required components” on page 9-12.

Procedure

1. In your application to be migrated, find and replace all of the references to `IMF/string` with references to `IMFCompatibility`.
 - a. Search for all import directives that contain the string `#import <IMF`.
 - b. In all instances of `#import <IMF/string/IMFstring.h>`, replace `string` with `IMFCompatibility`,
where

string is any string appended to #import <IMF and to /IMF, such as IMFCore or IMFPush. For example, #import <IMFCore/IMFCore.h> would change to #import <IMFCompatibility/IMFCompatibility.h>.

2. Look for a call to the initializeWithBackendRoute method and replace the route URL with your on-premises MobileFirst Server URL. For example, replace

```
[[ IMFClient sharedInstance ] initializeWithBackendRoute:@"http://compatibilitydemo.ng.mybluemix.com"]
```

with

```
[[ IMFClient sharedInstance ] initializeWithBackendRoute:@"http://localhost:10080/customAuthApp"]
```

where customAuthApp is the name of your application.

Note: The **backendGUID** parameter is ignored.

3. Look for all instantiations of the IMFResourceRequest class and update the request URL with an absolute or relative path to the resource. For example, replace

```
IMFResourceRequest * request = [ IMFResourceRequest requestWithPath:@"http://customAuthApp.ng.mybluemix.com"]  
[request setHTTPMethod:@"GET"];
```

with the absolute path:

```
IMFResourceRequest * request = [ IMFResourceRequest requestWithPath:@"http://localhost:10080/customAuthApp"]
```

or the relative path:

```
IMFResourceRequest * request = [ IMFResourceRequest requestWithPath:@"adapters/customAuth/health"]
```

Note: The setHTTPMethod is not supported in IBM MobileFirst Platform Foundation. IMFResourceRequest:requestWithPath sets the GET HTTP method by default. If you need to use other HTTP methods, call IMFResourceRequest:requestWithPath:method.

Additional steps for migrating a Bluemix application with Push for iOS 8

4. If the existing application is enabled with the Push for iOS 8 service, you must add other libraries to your Objective-C or Swift project. To do this, select your target > BuildPhases > Link binary with Libraries and then add the following libraries:

- libz.dylib
- libstdc++.6.dylib
- libc++.dylib
- libc.dylib
- sqlcipher.framework

Important: If you are using Xcode 7, link libz.tbd, libstdc++.6.tbd, libc++.tbd, and libc.tbd instead of the corresponding .dylib files.

5. Remove any helper methods from IMFResponse+IMFPushCategory.h. Alternatively, you can directly print the responseJson on the response (instead of calling the method on the IMFResponse).
6. In the AppDelegate.m file, add [[WLPush sharedInstance]setTokenFromClient:deviceToken.description]; to method -(void)application:(UIApplication *)application didRegisterForRemoteNotificationsWithDeviceTokenNSData *(*)deviceToken {}.

Tip: Ensure that the registerDeviceToken method is called and the On_Ready_To_Subscribe window is displayed before calling any of the APIs.

What to do next

Deploy the application. For more information, see “Deploying MobileFirst projects” on page 12-1

Additional migration steps for Cloudant data

Complete these additional steps if your application stores data in a Cloudant database.

About this task

Note: The IMFData API is deprecated. For more information about how to migrate to the Cloudant Sync API, see “Storing mobile data in Cloudant” on page 8-471. If you are already using the Cloudant Sync API, no further migration steps are required.

These instructions only cover migrating your app from Bluemix to IBM MobileFirst Platform Foundation. If you need to migrate your data between Cloudant databases, see Cloudant replication.

Procedure

1. In the Podfile file, replace the pod name IMFData with the pod name IMFDataLocal. For example, the resulting Podfile might look like:

```
source 'https://github.com/CocoaPods/Specs.git'
platform :ios, '7.1'
pod 'IMFCompatibility'
pod 'IMFDataLocal'
```

2. Update the initialization method to point to the location of the data proxy. Change the code that is in your original Bluemix application as follows:
Change

Objective-C

```
// Get reference to data managerIMFDataManager
*manager = [IMFDataManager sharedInstance];
```

Swift

```
//Get reference to data manager
let manager = IMFDataManager.sharedInstance()
```

to

Objective-C

```
// Initialize the IMFDataManager
IMFDataManager *manager = [IMFDataManager initWithUrl: CLOUDANT_PROXY_URL];
```

Swift

```
// Initialize the IMFDataManager
let manager: IMFDataManager = IMFDataManager.initiateWithUrl(CLOUDANT_PROXY_URL)
```

3. Configure additional security setup. Follow these steps for OAuth TAI configuration in the authenticationConfig.xml file:
 - a. The realm must be either be defined as cloudant or must have a grantScope of cloudant defined.

```
<realm name="cloudant" loginModule="myUserAuthLoginModule">
  <className>com.worklight.core.auth.ext.AdapterAuthenticator</className>
</realm>
```

```

<realm name="myUserAuthRealm" loginModule="myUserAuthLoginModule">
  <className>com.worklight.core.auth.ext.AdapterAuthenticator</className>
  <parameter name="grantScope" value="cloudant"/>
</realm>

```

Create a cloudant realm. For example:

```

<realms>
  <realm loginModule="CustomAuthLoginModule" name="cloudant">
    <className>com.worklight.integration.auth.AdapterAuthenticator</className>
    <parameter name="login-function" value="CustomAuthAdapter.onAuthRequired"/>
    <parameter name="logout-function" value="CustomAuthAdapter.onLogout"/>
  </realm>

  <realm loginModule="CustomAuthLoginModule" name="customIdentityRealm">
    <className>com.worklight.integration.auth.AdapterAuthenticator</className>
    <parameter name="login-function" value="CustomAuthAdapter.onAuthRequired"/>
    <parameter name="logout-function" value="CustomAuthAdapter.onLogout"/>
  </realm>
</realms>

<loginModules>
  <loginModule name="CustomAuthLoginModule">
    <className>com.worklight.core.auth.ext.NonValidatingLoginModule</className>
  </loginModule>
</loginModules>

```

- b. To use the MobileFirst Data Proxy for security protection, you must use the IMFData SDK.

When you initialize the IMFData SDK, you provide the URL of the MobileFirst Data Proxy.

The databases that you create with the IMFDataManager API are primed with the proxy URL. You can obtain an OAuth token with the cloudant scope through coordination with the MobileFirst native authorization manager. This token is then propagated on all requests to the MobileFirst Data Proxy.

Testing with IBM MobileFirst Platform Foundation

The mobile testing features of IBM MobileFirst Platform Test Workbench automate the creation, execution, and analysis of functional tests for MobileFirst native, hybrid, and web applications on Android and iOS devices. A superset of these features is available in Rational Test Workbench Mobile Test Edition. Testing BlackBerry applications is not currently supported.

Installation

To use the test workbench, you must install it as an extra component in MobileFirst Studio. For instructions about installing the test workbench within MobileFirst Studio, see “Installing and configuring IBM MobileFirst Platform Test Workbench” on page 6-12.

Note: Testing Android applications with the test workbench requires a JDK. Make sure to also add the path to the JDK in **Window > Preferences > Java > Installed JREs**, and to set it as the default JRE by selecting its corresponding check box.

Tools for testing mobile applications in IBM MobileFirst Platform Foundation

The tools for preparing and testing mobile applications in IBM MobileFirst Platform Foundation include:

- MobileFirst Studio for developing your application, preparing it for test, and uploading it to the mobile test workbench for testing by the developer.
- Application Center for sharing applications when the person who develops the application is different from the person who tests the application.
- A mobile test client that runs on Android and iOS devices, as well as Android emulators and iOS simulators. This client is used to record, to run tests, and to view reports. With the Android client, you can also upload apps to the test workbench.

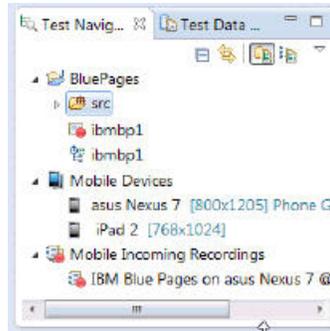

The Android client is a native, Android application. The iOS client is a Web app that runs in a browser on the iOS device. In addition, there is a native iOS client that can be used to test with the iOS Simulator. For details, see [Testing Android applications: overview](#) and [Testing iOS applications: overview](#).

- The test workbench, which works together with the mobile test client for testing the application. See “Stages in the testing process” on page 10-3 for details.

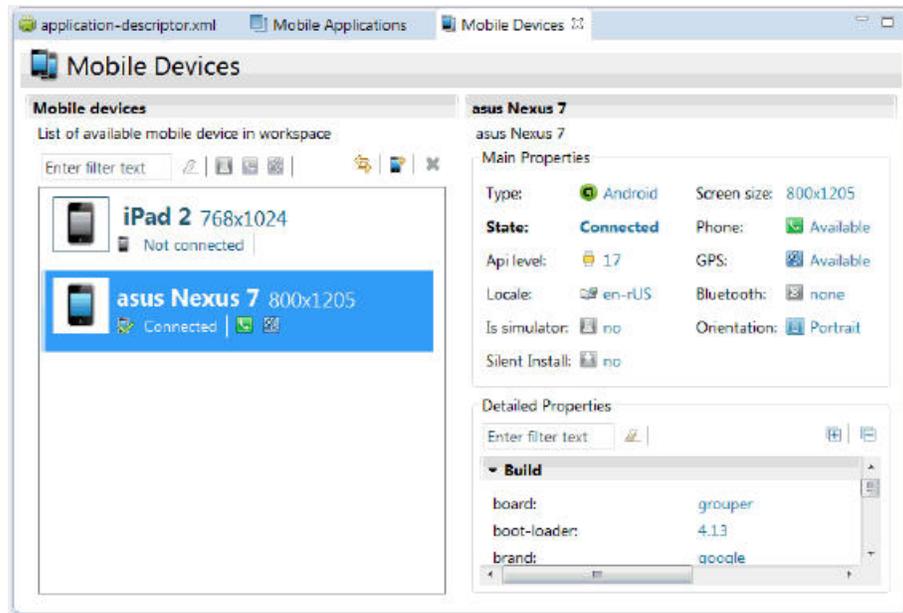

The test workbench

The test workbench runs on a Windows, Linux, or Macintosh computer and includes the following main components:

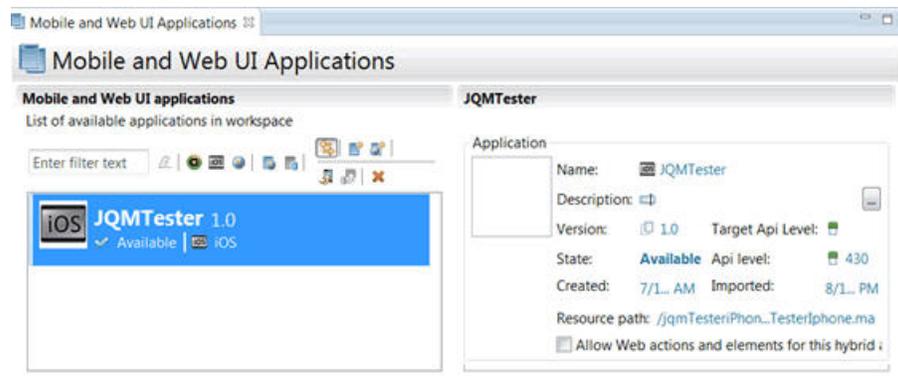

- The Test Navigator lists test projects, tests, mobile devices, and the mobile incoming recordings that are used to generate tests.

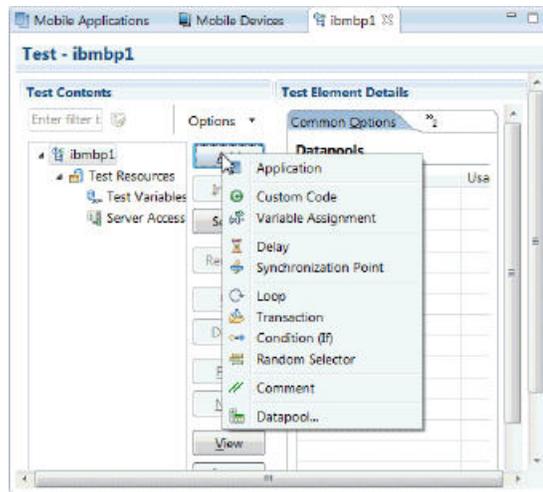

- The Mobile Devices editor lists the devices that are connected to the test workbench. This editor displays detailed specifications of each device, which allows you to select the hardware platforms on which you can deploy and run your tests.

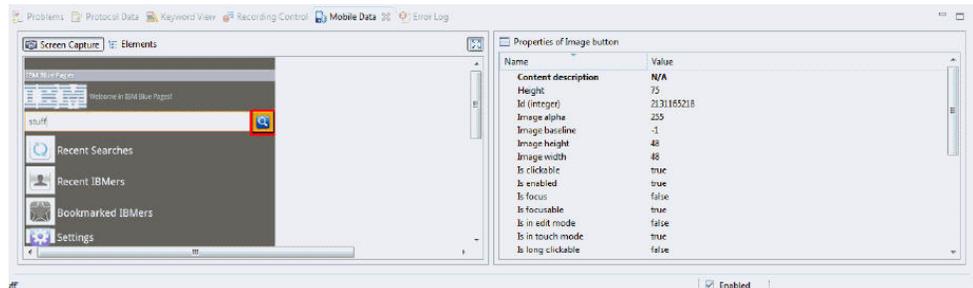

- The Mobile and Web UI Applications editor lists the managed apps that are uploaded and prepared for testing.

- A test editor enables you to edit test scripts in natural language, and add actions, verification points, data pools, test variables, stubs, and so on.

- A Mobile Data view displays the screen captures that were uploaded from the mobile device during the recording. Use this view to display and select user interface elements, and optionally to add verification points to the test script.

Stages in the testing process

The goal of mobile testing is to ensure that your mobile application meets the requirements that guided its design and development. To help you meet this goal, IBM MobileFirst Platform Test Workbench implements the following stages in the testing process:

1. **Configuration:** Set up your test environment with IBM MobileFirst Platform Test Workbench and the Android SDKs for the mobile operating systems. Install the mobile test client on one or more Android devices. Ensure that the mobile devices have connectivity through WiFi, 3G, or 4G, and add those devices to the test workbench. For details, see *Configuring the mobile test client*.
2. **Application preparation:** Import the application that you want to test into the test workbench, or for Android applications, use the device to upload the application under test to the test workbench. For iOS applications, instrument and install the applications. For details, see *“Managing mobile applications for testing”* on page 10-7.
3. **Test recording:** Run the app from the mobile test client to start a recording. The recorder records all user interactions, sensor inputs, and application behavior, and uploads the recorded data to the test workbench, where it can be converted into a mobile test. For details, see *“Creating mobile tests”* on page 10-7.
4. **Test editing:** After recording, you can edit the test in the natural language editor. You can use the mobile data view to display and select UI elements

from the recorded applications. You can replace recorded test values with variable test data, or add dynamic data to the test. For details, see “Editing mobile tests” on page 10-8.

5. **Test execution:** You can run automated tests on multiple devices to ensure that the app matches the expected behavior that is defined in *verification points*. During the run, each verification point is checked and receives a *pass*, *fail*, or *inconclusive* status. Information about each step is saved in the test results. For details, see “Running mobile tests” on page 10-9.
6. **Evaluation of results:** After the test, the device uploads the test data to the test workbench. You evaluate the test results through the performance and verification point reports that are generated with the uploaded data. You can also design custom reports by manipulating a wide range of counters. Functional reports provide a comprehensive view of the behavior of the app under test. Reports can be exported and archived for validation. For details, see “Evaluating results” on page 10-9.

When the tester is the same person as the developer, this person can develop and test the application in the same Eclipse environment.

When the person who develops the application is different than the person who tests it, the application must be shared between the developer and the tester by using the Application Center. In this case, the testing process includes the following additional stages:

- **Publication:** You can publish Android applications to the Application Center from MobileFirst Studio by right-clicking an Android project and clicking **IBM Application Center > Publish on IBM Application Center**. For iOS, the application must first be instrumented for testing. You right-click an iOS project, and click **IBM Application Center > Publish Test-Ready Application**. The iOS application is then instrumented and published.
- **Import of the application:** When the application is published in the Application Center, the tester imports this app into the list of managed applications into the test workbench.

Support for testing native, hybrid, and web applications

Use the test workbench to test various types of mobile applications, including native applications, hybrid applications, and browser-based, web applications that were created with MobileFirst Studio.

A *native* Android or iOS application is built using a native SDK, whose services are defined according to each platform architecture. Android applications are typically created with Java or C++, whereas iOS applications are created with Objective-C.

A *hybrid* application is an application that combines native and web technologies. The web part relies on HTML 5, CSS3, and javascript.

A browser-based *web* application is developed using pure web technologies, such as HTML 5, CSS3, and JavaScript libraries, such as Dojo and JQuery. Web applications are developed to run in multiple browsers and are platform-independent. This release includes support for Dojo Mobile 1.9 and JQuery Mobile 1.3.

Note: To test applications that are not created with IBM MobileFirst Platform Foundation, you must use IBM Rational Test Workbench or IBM Rational Test Workbench Mobile Test Edition.

Compound tests

If you need to combine various mobile tests into a single workflow or end-to-end scenario, you can organize the tests into a compound test. Each test may perform a part of the scenario. For details, see [Compound tests](#).

Note: Rational Test Workbench is required to combine mobile tests with other types of tests in a compound test.

Extending test execution with custom code

You can extend how you run your tests by writing custom Java code and calling the code from the test. You can also specify that results from the tests that are affected by your custom code be included in reports. For details, see [Extending test execution with custom code](#).

Using IBM Rational Test Workbench with IBM MobileFirst Platform Foundation

You can enhance the testing capabilities in IBM MobileFirst Platform Test Workbench by licensing either IBM Rational Test Workbench Mobile Test Edition or the full IBM Rational Test Workbench product.

With both products, you can test mobile apps that are developed with tools other than IBM MobileFirst Platform Foundation.

The full IBM Rational Test Workbench product provides several extra capabilities:

- Integration with IBM Rational Quality Manager (RQM), which provides advanced test execution and test management capabilities. When you provide IBM Rational Test Workbench access to the test assets in the project created with IBM MobileFirst Platform Test Workbench, you can use RQM to drive test execution. For more information, see the IBM Rational Quality Manager section in IBM Rational solution for Collaborative Lifecycle Management.
- Ability to test non-mobile applications, such as desktop Web UI applications, Selenium, HTTP, Citrix, SAP, and other test domains. In addition, you can combine multiple types of tests in a single compound test and run them as a single workflow.
- Load testing with IBM Rational Performance Tester
- Test virtualization with IBM Rational Integration Tester

Getting started

For conceptual information about testing mobile applications, as well as flow diagrams and step-by-step instructions, see the following topics and tutorials.

- Getting started with mobile application testing
- Videos about mobile testing
- Tutorial: Test a native Android app
- Tutorial: Test a native iOS app

Creating a Test Workbench project

The tests that you create, and the assets associated with the tests, reside in a Test Workbench project. You can create a Test Workbench project in the test workbench itself, or you can create one when you create your MobileFirst project. This topic describes the steps for creating the Test Workbench project when you create your MobileFirst project.

About this task

For details about creating a Test Workbench project in the test workbench itself, see [Creating a test workbench project](#).

Note: The IBM MobileFirst Platform Test Workbench allows testing only the mobile applications that are created with IBM MobileFirst Platform Foundation. To test applications that are not created with IBM MobileFirst Platform Foundation, or if you need more tools for extra testing scenarios, you must use the IBM Rational Test Workbench product.

Procedure

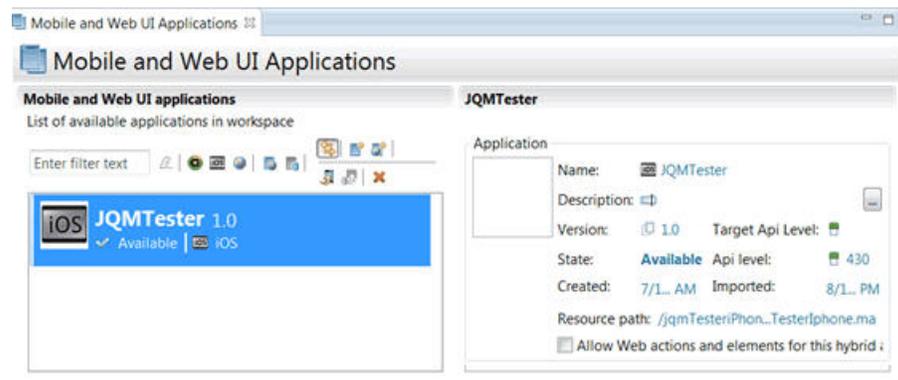

1. In MobileFirst Studio, select **File > New > Worklight Project** and follow the steps to create a MobileFirst project (see “Creating MobileFirst projects with MobileFirst Studio” on page 8-6).
2. On the last page of the project creation wizard, click **IBM Mobile Test Workbench**, select **Create a Test Project** and enter the name of the test project.
3. Click **Finish**.

Managing mobile applications for testing

Before you can record a test from an Android or iOS application, the application must be instrumented, imported into the test workbench, and installed on a mobile device.

Android applications can be instrumented by uploading the application from a mobile device to the test workbench, or by importing the application into the test workbench. iOS applications are instrumented by running a script on a Macintosh computer.

You can view the mobile applications that are available for testing, and information about each application in the Mobile and Web UI Applications editor.

For details about managing mobile applications for testing, see the following topics:

- Adding native and hybrid applications to the test workbench
- Uploading Android applications from the mobile test client
- Instrumenting iOS applications
- Installing instrumented iOS applications
- Tutorial: Test a native Android app, Preparing app for recording
- Tutorial: Test a native iOS app, Preparing the application under test

For videos that show you different ways of using Rational Test Workbench, see Testing Mobile Applications with IBM Rational Test Workbench.

Creating mobile tests

You create a mobile test by recording a session with the app under test. At the end of the session, the recording is uploaded to the IBM MobileFirst Platform Test Workbench, where it is used to generate a test.

For details about recording mobile tests, see the following topics and tutorials:

- Recording tests from the Android mobile test client
- Recording tests from the iOS mobile test client
- Tutorial: Test a native Android app, Recording a test
- Tutorial: Test a native iOS app, Recording a test

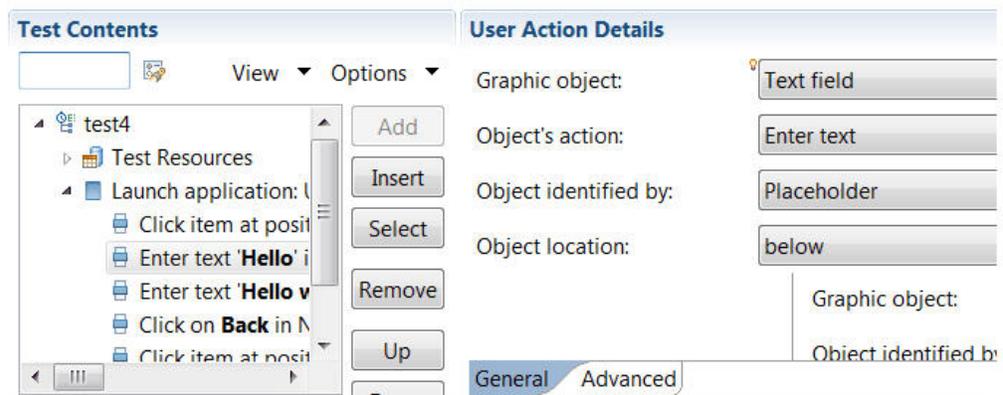

In addition, you can find videos about creating mobile tests in the following YouTube playlist:

- Testing Mobile Applications with IBM Rational Test Workbench

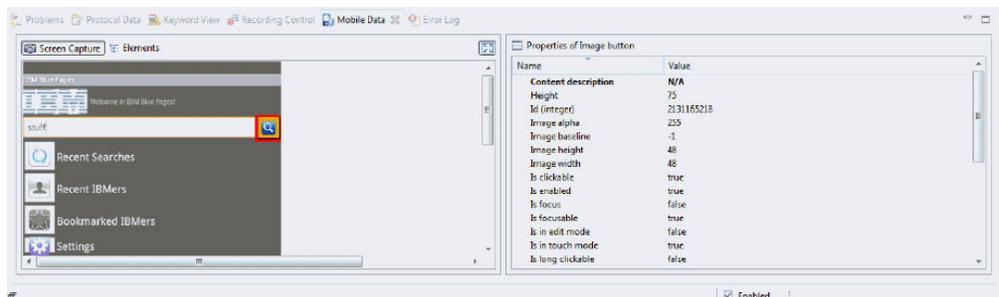

Editing mobile tests

After you record a test, you can edit the test in the natural language editor, which allows you to modify the test manually.

The edited test displays the list of actions and UI elements uploaded from a mobile device during the recording. The Test Contents view of the test editor displays the chronological sequence of events in the test. The view on the right, User Action Details, displays details about the currently selected action in the test script.

You can use the Mobile Data view to display and select UI elements from the recorded application. You can replace recorded test values with variable test data, or add dynamic data to the test.

For details about editing mobile tests, see the following topics and tutorials:

- Editing mobile tests
- Actions from the Mobile and Web UI data view
- Tutorial: Test a native Android app, Editing a test
- Tutorial: Test a native iOS app, Creating a verification point
- Tutorial: Test a native iOS app, Enhancing a test with a loop and a datapool

In addition, you can find videos about editing mobile tests in the following YouTube playlist:

- Testing Mobile Applications with IBM Rational Test Workbench

Running mobile tests

You can run tests from mobile devices, Android emulators, and iOS Simulators. You can also initiate a test from the test workbench so that the test runs on up to five devices or simulators simultaneously.

You can deploy and run automated tests on multiple devices to ensure that the app matches the expected behavior that is defined in *verification points*. During the run, each verification point is checked and receives a *pass*, *fail*, or *inconclusive* status and functional data is recorded.

For details about running mobile tests, see the following topics and video:

- Running mobile tests
- Running tests from an Android mobile test client
- Running tests from an iOS mobile test client
- Running tests on multiple devices in parallel
- Tutorial: Test a native iOS app, Running a test
- Running Mobile App Tests with Rational Test Workbench (video)

Evaluating results

You evaluate test results by viewing the report that is generated at the end of a test run. Functional reports provide a comprehensive view of the behavior of the app under test. Reports can be exported and archived for validation.

For details about viewing test results and test logs, see the following topics:

- Evaluating results
- Managing logs for the Android mobile test client
- Test log overview
- Tutorial: Test a native Android app, Evaluating functional results
- Tutorial: Test a native iOS app, Running the test and evaluating the results

In addition, you can find videos about evaluating mobile test results in the following YouTube playlist:

- Testing Mobile Applications with IBM Rational Test Workbench

Using MobileFirst Studio and Application Center

These topics describe how to initiate tests from IBM MobileFirst Platform Studio and how to work with IBM MobileFirst Platform Application Center.

Initiating mobile testing from Android, iPad, and iPhone environments in MobileFirst Studio

With MobileFirst Studio, you can easily add iOS or Android applications to IBM MobileFirst Platform Test Workbench, and make them available for the recording and playback of test scripts.

Before you begin

You must prepare your application for testing by building the environment, and by running your app on the MobileFirst Development Server. To do so, complete the following steps:

1.
 - For Android apps:
 - a. Create the native Android project in MobileFirst Studio by right-clicking your application, and clicking **Run As > Build Android Environment**.
 - b. Create the application binary file (the APK file) by using the Android tools.
 - For iOS apps: Create the Xcode project in MobileFirst Studio by right-clicking your application, and clicking **Run As > Build iPhone Environment**. The appropriate certificate is specified in the Xcode project, in case you want to test your app on a real device.
2. Perform a build and deployment action on your project by right-clicking the project name, and clicking **Run As > Run on MobileFirst Development Server** to make the iOS .ipa file or the Android .apk file available, and to update the Android project.
3. (For Android only) Compile the APK by right-clicking the name of the automatically generated Android project, and clicking **Run As > Android Studio project**.

About this task

If you developed an iOS or an Android hybrid application with MobileFirst Studio, you can add it to the test workbench in either of these two ways:

- By following the instructions from the section Adding native and hybrid applications to the test workbench.
- Or, more easily, by completing the following steps.

Note: The following procedure applies only to MobileFirst hybrid applications. To test native applications that you created with a MobileFirst native project, you can also use the test workbench, but you must follow the steps that are described in Adding native and hybrid applications to the test workbench.

Procedure

1. Right-click the iPad, iPhone, or Android environment of your MobileFirst application.
2. Click **Run As > Test with IBM Mobile Test Workbench**.
 - For Android applications, this action places the .apk file in the test workbench. The application is ready for testing.
 - iOS applications must be first instrumented for testing. For iOS environments, the application is first instrumented and the resulting instrumented application is then added to the test workbench. This operation is only applicable on Mac OS.

Note: On iOS, this action performs the necessary instrumentation, as an alternative to manually instrumenting your application, by using the provided script as described in Instrumenting iOS applications on the iOS Simulator.

Note: You can also use the Application Center to share applications among team members. To know how to share applications between developers and testers, see “Using the Application Center and the MobileFirst Test Workbench to share applications” on page 10-11.

Using the Application Center and the MobileFirst Test Workbench to share applications

Share applications ready for testing with IBM MobileFirst Platform Studio. Simplify communication between development and test teams by using the Application Center in conjunction with IBM MobileFirst Platform Test Workbench.

In the mobile application development lifecycle, the development and testing of a mobile application can be done by the same person or by different teams. When the person who develops the application is different from the person who tests the application, the application must be shared between the developer and the tester. The Application Center and IBM MobileFirst Platform Test Workbench can simplify the communication between the development team and the test team.

The Application Center is a private application store that can be used to streamline the distribution of applications among an extended development team. The Application Center is similar to public application stores such as Google Play or Apple App Store, but you use it to distribute applications within an enterprise.

With the Application Center, you can create a catalog of mobile applications. Every authorized user can then install mobile applications on their mobile device through the Application Center client.

MobileFirst Studio and IBM MobileFirst Platform Test Workbench provide an easy way to share applications for test purposes. A developer can upload an Android or iOS application to the Application Center to make this application available to all the members of the test team.

Sharing Android applications for testing

To share an Android application for mobile testing through the Application Center, you must first prepare your application by building the APK file from the Android environment in your application. See “Publishing MobileFirst applications to the Application Center” on page 13-118 for more information.

To publish the APK file to the Application Center, choose **IBM Application Center > Publish on IBM Application Center**.

No specific instrumentation is required for Android applications. You can use any Android application that is available in the Application Center for testing.

Sharing iOS applications for testing

Testing iOS applications requires that each application is instrumented before you can record tests on it with IBM MobileFirst Platform Test Workbench. Applications must be instrumented before they are published in the Application Center catalog.

To instrument and publish an iOS application to the Application Center in a single operation, choose **IBM Application Center > Publish test-ready application**. This operation is only available when you run MobileFirst Studio on MacOS.

The instrumentation of the application uses the Xcode project to do the instrumentation. See Publishing test-ready iOS applications to the Application Center for more information.

Alternatively, you can use a script to instrument an iOS application. See Instrumenting an iOS application with `rtwBuildXcode.sh` for the command line and parameters to use to instrument an iOS application manually. This script produces an archive file that you can manually upload to the Application Center console.

An instrumented iOS application appears with a special test icon in the Application Center catalog. The icon for IBM MobileFirst Platform Test Workbench overlays the application icon.

Figure 10-1. Instrumented application in the Application Center console

Importing applications into the mobile test workbench

When an application is published for test purposes in the Application Center, a tester can import the application into the list of managed applications in IBM MobileFirst Platform Test Workbench.

In the Perspectives toolbar of IBM MobileFirst Platform Test Workbench, click this icon  to open the editor for mobile applications. In this editor, you can browse the applications available for testing in the Application Center. You can select the applications that you want to import into IBM MobileFirst Platform Test Workbench. See Adding native and hybrid applications to the test workbench for more information.

Publishing test-ready iOS applications to the Application Center

Deploy iOS applications that are ready to be tested with the Mobile Test Workbench to the Application Center directly from the MobileFirst Studio IDE.

About this task

MobileFirst Studio provides an easy way to publish test-ready iOS applications to the Application Center. In MobileFirst Studio, you can instrument a MobileFirst application for mobile testing and publish it to the Application Center. When an application is available in the Application Center, a member of another team can easily import it into the IBM MobileFirst Platform Test Workbench for testing.

Procedure

1. Specify the publication preferences for the Application Center.
 - a. In the main menu, click **Window > Preferences**.
 - b. In the tree, expand **IBM Application Center** and select **Publish Preferences**.
 - c. Enter the user credentials and server URL for publishing a MobileFirst application to the Application Center

See this table for a description of the required publication preferences.

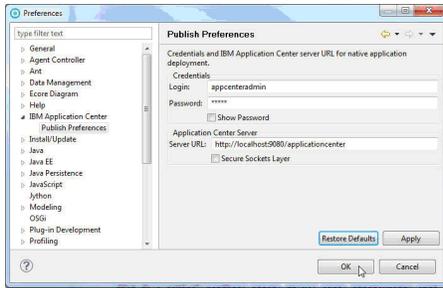

Figure 10-2. User credentials and server URL for deploying applications to the Application Center

Table 10-1. Publication preferences for deploying an application to the Application Center

Preference	Description
Credentials	Login name and password for accessing the repository of the Application Center.
Server URL	URL of the Application Center server to use for publishing applications.

2. Publish an iOS application to the Application Center.
 - a. Right-click the iPad or iPhone environment of the MobileFirst project, or the Xcode project directory, and select **IBM Application Center > Publish Test-Ready Application**. The instrumentation of the project starts.
 - b. When instrumentation is complete, click **Publish** to publish the application with the current preferences or click **Preferences** to change any of the preferences before publishing.

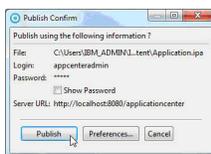

Figure 10-3. Options to publish the application or change the publication preferences

If the application already exists, publication will fail.

Figure 10-4. Failed publication of an existing published application

- c. **Option for existing published applications:** Select **Yes** to overwrite the existing version of the application and to publish the new version.

API reference

To develop your native or hybrid applications, refer to the MobileFirst API in JavaScript, Java Platform, Micro Edition (Java ME), Java for Android, and Objective-C for iOS.

Use the MobileFirst API to develop your applications in JavaScript, Java Platform, Micro Edition (Java ME), Java for Android, and Objective-C for iOS.

MobileFirst client-side API

This collection of topics contains a description of the application programming interface (API) for use in writing client applications with IBM MobileFirst Platform Foundation.

You can use MobileFirst client-side API capabilities to improve application development, and MobileFirst server-side API to improve client/server integration and communication between mobile applications and back-end systems.

With the MobileFirst client-side API, your mobile application has access to various MobileFirst features during run time, by using libraries that are bundled into the application. The libraries integrate your mobile application with MobileFirst Server by using predefined communication interfaces. The libraries also provide unified access to native device functionality, which simplifies application development.

MobileFirst client-side API includes native, hybrid, mixed hybrid, and web-based APIs. These APIs provide support for all mobile development approaches with enhanced security and integration features. MobileFirst client-side API components deliver a uniform bridge between web technologies (HTML5, CSS3, JavaScript) and the native functions that are available on different mobile platforms.

For hybrid and mixed hybrid applications, the Apache Cordova plug-ins that are included add native capabilities and cross-platform user interface controls.

The MobileFirst client-side API provide access to MobileFirst functions across multiple device platforms and development approaches. Applications that are built by using web technologies can access MobileFirst Server through the APIs by using JavaScript, and application using native components can access the APIs directly by using Java and Objective-C. Mobile applications developed with the hybrid and native development approaches, including the applications that run on Android, iOS, or Java ME, benefit from simplified application security and integration features of IBM MobileFirst Platform Foundation.

MobileFirst client-side API components also provide the following features, which improve application development.

Cross-platform compatibility layer

This cross-platform compatibility layer supports development for all supported platforms. If you develop hybrid mobile applications, you can access common control elements such as tab bars and clipboards, and native device capabilities such as the location service or camera. You can extend these functions for Android and iOS by using a custom shell.

Client to server integration

Client to server integration ensures transparent communication between a mobile application that is built with MobileFirst technology, and MobileFirst Server. MobileFirst mobile applications always use an SSL-enabled connection to the server, including for authentication. With such an integration, you can manage your applications and implement security features such as remotely disabling the ability to connect to MobileFirst Server, or updating the web resources of an application.

Encrypted data store

This encrypted data store is located on the device and can access private data by using an API. This helps prevent malicious users to access private data, because all they can obtain is highly encrypted data. The encryption uses ISO/IEC 18033-3 security standards, such as AES256 or PKCS#5, that complies with the United States National Security Agency regulations for transmitting confidential or secret information. The key that is used to encrypt the information is unique to the current user of the application and the device. MobileFirst Server issues a special key when a new encrypted data store is created.

JSONStore

A JSONStore store is included in IBM MobileFirst Platform Foundation to synchronize mobile application data with related data on the back-end. JSONStore provides an offline-capable, key-value database that can be synchronized. JSONStore implements the application local read, write, update, and delete operations and use the MobileFirst adapter technology to synchronize the related back-end data.

Runtime skinning

Runtime skinning is a feature that helps you incorporate an adaptive design that you can adapt to each mobile device. The MobileFirst runtime skin is a user-interface variant that you can apply during application run time, which is based on device properties such as operating system, screen resolution, and form factor. This type of user-interface abstraction helps you develop applications for multiple mobile device models at the same time.

Location services API

IBM MobileFirst Platform Foundation provides a number of functions for location services. Location services enable you to use Geo and WiFi positions to perform various actions.

JavaScript client-side API

You can use JavaScript API to develop apps for all environments.

You can find the description of the API in the following file: JavaScript client-side API.

The other topics in this section contain additional information that you need to use this API to full advantage.

The options Object

The options object contains properties that are common to all methods. It is used in all asynchronous calls to the IBM MobileFirst Platform Server

Pass an options object for all asynchronous calls to MobileFirst Server. The options object contains properties that are common to all methods. Sometimes it is augmented by properties that are only applicable to specific methods. These additional properties are detailed as part of the description of the specific methods.

The common properties of the options object are as follows:

```
options = {  
  onSuccess: success-handler-function(response),  
  onFailure: failure-handler-function(response),  
  invocationContext: invocation-context  
};
```

The meaning of each property is as follows:

Table 11-1. Options object properties

Property	Description
onSuccess	<p>Optional. The function to be invoked on successful completion of the asynchronous call.</p> <p>The syntax of the onSuccess function is: <i>success-handler-function(response)</i></p> <p>where <i>response</i> is an object that contains at a minimum the following property:</p> <p>invocationContext The invocationContext object that was originally passed to the MobileFirst Server in the options object, or undefined if no invocationContext object was passed.</p> <p>status The HTTP response status</p> <p>Note: For methods for which the <i>response</i> object contains additional properties, these properties are detailed as part of the description of the specific method.</p>

Table 11-1. Options object properties (continued)

Property	Description
onFailure	<p>Optional. The function to be invoked when the asynchronous call fails. Such failures include both server-side errors, and client-side errors that occurred during asynchronous calls, such as server connection failure or timed out calls.</p> <p>Note: The function is not called for client-side errors that stop the execution by throwing an exception.</p> <p>The syntax of the onFailure function is: <code>failure-handler-function(response)</code></p> <p>where <i>response</i> is an object that contains the following properties:</p> <p>invocationContext The invocationContext object that was originally passed to the MobileFirst Server in the options object, or undefined if no invocationContext object was passed.</p> <p>errorCode An error code string. All error codes that can be returned are defined as constants in the WL.ErrorCode object in the worklight.js file.</p> <p>errorMsg An error message that is provided by the MobileFirst Server. This message is for the developer's use only, and should not be displayed to the user. It will not be translated to the user's language.</p> <p>status The HTTP response status</p> <p>Note: For methods for which the <i>response</i> object contains additional properties, these properties are detailed as part of the description of the specific method.</p>

Table 11-1. Options object properties (continued)

Property	Description
invocationContext	<p>Optional. An object that is returned to the success and failure handlers.</p> <p>The <code>invocationContext</code> object is used to preserve the context of the calling asynchronous service upon returning from the service.</p> <p>For example, the <code>invokeProcedure</code> method might be called successively, using the same success handler. The success handler needs to be able to identify which call to <code>invokeProcedure</code> is being handled. One solution is to implement the <code>invocationContext</code> object as an integer, and increment its value by one for each call of <code>invokeProcedure</code>. When it invokes the success handler, the MobileFirst framework passes to it the <code>invocationContext</code> object of the options object associated with the <code>invokeProcedure</code> method. The value of the <code>invocationContext</code> object can be used to identify the call to <code>invokeProcedure</code> with which the results that are being handled are associated.</p>

The WL.ClientMessages object

You can see a list of the system messages that are stored in the `WL.ClientMessages` object, and enable the translation of these system messages.

The `WL.ClientMessages` object is an object that stores the system messages that are defined in the `worklight/messages/messages.json` file. This file is in the environment folder of the projects that you generated with IBM MobileFirst Platform Foundation. To enable the translation of a system message, you must override the value of this message in the `WL.ClientMessages` object, as indicated in the following code example:

```
WL.ClientMessages.invalidUsernamePassword="The custom user name and password are not valid";
```

Note: You must override the system messages on a global JavaScript level because some parts of the code run only after the application successfully initialized.

Objective-C client-side API for iOS apps

Use this API to develop native app for iOS environment.

You can access MobileFirst services from iOS applications by using this Objective-C client-side API.

Note: To develop native iOS applications, you can also use Apple Swift. This language is compatible with Objective-C. For more information about using MobileFirst API from within the Swift project, see “Configuring a Swift application” on page 8-194.

For more information, see “Developing native applications ” on page 8-182.

You can find the description of the API in the following file: Objective-C client-side API for iOS apps.

Objective-C client-side API for hybrid apps

Use this API to develop hybrid apps for iOS environment.

You can use the WL class to handle the initialization of your MobileFirst hybrid application and extend WAppDelegate class to use the MobileFirst framework API.

For more information, see “Developing hybrid applications for iOS” on page 8-61.

You can find the description of the API in the following file: Objective-C client-side API for hybrid apps.

Objective-C client-side API for migrated Bluemix iOS apps

The Objective-C client-side API for migrated apps from IBM Bluemix provides a compatibility layer that translates the code that is in your original Bluemix app to code that is recognized by IBM MobileFirst Platform Foundation.

You can find the description of the API in the following file: Objective-C client-side API for migrated Bluemix iOS apps

Java client-side API for Android apps

You can use Java API to develop apps for the Android environment.

Use the Java client-side API for Android apps that IBM MobileFirst Platform Foundation provides if you want to access MobileFirst services from Android mobile applications.

You can use this API to develop native apps. If you develop hybrid apps, you can also use the relevant part of this API, either directly by using the WL.NativePage API or by using Cordova.

You can find the description of the API in the following file: Java client-side API for Android apps.

Java client-side API for Java Platform, Micro Edition (Java ME) apps

You can use Java API to develop Java Platform, Micro Edition (Java ME) apps.

Use the Java client-side API for Java Platform, Micro Edition (Java ME) that IBM MobileFirst Platform Foundation provides if you want to access MobileFirst services from Java ME apps.

You can find the description of the API in the following file: Java client-side API for Java Platform, Micro Edition (Java ME) apps.

C# client-side API for Windows Phone Silverlight 8 apps

You can use C# API to develop apps for the Windows Phone Silverlight 8 environment.

Use the C# client-side API for Windows Phone Silverlight 8 apps that IBM MobileFirst Platform Foundation provides if you want to access MobileFirst services from Windows Phone Silverlight 8 mobile applications.

You can use this API to develop native apps. If you develop hybrid apps, you can also use the relevant part of this API, either directly by using the WL.NativePage API or by using Cordova.

You can find the description of this API in the following file: C# client-side API for Windows Phone Silverlight 8 apps

C# client-side API for Windows 8 Universal and Windows Phone 8 Universal apps

You can use C# API to develop apps for the Windows 8 Universal or Windows Phone 8 Universal environment.

Use this C# client-side API that IBM MobileFirst Platform Foundation provides if you want to access MobileFirst services from Windows 8 Universal or Windows Phone 8 Universal applications.

You can use this API to develop native Windows 8 Universal or Windows Phone 8 Universal apps.

You can find the description of this API in the following file: C# client-side API for Windows 8 Universal apps.

MobileFirst server-side API

Use the server-side API that IBM MobileFirst Platform Foundation defines to modify the behavior of the servers that your mobile applications rely on.

MobileFirst Server provides a set of mobile capabilities with the use of client/server integration and communication between mobile applications and back-end systems.

Server-side application code

You can develop server-side application code and optimize performance, security, and maintenance. By developing server-side application code, your mobile application has direct access to back-end transactional capabilities and cloud-based services. This improves error handling, and enhances security by including more custom steps for request validation or process authorization.

Built-in JSON translation capability

A built-in JSON translation capability reduces the footprint of data transferred between the mobile application and MobileFirst Server. JSON is a lightweight and human-readable data interchange format. Because JSON messages have a smaller footprint than other comparable data-interchange formats, such as XML, they can be more quickly parsed and generated by mobile devices. In addition, MobileFirst Server can automatically convert hierarchical data to the JSON format to optimize delivery and consumption.

Built-in security framework

You can use encryption and obfuscation techniques with a built-in security framework to protect both user-specific and application business logic. A built-in security framework provides easy connectivity or integration into your existing enterprise security mechanisms. This security framework handles connection credentials for back-end connectivity, so the mobile application can use a back-end service, without having to know how to authenticate with it. The authentication credentials stay with MobileFirst Server, and do not stay on the mobile device. If you are running MobileFirst Server with IBM WebSphere Application Server, you can use enterprise-class security and enable Single-Sign-On (SSO) by using IBM Lightweight Third Party Authentication (LTPA).

Adapter library

You can use the adapter library to connect to various back-end systems, such as web services, databases, and messaging applications. For example, IBM MobileFirst Platform Foundation provides adapters for SOAP or XML over HTTP, JDBC, and JMS. Extra adapters simplify integration with IBM WebSphere Cast Iron, which in turn supplies connectors for various cloud-based or on-premise services and systems. With the adapter library, you can define complex lookup procedures and combine data from multiple back-end services. This aggregation helps to reduce overall traffic between a mobile application and MobileFirst Server.

Unified push notification

You can use unified push notification, which simplifies the notification process because the application remains platform-neutral. Unified push notification is an abstraction layer for sending notifications to mobile devices by using either the device vendor's infrastructure or MobileFirst Server SMS capabilities. The user of a mobile application can subscribe to notifications through the mobile application. This request, which contains information about the device and platform, is sent to the MobileFirst Server. The system administrator can manage subscriptions, push or poll notifications from back-end systems, and use the Application Center to send notifications to mobile devices.

JavaScript server-side API

The MobileFirst server-side JavaScript API comprises a series of packages.

You can find the description of the API in the following file: JavaScript server-side API.

Java server-side API

The MobileFirst server-side Java API comprises a series of packages.

You can find the description of the API in the following file: Java server-side API.

MobileFirst OAuth TAI API

Use this API when your application uses OAuth TAI (Trust Association Interceptors) security. It contains the WLCredential class, which stores the IBM MobileFirst token information of an authenticated principal.

You can find the description of the API in the following file: OAuth TAI API

REST API Administration Services

The REST API provides several services to administer the runtime environments concerning adapters, applications, devices, audit, transactions, security, and push notifications.

The REST service API for adapters and applications for each runtime environment is located in `/management-apis/1.0/runtimes/runtime-name/`, where *runtime-name* is the name of the runtime environment that is administered through the REST service. Then, the type of object addressed by the service is identified together with the appropriate method. For example, `/management-apis/1.0/runtimes/runtime-name/Adapters` (POST) refers to the service for deploying an adapter.

Adapter Binary (GET, HEAD)

Retrieves the binary of a specific adapter.

Description

It supports range requests to deliver only a range of the bytes of the adapter. Clients can use this feature to resume a download after interruption.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**

Method

GET, HEAD

Path

`/otu/1.0/one-time-url-hash/runtimes/runtime-name/downloads/adapters/adapter-name`

Example

`https://www.example.com/worklightadmin/otu/1.0/ffabc301/runtimes/myruntime/downloads/adapters/myac`

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

adapter-name

The name of the adapter.

one-time-url-hash

The one-time-url hash code.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/octet-stream

Response

The binary data of the specified adapter.

Errors

400

The request is invalid.

403

The user is not authorized to call this service.

404

The corresponding runtime or the adapter is not found.

416

The requested range of bytes is not satisfiable.

500

An internal error occurred.

Adapter (DELETE)

Deletes a specific adapter.

Description

This transaction can run synchronously or asynchronously. If processed asynchronously, the REST service returns before the transaction is completed. In this case, you can query the transaction result later with the transaction REST service.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**

Method

DELETE

Path

/management-apis/1.0/runtimes/runtime-name/adapters/adapter-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/adapters/myadapter?asyn>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

adapter-name

The name of the adapter.

Query Parameters

Query parameters are optional.

async

Whether the transaction is processed synchronously or asynchronously. Allowed values are true and false. The default is synchronous processing.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The metadata of the deleted adapter.

JSON Example

```
{
  "ok" : false,
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "description" : {
      "filename" : "myadapter.adapter",
      "name" : "myadapter",
    },
  },
  "errors" : [
    {
      "details" : "An internal error occured.",
    },
    ...
  ],
  "id" : 1,
  "project" : {
    "name" : "myproject",
  },
  "status" : "FAILURE",
  "timeCreated" : "2014-04-13T00:18:36.979Z",
  "timeUpdated" : "2014-04-14T00:18:36.979Z",
  "type" : "DELETE_ADAPTER",
  "userName" : "demouser",
},
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<delete-adapter-result
  ok="false"
  productVersion="7.1.0">
  <transaction
    appServerId="Tomcat"
```

```

    id="1"
    status="FAILURE"
    timeCreated="2014-04-13T00:18:36.979Z"
    timeUpdated="2014-04-14T00:18:36.979Z"
    type="DELETE_ADAPTER"
    userName="demouser">
    <description
      filename="myadapter.adapter"
      name="myadapter"/>
    <errors>
      <error details="An internal error occured."/>
      ...
    </errors>
    <project name="myproject"/>
  </transaction>
</delete-adapter-result>

```

Response Properties

The response has the following properties:

ok Whether the transaction was successful.

productVersion

The exact product version.

transaction

The details of the transaction.

The *transaction* has the following properties:

appServerId

The id of the web application server.

description

The details of the adapter.

errors

The errors occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: PENDING, PREPARING, COMMITTING, REJECTING, SUCCESS, FAILURE, CANCELED. Synchronous transactions can have the state SUCCESS and FAILURE. Asynchronous transactions can also have the other states.

timeCreated

The date in ISO 8601 format when the adapter was created.

timeUpdated

The date in ISO 8601 format when the adapter was updated.

type

The type of the transaction, here always DELETE_ADAPTER.

userName

The user that initiated the transaction.

The *description* has the following properties:

filename

The optional file name of the adapter.

name

The name of the adapter.

The *error* has the following properties:

details

The main error message.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime or the adapter is not found.

500

An internal error occurred.

Adapter (GET)

Retrieves metadata of a specific adapter.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/adapters/adapter-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/adapters/myadapter?1>

Path Parameters**runtime-name**

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

adapter-name

The name of the adapter.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The metadata of the specified adapter.

JSON Example

```
{
  "deployTime" : "2014-04-13T00:18:36.979Z",
  "description" : "My first sample adapter",
  "link" : "https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/adapters/myadapter",
  "name" : "myadapter",
  "platformVersion" : "6.1.0.00.20131126-0630",
  "procedureDetails" : [
    {
      "audit" : false,
      "connectAs" : "SERVER",
      "description" : "Returns something.",

        name="param"/>
      ...
    </pathParameters>
    <queryParameters>
      <queryParameter
        defaultValue="n/a"
        javaType="java.lang.String"
        name="param"/>
      ...
    </queryParameters>
  </url>
  ...
</urls>
</adapter>

```

Response Properties

The response has the following properties:

deployTime

The date in ISO 8601 format when the adapter was deployed.

description

The description of the adapter.

link

The URL to access detail information about the adapter.

name

The name of the adapter.

platformVersion

The exact version number of the IBM MobileFirst Platform Foundation development tools (Studio) that built the adapter.

procedureDetails

The JavaScript procedures of the adapter.

productVersion

The exact product version.

projects

The projects the adapter belong to.

resourceSize

The size of the adapter resource.

urls

The API documentation of the URLs of the REST API provided by the adapter.

The *adapter procedure details* has the following properties:

audit

true if calls to the Javascript procedure are logged in the audit log.

connectAs

The optional type of the connection to the back end. Possible values are: SERVER (use the connection policy defined for the adapter) or END_USER (use the user's identity for the connection).

description

The optional description of the procedure.

displayName

The optional display name of the procedure.

name

The Javascript name of the adapter procedure.

securityTest

The optional name of the security test used to protect the adapter procedure, as defined in the authenticationConfig.xml file.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

The *url* has the following properties:

formParameters

The form parameters.

headerParameters

The header parameters.

javaClass

The Java class

javaMethodName

The Java method

method

The HTTP method.

pathParameters

The path parameters.

queryParameters

The query parameters.

securedWithScope

The set of realms that secure the REST API.

uri

The URI of the REST API.

The *REST API parameter* has the following properties:

defaultValue

The default value.

javaType

The Java type name.

name

The name of the parameter.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime or the adapter is not found.

500

An internal error occurred.

Adapter (POST)

Deploys an adapter.

Description

It first checks whether the input adapter is valid. Then, it transfers the adapter to the database and to the runtime.

This transaction can run synchronously or asynchronously. If processed asynchronously, the REST service returns before the transaction is completed. In this case, you can query the transaction result later with the transaction REST service.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**

Method

POST

Path

/management-apis/1.0/runtimes/runtime-name/adapters

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/adapters?async=false&1>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

async

Whether the transaction is processed synchronously or asynchronously. Allowed values are true and false. The default is synchronous processing.

locale

The locale used for error messages.

Consumes

multipart/form-data

Produces

application/json, application/xml, text/xml

Response

The metadata of the deployed adapter.

JSON Example

```
{
  "ok" : false,
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "description" : {
      "alreadyDeployed" : false,
      "filename" : "myadapter.adapter",
      "name" : "myadapter",
    },
    "errors" : [
      {
        "details" : "An internal error occured.",
      },
      ...
    ],
    "id" : 1,
    "project" : {
      "name" : "myproject",
    },
    "status" : "FAILURE",
    "timeCreated" : "2014-04-13T00:18:36.979Z",
    "timeUpdated" : "2014-04-14T00:18:36.979Z",
    "type" : "UPLOAD_ADAPTER",
    "userName" : "demouser",
  },
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<deploy-adapter-result
  ok="false"
  productVersion="7.1.0">
  <transaction
    appServerId="Tomcat"
    id="1"
    status="FAILURE"
    timeCreated="2014-04-13T00:18:36.979Z"
    timeUpdated="2014-04-14T00:18:36.979Z"
    type="UPLOAD_ADAPTER"
    userName="demouser">
    <description
      alreadyDeployed="false"
      filename="myadapter.adapter"
      name="myadapter"/>
    <errors>
      <error details="An internal error occured."/>
      ...
    </errors>
    <project name="myproject"/>
  </transaction>
</deploy-adapter-result>
```

Response Properties

The response has the following properties:

ok Whether the transaction was successful.

productVersion

The exact product version.

transaction

The details of the transaction.

The *transaction* has the following properties:

appServerId

The id of the web application server.

description

The details of the adapter.

errors

The errors occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: PENDING, PREPARING, COMMITTING, REJECTING, SUCCESS, FAILURE, CANCELED. Synchronous transactions can have the state SUCCESS and FAILURE. Asynchronous transactions can also have the other states.

timeCreated

The date in ISO 8601 format when the adapter was created.

timeUpdated

The date in ISO 8601 format when the adapter was updated.

type

The type of the transaction, here always UPLOAD_ADAPTER.

userName

The user that initiated the transaction.

The *description* has the following properties:

alreadyDeployed

Whether a version of the adapter was already previously deployed.

filename

The optional file name of the adapter.

name

The name of the adapter.

The *error* has the following properties:

details

The main error message.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

400

No adapter data is provided.

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Adapters (GET)

Retrieves metadata for the list of deployed adapters.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/adapters

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/adapters?bookmark=AB>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

bookmark

The bookmark for the page if only a part of the list (a page) should be returned. If a bookmark is specified, the offset parameter is ignored.

locale

The locale used for error messages.

offset

The offset from the beginning of the list if only a part of the list (a page) should be returned.

orderBy

The sort mode. By default, the elements are sorted in increasing order. If the sort mode starts with - (minus sign), the elements are sorted in decreasing order. Possible sort modes are: name, deployTime. The default sort mode is: name.

pageSize

The number of elements if only a part of the list (a page) should be returned. The default value is 100.

Produces

application/json, application/xml, text/xml

Response

The metadata of the deployed adapters.

JSON Example

```
{
  "items" : [
    {
      "deployTime" : "2014-04-13T00:18:36.979Z",
      "description" : "My first sample adapter",

        name="param"/>
      ...
    </pathParameters>
    <queryParameters>
      <queryParameter
        defaultValue="n/a"
        javaType="java.lang.String"
        name="param"/>
      ...
    </queryParameters>
  </url>
  ...
</urls>
</item>
...
</items>
</adapters>

```

Response Properties

The response has the following properties:

items

The array of adapter metadata

nextPageBookmark

The bookmark of the next page if only a page of adapters is returned.

pageNumber

The page index if only a page of adapters is returned.

pageSize

The page size if only a page of adapters is returned.

prevPageBookmark

The bookmark of the previous page if only a page of adapters is returned.

productVersion

The exact product version.

startIndex

The start index in the total list if only a page of adapters is returned.

totalListSize

The total number of adapters.

The *adapter* has the following properties:

deployTime

The date in ISO 8601 format when the adapter was deployed.

description

The description of the adapter.

link

The URL to access detail information about the adapter.

name

The name of the adapter.

platformVersion

The exact version number of the IBM MobileFirst Platform Foundation development tools (Studio) that built the adapter.

procedureDetails

The JavaScript procedures of the adapter.

projects

The projects the adapter belong to.

resourceSize

The size of the adapter resource.

urls

The API documentation of the URLs of the REST API provided by the adapter.

The *adapter procedure details* has the following properties:

audit

true if calls to the Javascript procedure are logged in the audit log.

connectAs

The optional type of the connection to the back end. Possible values are: SERVER (use the connection policy defined for the adapter) or END_USER (use the user's identity for the connection).

description

The optional description of the procedure.

displayName

The optional display name of the procedure.

name

The Javascript name of the adapter procedure.

securityTest

The optional name of the security test used to protect the adapter procedure, as defined in the authenticationConfig.xml file.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

The *url* has the following properties:

formParameters

The form parameters.

headerParameters

The header parameters.

javaClass

The Java class

javaMethodName

The Java method

method

The HTTP method.

pathParameters

The path parameters.

queryParameters

The query parameters.

securedWithScope

The set of realms that secure the REST API.

uri

The URI of the REST API.

The *REST API parameter* has the following properties:

defaultValue

The default value.

javaType

The Java type name.

name

The name of the parameter.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found.

500

An internal error occurred.

Adobe Air Application Binary (GET)

Retrieves the Adobe Air binary of a specific app version.

Description

It supports range requests to deliver only a range of the bytes of the app version. Clients can use this feature to resume a download after interruption.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/otu/1.0/one-time-url-hash/runtimes/runtime-name/downloads/air/application-name/application-version

Example

<https://www.example.com/worklightadmin/otu/1.0/ffabc301/runtimes/myruntime/downloads/air/myapplication>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-version

The application version number.

one-time-url-hash

The one-time-url hash code.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/octet-stream

Response

The binary data of the specified app version.

Errors

400

The request is invalid.

403

The user is not authorized to call this service.

404

The corresponding runtime or the app version is not found.

416

The requested range of bytes is not satisfiable.

500

An internal error occurred.

APNS Credentials (DELETE)

Deletes Apple Push Notification Service (APNS) credentials of the application with the application ID, environment, and version.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

DELETE

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/apnsConf/application-env/application-version/

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/apnsConf/application-env/application-version/>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The delete status of APNS credentials.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "DELETE_PUSH_CREDENTIALS",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<deleteAPNSCredentialsStatus
  status="Success"
  type="DELETE_PUSH_CREDENTIALS">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</deleteAPNSCredentialsStatus>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The APNS credentials are deleted successfully.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name

Name of the project

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

APNS Credentials (GET)

Retrieves Apple Push Notification Service (APNS) credentials of the application with the application ID, environment, and version.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/apnsConf/application-env/application-version/

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/apnsConf/application-env/application-version/>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The APNS credentials of the application such as certificate information, password, and product version.

JSON Example

```
{
  "certificateExpirationDate" : 2015-05-05T06:29:10.000Z,
  "certificateFileName" : "apns-certificate-sandbox.p12",
  "password" : "password",
  "productVersion" : "7.1.0",
  "sandbox" : true,
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<apnsCredentials
  certificateExpirationDate="2015-05-05T06:29:10.000Z"
  certificateFileName="apns-certificate-sandbox.p12"
  password="password"
  productVersion="7.1.0"
  sandbox="true"/>
```

Response Properties

The response has the following properties:

certificateExpirationDate

The expiry date of Certificate.

certificateFileName

The name of the certificate.

password

The password of the certificate.

productVersion

The exact product version.

sandbox

The sandbox is true if certificate is of sandbox type.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

APNS Credentials (PUT)

Sets Apple Push Notification Service (APNS) credentials of the application with the application ID, environment, version, password, certificate file name, and certificate.

Description

The payload is the form data in which password, certificate file name, and certificate are submitted.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

PUT

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/apnsConf/application-env/application-version/

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/apnsConf/application-env/application-version/>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

multipart/form-data

Produces

application/json, application/xml, text/xml

Form-data Parameters

certificateFileName

(string) The certificate file name.

password

(string) The certificate password.

certificate

(File) The certificate file.

Response

The status of set APNS credentials.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "SET_APNS_CREDENTIALS",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<setAPNSCredentialsStatus
  status="Success"
  type="SET_APNS_CREDENTIALS">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</setAPNSCredentialsStatus>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The APNS credentials are saved successfully.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name

Name of the project

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

App Version Access Rule (PUT)

Sets the access rule of a specific app version.

Description

The access rule specifies the behavior when a user accesses the application on the device.

This transaction can run synchronously or asynchronously. If processed asynchronously, the REST service returns before the transaction is completed. In this case, you can query the transaction result later with the transaction REST service.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightoperator**

Method

PUT

Path

*/management-apis/1.0/runtimes/runtime-name/applications/application-name/
application-env/application-version/accessRule*

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/applications/myapplication-version/accessRule>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

async

Whether the transaction is processed synchronously or asynchronously. Allowed values are true and false. The default is synchronous processing.

locale

The locale used for error messages.

Consumes

application/json, application/xml, text/xml

Produces

application/json, application/xml, text/xml

Payload**JSON Example**

```
{
  "action" : "NOTIFY",
  "downloadLink" : "ibmappctr://myapp",
  "message" : "Please update!",
  "multiLanguageMessage" : [
    {
      "locale" : "de",
      "message" : "Bitte updaten!",
    },
    ...
  ],
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<accessrule
  action="NOTIFY"
  downloadLink="ibmappctr://myapp"
  message="Please update!">
  <multiLanguageMessage>
    <localizedMessage
      locale="de"
      message="Bitte updaten!"/>
    ...
  </multiLanguageMessage>
</accessrule>
```

Payload Properties

The payload has the following properties:

action

The action to be performed. It can have the following values: NOTIFY (notify the user of some message), BLOCK (block the execution the application), DELETE (remove the access rule).

downloadLink

An optional link displayed with the message where to download a new version of the application.

message

The message to be displayed when the action is NOTIFY or BLOCK.

multiLanguageMessage

Messages in additional languages

The *multilanguage message* has the following properties:

locale

The locale of the message.

message

The translated message.

Response

The metadata of the app version and its access rule.

JSON Example

```
{
  "ok" : false,
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "description" : {
      "action" : "NOTIFY",
      "appVersion" : {
        "applicationName" : "myapplication",
        "environment" : "android",
        "version" : "1.0",
      },
      "createdAtDate" : "2014-02-13T00:18:36.979Z",
      "message" : "This version is no longer supported.",
    },
  },
  "errors" : [
    {
      "details" : "An internal error occurred.",
    },
    ...
  ],
  "id" : 1,
  "project" : {
    "name" : "myproject",
  },
  "status" : "FAILURE",
  "timeCreated" : "2014-04-13T00:18:36.979Z",
  "timeUpdated" : "2014-04-14T00:18:36.979Z",
  "type" : "SET_APPLICATION_ENV_VERSION_ACCESS_RULE",
  "userName" : "demouser",
},
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<set-appversion-accessrule-result
  ok="false"
  productVersion="7.1.0">
  <transaction
    appServerId="Tomcat"
    id="1"
```

```

status="FAILURE"
timeCreated="2014-04-13T00:18:36.979Z"
timeUpdated="2014-04-14T00:18:36.979Z"
type="SET_APPLICATION_ENV_VERSION_ACCESS_RULE"
userName="demouser">
<description
  action="NOTIFY"
  createdAtDate="2014-02-13T00:18:36.979Z"
  message="This version is no longer supported.">
  <appVersion
    applicationName="myapplication"
    environment="android"
    version="1.0"/>
</description>
<errors>
  <error details="An internal error occured."/>
  ...
</errors>
<project name="myproject"/>
</transaction>
</set-appversion-accessrule-result>

```

Response Properties

The response has the following properties:

ok Whether the transaction was successful.

productVersion

The exact product version.

transaction

The details of the transaction.

The *transaction* has the following properties:

appServerId

The id of the web application server.

description

The details of the application.

errors

The errors occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: PENDING, PREPARING, COMMITTING, REJECTING, SUCCESS, FAILURE, CANCELED. Synchronous transactions can have the state SUCCESS and FAILURE. Asynchronous transactions can also have the other states.

timeCreated

The date in ISO 8601 format when the adapter was created.

timeUpdated

The date in ISO 8601 format when the adapter was updated.

type

The type of the transaction, here always SET_APPLICATION_ENV_VERSION_ACCESS_RULE.

userName

The user that initiated the transaction.

The *description* has the following properties:

action

The action to be done when a disabled app version is accessed. Possible values are: NOTIFY, BLOCK, NA, DELETE.

appVersion

The corresponding app version

createdAtDate

The date in ISO 8601 format when the app version access rule was created.

downloadLink

The download link where to obtain a new version of the application.

message

The message to be displayed when a disabled app version is accessed.

The *app version* has the following properties:

applicationName

The name of the application.

environment

The environment of the application.

version

The version of the application.

The *error* has the following properties:

details

The main error message.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

400

The payload is invalid.

403

The user is not authorized to call this service.

404

The corresponding runtime or the app version is not found.

500

An internal error occurred.

App Version (DELETE)

Deletes a specific app version.

Description

This transaction can run synchronously or asynchronously. If processed asynchronously, the REST service returns before the transaction is completed. In this case, you can query the transaction result later with the transaction REST service.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**

Method

DELETE

Path

/management-apis/1.0/runtimes/runtime-name/applications/application-name/application-env/application-version

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/applications/myapp1>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

async

Whether the transaction is processed synchronously or asynchronously. Allowed values are true and false. The default is synchronous processing.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The metadata of the deleted app version.

JSON Example

```
{
  "ok" : false,
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "description" : {
      "applicationName" : "myapplication",
      "environment" : "android",
      "version" : "1.0",
    },
    "errors" : [
      {
        "details" : "An internal error occured.",
      },
      ...
    ],
    "id" : 1,
    "project" : {
      "name" : "myproject",
    },
    "status" : "FAILURE",
    "timeCreated" : "2014-04-13T00:18:36.979Z",
    "timeUpdated" : "2014-04-14T00:18:36.979Z",
    "type" : "DELETE_APPLICATION_ENV_VERSION",
    "userName" : "demouser",
  },
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<delete-appversion-result
  ok="false"
  productVersion="7.1.0">
  <transaction
    appServerId="Tomcat"
    id="1"
    status="FAILURE"
    timeCreated="2014-04-13T00:18:36.979Z"
    timeUpdated="2014-04-14T00:18:36.979Z"
    type="DELETE_APPLICATION_ENV_VERSION"
    userName="demouser">
    <description
      applicationName="myapplication"
      environment="android"
      version="1.0"/>
    <errors>
      <error details="An internal error occured."/>
      ...
    </errors>
    <project name="myproject"/>
  </transaction>
</delete-appversion-result>
```

Response Properties

The response has the following properties:

ok Whether the transaction was successful.

productVersion

The exact product version.

transaction

The details of the transaction.

The *transaction* has the following properties:

appServerId

The id of the web application server.

description

The details of the application.

errors

The errors occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: PENDING, PREPARING, COMMITTING, REJECTING, SUCCESS, FAILURE, CANCELED. Synchronous transactions can have the state SUCCESS and FAILURE. Asynchronous transactions can also have the other states.

timeCreated

The date in ISO 8601 format when the adapter was created.

timeUpdated

The date in ISO 8601 format when the adapter was updated.

type

The type of the transaction, here always DELETE_APPLICATION_ENV_VERSION.

userName

The user that initiated the transaction.

The *description* has the following properties:

applicationName

The name of the application.

environment

The environment of the application.

version

The version of the application.

The *error* has the following properties:

details

The main error message.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime or the app version is not found.

500

An internal error occurred.

App Version Lock (PUT)

Locks a specific app version.

Description

A locked app version cannot be updated anymore.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightoperator**

Method

PUT

Path

*/management-apis/1.0/runtimes/runtime-name/applications/application-name/
application-env/application-version/lock*

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/applications/myapplication-env/application-version/lock>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

application/json

Produces

application/json, application/xml, text/xml

Payload

JSON Example

```
{
  "lock" : true,
  "warning" : "true",
}
```

Payload Properties

The payload has the following properties:

lock

Whether the app version is locked.

warning

When a warning happens, provides the details.

Response

JSON Example

```
{
  "ok" : true,
  "warning" : "true",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<set-appversion-lock-result
  ok="true"
  warning="true"/>
```

Response Properties

The response has the following properties:

ok Whether the operation was successful.

warning

When a warning happens, provides the details.

Errors

400

The payload is invalid.

403

The user is not authorized to call this service.

404

The corresponding runtime or the app version is not found.

500

An internal error occurred.

Application Binary (GET, HEAD)

Retrieves the binary of a specific app version.

Description

It supports range requests to deliver only a range of the bytes of the app version. Clients can use this feature to resume a download after interruption.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**

Method

GET, HEAD

Path

*/otu/1.0/one-time-url-hash/runtimes/runtime-name/downloads/applications/
application-name/application-env/application-version*

Example

<https://www.example.com/worklightadmin/otu/1.0/ffabc301/runtimes/myruntime/downloads/applications/my>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

one-time-url-hash

The one-time-url hash code.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/octet-stream

Response

The binary data of the specified app version.

Errors

400

The request is invalid.

403

The user is not authorized to call this service.

404

The corresponding runtime or the app version is not found.

416

The requested range of bytes is not satisfiable.

500

An internal error occurred.

Application (DELETE)

Deletes a specific application and all its app versions.

Description

This transaction can run synchronously or asynchronously. If processed asynchronously, the REST service returns before the transaction is completed. In this case, you can query the transaction result later with the transaction REST service.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**

Method

DELETE

Path

/management-apis/1.0/runtimes/runtime-name/applications/application-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/applications/myappli>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

Query Parameters

Query parameters are optional.

async

Whether the transaction is processed synchronously or asynchronously.
Allowed values are true and false. The default is synchronous processing.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The metadata of the deleted application.

JSON Example

```
{
  "ok" : false,
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "description" : {
      "applicationName" : "myapplication",
    },
  },
  "errors" : [
    {
      "details" : "An internal error occurred.",
    },
    ...
  ],
  "id" : 1,
  "project" : {
    "name" : "myproject",
  },
  "status" : "FAILURE",
  "timeCreated" : "2014-04-13T00:18:36.979Z",
  "timeUpdated" : "2014-04-14T00:18:36.979Z",
  "type" : "DELETE_APPLICATION",
  "userName" : "demouser",
},
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<delete-application-result
  ok="false"
  productVersion="7.1.0">
  <transaction
    appServerId="Tomcat"
    id="1"
    status="FAILURE"
    timeCreated="2014-04-13T00:18:36.979Z"
    timeUpdated="2014-04-14T00:18:36.979Z"
    type="DELETE_APPLICATION"
    userName="demouser">
    <description applicationName="myapplication"/>
  <errors>
    <error details="An internal error occurred."/>
    ...
  </errors>
  </transaction>
</delete-application-result>
```

```
</errors>
<project name="myproject"/>
</transaction>
</delete-application-result>
```

Response Properties

The response has the following properties:

ok Whether the transaction was successful.

productVersion

The exact product version.

transaction

The details of the transaction.

The *transaction* has the following properties:

appServerId

The id of the web application server.

description

The details of the application.

errors

The errors occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: PENDING, PREPARING, COMMITTING, REJECTING, SUCCESS, FAILURE, CANCELED. Synchronous transactions can have the state SUCCESS and FAILURE. Asynchronous transactions can also have the other states.

timeCreated

The date in ISO 8601 format when the adapter was created.

timeUpdated

The date in ISO 8601 format when the adapter was updated.

type

The type of the transaction, here always DELETE_APPLICATION.

userName

The user that initiated the transaction.

The *description* has the following properties:

applicationName

The name of the application.

The *error* has the following properties:

details

The main error message.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime or the application is not found.

500

An internal error occurred.

Application (GET)

Retrieves metadata of a specific application.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/applications/application-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/applications/myapplication>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The metadata of the specified application.

JSON Example

```
{
  "description" : "My first sample application",
  "displayName" : "My Sample Application",
  "environments" : [
    {
      "applicationEnvironmentDataAccess" : {
        "action" : "NOTIFY",
        "createdTime" : "2014-04-13T00:18:36.979Z",
        "message" : "This version is no longer supported.",
      },
      "authenticityConfig" : "BASIC",
      "buildTime" : "2014-03-29T00:18:36.979Z",
      "deployTime" : "2014-04-13T00:18:36.979Z",
      "deviceProvisioningRealm" : "myProvRealm",
      "envPlatformVersion" : "7.1.0",
      "environment" : "android",

  "productVersion" : "7.1.0",
  "projects" : [
    {
      "name" : "myproject",
    },
    ...
  ],
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<application
  description="My first sample application"
  displayName="My Sample Application"
  link="https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/applications/myapplication"
  name="myapplication"
  platformVersion="6.1.0.00.20131126-0630"
  productVersion="7.1.0">
  <environments>
    <environment
      authenticityConfig="BASIC"
      buildTime="2014-03-29T00:18:36.979Z"
      deployTime="2014-04-13T00:18:36.979Z"
      deviceProvisioningRealm="myProvRealm"
      envPlatformVersion="7.1.0"
      environment="android"
      link="https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/applications/myapplication"
      prevBuildTime="2014-03-29T00:18:36.979Z"
      resourceSize="5120"
    />
  </environments>
</application>
```

```

        securityTest="mobileTest"
        supportRemoteDisable="true"
        supportsAuthenticity="true"
        userAuthenticationRealm="myAuthRealm"
        version="1.0"
        versionLocked="false">
    <applicationEnvironmentDataAccess
        action="NOTIFY"
        createTime="2014-04-13T00:18:36.979Z"
        message="This version is no longer supported."/>
    </environment>
    ...
</environments>
<projects>
    <project name="myproject"/>
    ...
</projects>
</application>

```

Response Properties

The response has the following properties:

description

The description of the application.

displayName

The display name of the application.

environments

The array of application environments.

link

The URL to access detail information about the application.

name

The name of the application.

platformVersion

The exact version number of the IBM MobileFirst Platform Foundation development tools (Studio) that built the application.

productVersion

The exact product version.

projects

The projects the application belong to.

The *environment* has the following properties:

applicationEnvironmentDataAccess

The access rule to be executed when the app version is disabled.

authenticityConfig

The application authenticity configuration. Possible values are: NONE, BASIC, EXTENDED.

buildTime

The time stamp when the app version was built.

deployTime

The date in ISO 8601 format when the application was deployed.

deviceProvisioningRealm

The name of the realm used for device provisioning.

envPlatformVersion

The version of the platform of the environment.

environment

The platform environment of the app version: android, iphone, ...

link

The URL to access detail information about the application version.

prevBuildTime

The time stamp when the app that was previously deployed was built.

publishUrl

For web applications, this is the URL under which the web application was published.

resourceSize

The size of the wlapp file of the application version.

securityTest

The name of the security test for a protected resource.

supportRemoteDisable

true if the application version supports remote disabling.

supportsAuthenticity

true if the application version supports authentication.

userAuthenticationRealm

The name of the realm used to authenticate users.

version

The version number of the app version.

versionLocked

Whether the version is locked.

The *applicationEnvironmentDataAccess* has the following properties:

action

The action to be done when a disabled app version is accessed. Possible values are: NOTIFY, BLOCK, NA.

createdTime

The date in ISO 8601 format when the app version access rule was created.

downloadLink

The download link where to obtain a new version of the application.

message

The message to be displayed when a disabled app version is accessed.

multiLanguageMessage

Internationalized variants of the message to be displayed when a disabled app version is accessed.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running, or the application is not found.

500

An internal error occurred.

Application (POST)

Deploys an application.

Description

It first checks whether the input application is valid. Then, it transfers the application to the database and to the runtime.

This transaction can run synchronously or asynchronously. If processed asynchronously, the REST service returns before the transaction is completed. In this case, you can query the transaction result later with the transaction REST service.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**

Method

POST

Path

`/management-apis/1.0/runtimes/runtime-name/applications`

Example

`https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/applications?async=false`

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

async

Whether the transaction is processed synchronously or asynchronously. Allowed values are true and false. The default is synchronous processing.

locale

The locale used for error messages.

Consumes

multipart/form-data

Produces

application/json, application/xml, text/xml, text/html

Response

The metadata of the deployed application.

JSON Example

```
{
  "ok" : false,
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "description" : {
      "appVersionsAlreadyDeployed" : [
        {
          "applicationName" : "myapplication",
          "environment" : "android",
          "version" : "1.0",
        },
        ...
      ],
      "appVersionsDeployed" : [
        {
          "applicationName" : "myapplication",
          "environment" : "android",
          "version" : "1.0",
        },
        ...
      ],
      "filename" : "myapplication.wlapp",
    },
    "errors" : [
      {
        "details" : "An internal error occured.",
      },
      ...
    ],
    "id" : 1,
    "project" : {
      "name" : "myproject",
    },
    "status" : "FAILURE",
    "timeCreated" : "2014-04-13T00:18:36.979Z",
    "timeUpdated" : "2014-04-14T00:18:36.979Z",
    "type" : "UPLOAD_APPLICATION",
    "userName" : "demouser",
  },
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<deploy-application-result
  ok="false"
  productVersion="7.1.0">
```

```

<transaction
  appServerId="Tomcat"
  id="1"
  status="FAILURE"
  timeCreated="2014-04-13T00:18:36.979Z"
  timeUpdated="2014-04-14T00:18:36.979Z"
  type="UPLOAD_APPLICATION"
  userName="demouser">
  <description filename="myapplication.wlapp">
    <appVersionsAlreadyDeployedArray>
      <appVersionsAlreadyDeployed
        applicationName="myapplication"
        environment="android"
        version="1.0"/>
      ...
    </appVersionsAlreadyDeployedArray>
    <appVersionsDeployedArray>
      <appVersionsDeployed
        applicationName="myapplication"
        environment="android"
        version="1.0"/>
      ...
    </appVersionsDeployedArray>
  </description>
  <errors>
    <error details="An internal error occured."/>
    ...
  </errors>
  <project name="myproject"/>
</transaction>
</deploy-application-result>

```

Response Properties

The response has the following properties:

ok Whether the transaction was successful.

productVersion

The exact product version.

transaction

The details of the transaction.

The *transaction* has the following properties:

appServerId

The id of the web application server.

description

The details of the application.

errors

The errors occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: PENDING, PREPARING, COMMITTING, REJECTING, SUCCESS, FAILURE, CANCELED. Synchronous transactions can have the state SUCCESS and FAILURE. Asynchronous transactions can also have the other states.

timeCreated

The date in ISO 8601 format when the adapter was created.

timeUpdated

The date in ISO 8601 format when the adapter was updated.

type

The type of the transaction, here always UPLOAD_APPLICATION.

userName

The user that initiated the transaction.

The *description* has the following properties:

appVersionsAlreadyDeployed

The app versions that were already previously deployed and remain unchanged.

appVersionsDeployed

The app versions deployed.

filename

The optional file name of the application.

The *app version* has the following properties:

applicationName

The name of the application.

environment

The environment of the application.

version

The version of the application.

The *error* has the following properties:

details

The main error message.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

400

No application data is provided.

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Applications (GET)

Retrieves metadata for the list of deployed applications.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

`/management-apis/1.0/runtimes/runtime-name/applications`

Example

`https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/applications?bookmark=`

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

bookmark

The bookmark for the page if only a part of the list (a page) should be returned. If a bookmark is specified, the offset parameter is ignored.

locale

The locale used for error messages.

offset

The offset from the beginning of the list if only a part of the list (a page) should be returned.

orderBy

The sort mode. By default, the elements are sorted in increasing order. If the sort mode starts with - (minus sign), the elements are sorted in decreasing order. Possible sort modes are: name. The default sort mode is: name.

pageSize

The number of elements if only a part of the list (a page) should be returned. The default value is 100.

Produces

`application/json, application/xml, text/xml`

Response

The metadata of the deployed applications.

JSON Example

```
{
  "items" : [
    {
      "description" : "My first sample application",
      "displayName" : "My Sample Application",
      "environments" : [
        {
          "applicationEnvironmentDataAccess" : {
            "action" : "NOTIFY",
            "createdTime" : "2014-04-13T00:18:36.979Z",
            "message" : "This version is no longer supported.",
          },
          "authenticityConfig" : "BASIC",

  </item>
  ...
</items>
</applications>

```

Response Properties

The response has the following properties:

items

The array of application metadata

nextPageBookmark

The bookmark of the next page if only a page of applications is returned.

pageNumber

The page index if only a page of applications is returned.

pageSize

The page size if only a page of applications is returned.

prevPageBookmark

The bookmark of the previous page if only a page of applications is returned.

productVersion

The exact product version.

startIndex

The start index in the total list if only a page of applications is returned.

totalListSize

The total number of applications.

The *application* has the following properties:

description

The description of the application.

displayName

The display name of the application.

environments

The array of application environments.

link

The URL to access detail information about the application.

name

The name of the application.

platformVersion

The exact version number of the IBM MobileFirst Platform Foundation development tools (Studio) that built the application.

projects

The projects the application belong to.

The *environment* has the following properties:

applicationEnvironmentDataAccess

The access rule to be executed when the app version is disabled.

authenticityConfig

The application authenticity configuration. Possible values are: NONE, BASIC, EXTENDED.

buildTime

The time stamp when the app version was built.

deployTime

The date in ISO 8601 format when the application was deployed.

deviceProvisioningRealm

The name of the realm used for device provisioning.

envPlatformVersion

The version of the platform of the environment.

environment

The platform environment of the app version: android, iphone, ...

link

The URL to access detail information about the application version.

prevBuildTime

The time stamp when the app that was previously deployed was built.

publishUrl

For web applications, this is the URL under which the web application was published.

resourceSize

The size of the wlappp file of the application version.

securityTest

The name of the security test for a protected resource.

supportRemoteDisable

true if the application version supports remote disabling.

supportsAuthenticity

true if the application version supports authentication.

userAuthenticationRealm

The name of the realm used to authenticate users.

version

The version number of the app version.

versionLocked

Whether the version is locked.

The *applicationEnvironmentDataAccess* has the following properties:

action

The action to be done when a disabled app version is accessed. Possible values are: NOTIFY, BLOCK, NA.

createdTime

The date in ISO 8601 format when the app version access rule was created.

downloadLink

The download link where to obtain a new version of the application.

message

The message to be displayed when a disabled app version is accessed.

multiLanguageMessage

Internationalized variants of the message to be displayed when a disabled app version is accessed.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Associate beacons and triggers (DELETE)

Deletes the association of beacons and triggers with the UUID, major number, minor number and triggerName.

Description

Deleting a beacon or beacon-trigger would delete the corresponding beacon-to-trigger associations as well.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

DELETE

Path

/management-apis/1.0/runtimes/runtime-name/beaconTriggerAssociations/applications/application-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/beaconTriggerAssociations/>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

major

Mandatory. The major number of the beacon whose trigger-association must be deleted.

minor

Mandatory. The minor number of the beacon whose trigger-association must be deleted.

triggerName

Mandatory. The name of the beacon trigger whose beacon-association must be deleted.

uuid

Mandatory. The UUID of the beacon whose trigger-association must be deleted.

Produces

application/json, application/xml, text/xml

Response

The status of the delete of the beacon trigger association.

JSON Example

```
{
  "beaconTriggerAssociations" : {
    "major" : 1,
    "minor" : 4439,
    "triggerName" : "DwellInsideLoanSection",
    "uuid" : "3d402cf0-3691-4bd9-97ff-0b0a93a160ef",
  },
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "errors" : [
      {
      },
      ...
    ],
    "id" : 1,
    "project" : {
      "name" : "myproject",
    },
    "status" : "SUCCESS",
    "timeCreated" : "2014-11-14T05:21:13.404Z",
    "timeUpdated" : "2014-11-14T05:21:13.456Z",
    "type" : "DELETE_BEACON_AND_TRIGGER_ASSOCIATION",
    "userName" : "demouser",
    "warnings" : [
      {
      },
      ...
    ],
  },
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<delete-beacon-trigger-association-result productVersion="7.1.0">
  <beaconTriggerAssociations
    major="1"
    minor="4439"
    triggerName="DwellInsideLoanSection"
    uuid="3d402cf0-3691-4bd9-97ff-0b0a93a160ef"/>
  <transaction
    appServerId="Tomcat"
    id="1"
    status="SUCCESS"
    timeCreated="2014-11-14T05:21:13.404Z"
    timeUpdated="2014-11-14T05:21:13.456Z"
    type="DELETE_BEACON_AND_TRIGGER_ASSOCIATION"
    userName="demouser">
    <errors>
      <error/>
      ...
    </errors>
    <project name="myproject"/>
    <warnings>
      <warning/>
    </warnings>
  </transaction>
</delete-beacon-trigger-association-result>
```

```
    ...
  </warnings>
</transaction>
</delete-beacon-trigger-association-result>
```

Response Properties

The response has the following properties:

beaconTriggerAssociations

The details of the beacon trigger association that is deleted.

productVersion

The exact product version.

transaction

The details of the transaction.

The *beaconTriggerAssociations* has the following properties:

major

The major number of the beacon whose trigger-associations must be deleted.

minor

The minor number of the beacon whose trigger-associations must be deleted.

triggerName

An unique name for this beacon trigger.

uuid

The UUID of beacon whose trigger-associations must be deleted

The *transaction* has the following properties:

appServerId

The id of the web application server.

errors

Errors, if any, that occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: SUCCESS, FAILURE.

timeCreated

The date in ISO 8601 format when the transaction was started.

timeUpdated

The date in ISO 8601 format when the transaction was completed.

type

The type of the transaction: DELETE_BEACON_AND_TRIGGER_ASSOCIATION.

userName

The user that initiated the transaction.

warnings

Warnings, if any, that occurred during the transaction.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

Not Found - Either: a) beacon with specified by UUID, major and minor is not found, OR b) trigger with

500

An internal error occurred.

Associate beacons and triggers (GET)

Retrieves the association of beacons and triggers with the UUID, major number, minor number, and triggerName.

Description

The beacons and triggers associations are retrieved based on the following query parameters:

- None are specified: Returns all beacon and trigger associations of this application.
- Only triggerName is specified: Returns the associations of the specified trigger with any of the beacons.
- Only UUID is specified with/without triggerName (major and minor number are not specified): Returns the associations of the specified/any trigger with any of the beacons that have matching UUID.
- Only UUID and major number are specified with/without triggerName (minor is not specified): Returns the associations of the specified/any trigger with any of the beacons that have matching UUID and major number.
- Only UUID and minor number are specified with/without triggerName (major is not specified): Returns the associations of the specified/any trigger with any of the beacons that have matching UUID and minor number.
- UUID, major, and minor number are specified with/without triggerName: Returns the associations of the specified/any trigger with the specified beacon.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/*runtime-name*/beaconTriggerAssociations/
applications/*application-name*

Example

https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/beaconTriggerAssociations

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

Query Parameters

Query parameters are optional.

errorIfNotFound

If this flag is set to true (default value) with any of the `uuid`/`major`/`minor`/`triggerName` parameters specified, and there are no matching beacon trigger associations, then 'HTTP 404 Not Found' error is returned instead of an empty list in the output.

locale

The locale used for error messages.

major

The major number of the beacon whose trigger-associations must be fetched.

minor

The minor number of the beacon whose trigger-associations must be fetched.

triggerName

The name of beacon trigger whose beacon-associations must be fetched.

uuid

The UUID of the beacon whose trigger-associations must be fetched.

Produces

application/json, application/xml, text/xml

Response

The details of all the beacon trigger associations that are retrieved.

JSON Example

```
{
  "beaconTriggerAssociations" : [
    {
      "major" : 1,
      "minor" : 4439,
      "triggerName" : "DwellInsideLoanSection",
      "uuid" : "3d402cf0-3691-4bd9-97ff-0b0a93a160ef",
    },
  ],
}
```

```

    ...
  ],
  "productVersion" : "7.1.0",
}

```

XML Example

```

<?xml version="1.0" encoding="UTF-8"?>
<list-beacon-trigger-associations-result productVersion="7.1.0">
  <beaconTriggerAssociations>
    <beaconTriggerAssociation
      major="1"
      minor="4439"
      triggerName="DwellInsideLoanSection"
      uuid="3d402cf0-3691-4bd9-97ff-0b0a93a160ef"/>
    ...
  </beaconTriggerAssociations>
</list-beacon-trigger-associations-result>

```

Response Properties

The response has the following properties:

beaconTriggerAssociations

The array of beacon trigger associations.

productVersion

The exact product version.

The *beaconTriggerAssociations* has the following properties:

major

The major number of the beacon.

minor

The minor number of the beacon.

triggerName

The unique name of the beacon trigger.

uuid

The UUID of the beacon.

Errors

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

The `errorIfNotFound` flag is set to true (or not specified) and one of the following conditions happen:

406

Unsupported Accept type - The content type specified in Accept header is not `application/json`, `application/javascript`, or `application/xml`.

500

An internal error occurred.

Associate beacons and triggers (PUT)

Associates the specified beacons with the specified triggers.

Description

Use this API to specify a trigger and the list of beacons to associate with it. Or to specify a beacon and the list of triggers to associate with it.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

PUT

Path

/management-apis/1.0/runtimes/runtime-name/beaconTriggerAssociations/applications/application-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/beaconTriggerAssociations>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

application/json, application/xml, text/xml

Produces

application/json, application/xml, text/xml

Payload

The payload has values for the beacons and the trigger names. It can be in JSON or XML format.

JSON Example

```
{
  "beacons" : [
    {
      "major" : 1,
      "minor" : 4439,
      "uuid" : "3d402cf0-3691-4bd9-97ff-0b0a93a160ef",
    },
    ...
  ],
  "triggers" : [
    {
      "triggerName" : "DwellInsideLoanSection",
    },
    ...
  ],
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<beaconTriggerAssociations>
  <beacons>
    <beacon
      major="1"
      minor="4439"
      uuid="3d402cf0-3691-4bd9-97ff-0b0a93a160ef"/>
    ...
  </beacons>
  <triggers>
    <trigger triggerName="DwellInsideLoanSection"/>
    ...
  </triggers>
</beaconTriggerAssociations>
```

Payload Properties

The payload has the following properties:

beacons

List of beacons to which each of the listed triggers must be associated with. Each beacon is identified by its UUID, major and minor number.

triggers

List of triggers to which each of the listed beacons must be associated with. Each beacon-trigger is identified by its triggerName.

The *beaconTriggers* has the following properties:

triggerName

The name of beacon-trigger.

The *beacons* has the following properties:

major

The major number of the beacon.

minor

The minor number of the beacon.

uuid

The UUID of the beacon.

Response

The status of the association of beacons and triggers.

JSON Example

```
{
  "beaconTriggerAssociations" : [
    {
      "major" : 1,
      "minor" : 4439,
      "triggerName" : "DwellInsideLoanSection",
      "uuid" : "3d402cf0-3691-4bd9-97ff-0b0a93a160ef",
    },
    ...
  ],
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "errors" : [
      {
      },
      ...
    ],
    "id" : 1,
    "project" : {
      "name" : "myproject",
    },
    "status" : "SUCCESS",
    "timeCreated" : "2014-11-14T05:21:13.404Z",
    "timeUpdated" : "2014-11-14T05:21:13.456Z",
    "type" : "ASSOCIATE_BEACONS_AND_TRIGGERS",
    "userName" : "demouser",
    "warnings" : [
      {
      },
      ...
    ],
  },
},
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<add-beacon-trigger-associations-result productVersion="7.1.0">
  <beaconTriggerAssociations>
    <beaconTriggerAssociation
      major="1"
      minor="4439"
      triggerName="DwellInsideLoanSection"
      uuid="3d402cf0-3691-4bd9-97ff-0b0a93a160ef"/>
    ...
  </beaconTriggerAssociations>
  <transaction
    appServerId="Tomcat"
    id="1"
    status="SUCCESS"
    timeCreated="2014-11-14T05:21:13.404Z"
    timeUpdated="2014-11-14T05:21:13.456Z"
    type="ASSOCIATE_BEACONS_AND_TRIGGERS"
    userName="demouser">
    <errors>
      <error/>
      ...
    </errors>
    <project name="myproject"/>
    <warnings>
```

```
        <warning/>
        ...
    </warnings>
</transaction>
</add-beacon-trigger-associations-result>
```

Response Properties

The response has the following properties:

beaconTriggerAssociations

The list of the beacon trigger associations that are created.

productVersion

The exact product version.

transaction

The details of the transaction.

The *beaconTriggerAssociations* has the following properties:

major

The major number of the beacon that is associated with a specified beacon-trigger.

minor

The minor number of the beacon that is associated with a specified beacon-trigger.

triggerName

An unique name for this beacon trigger.

uuid

The UUID of the beacon that is associated with a specified beacon-trigger.

The *transaction* has the following properties:

appServerId

The id of the web application server.

errors

Errors, if any, that occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: SUCCESS, FAILURE.

timeCreated

The date in ISO 8601 format when the transaction was started.

timeUpdated

The date in ISO 8601 format when the transaction was completed.

type

The type of the transaction: ASSOCIATE_BEACONS_AND_TRIGGERS.

userName

The user that initiated the transaction.

warnings

Warnings, if any, that occurred during the transaction.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

400

Bad Request - The request could not be understood by the server due to malformed syntax.

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

Not Found - One/more of the specified beacons or beacon-triggers not found.

406

Unsupported Accept type - The content type specified in Accept header is not application/json, app

415

Unsupported Media Type - The server is refusing to service the request because the request payload

500

An internal error occurred.

Beacon Trigger (DELETE)

Deletes the beacon trigger by using the triggerName.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

DELETE

Path

/management-apis/1.0/runtimes/runtime-name/BeaconTriggers/trigger-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/BeaconTriggers/mytrigger>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

trigger-name

The name of the beacon trigger.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The status of the delete of the beacon trigger.

JSON Example

```
{
  "beaconTrigger" : {
    "actionPayload" : {
      "alert" : "Avail lowest interest rate of just 7.5% on home loans!",
    },
    "dwellingTime" : 5000,
    "proximityState" : "Far",
    "triggerName" : "DwellInsideLoanSection",
    "triggerType" : "Enter",
  },
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "errors" : [
      {
      },
      ...
    ],
    "id" : 1,
    "project" : {
      "name" : "myproject",
    },
    "status" : "SUCCESS",
    "timeCreated" : "2014-11-14T05:21:13.404Z",
    "timeUpdated" : "2014-11-14T05:21:13.456Z",
    "type" : "DELETE_BEACON_TRIGGER",
    "userName" : "demouser",
    "warnings" : [
      {
      },
      ...
    ],
  },
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<delete-beacon-trigger-result productVersion="7.1.0">
  <beaconTrigger
    dwellingTime="5000"
    proximityState="Far"
    triggerName="DwellInsideLoanSection"
    triggerType="Enter">
    <actionPayload alert="Avail lowest interest rate of just 7.5% on home loans!"/>
  </beaconTrigger>
  <transaction
    appServerId="Tomcat"
```

```

    id="1"
    status="SUCCESS"
    timeCreated="2014-11-14T05:21:13.404Z"
    timeUpdated="2014-11-14T05:21:13.456Z"
    type="DELETE_BEACON_TRIGGER"
    userName="demouser">
    <errors>
      <error/>
      ...
    </errors>
    <project name="myproject"/>
    <warnings>
      <warning/>
      ...
    </warnings>
  </transaction>
</delete-beacon-trigger-result>

```

Response Properties

The response has the following properties:

beaconTrigger

The details of the beacon trigger that is deleted.

productVersion

The exact product version.

transaction

The details of the transaction.

The *beaconTrigger* has the following properties:

actionPayload

The details of an action to be taken when the trigger is activated.

dwellingTime

Optional: Applicable only for triggerTypes: DwellInside and DwellOutside. It should be specified in milliseconds and defines how long the device must be inside, or outside a beacon region before the dwellInside or dwellOutside trigger is activated. Mandatory with triggerType of DwellInside and DwellOutside.

proximityState

Optional: The proximity state that is specified for a beacon trigger. It can be either Immediate, Near, or Far. The default value is Far.

triggerName

An unique name for this beacon trigger.

triggerType

The type of beacon trigger. The value of the type can be either Enter, Exit, DwellInside, or DwellOutside.

The *actionPayload* has the following properties:

alert

The alert message to be sent when a trigger is activated.

The *transaction* has the following properties:

appServerId

The id of the web application server.

errors

Errors, if any, that occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: SUCCESS, FAILURE.

timeCreated

The date in ISO 8601 format when the transaction was started.

timeUpdated

The date in ISO 8601 format when the transaction was completed.

type

The type of the transaction: DELETE_BEACON_TRIGGER.

userName

The user that initiated the transaction.

warnings

Warnings, if any, that occurred during the transaction.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

Not Found - A beacon trigger with the specified triggerName is not found.

500

An internal error occurred.

Beacon Trigger (GET)

Retrieves the beacon trigger with the triggerName.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/beaconTriggers/trigger-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/beaconTriggers/mytr>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

trigger-name

The name of the beacon trigger.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The details of the beacon trigger that is retrieved.

JSON Example

```
{
  "beaconTrigger" : {
    "actionPayload" : {
      "alert" : "Avail lowest interest rate of just 7.5% on home loans.",
    },
    "dwellingTime" : 5000,
    "proximityState" : "Near",
    "triggerName" : "DwellInsideLoanSection",
    "triggerType" : "Enter",
  },
  "productVersion" : "7.1.0",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<show-beacon-trigger-result productVersion="7.1.0">
  <beaconTrigger
    dwellingTime="5000"
    proximityState="Near"
    triggerName="DwellInsideLoanSection"
    triggerType="Enter">
    <actionPayload alert="Avail lowest interest rate of just 7.5% on home loans."/>
  </beaconTrigger>
</show-beacon-trigger-result>
```

Response Properties

The response has the following properties:

- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/*runtime-name*/beaconTriggers

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/beaconTriggers?locale=en>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The details of all the beacon triggers that are retrieved.

JSON Example

```
{
  "beaconTriggers" : [
    {
      "actionPayload" : {
        "alert" : "Avail lowest interest rate of just 7.5% on home loans.",
      },
      "dwellingTime" : 5000,
      "proximityState" : "Near",
      "triggerName" : "DwellInsideLoanSection",
      "triggerType" : "Enter",
    },
    ...
  ],
  "productVersion" : "7.1.0",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<list-beacon-triggers-result productVersion="7.1.0">
  <beaconTriggers>
    <beaconTrigger
      dwellingTime="5000"
      proximityState="Near"
      triggerName="DwellInsideLoanSection"
      triggerType="Enter">
```

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

POST

Path

*/management-apis/1.0/runtimes/runtime-name/*beaconTriggers

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/beaconTriggers?locale=en>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

application/json, application/xml, text/xml

Produces

application/json, application/xml, text/xml

Payload

The payload has values for the `triggerName`, `triggerType`, `proximityState`, `dwellingTime`, and `actionPayload` properties. It can be in JSON or XML format

JSON Example

```
{
  "actionPayload" : {
    "alert" : "Avail lowest interest rate of just 7.5% on home loans!",
  },
  "dwellingTime" : 5000,
  "proximityState" : "Far",
  "triggerName" : "DwellInsideLoanSection",
  "triggerType" : "Enter",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<beaconTrigger
  dwellingTime="5000"
  proximityState="Far"
  triggerName="DwellInsideLoanSection"
  triggerType="Enter">
  <actionPayload alert="Avail lowest interest rate of just 7.5% on home loans!"/>
</beaconTrigger>
```

Payload Properties

The payload has the following properties:

actionPayload

The details of an action to be taken when the trigger is activated.

dwellingTime

Optional: Applicable only for triggerTypes: DwellInside and DwellOutside. It should be specified in milliseconds and defines how long the device must be inside, or outside a beacon region before the dwellInside or dwellOutside trigger is activated. Mandatory with triggerType of DwellInside and DwellOutside.

proximityState

Optional: The proximity state that is specified for a beacon trigger. It can be either Immediate, Near, or Far. The default value is Far.

triggerName

An unique name for this beacon trigger (consisting of alphanumeric or underscore characters and beginning with an alphabet).

triggerType

The type of beacon trigger. The value of the type can be either Enter, Exit, DwellInside, or DwellOutside.

The *actionPayload* has the following properties:

alert

The alert message to be sent when a trigger is activated.

Response

The status of the adding of the beacon trigger.

JSON Example

```
{
  "beaconTrigger" : {
    "actionPayload" : {
      "alert" : "Avail lowest interest rate of just 7.5% on home loans!",
    },
    "dwellingTime" : 5000,
    "proximityState" : "Far",
    "triggerName" : "DwellInsideLoanSection",
    "triggerType" : "Enter",
  },
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "errors" : [
      {
      },
    ],
  },
}
```

```

    ...
  ],
  "id" : 1,
  "project" : {
    "name" : "myproject",
  },
  "status" : "SUCCESS",
  "timeCreated" : "2014-11-14T05:21:13.404Z",
  "timeUpdated" : "2014-11-14T05:21:13.456Z",
  "type" : "ADD_BEACON_TRIGGER",
  "userName" : "demouser",
  "warnings" : [
    {
    },
    ...
  ],
},
}

```

XML Example

```

<?xml version="1.0" encoding="UTF-8"?>
<set-beacon-trigger-result productVersion="7.1.0">
  <beaconTrigger
    dwellingTime="5000"
    proximityState="Far"
    triggerName="DwellInsideLoanSection"
    triggerType="Enter">
    <actionPayload alert="Avail lowest interest rate of just 7.5% on home loans!"/>
  </beaconTrigger>
  <transaction
    appServerId="Tomcat"
    id="1"
    status="SUCCESS"
    timeCreated="2014-11-14T05:21:13.404Z"
    timeUpdated="2014-11-14T05:21:13.456Z"
    type="ADD_BEACON_TRIGGER"
    userName="demouser">
    <errors>
      <error/>
      ...
    </errors>
    <project name="myproject"/>
    <warnings>
      <warning/>
      ...
    </warnings>
  </transaction>
</set-beacon-trigger-result>

```

Response Properties

The response has the following properties:

beaconTrigger

The details of the beacon trigger that is created.

productVersion

The exact product version.

transaction

The details of the transaction.

The *beaconTrigger* has the following properties:

actionPayload

The details of an action to be taken when the trigger is activated.

dwellingTime

Optional: Applicable only for triggerTypes: DwellInside and DwellOutside. It should be specified in milliseconds and defines how long the device must be inside, or outside a beacon region before the dwellInside or dwellOutside trigger is activated. Mandatory with triggerType of DwellInside and DwellOutside.

proximityState

Optional: The proximity state that is specified for a beacon trigger. It can be either Immediate, Near, or Far. The default value is Far.

triggerName

An unique name for this beacon trigger.

triggerType

The type of beacon trigger. The value of the type can be either Enter, Exit, DwellInside, or DwellOutside.

The *actionPayload* has the following properties:

alert

The alert message to be sent when a trigger is activated.

The *transaction* has the following properties:

appServerId

The id of the web application server.

errors

Errors, if any, that occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: SUCCESS, FAILURE.

timeCreated

The date in ISO 8601 format when the transaction was started.

timeUpdated

The date in ISO 8601 format when the transaction was completed.

type

The type of the transaction: ADD_BEACON_TRIGGER.

userName

The user that initiated the transaction.

warnings

Warnings, if any, that occurred during the transaction.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

locale

The locale used for error messages.

Consumes

application/json, application/xml, text/xml

Produces

application/json, application/xml, text/xml

Payload

The payload has values for the `triggerName`, `triggerType`, `proximityState`, `dwellingTime`, and `actionPayload` properties. It can be in JSON or XML format.

JSON Example

```
{
  "actionPayload" : {
    "alert" : "Avail lowest interest rate of just 7.25% on home loans!",
  },
  "triggerName" : "DwellInsideLoanSection",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<beaconTrigger triggerName="DwellInsideLoanSection">
  <actionPayload alert="Avail lowest interest rate of just 7.25% on home loans!"/>
</beaconTrigger>
```

Payload Properties

The payload has the following properties:

actionPayload

The details of an action to be taken when the trigger is activated.

triggerName

An unique name for this beacon trigger.

The *actionPayload* has the following properties:

alert

The alert message to be sent when a trigger is activated.

Response

The status of the update of the beacon trigger.

JSON Example

```
{
  "beaconTrigger" : {
    "actionPayload" : {
      "alert" : "Avail lowest interest rate of just 7.25% on home loans!",
    },
    "dwellingTime" : 5000,
    "proximityState" : "Far",
    "triggerName" : "DwellInsideLoanSection",
    "triggerType" : "Enter",
  },
}
```

```

"productVersion" : "7.1.0",
"transaction" : {
  "appServerId" : "Tomcat",
  "errors" : [
    {
    },
    ...
  ],
  "id" : 1,
  "project" : {
    "name" : "myproject",
  },
  "status" : "SUCCESS",
  "timeCreated" : "2014-11-14T05:21:13.404Z",
  "timeUpdated" : "2014-11-14T05:21:13.456Z",
  "type" : "UPDATE_BEACON_TRIGGER",
  "userName" : "demouser",
  "warnings" : [
    {
    },
    ...
  ],
},
}

```

XML Example

```

<?xml version="1.0" encoding="UTF-8"?>
<set-beacon-trigger-result productVersion="7.1.0">
  <beaconTrigger
    dwellingTime="5000"
    proximityState="Far"
    triggerName="DwellInsideLoanSection"
    triggerType="Enter">
    <actionPayload alert="Avail lowest interest rate of just 7.25% on home loans!"/>
  </beaconTrigger>
  <transaction
    appServerId="Tomcat"
    id="1"
    status="SUCCESS"
    timeCreated="2014-11-14T05:21:13.404Z"
    timeUpdated="2014-11-14T05:21:13.456Z"
    type="UPDATE_BEACON_TRIGGER"
    userName="demouser">
    <errors>
      <error/>
      ...
    </errors>
    <project name="myproject"/>
    <warnings>
      <warning/>
      ...
    </warnings>
  </transaction>
</set-beacon-trigger-result>

```

Response Properties

The response has the following properties:

beaconTrigger

The details of the beacon trigger that is updated.

productVersion

The exact product version.

transaction

The details of the transaction.

The *beaconTrigger* has the following properties:

actionPayload

The details of an action to be taken when the trigger is activated.

dwellingTime

Optional: Applicable only for triggerTypes: DwellInside and DwellOutside. It should be specified in milliseconds and defines how long the device must be inside, or outside a beacon region before the dwellInside or dwellOutside trigger is activated. Mandatory with triggerType of DwellInside and DwellOutside.

proximityState

Optional: The proximity state that is specified for a beacon trigger. It can be either Immediate, Near, or Far. The default value is Far.

triggerName

An unique name for this beacon trigger.

triggerType

The type of beacon trigger. The value of the type can be either Enter, Exit, DwellInside, or DwellOutside.

The *actionPayload* has the following properties:

alert

The alert message to be sent when a trigger is activated.

The *transaction* has the following properties:

appServerId

The id of the web application server.

errors

Errors, if any, that occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: SUCCESS, FAILURE.

timeCreated

The date in ISO 8601 format when the transaction was started.

timeUpdated

The date in ISO 8601 format when the transaction was completed.

type

The type of the transaction: UPDATE_BEACON_TRIGGER.

userName

The user that initiated the transaction.

warnings

Warnings, if any, that occurred during the transaction.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

400

Bad Request - The request could not be understood by the server due to malformed syntax.

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

Not Found - A beacon-trigger with specified triggerName does not exist.

406

Unsupported Accept type - The content type specified in Accept header is not application/json, app

415

Unsupported Media Type - The server is refusing to service the request because the request payload

500

An internal error occurred.

Beacons (DELETE)

Deletes the beacon by using the UUID, the major number, and minor number.

Description

Each of these query parameters (uuid, major and minor) are mandatory. If any of them are missing, the request fails with 400 Bad Request.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

DELETE

Path

/management-apis/1.0/beacons

Example

https://www.example.com/worklightadmin/management-apis/1.0/beacons?locale=de_DE&major=1&minor=4439

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

major

Mandatory. The major number of the beacon.

minor

Mandatory. The minor number of the beacon.

uuid

Mandatory. The UUID of the beacon.

Produces

application/json, application/xml, text/xml

Response

The status of the delete of the beacon. The transaction details might be empty if there are no runtimes deployed.

JSON Example

```
{
  "beacon" : {
    "major" : 1,
    "minor" : 4439,
    "uuid" : "3d402cf0-3691-4bd9-97ff-0b0a93a160ef",
  },
  "ok" : false,
  "productVersion" : "7.1.0",
  "transactions" : [
    {
      "appServerId" : "Tomcat",
      "errors" : [
        {
          ...
        }
      ],
      "id" : 1,
      "project" : {
        "name" : "myproject",
      },
      "status" : "SUCCESS",
      "timeCreated" : "2014-11-14T05:21:13.404Z",
      "timeUpdated" : "2014-11-14T05:21:13.456Z",
      "type" : "DELETE_BEACON",
      "userName" : "demouser",
      "warnings" : [
        {
          ...
        }
      ],
    },
    ...
  ],
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<remove-beacon-result
  ok="false"
  productVersion="7.1.0">
  <beacon
```

```

    major="1"
    minor="4439"
    uuid="3d402cf0-3691-4bd9-97ff-0b0a93a160ef"/>
<transactions>
  <transaction
    appServerId="Tomcat"
    id="1"
    status="SUCCESS"
    timeCreated="2014-11-14T05:21:13.404Z"
    timeUpdated="2014-11-14T05:21:13.456Z"
    type="DELETE_BEACON"
    userName="demouser">
    <errors>
      <error/>
      ...
    </errors>
    <project name="myproject"/>
    <warnings>
      <warning/>
      ...
    </warnings>
  </transaction>
  ...
</transactions>
</remove-beacon-result>

```

Response Properties

The response has the following properties:

beacon

The details of the beacon that is deleted.

ok Whether all transactions were successful.

productVersion

The exact product version.

transactions

The details of the transactions, one for each runtime.

The *beacon* has the following properties:

major

The major number of the beacon.

minor

The minor number of the beacon.

uuid

The UUID of the beacon.

The *transaction* has the following properties:

appServerId

The id of the web application server.

errors

Errors, if any, that occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: SUCCESS, FAILURE.

timeCreated

The date in ISO 8601 format when the transaction was started.

timeUpdated

The date in ISO 8601 format when the transaction was completed.

type

The type of the transaction: DELETE_BEACON.

userName

The user that initiated the transaction.

warnings

Warnings, if any, that occurred during the transaction.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

400

Bad Request - The request could not be understood by the server due to missing mandatory parameters

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

A beacon with the specified uuid+major+minor numbers is not found.

500

An internal error occurred.

Beacons (GET)

Retrieves the beacon with the UUID, major number, and minor number.

Description

The beacons are retrieved based on which of the query parameters are mentioned:

- UUID, major number, and minor number are all specified: returns the details of a specific beacon.
- Only UUID and major number are specified: returns the details of all beacons with matching UUID and major number.
- Only UUID and minor number are specified: returns the details of all beacons with matching UUID and minor number.
- Only UUID is specified: returns the details of all beacons with matching UUID.
- None are specified: returns the details of all beacons.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**

- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/beacons

Example

https://www.example.com/worklightadmin/management-apis/1.0/beacons?errorIfNotFound=true&locale=de_

Query Parameters

Query parameters are optional.

errorIfNotFound

If this flag is set to true (default value), and uuid and/or major/minor parameters are specified for which there are no matching beacons, then 'HTTP 404 Not Found' error is returned instead of an empty list in the output.

locale

The locale used for error messages.

major

The major number of the beacon.

minor

The minor number of the beacon.

uuid

The UUID of the beacon.

Produces

application/json, application/xml, text/xml

Response

The details of all the beacons that are retrieved.

JSON Example

```
{
  "beacons" : [
    {
      "customData" : {
        "beaconLocation" : "loanSection",
        "branchName" : "Indiranagar, Bangalore",
      },
      "latitude" : 12.952,
      "longitude" : 77.644,
      "major" : 1,
      "minor" : 4439,
      "uuid" : "3d402cf0-3691-4bd9-97ff-0b0a93a160ef",
    },
  ],
}
```

```

    ...
  ],
  "productVersion" : 7.1.0,
}

```

XML Example

```

<?xml version="1.0" encoding="UTF-8"?>
<list-beacons-result productVersion="7.1.0">
  <beacons>
    <beacon
      latitude="12.952"
      longitude="77.644"
      major="1"
      minor="4439"
      uuid="3d402cf0-3691-4bd9-97ff-0b0a93a160ef">
      <customData
        beaconLocation="loanSection"
        branchName="Indiranagar, Bangalore"/>
    </beacon>
    ...
  </beacons>
</list-beacons-result>

```

Response Properties

The response has the following properties:

beacons

The array of beacons

productVersion

The exact product version.

The *beacons* has the following properties:

customData

Optional: Any other customer-specific data that is associated with this beacon like branch/store where this beacon is deployed.

latitude

Optional latitude where the beacon is deployed.

longitude

Optional longitude where the beacon is deployed.

major

The major number of the beacon.

minor

The minor number of the beacon.

uuid

The UUID of the beacon.

The *customData* has the following properties:

beaconLocation

The physical location of the beacon.

branchName

The branch where the beacon is installed.

Errors

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

A beacon with the specified uuid and/or major/minor is not found and errorIfNotFound flag was either true or not specified.

406

Unsupported Accept type - The content type specified in Accept header is not application/json, application/xml, or text/xml.

500

An internal error occurred.

Beacons (PUT)

Registers (Adds/Updates) the beacon that is identified by UUID, major number, and minor number in the payload.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

PUT

Path

/management-apis/1.0/beacons

Example

https://www.example.com/worklightadmin/management-apis/1.0/beacons?locale=de_DE

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

application/json, application/xml, text/xml

Produces

application/json, application/xml, text/xml

Payload

The payload can be in JSON or XML format and has values for UUID, major number, minor number, latitude, longitude, and customData properties.

JSON Example

```
{
  "customData" : {
    "beaconLocation" : "loanSection",
    "branchName" : "Indiranagar, Bangalore",
  },
  "latitude" : "12.95213",
  "longitude" : "77.64482",
  "major" : 1,
  "minor" : 4439,
  "uuid" : "3d402cf0-3691-4bd9-97ff-0b0a93a160ef",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<beacon
  latitude="12.95213"
  longitude="77.64482"
  major="1"
  minor="4439"
  uuid="3d402cf0-3691-4bd9-97ff-0b0a93a160ef">
  <customData
    beaconLocation="loanSection"
    branchName="Indiranagar, Bangalore"/>
</beacon>
```

Payload Properties

The payload has the following properties:

customData

Optional: Any other customer-specific data that is associated with this beacon like branch/store where this beacon is deployed.

latitude

Optional latitude where the beacon is deployed.

longitude

Optional longitude where the beacon is deployed.

major

The major number of the beacon (positive number in the range 0-65535 inclusive).

minor

The minor number of the beacon (positive number in the range 0-65535 inclusive).

uuid

UUID of beacon. UUID must be specified in canonical form and has 32 hexadecimal digits. The digits are specified in five groups and separated by hyphens, in the form 8-4-4-4-12 for a total of 36 characters (32 alphanumeric characters and 4 hyphens).

The *customData* has the following properties:

beaconLocation

The physical location of the beacon.

branchName

The branch where the beacon is installed.

Response

The status of the add/update of the beacon. The transaction details might be empty if there are no runtimes deployed.

JSON Example

```
{
  "beacon" : {
    "customData" : {
      "beaconLocation" : "loanSection",
      "branchName" : "Indiranagar, Bangalore",
    },
    "latitude" : "12.952",
    "longitude" : 77.644,
    "major" : 1,
    "minor" : 4439,
    "uuid" : "3d402cf0-3691-4bd9-97ff-0b0a93a160ef",
  },
  "ok" : true,
  "productVersion" : "7.1.0",
  "transactions" : [
    {
      "appServerId" : "Tomcat",
      "errors" : [
        {
        },
        ...
      ],
      "id" : 1,
      "project" : {
        "name" : "myproject",
      },
      "status" : "SUCCESS",
      "timeCreated" : "2014-11-14T05:21:13.404Z",
      "timeUpdated" : "2014-11-14T05:21:13.456Z",
      "type" : "REGISTER_BEACON",
      "userName" : "demouser",
      "warnings" : [
        {
        },
        ...
      ],
    },
    ...
  ],
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<set-beacon-result
  ok="true"
  productVersion="7.1.0">
  <beacon
    latitude="12.952"
    longitude="77.644"
    major="1"
    minor="4439"

        ...
      </warnings>
    </transaction>
    ...
  </transactions>
</set-beacon-result>

```

Response Properties

The response has the following properties:

beacon

The details of the beacon that is added/updated.

ok Whether all transactions were successful.

productVersion

The exact product version.

transactions

The details of the transactions, one for each runtime.

The *beacon* has the following properties:

customData

Optional: Any other customer-specific data that is associated with this beacon like branch/store where this beacon is deployed.

latitude

Optional latitude where the beacon is deployed.

longitude

Optional longitude where the beacon is deployed.

major

The major number of the beacon.

minor

The minor number of the beacon.

uuid

The UUID of the beacon.

The *customData* has the following properties:

beaconLocation

The physical location of the beacon.

branchName

The branch where the beacon is installed.

The *transaction* has the following properties:

appServerId

The id of the web application server.

errors

Errors, if any, that occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: SUCCESS, FAILURE.

timeCreated

The date in ISO 8601 format when the transaction was started.

timeUpdated

The date in ISO 8601 format when the transaction was completed.

type

The type of the transaction: REGISTER_BEACON.

userName

The user that initiated the transaction.

warnings

Warnings, if any, that occurred during the transaction.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

400

Bad Request - The request could not be understood by the server due to malformed syntax or missing

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

406

Unsupported Accept type - The content type specified in Accept header is not application/json, app

415

Unsupported Media Type - The server is refusing to service the request because the request payload

500

An internal error occurred.

Device Application Status (PUT)

Changes the status of a specific application on a specific device.

Description

A device can be marked as enabled or disabled for a specific device. Disabled applications cannot access the server.

This transaction can run synchronously or asynchronously. If processed asynchronously, the REST service returns before the transaction is completed. In this case, you can query the transaction result later with the transaction REST service.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightoperator**

Method

PUT

Path

/management-apis/1.0/runtimes/runtime-name/devices/device-id/applications/application-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/devices/12345-6789/app>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

device-id

The device id.

Query Parameters

Query parameters are optional.

async

Whether the transaction is processed synchronously or asynchronously. Allowed values are true and false. The default is synchronous processing.

locale

The locale used for error messages.

Consumes

application/json

Produces

application/json, application/xml, text/xml

Payload

JSON Example

```
{
  "status" : "ENABLED",
}
```

Payload Properties

The payload has the following properties:

status

The status of the application: ENABLED or DISABLED.

Response

The metadata of the transaction.

JSON Example

```
{
  "ok" : false,
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "description" : {
      "appName" : "myapplication",
      "deviceId" : "12345-6789",
      "status" : "ENABLED",
    },
    "errors" : [
      {
        "details" : "An internal error occured.",
      },
      ...
    ],
    "id" : 1,
    "project" : {
      "name" : "myproject",
    },
    "status" : "FAILURE",
    "timeCreated" : "2014-04-13T00:18:36.979Z",
    "timeUpdated" : "2014-04-14T00:18:36.979Z",
    "type" : "CHANGE_DEVICE_APPLICATION_STATUS",
    "userName" : "demouser",
  },
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<set-applicationdevice-status-result
  ok="false"
  productVersion="7.1.0">
<transaction
  appServerId="Tomcat"
  id="1"
  status="FAILURE"
  timeCreated="2014-04-13T00:18:36.979Z"
  timeUpdated="2014-04-14T00:18:36.979Z"
```

```

    type="CHANGE_DEVICE_APPLICATION_STATUS"
    userName="demouser">
    <description
      appName="myapplication"
      deviceId="12345-6789"
      status="ENABLED"/>
    <errors>
      <error details="An internal error occured."/>
      ...
    </errors>
    <project name="myproject"/>
  </transaction>
</set-applicationdevice-status-result>

```

Response Properties

The response has the following properties:

ok Whether the transaction was successful.

productVersion

The exact product version.

transaction

The details of the transaction.

The *transaction* has the following properties:

appServerId

The id of the web application server.

description

The details of the status change.

errors

The errors occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: PENDING, PREPARING, COMMITTING, REJECTING, SUCCESS, FAILURE, CANCELED. Synchronous transactions can have the state SUCCESS and FAILURE. Asynchronous transactions can also have the other states.

timeCreated

The date in ISO 8601 format when the adapter was created.

timeUpdated

The date in ISO 8601 format when the adapter was updated.

type

The type of the transaction, here always CHANGE_DEVICE_APPLICATION_STATUS.

userName

The user that initiated the transaction.

The *description* has the following properties:

appName

The application name.

deviceId

The device id.

status

The status of the application: ENABLED or DISABLED.

The *error* has the following properties:

details

The main error message.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

400

The payload is invalid.

403

The user is not authorized to call this service.

404

The corresponding runtime or the device is not found.

500

An internal error occurred.

Device (DELETE)

Deletes all metadata of a specific device.

Description

This transaction can run synchronously or asynchronously. If processed asynchronously, the REST service returns before the transaction is completed. In this case, you can query the transaction result later with the transaction REST service.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightoperator**

Method

DELETE

Path

/management-apis/1.0/runtimes/runtime-name/devices/device-id

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/devices/12345-6789?>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

device-id

The device id.

Query Parameters

Query parameters are optional.

async

Whether the transaction is processed synchronously or asynchronously. Allowed values are true and false. The default is synchronous processing.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The metadata of the deleted device.

JSON Example

```
{
  "ok" : false,
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "description" : {
      "deviceId" : "12345-6789",
      "status" : "LOST",
    },
  },
  "errors" : [
    {
      "details" : "An internal error occurred.",
    },
    ...
  ],
  "id" : 1,
  "project" : {
    "name" : "myproject",
  },
  "status" : "FAILURE",
  "timeCreated" : "2014-04-13T00:18:36.979Z",
  "timeUpdated" : "2014-04-14T00:18:36.979Z",
  "type" : "REMOVE_DEVICE",
  "userName" : "demouser",
},
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<remove-device-result
  ok="false"
  productVersion="7.1.0">
  <transaction
    appServerId="Tomcat"
```

```

    id="1"
    status="FAILURE"
    timeCreated="2014-04-13T00:18:36.979Z"
    timeUpdated="2014-04-14T00:18:36.979Z"
    type="REMOVE_DEVICE"
    userName="demouser">
    <description
      deviceId="12345-6789"
      status="LOST"/>
    <errors>
      <error details="An internal error occured."/>
      ...
    </errors>
    <project name="myproject"/>
  </transaction>
</remove-device-result>

```

Response Properties

The response has the following properties:

ok Whether the transaction was successful.

productVersion

The exact product version.

transaction

The details of the transaction.

The *transaction* has the following properties:

appServerId

The id of the web application server.

description

The details of the device.

errors

The errors occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: PENDING, PREPARING, COMMITTING, REJECTING, SUCCESS, FAILURE, CANCELED. Synchronous transactions can have the state SUCCESS and FAILURE. Asynchronous transactions can also have the other states.

timeCreated

The date in ISO 8601 format when the adapter was created.

timeUpdated

The date in ISO 8601 format when the adapter was updated.

type

The type of the transaction, here always REMOVE_DEVICE.

userName

The user that initiated the transaction.

The *description* has the following properties:

deviceId

The device id.

status

The status of the device: ACTIVE, LOST, STOLEN, EXPIRED, DISABLED.

The *error* has the following properties:

details

The main error message.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime or the device is not found.

500

An internal error occurred.

Device Status (PUT)

Changes the status of a specific device.

Description

A device can be marked as active, lost, stolen, disabled, or expired. Lost, stolen or disabled devices cannot access the server. A device is marked expired if it has not connected to the MobileFirst server for 90 days.

This transaction can run synchronously or asynchronously. If processed asynchronously, the REST service returns before the transaction is completed. In this case, you can query the transaction result later with the transaction REST service.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightoperator**

Method

PUT

Path

/management-apis/1.0/runtimes/runtime-name/devices/device-id

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/devices/12345-6789?asyn>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

device-id

The device id.

Query Parameters

Query parameters are optional.

async

Whether the transaction is processed synchronously or asynchronously. Allowed values are true and false. The default is synchronous processing.

locale

The locale used for error messages.

Consumes

application/json

Produces

application/json, application/xml, text/xml

Payload

JSON Example

```
{
  "status" : "LOST",
}
```

Payload Properties

The payload has the following properties:

status

The new status of the device: ACTIVE, LOST, STOLEN, EXPIRED, DISABLED.

Response

The metadata of the transaction.

JSON Example

```
{
  "ok" : false,
  "productVersion" : "7.1.0",
  "transaction" : {
    "appServerId" : "Tomcat",
    "description" : {
      "deviceId" : "12345-6789",
      "status" : "LOST",
    },
  },
  "errors" : [
    {
      "details" : "An internal error occured.",
    },
    ...
  ]
}
```

```

    ],
    "id" : 1,
    "project" : {
        "name" : "myproject",
    },
    "status" : "FAILURE",
    "timeCreated" : "2014-04-13T00:18:36.979Z",
    "timeUpdated" : "2014-04-14T00:18:36.979Z",
    "type" : "CHANGE_DEVICE_STATUS",
    "userName" : "demouser",
  },
}

```

XML Example

```

<?xml version="1.0" encoding="UTF-8"?>
<set-device-status-result
  ok="false"
  productVersion="7.1.0">
  <transaction
    appServerId="Tomcat"
    id="1"
    status="FAILURE"
    timeCreated="2014-04-13T00:18:36.979Z"
    timeUpdated="2014-04-14T00:18:36.979Z"
    type="CHANGE_DEVICE_STATUS"
    userName="demouser">
    <description
      deviceId="12345-6789"
      status="LOST"/>
    <errors>
      <error details="An internal error occured."/>
      ...
    </errors>
    <project name="myproject"/>
  </transaction>
</set-device-status-result>

```

Response Properties

The response has the following properties:

ok Whether the transaction was successful.

productVersion

The exact product version.

transaction

The details of the transaction.

The *transaction* has the following properties:

appServerId

The id of the web application server.

description

The details of the status change.

errors

The errors occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: PENDING, PREPARING, COMMITTING, REJECTING, SUCCESS, FAILURE, CANCELED. Synchronous transactions can have the state SUCCESS and FAILURE. Asynchronous transactions can also have the other states.

timeCreated

The date in ISO 8601 format when the adapter was created.

timeUpdated

The date in ISO 8601 format when the adapter was updated.

type

The type of the transaction, here always CHANGE_DEVICE_STATUS.

userName

The user that initiated the transaction.

The *description* has the following properties:

deviceId

The device id.

status

The status of the device: ACTIVE, LOST, STOLEN, EXPIRED, DISABLED.

The *error* has the following properties:

details

The main error message.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

400

The payload is invalid.

403

The user is not authorized to call this service.

404

The corresponding runtime or the device is not found.

500

An internal error occurred.

Devices (GET)

Retrieves metadata for the list of devices that accessed this project.

Note

Since 7.1, the offset parameter is no longer supported. Use the bookmark parameter instead for paging.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/devices

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/devices?bookmark=ABC&1>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

bookmark

The bookmark for the page if only a part of the list (a page) should be returned.

locale

The locale used for error messages.

orderBy

The sort mode. By default, the elements are sorted in increasing order. If the sort mode starts with - (minus sign), the elements are sorted in decreasing order. Possible sort modes are: uid, friendlyName, deviceModel, deviceEnvironment, status, lastAccessed. The default sort mode is: uid.

pageSize

The number of elements if only a part of the list (a page) should be returned. The default value is 100.

query

A device friendly name or a user to search for.

Produces

application/json, application/xml, text/xml

Response

The metadata of the devices that accessed this project.

JSON Example

```
{
  "items" : [
    {
      "applicationDeviceAssociations" : [
        {
          "appName" : "myapplication",
          "deviceId" : "12345-6789",
          "deviceStatus" : "LOST",
          "status" : "ENABLED",
        },
        ...
      ],
      "deviceEnvironment" : "android",
      "deviceModel" : "Nexus 7",
      "deviceOs" : "4.4",
      "friendlyName" : "Jeremy's Personal Phone",
      "id" : "12345-6789",
      "lastAccessed" : "2014-05-13T00:18:36.979Z",
      "status" : "LOST",
      "uid" : "Jeremy",
    },
    ...
  ],
  "nextPageBookmark" : "DEF",
  "pageNumber" : 2,
  "pageSize" : 100,
  "prevPageBookmark" : "ABC",
  "productVersion" : "7.1.0",
  "startIndex" : 0,
  "totalListSize" : 33,
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<devices
  nextPageBookmark="DEF"
  pageNumber="2"
  pageSize="100"
  prevPageBookmark="ABC"
  productVersion="7.1.0"
  startIndex="0"
  totalListSize="33">
  <items>
    <item
      deviceEnvironment="android"
      deviceModel="Nexus 7"
      deviceOs="4.4"
      friendlyName="Jeremy's Personal Phone"
      id="12345-6789"
      lastAccessed="2014-05-13T00:18:36.979Z"
      status="LOST"
      uid="Jeremy">
      <applicationDeviceAssociations>
        <applicationDeviceAssociation
          appName="myapplication"
          deviceId="12345-6789"
          deviceStatus="LOST"
          status="ENABLED"/>
        ...
      </applicationDeviceAssociations>
    </item>
    ...
  </items>
</devices>
```

Response Properties

The response has the following properties:

items

The array of device metadata

nextPageBookmark

The bookmark of the next page if only a page of devices is returned.

pageNumber

The page index if only a page of devices is returned.

pageSize

The page size if only a page of devices is returned.

prevPageBookmark

The bookmark of the previous or first page if only a page of devices is returned.

productVersion

The exact product version.

startIndex

The start index in the total list if only a page of devices is returned.

totalListSize

The total number of devices.

The *device* has the following properties:

applicationDeviceAssociations

The applications on the device.

deviceEnvironment

The platform environment of the app version: android, iphone, ...

deviceModel

The device model.

deviceOs

The device operating system.

friendlyName

The friendly name of the device.

id The device id.

lastAccessed

The date in ISO 8601 format when the device was last accessed.

status

The status of the device: ACTIVE, LOST, STOLEN, EXPIRED, DISABLED.

uid

The user name of the device.

The *device application* has the following properties:

appName

The name of the application.

deviceId

The device id.

deviceStatus

The status of the device:ACTIVE, LOST, STOLEN, EXPIRED, DISABLED.

status

The status of the application: ENABLED or DISABLED.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Event Source (GET)

Retrieves metadata for the event source.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/notifications/eventsources/adapter-name/eventsource-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/eventsource-name>

Path Parameters**runtime-name**

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

adapter-name

The name of the adapter.

eventsource-name

The name of the event source.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The metadata of the event source.

JSON Example

```
{
  "numberOfMessagesSent" : 1,
  "numberOfSubscribedUsers" : 1,
  "productVersion" : "7.1.0",
  "qname" : "SampleAdapter.SampleEventSource",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<eventsources
  numberOfMessagesSent="1"
  numberOfSubscribedUsers="1"
  productVersion="7.1.0"
  qname="SampleAdapter.SampleEventSource"/>
```

Response Properties

The response has the following properties:

numberOfMessagesSent

Number of messages sent to this event source.

numberOfSubscribedUsers

Number of subscribed users of this event source.

productVersion

The exact product version.

qname

The name of the event source.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Event Sources (GET)

Retrieves metadata for the list of event sources.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/notifications/eventsources

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/eventsources>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The metadata of the event sources.

JSON Example

```
{
  "eventsources" : [
    {
      "numberOfMessagesSent" : 1,
      "numberOfSubscribedUsers" : 1,
      "qname" : "myadapter.myeventsource",
    },
    ...
  ],
  "productVersion" : "7.1.0",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<eventsources productVersion="7.1.0">
  <eventsources>
    <eventsource
```

```
        numberOfMessagesSent="1"
        numberOfSubscribedUsers="1"
        qname="myadapter.myeventsource"/>
    ...
</eventsources>
</eventsources>
```

Response Properties

The response has the following properties:

eventsources

The array of event source metadata

productVersion

The exact product version.

The *eventsource* has the following properties:

numberOfMessagesSent

Number of messages sent to this event source.

numberOfSubscribedUsers

Number of subscribed users of this event source.

qname

The name of the event source.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Farm topology members (GET)

Retrieves the list of members of the farm.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/*runtime-name*/farm

Example

https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/farm?locale=de_DE

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The list of nodes registered in the current farm topology

JSON Example

```
{
  "nodes" : [
    {
      "adminUser" : "johndoe",
      "appServerType" : "LIBERTY",
      "heartbeatTime" : "2014-12-08T23:32:04.700Z",
      "host" : "192.168.0.4",
      "pk" : {
        "projectName" : "mytestproject",
        "serverId" : "Farm_Node_3",
      },
      "port" : "8686",
      "status" : "ALIVE",
      "tomcatPort" : "8989",
    },
    ...
  ],
  "numberOfNodes" : 3,
  "productVersion" : "7.0",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<farm-members
  numberOfNodes="3"
  productVersion="7.0">
  <nodes>
    <node
      adminUser="johndoe"
      appServerType="LIBERTY"
      heartbeatTime="2014-12-08T23:32:04.700Z"
      host="192.168.0.4"
      port="8686"
      status="ALIVE"
      tomcatPort="8989">
      <pk
        projectName="mytestproject"
```

```
        serverId="Farm_Node_3"/>
    </node>
    ...
</nodes>
</farm-members>
```

Response Properties

The response has the following properties:

nodes

The array of farm nodes

numberOfNodes

The total number of nodes.

productVersion

The exact product version.

The *farm node* has the following properties:

adminUser

The user id to use for REST

appServerType

The server type of this node

heartbeatTime

The last heartbeat time

host

The hostname of this node

pk The farm node primary key, that is, the attributes that uniquely identify this node.

port

The port to use for REST or RMI

status

The status of this node

tomcatPort

The port to use for RMI if behind a firewall

The *farm node primary key* has the following properties:

projectName

The MobileFirst runtime related to this farm member

serverId

The server identifier of this farm member

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found.

500

An internal error occurred.

Farm topology members (DELETE)

Unregisters a farm node.

Description

This service removes a farm node. By default, the service will remove a farm node only if it is marked as being Down. If you want to force the deletion, even if the farm member is marked as being Alive, you should set the `force` argument to true.

Roles

Users in the following roles are authorized to perform this operation:

- `worklightadmin`

Method

DELETE

Path

`/management-apis/1.0/runtimes/runtime-name/farm/server-id`

Example

`https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/farm/farm_member_1234`

Path Parameters

`runtime-name`

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

`server-id`

The server id of the farm member to remove.

Query Parameters

Query parameters are optional.

`force`

Whether the service should unregister a farm member, even if it is marked as being Alive. The default is false.

`locale`

The locale used for error messages.

Produces

`application/json`, `application/xml`, `text/xml`

Response

The status of the unregistration of the farm member.

JSON Example

```
{
  "ok" : true,
  "productVersion" : "7.0",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<remove-farm-member-result
  ok="true"
  productVersion="7.0"/>
```

Response Properties

The response has the following properties:

ok Whether the operation was successful.

productVersion

The exact product version.

Errors

403

The user is not authorized to call this service.

404

The corresponding farm member is not found.

500

An internal error occurred.

GCM Credentials (DELETE)

Deletes Google Cloud Messaging (GCM) credentials of the application with the application ID, environment, and version.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

DELETE

Path

*/management-apis/1.0/runtimes/runtime-name/notifications/applications/
application-name/gcmConf/application-env/application-version/*

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The delete status of GCM credentials.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "DELETE_PUSH_CREDENTIALS",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<deleteGCMCredentialsStatus
  status="Success"
  type="DELETE_PUSH_CREDENTIALS">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</deleteGCMCredentialsStatus>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The GCM credentials are deleted successfully.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name

Name of the project

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

GCM Credentials (GET)

Retrieves Google Cloud Messaging (GCM) credentials of the application with the application ID, environment, and version.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/gcmConf/application-env/application-version/

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/gcmConf/application-env/application-version/>

Path Parameters**runtime-name**

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The GCM Credentials of the application with the application ID, environment, and version.

JSON Example

```
{
  "apiKey" : "AIzaSyDSJrULbNZZZzzZzzxyX7ZTmnoRLkwiU",
  "productVersion" : "7.1.0",
  "senderId" : "999999999999",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<gcmCredentials
  apiKey="AIzaSyDSJrULbNZZZzzZzzxyX7ZTmnoRLkwiU"
  productVersion="7.1.0"
  senderId="999999999999"/>
```

Response Properties

The response has the following properties:

apiKey

The key value received from GCM.

productVersion

The exact product version.

senderId

The project ID received from GCM.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

GCM Credentials (PUT)

Set Google Cloud Messaging (GCM) credentials of the application with the application ID, environment, and version.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

PUT

Path

*/management-apis/1.0/runtimes/runtime-name/notifications/applications/
application-name/gcmConf/application-env/application-version/*

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

application/json

Produces

application/json, application/xml, text/xml

Payload

The payload in JSON format has values for apiKey and senderId.

JSON Example

```
{
  "apiKey" : "AIZAyDSJrrrrrrrrrrZZZZZZX7ZTmnoRLkwiU",
  "senderId" : "1099999999999",
}
```

Payload Properties

The payload has the following properties:

apiKey

The key value received from GCM.

senderId

The project ID received from GCM.

Response

The status of set GCM credentials.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "SET_GCM_CREDENTIALS",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<setGCMcredentialsStatus
  status="Success"
  type="SET_GCM_CREDENTIALS">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</setGCMcredentialsStatus>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The GCM credentials are saved successfully.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name

Name of the project

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Mediator (GET)

Retrieves metadata of the mediator.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/notifications/mediators/mediator-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/mediators/>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

mediator-name

The name of the mediator.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The metadata of the mediator.

JSON Example

```
{
  "productVersion" : "7.1.0",
  "type" : "Google",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<mediators
  productVersion="7.1.0"
  type="Google"/>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

type

The type of the mediator.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Mediators (GET)

Retrieves the list of all supported mediators for sending notifications.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/*runtime-name*/notifications/mediators

Example

https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/mediators

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The list of all supported mediators for sending notifications.

JSON Example

```
{
  "mediators" : [
    {
      "type" : "Google",
    },
    ...
  ],
  "productVersion" : "7.1.0",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<mediators productVersion="7.1.0">
  <mediators>
    <mediator type="Google"/>
    ...
  </mediators>
</mediators>
```

Response Properties

The response has the following properties:

mediators

The array of mediator metadata

productVersion

The exact product version.

The *mediator* has the following properties:

type

The type of the mediator.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

MPNS Credentials (DELETE)

Deletes MPNS credentials of the application with the application ID, environment, and version.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

DELETE

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/mpnsConf/application-env/application-version/

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/mpnsConf/application-env/application-version/>

Path Parameters**runtime-name**

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The delete status of MPNS credentials.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "DELETE_PUSH_CREDENTIALS",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<deleteMPNScredentials
  status="Success"
  type="DELETE_PUSH_CREDENTIALS">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</deleteMPNScredentials>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The MPNS credentials are deleted successfully.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name

Name of the project

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

MPNS Credentials (GET)

Retrieves MPNS credentials of the application with the application ID, environment, and version.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

*/management-apis/1.0/runtimes/runtime-name/notifications/applications/
application-name/mpnsConf/application-env/application-version/*

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/mpnsConf/application-env/application-version/>

Path Parameters**runtime-name**

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The MPNS Credentials of the application with the application ID, environment, and version.

JSON Example

```
{
  "authenticated" : true,
  "keyAlias" : "aliasName",
  "keyAliasPassword" : "password",
  "productVersion" : "7.1.0",
  "serviceName" : "wl.ibm.push",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<mpnsCredentials
  authenticated="true"
  keyAlias="aliasName"
  keyAliasPassword="password"
  productVersion="7.1.0"
  serviceName="wl.ibm.push"/>
```

Response Properties

The response has the following properties:

authenticated

Returns whether the push configuration is authenticated.

keyAlias

The alias used to access the keystore specified in the worklight.properties.

keyAliasPassword

The password for the key alias.

productVersion

The exact product version.

serviceName

The common name (CN) found in the MPNS certificate's Subject value.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

MPNS Credentials (PUT)

Set MPNS credentials of the application with the application ID, environment, version, keyAlias, keyAliasPassword, and serviceName.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

PUT

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/mpnsConf/application-env/application-version/

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/mpnsConf/application-env/application-version/>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

application/json

Produces

application/json, application/xml, text/xml

Payload

The payload in JSON format has values for keyAlias, keyAliasPassword, and serviceName.

JSON Example

```
{
  "authenticated" : true,
  "keyAlias" : "aliasName",
  "keyAliasPassword" : "password",
  "serviceName" : "wl.ibm.push",
}
```

Payload Properties

The payload has the following properties:

authenticated

Returns whether the push configuration is authenticated.

keyAlias

The alias is used to access the keystore that is specified in the worklight.properties file.

keyAliasPassword

The password for your key alias.

serviceName

The common name (CN) found in the MPNS certificate's Subject value.

Response

The status of set MPNS credentials.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "SET_MPNS_CREDENTIALS",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<setMPNScredentialsStatus
  status="Success"
  type="SET_MPNS_CREDENTIALS">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</setMPNScredentialsStatus>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The MPNS credentials are saved successfully.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name

Name of the project

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Push Device Registration (DELETE)

Deletes the device with the device ID and application ID.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

DELETE

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/devices/device-id

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/appli>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

device-id

The device id.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

Deletes the device with the device ID and application ID.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "REMOVE_DEVICE",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<deleteDevice
  status="Success"
  type="REMOVE_DEVICE">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</deleteDevice>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The device is deleted successfully.

type
Transaction type.

The *productVersion* has the following properties:

productVersion
The exact product version

The *project* has the following properties:

name
Name of the project

Errors

403
The user is not authorized to call this service.

404
The corresponding runtime is not found or not running.

500
An internal error occurred.

Push Device Registration (GET)

Retrieves metadata of the device with the given device ID.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

*/management-apis/1.0/runtimes/runtime-name/notifications/applications/
application-name/devices/device-id*

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/appli>

Path Parameters

runtime-name
The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name
The name of the application.

device-id

The device id.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The metadata of the device with the given device ID.

JSON Example

```
{
  "deviceId" : "testdevice",
  "platform" : "G",
  "productVersion" : "7.1.0",
  "token" : "testtoken",
  "userId" : "worklight",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<devices
  deviceId="testdevice"
  platform="G"
  productVersion="7.1.0"
  token="testtoken"
  userId="worklight"/>
```

Response Properties

The response has the following properties:

deviceId

The unique id of the device.

platform

The device platform.

productVersion

The exact product version.

token

The unique push token of the device.

userId

The userId of the device.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Push Device Subscription (DELETE)

Delete subscriptions of a combination of application, tag name, and device ID.

Description

The subscriptions that are deleted are for a combination of application, tag name, and device ID.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

DELETE

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/subscriptions

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/subscriptions>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

Query Parameters

Query parameters are optional.

deviceId

The unique deviceId of the device.

locale

The locale used for error messages.

tag-Name

The tag name.

Produces

application/json, application/xml, text/xml

Response

The status of delete subscriptions.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "DELETE_SUBSCRIPTIONS",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<deleteSubscriptionsStatus
  status="Success"
  type="DELETE_SUBSCRIPTIONS">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</deleteSubscriptionsStatus>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The subscription is deleted successfully.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name

Name of the project

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Push Device Subscription (GET)

Retrieves metadata of the subscriptions.

Description

The subscriptions can be obtained for application, for a particular tag, for a particular userId, for a particular deviceId and a combination of application, tag name, userId and deviceId

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/subscriptions

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/subscriptions>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

Query Parameters

Query parameters are optional.

deviceId

The unique id of the device.

locale

The locale used for error messages.

offset

The offset from the beginning of the list if only a part of the list (a page) should be returned.

size

The number of elements to be returned.

tag-Name

The name of the tag.

userId

The user id.

Produces

application/json, application/xml, text/xml

Response

The metadata of the subscriptions.

JSON Example

```
{
  "offset" : 1,
  "productVersion" : "7.1.0",
  "size" : 6,
  "subscriptions" : [
    {
      "deviceId" : "testdevice",
      "tag-Name" : "testtag",
    },
    ...
  ],
  "totalListSize" : 6,
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<pushDevicesubscription
  offset="1"
  productVersion="7.1.0"
  size="6"
  totalListSize="6">
  <subscriptions>
    <subscription
      deviceId="testdevice"
      tag-Name="testtag"/>
    ...
  </subscriptions>
</pushDevicesubscription>
```

Response Properties

The response has the following properties:

offset

The offset from the beginning of the list if only a part of the list (a page) should be returned.

productVersion

The exact product version.

size

The number of elements to be returned.

subscriptions

The array of subscription metadata

totalListSize

The total number of subscriptions.

The *pushDevicesubscription* has the following properties:

deviceId

The unique id of the device.

tag-Name

The name of the tag.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Push Devices Registration (GET)

Retrieves metadata for the list of devices of an application.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/devices

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/appli>

Path Parameters**runtime-name**

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

offset

The offset from the beginning of the list if only a part of the list (a page) should be returned.

size

The number of elements to be returned.

Produces

application/json, application/xml, text/xml

Response

The metadata of the devices of an application.

JSON Example

```
{
  "devices" : [
    {
      "deviceId" : "testdevice",
      "platform" : "G",
      "token" : "testtoken",
      "userId" : "worklight",
    },
    ...
  ],
  "offset" : 1,
  "productVersion" : "7.1.0",
  "size" : 6,
  "totalListSize" : 6,
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<devices
  offset="1"
  productVersion="7.1.0"
  size="6"
  totalListSize="6">
  <devices>
    <device
      deviceId="testdevice"
      platform="G"
      token="testtoken"
      userId="worklight"/>
    ...
  </devices>
</devices>
```

Response Properties

The response has the following properties:

devices

The array of device metadata

offset

The offset from the beginning of the list if only a part of the list (a page) should be returned.

productVersion

The exact product version.

size

The number of elements to be returned.

totalListSize

The total number of devices.

The *pushDeviceRegistration* has the following properties:

deviceId

The unique id of the device.

platform

The device platform.

token

The unique push token of the device.

userId

The userId of the device.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Push Enabled Applications (GET)

Retrieves metadata for the list of deployed push enabled applications.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/*runtime-name*/notifications/applications

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The metadata of the deployed push enabled applications.

JSON Example

```
{
  "applications" : [
    {
      "applicationEnvironments" : [
        {
          "deviceCount" : 1,
          "mediatorType" : "Google",
          "numberOfMessagesSent" : 1,
          "userCount" : 1,
        },
        ...
      ],
      "deviceCount" : 1,
      "displayName" : "SampleApplication",
      "name" : "SampleApplication",
      "userCount" : 1,
    },
    ...
  ],
  "productVersion" : "7.1.0",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<pushnotification productVersion="7.1.0">
  <applications>
    <application
      deviceCount="1"
      displayName="SampleApplication"
      name="SampleApplication"
      userCount="1">
      <applicationEnvironments>
        <applicationEnvironment
          deviceCount="1"
          mediatorType="Google"
          numberOfMessagesSent="1"
          userCount="1"/>
      </applicationEnvironments>
    </application>
  </applications>
</pushnotification>
```

```
    ...
  </applicationEnvironments>
</application>
...
</applications>
</pushnotification>
```

Response Properties

The response has the following properties:

applications

The array of push enabled application metadata

productVersion

The exact product version.

The *application* has the following properties:

applicationEnvironments

The array of application environments.

deviceCount

Number of subscribed devices of this application.

displayName

The display name of the application.

name

The name of the application.

userCount

Number of subscribed users of this application.

The *applicationEnvironment* has the following properties:

deviceCount

Number of subscribed devices of this application environment.

mediatorType

The name of the application environment.

numberOfMessagesSent

Number of messages sent for this application environment.

userCount

Number of subscribed users of this application environment.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Push Tags (DELETE)

Deletes tag of the application with the application ID and tag.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

DELETE

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/tags/tag-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/tags/tag-name>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

tag-name

The name of the tag.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The delete status of delete tag.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "DELETE_TAGS",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<deleteTagStatus
  status="Success"
  type="DELETE_TAGS">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</deleteTagStatus>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The tags are deleted successfully.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name

Name of the project

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Push Tags (GET)

Retrieves tags of the application with the application ID.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

*/management-apis/1.0/runtimes/runtime-name/notifications/applications/
application-name/tags*

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The Tags of the application with details such as description, name, and product version.

JSON Example

```
{
  "description" : "This is a Gold tag.",
  "name" : "Gold",
  "productVersion" : "7.1.0",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<tags
  description="This is a Gold tag."
  name="Gold"
  productVersion="7.1.0"/>
```

Response Properties

The response has the following properties:

description

The description of the Tag.

name

The name of the Tag.

productVersion

The exact product version.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Push Tags (POST)

Create Tags of the application with the application ID.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

POST

Path

*/management-apis/1.0/runtimes/runtime-name/notifications/applications/
application-name/tags*

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/tags>

Path Parameters**runtime-name**

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

application/json

Produces

application/json, application/xml, text/xml

Payload

The payload in JSON format has values for name and description.

JSON Example

```
{
  "description" : "This is a Gold tag.",
  "name" : "Gold",
}
```

Payload Properties

The payload has the following properties:

description

The description of the tag.

name

The name of the tag.

Response

The status of create tags.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "CREATE_TAGS",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<createTagsStatus
  status="Success"
  type="CREATE_TAGS">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</createTagsStatus>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The tags are created successfully.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name

Name of the project

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Push Tags (PUT)

Update Tags of the application with the application ID and tag.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

PUT

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/tags/tag-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/appli>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

tag-name

The name of the tag.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

application/json

Produces

application/json, application/xml, text/xml

Payload

The payload in JSON format has values for name and description. The tag description is updated based on the given tag name.

JSON Example

```
{
  "description" : "This is modified description of the Gold tag.",
  "name" : "Gold",
}
```

Payload Properties

The payload has the following properties:

description

The description of the tag.

name

The name of the tag.

Response

The status of update tags.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  }
}
```

```
    },  
    "status" : "Success",  
    "type" : "UPDATE_TAGS",  
  }  
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>  
<updateTagsStatus  
  status="Success"  
  type="UPDATE_TAGS">  
  <productVersion productVersion="7.1.0"/>  
  <project name="PushNotifications"/>  
</updateTagsStatus>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The tags are updated successfully.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name

Name of the project

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Runtime (DELETE)

Deletes a specific runtime.

Description

The purpose of this API is to allow to cleanup the database. You can delete a runtime only when it is stopped. A runtime that is currently active cannot be deleted.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**

Method

DELETE

Path

/management-apis/1.0/runtimes/runtime-name

Example

https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime?locale=de_DE&mode=empty

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

mode

Whether to delete the runtime only if it has no applications or adapters. Possible values are **empty** (delete only when empty) and **always** (delete even when not empty, the default).

Produces

application/json, application/xml, text/xml

Errors

403

The user is not authorized to call this service.

409

The corresponding runtime cannot be deleted. Possible reasons: It is still running, hence you must stop it. It is not empty but you passed the mode **empty** to delete only an empty runtime.

500

An internal error occurred.

Runtime (GET)

Retrieves metadata for a specific runtime.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime?expand=true&locale=c>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

expand

Set to true to show details of the applications and adapters. The default is false

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The metadata for the runtime.

JSON Example

```
{
  "adapters" : [
    {
      "deployTime" : "2014-04-13T00:18:36.979Z",
      "description" : "My first sample adapter",

```

Response Properties

The response has the following properties:

adapters

The array of adapters (shown only with `expand=true`).

applications

The array of applications (shown only with `expand=true`).

auditEnabled

Whether audit is enabled.

bitlyApiKey

The key for the Bitly service.

bitlyUsername

The user name for the Bitly service.

name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

numberOfActiveDevices

The number of active devices using this runtime.

numberOfAdapters

The number of adapters deployed in this runtime (shown only with `expand=false`).

numberOfApplications

The number of applications deployed in this runtime (shown only with `expand=false`).

numberOfDecommissionedDevices

The number of devices decommissioned for this runtime.

platformVersion

The exact version number of the IBM MobileFirst Platform Foundation development tools (Studio) that built the project WAR file.

productVersion

The exact product version.

running

Whether the runtime is currently active or has stopped.

serverVersion

The exact IBM MobileFirst Platform Server version number from which `worklight-jee-library.jar` is taken.

synchronizationStatus

The status of the nodes of the runtime. Can contain the values "ok" if all nodes of the runtime are running without error, "synchronizing" if some node is in progress of synchronizing, or an error message if some nodes failed to synchronize.

topology

Server topology. Can contain the values "STANDALONE", "CLUSTER" or "FARM"

The *adapter* has the following properties:

deployTime

The date in ISO 8601 format when the adapter was deployed.

description

The description of the adapter.

link

The URL to access detail information about the adapter.

name

The name of the adapter.

platformVersion

The exact version number of the IBM MobileFirst Platform Foundation development tools (Studio) that built the adapter.

procedureDetails

The JavaScript procedures of the adapter.

projects

The projects the adapter belong to.

resourceSize

The size of the adapter resource.

urls

The API documentation of the URLs of the REST API provided by the adapter.

The *adapter procedure details* has the following properties:

audit

true if calls to the Javascript procedure are logged in the audit log.

connectAs

The optional type of the connection to the back end. Possible values are: SERVER (use the connection policy defined for the adapter) or END_USER (use the user's identity for the connection).

description

The optional description of the procedure.

displayName

The optional display name of the procedure.

name

The Javascript name of the adapter procedure.

securityTest

The optional name of the security test used to protect the adapter procedure, as defined in the authenticationConfig.xml file.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

The *url* has the following properties:

formParameters

The form parameters.

headerParameters

The header parameters.

javaClass

The Java class

javaMethodName

The Java method

method

The HTTP method.

pathParameters

The path parameters.

queryParameters

The query parameters.

securedWithScope

The set of realms that secure the REST API.

uri

The URI of the REST API.

The *REST API parameter* has the following properties:

defaultValue

The default value.

javaType

The Java type name.

name

The name of the parameter.

The *application* has the following properties:

description

The description of the application.

displayName

The display name of the application.

environments

The array of application environments.

link

The URL to access detail information about the application.

name

The name of the application.

platformVersion

The exact version number of the IBM MobileFirst Platform Foundation development tools (Studio) that built the application.

projects

The projects the application belong to.

The *environment* has the following properties:

applicationEnvironmentDataAccess

The access rule to be executed when the app version is disabled.

authenticityConfig

The application authenticity configuration. Possible values are: NONE, BASIC, EXTENDED.

buildTime

The time stamp when the app version was built.

deployTime

The date in ISO 8601 format when the application was deployed.

deviceProvisioningRealm

The name of the realm used for device provisioning.

envPlatformVersion

The version of the platform of the environment.

environment

The platform environment of the app version: android, iphone, ...

link

The URL to access detail information about the application version.

prevBuildTime

The time stamp when the app that was previously deployed was built.

publishUrl

For web applications, this is the URL under which the web application was published.

resourceSize

The size of the wlapp file of the application version.

securityTest

The name of the security test for a protected resource.

supportRemoteDisable

true if the application version supports remote disabling.

supportsAuthenticity

true if the application version supports authentication.

userAuthenticationRealm

The name of the realm used to authenticate users.

version

The version number of the app version.

versionLocked

Whether the version is locked.

The *applicationEnvironmentDataAccess* has the following properties:

action

The action to be done when a disabled app version is accessed. Possible values are: NOTIFY, BLOCK, NA.

createdTime

The date in ISO 8601 format when the app version access rule was created.

downloadLink

The download link where to obtain a new version of the application.

message

The message to be displayed when a disabled app version is accessed.

multiLanguageMessage

Internationalized variants of the message to be displayed when a disabled app version is accessed.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found.

500

An internal error occurred.

Runtime Lock (DELETE)

Forces the release of the transaction lock of a runtime.

Description

This API should not be used in normal operations.

Transactions are performed sequentially. Hence each transaction such as deploying an application or adapter takes the runtime lock. The next transaction waits until the lock is released. After a serious crash, it may happen that the lock is still taken even though the corresponding transaction crashed. The lock will get automatically released after 30 minutes. However, with this API, you can force the release of the lock earlier.

Forcing the release of the lock when a transaction is currently active may corrupt the system. You should use this API only when you are sure that no transaction is currently active.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**

Method

DELETE

Path

/management-apis/1.0/runtimes/*runtime-name*/lock

Example

https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/lock?locale=de_DE

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

JSON Example

```
{
  "busy" : false,
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<lock busy="false"/>
```

Response Properties

The response has the following properties:

busy

Whether the runtime is still busy with a transaction after forcing the release of the lock.

Errors

403

The user is not authorized to call this service.

500

An internal error occurred.

Runtime Lock (GET)

Retrieves information about the transaction lock of a runtime.

Description

Transactions are performed sequentially. Hence each transaction such as deploying an application or adapter takes the runtime lock. The next transaction waits until the lock is released. This API allowed to retrieve whether a runtime is currently busy with a transaction.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

`/management-apis/1.0/runtimes/runtime-name/lock`

Example

`https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/lock?locale=de_DE`

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

JSON Example

```
{
  "busy" : true,
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<lock busy="true"/>
```

Response Properties

The response has the following properties:

busy

Whether the runtime is currently busy with a transaction.

Errors

403

The user is not authorized to call this service.

500

An internal error occurred.

Runtimes (GET)

Retrieves metadata for the list of runtimes.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes

Example

https://www.example.com/worklightadmin/management-apis/1.0/runtimes?fullInfo=true&locale=de_DE&mode=

Query Parameters

Query parameters are optional.

fullInfo

The default value `false` returns basic list of properties of a runtime, while the value `true` returns all properties of this runtime (see a GET on a single runtime for the complete list of properties).

locale

The locale used for error messages.

mode

The default mode `running` retrieves only the running runtimes, while the mode `db` retrieves also the runtimes stored in the database that might not be running.

Produces

application/json, application/xml, text/xml

Response

The metadata for the list of runtimes.

JSON Example

```
{
  "productVersion" : "7.1.0",
  "projects" : [
    {
      "auditEnabled" : true,
      "link" : "https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime",
      "name" : "myruntime",
      "numberOfActiveDevices" : 100,
      "numberOfAdapters" : 1,
      "numberOfApplications" : 1,
      "numberOfDecommissionedDevices" : 5,
      "running" : true,
      "synchronizationStatus" : "ok",
      "topology" : "STANDALONE",
    },
    ...
  ],
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<projectconfiguration productVersion="7.1.0">
  <projects>
    <project
      auditEnabled="true"
      link="https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime"
      name="myruntime"
      numberOfActiveDevices="100"
      numberOfAdapters="1"
      numberOfApplications="1"
      numberOfDecommissionedDevices="5"
      running="true"
      synchronizationStatus="ok"
      topology="STANDALONE"/>
    ...
  </projects>
</projectconfiguration>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

projects

The array of runtimes.

The *runtime* has the following properties:

auditEnabled

Whether audit is enabled.

link

The URL to access detail information about the runtime.

name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

numberOfActiveDevices

The number of active devices using this runtime.

numberOfAdapters

The number of adapters deployed in this runtime.

numberOfApplications

The number of applications deployed in this runtime.

numberOfDecommissionedDevices

The number of devices decommissioned for this runtime.

running

Whether the runtime is currently active or has stopped.

synchronizationStatus

The status of the nodes of the runtime. Can contain the values "ok" if all nodes of the runtime are running without error, "synchronizing" if some node is in progress of synchronizing, or an error message if some nodes failed to synchronize.

topology

Server topology. Can contain the values "STANDALONE", "CLUSTER" or "FARM"

Errors

403

The user is not authorized to call this service.

500

An internal error occurred.

Send Bulk Messages (POST)

Send bulk messages with different options to be specified.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

POST

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/messages/bulk

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/appli>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

application/json

Produces

application/json, application/xml, text/xml

Payload

The payload in JSON format has values for array of messages, target, and settings.

JSON Example

```
{
  "//ArrayOfMessageBody" : [
    {
      "messages" : {
        "alert" : "Test message",
      },
      "settings" : {
        "apns" : {
          "badge" : 1,
          "iosActionKey" : "Ok",
          "payload" : "",
          "sound" : "song.mp3",
        },
        "gcm" : {
          "delayWhileIdle" : ,
          "payload" : "",
          "sound" : "song.mp3",
          "timeToLive" : ,
        },
        "mpns" : {
          "raw" : {
            "payload" : {
            },
          },
        },
      },
    },
  ],
}
```

```

        "title" : {
            "backBackgroundImage" : "Blue.jpg",
            "backContent" : "Back Title Content",
            "backTitle" : "Back Title",
            "backgroundImage" : "Red.jpg",
            "count" : 1,
            "title" : "Push Notification",
        },
        "toast" : {
            "param" : "/Page2.xaml?NavigatedFrom=Toast Notification",
            "title" : "Hello",
        },
    },
    },
    "target" : {
        "consumerIds" : [ "MyConsumerId1", ... ],
        "deviceIds" : [ "MyDeviceId1", ... ],
        "platforms" : [ "A,G", ... ],
        "tagNames" : [ "Gold", ... ],
    },
    ...
],
}

```

Payload Properties

The payload has the following properties:

//ArrayOfMessageBody

The array of message

The *bulk-messages* has the following properties:

messages

The array of message

settings

The settings are the different attributes of the notification.

target

Set of targets can be consumer Ids, devices, platforms, or tags.

The *message* has the following properties:

alert

A string to be displayed in the alert.

The *settings* has the following properties:

apns

Attributes for sending message to an iOS device.

gcm

Attributes for sending message to an Android device.

mpns

Attributes for sending message to an MPNS device.

The *apns* has the following properties:

badge

An integer value to be displayed in a badge on the application icon.

iosActionKey

The label of the dialog box button that allows the user to open the app upon receiving the notification.

payload

A JSON block that is transferred to the application if the application is opened by the user when the notification is received, or if the application is already open.

sound

The name of a file to play when the notification arrives.

The *gcm* has the following properties:

delayWhileIdle

A Boolean value that indicates that the message must not be sent if the device is idle. The server waits for the device to become active before the message is sent.

payload

A JSON block that is transferred to the application if the application is opened by the user when the notification is received, or if the application is already open.

sound

The name of a file to play when the notification arrives.

timeToLive

The duration (in seconds) that the message is kept on GCM storage if the device is offline. Default value is 4 weeks, and must be set as a JSON number.

The *mpns* has the following properties:

raw

Raw.

title

Title.

toast

Toast.

The *raw* has the following properties:

payload

A JSON block that is transferred to the application if the application is opened by the user when the notification is received, or if the application is already open.

The *title* has the following properties:

backBackgroundImage

URL of the back image on a medium flip Tile.

backContent

Content that displays on the back of a medium flip Tile.

backTitle

Title that displays on the back of a flip Tile.

backgroundImage

URL of the front image on a medium flip Tile.

count

An integer value from 1 to 99. If the value of count is not set or it is set to 0, the circle image and value do not display in the Tile. This property is also known as badge.

title

A string that indicates the title of the application. The title fits on a single line of text and must not be wider than the Tile. Approximately 15 characters can fit in the title before it is truncated.

The *toast* has the following properties:

param

Toast notification content.

title

Toast notification title.

The *target* has the following properties:

consumerIds

The array of consumer Ids.

deviceIds

JSON array of the device ids. Devices with these ids receive the notification.

platforms

JSON array of platforms. Devices running on these platforms receive the notification. Supported values are A, G, and M.

tagNames

JSON array of tags. Devices that are subscribed to these tags receive the notification.

Response

The status of send messages.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "SET_PUSH_NOTIFICATION_ENABLED",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<sendMessagesStatus
  status="Success"
  type="SET_PUSH_NOTIFICATION_ENABLED">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</sendMessagesStatus>
```

Response Properties

The response has the following properties:

productVersion
The exact product version.

project
Project name.

status
Message submitted for delivery.

type
Transaction type.

The *productVersion* has the following properties:

productVersion
The exact product version

The *project* has the following properties:

name
Name of the project

Errors

403
The user is not authorized to call this service.

404
The corresponding runtime is not found or not running.

500
An internal error occurred.

Send Message (POST)

Send message with different options to be specified.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

POST

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/messages

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/messages>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

application/json

Produces

application/json, application/xml, text/xml

Payload

The payload in JSON format has values for message, target, and settings.

JSON Example

```
{
  "message" : {
    "alert" : "Test message",
  },
  "settings" : {
    "apns" : {
      "badge" : 1,
      "iosActionKey" : "Ok",
      "payload" : "",
      "sound" : "song.mp3",
    },
    "gcm" : {
      "delayWhileIdle" : ,
      "payload" : "",
      "sound" : "song.mp3",
      "timeToLive" : ,
    },
    "mpns" : {
      "raw" : {
        "payload" : {
        },
      },
      "title" : {
        "backBackgroundImage" : "Blue.jpg",
        "backContent" : "Back Title Content",
        "backTitle" : "Back Title",
        "backgroundImage" : "Red.jpg",
        "count" : 1,
        "title" : "Push Notification",
      },
    },
    "toast" : {
      "param" : "/Page2.xaml?NavigatedFrom=Toast Notification",
      "title" : "Hello",
    },
  },
}
```

```

    },
  },
  "target" : {
    "consumerIds" : [ "MyConsumerId1", ... ],
    "deviceIds" : [ "MyDeviceId1", ... ],
    "platforms" : [ "A,G", ... ],
    "tagNames" : [ "Gold", ... ],
  },
}

```

Payload Properties

The payload has the following properties:

message

The alert message to be sent

settings

The settings are the different attributes of the notification.

target

Set of targets can be consumer Ids, devices, platforms, or tags.

The *message* has the following properties:

alert

A string to be displayed in the alert.

The *settings* has the following properties:

apns

Attributes for sending message to an iOS device.

gcm

Attributes for sending message to an Android device.

mpns

Attributes for sending message to an MPNS device.

The *apns* has the following properties:

badge

An integer value to be displayed in a badge on the application icon.

iosActionKey

The label of the dialog box button that allows the user to open the app upon receiving the notification.

payload

A JSON block that is transferred to the application if the application is opened by the user when the notification is received, or if the application is already open.

sound

The name of a file to play when the notification arrives.

The *gcm* has the following properties:

delayWhileIdle

A Boolean value that indicates that the message must not be sent if the device is idle. The server waits for the device to become active before the message is sent.

payload

A JSON block that is transferred to the application if the application is opened by the user when the notification is received, or if the application is already open.

sound

The name of a file to play when the notification arrives.

timeToLive

The duration (in seconds) that the message is kept on GCM storage if the device is offline. Default value is 4 weeks, and must be set as a JSON number.

The *mpns* has the following properties:

raw

Raw.

title

Title.

toast

Toast.

The *raw* has the following properties:

payload

A JSON block that is transferred to the application if the application is opened by the user when the notification is received, or if the application is already open.

The *title* has the following properties:

backBackgroundImage

URL of the back image on a medium flip Tile.

backContent

Content that displays on the back of a medium flip Tile.

backTitle

Title that displays on the back of a flip Tile.

backgroundImage

URL of the front image on a medium flip Tile.

count

An integer value from 1 to 99. If the value of count is not set or it is set to 0, the circle image and value do not display in the Tile. This property is also known as badge.

title

A string that indicates the title of the application. The title fits on a single line of text and must not be wider than the Tile. Approximately 15 characters can fit in the title before it is truncated.

The *toast* has the following properties:

param

Toast notification content.

title

Toast notification title.

The *target* has the following properties:

consumerIds

The array of consumer Ids.

deviceIds

JSON array of the device ids. Devices with these ids receive the notification.

platforms

JSON array of platforms. Devices running on these platforms receive the notification. Supported values are A, G, and M.

tagNames

JSON array of tags. Devices that are subscribed to these tags receive the notification.

Response

The status of send message.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "SET_PUSH_NOTIFICATION_ENABLED",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<sendMessageStatus
  status="Success"
  type="SET_PUSH_NOTIFICATION_ENABLED">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</sendMessageStatus>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

Message submitted for delivery.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name
Name of the project

Errors

403
The user is not authorized to call this service.

404
The corresponding runtime is not found or not running.

500
An internal error occurred.

Transaction (GET)

Retrieves information of a specific transaction.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/transactions/transaction-id

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/transactions/1?locale=>

Path Parameters

runtime-name
The name of the runtime. This is the context root of the runtime web application, without the leading slash.

transaction-id
The transaction id.

Query Parameters

Query parameters are optional.

locale
The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The information of the specified transaction.

JSON Example

```
{
  "appServerId" : "Tomcat",
  "description" : {
  },
  "errors" : [
    {
      "details" : "An internal error occured.",
    },
    ...
  ],
  "id" : 1,
  "productVersion" : "7.1.0",
  "project" : {
    "name" : "myproject",
  },
  "status" : "FAILURE",
  "timeCreated" : "2014-04-13T00:18:36.979Z",
  "timeUpdated" : "2014-04-14T00:18:36.979Z",
  "type" : "DELETE_ADAPTER",
  "userName" : "demouser",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<transaction
  appServerId="Tomcat"
  id="1"
  productVersion="7.1.0"
  status="FAILURE"
  timeCreated="2014-04-13T00:18:36.979Z"
  timeUpdated="2014-04-14T00:18:36.979Z"
  type="DELETE_ADAPTER"
  userName="demouser">
  <description/>
  <errors>
    <error details="An internal error occured."/>
    ...
  </errors>
  <project name="myproject"/>
</transaction>
```

Response Properties

The response has the following properties:

appServerId

The id of the web application server.

description

The details of the transaction, depending on the transaction type.

errors

The errors occurred during the transaction.

id The id of the transaction.

productVersion

The exact product version.

project

The current project.

status

The state of the transaction: PENDING, PREPARING, COMMITTING, REJECTING, SUCCESS, FAILURE, CANCELED. Synchronous transactions can have the state SUCCESS and FAILURE. Asynchronous transactions can also have the other states.

timeCreated

The date in ISO 8601 format when the adapter was created.

timeUpdated

The date in ISO 8601 format when the adapter was updated.

type

The type of the transaction.

userName

The user that initiated the transaction.

The *error* has the following properties:

details

The main error message.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime or the transaction is not found.

500

An internal error occurred.

Transactions (GET)

Retrieves information of failed transactions.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/*runtime-name*/transactions/errors

Example

https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/transactions/errors?

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

bookmark

The bookmark for the page if only a part of the list (a page) should be returned. If a bookmark is specified, the offset parameter is ignored.

locale

The locale used for error messages.

offset

The offset from the beginning of the list if only a part of the list (a page) should be returned.

orderBy

The sort mode. By default, the elements are sorted in increasing order. If the sort mode starts with - (minus sign), the elements are sorted in decreasing order. Possible sort modes are: created, updated, type, status, user, server. The default sort mode is: created.

pageSize

The number of elements if only a part of the list (a page) should be returned. The default value is 100.

Produces

application/json, application/xml, text/xml, application/zip

Response

The information of the transactions.

JSON Example

```
{
  "items" : [
    {
      "appServerId" : "Tomcat",
      "description" : {
      },
      "errors" : [
        {
          "details" : "An internal error occurred.",
        },
        ...
      ],
      "id" : 1,
      "project" : {
```

```

        "name" : "myproject",
      },
      "status" : "FAILURE",
      "timeCreated" : "2014-04-13T00:18:36.979Z",
      "timeUpdated" : "2014-04-14T00:18:36.979Z",
      "type" : "DELETE_ADAPTER",
      "userName" : "demouser",
    },
    ...
  ],
  "nextPageBookmark" : "DEF",
  "pageNumber" : 2,
  "pageSize" : 100,
  "prevPageBookmark" : "ABC",
  "productVersion" : "7.1.0",
  "startIndex" : 0,
  "totalListSize" : 33,
}

```

XML Example

```

<?xml version="1.0" encoding="UTF-8"?>
<transactions
  nextPageBookmark="DEF"
  pageNumber="2"
  pageSize="100"
  prevPageBookmark="ABC"
  productVersion="7.1.0"
  startIndex="0"
  totalListSize="33">
  <items>
    <item
      appServerId="Tomcat"
      id="1"
      status="FAILURE"
      timeCreated="2014-04-13T00:18:36.979Z"
      timeUpdated="2014-04-14T00:18:36.979Z"
      type="DELETE_ADAPTER"
      userName="demouser">
      <description/>
      <errors>
        <error details="An internal error occured."/>
        ...
      </errors>
      <project name="myproject"/>
    </item>
    ...
  </items>
</transactions>

```

Response Properties

The response has the following properties:

items

The array of transactions

nextPageBookmark

The bookmark of the next page if only a page of transactions is returned.

pageNumber

The page index if only a page of transactions is returned.

pageSize

The page size if only a page of transactions is returned.

prevPageBookmark

The bookmark of the previous page if only a page of transactions is returned.

productVersion

The exact product version.

startIndex

The start index in the total list if only a page of transactions is returned.

totalListSize

The total number of transactions.

The *transaction* has the following properties:

appServerId

The id of the web application server.

description

The details of the transaction, depending on the transaction type.

errors

The errors occurred during the transaction.

id The id of the transaction.

project

The current project.

status

The state of the transaction: PENDING, PREPARING, COMMITTING, REJECTING, SUCCESS, FAILURE, CANCELED. Synchronous transactions can have the state SUCCESS and FAILURE. Asynchronous transactions can also have the other states.

timeCreated

The date in ISO 8601 format when the adapter was created.

timeUpdated

The date in ISO 8601 format when the adapter was updated.

type

The type of the transaction.

userName

The user that initiated the transaction.

The *error* has the following properties:

details

The main error message.

The *project* has the following properties:

name

The name of the project, which is the context root of the runtime.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found.

500

An internal error occurred.

Unsubscribe SMS (POST)

Unsubscribes the list of given phone numbers for SMS.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**

Method

POST

Path

/management-apis/1.0/runtimes/runtime-name/notifications/unsubscribeSMS

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/unsubscribeSMS>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

application/json

Produces

application/json, application/xml, text/xml

Payload

The payload with comma separated list of phone numbers.

JSON Example

```
{
  "numbers" : "1234,5678",
}
```

Payload Properties

The payload has the following properties:

numbers

Comma separated list of phone numbers.

Response

The response status of SMS unsubscription.

JSON Example

```
{
  "failure" : "5678",
  "success" : "1234",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<unsubscribeSMS
  failure="5678"
  success="1234"/>
```

Response Properties

The response has the following properties:

failure

Comma separated list of phone numbers which are not deleted.

success

Comma separated list of phone numbers which are successfully deleted.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

WNS Credentials (DELETE)

Deletes Windows Push Notification Services (WNS) credentials of the application with the application ID, environment, and version.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

DELETE

Path

*/management-apis/1.0/runtimes/runtime-name/notifications/applications/
application-name/wmsConf/application-env/application-version/*

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The delete status of WNS credentials.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "DELETE_PUSH_CREDENTIALS",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<deleteWNSCredentialsStatus
  status="Success"
  type="DELETE_PUSH_CREDENTIALS">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</deleteWNSCredentialsStatus>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The WNS credentials are deleted successfully.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name

Name of the project

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

WNS Credentials (GET)

Retrieves Windows Push Notification Services (WNS) credentials of the application with the application ID, environment, and version.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

GET

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/wnsConf/application-env/application-version/

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/application>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Produces

application/json, application/xml, text/xml

Response

The WNS Credentials of the application with the application ID, environment, and version.

JSON Example

```
{
  "clientSecret" : "82e4569er",
  "packageSID" : "ms-app://s-123-566-78910",
  "productVersion" : "7.1.0",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<wnsCredentials
  clientSecret="82e4569er"
  packageSID="ms-app://s-123-566-78910"
  productVersion="7.1.0"/>
```

Response Properties

The response has the following properties:

clientSecret

The client secret received from WNS.

packageSID

The unique identifier of the app received from WNS.

productVersion

The exact product version.

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

WNS Credentials (PUT)

Sets Windows Push Notification Services (WNS) credentials of the application with the application ID, environment, and version.

Roles

Users in the following roles are authorized to perform this operation:

- **worklightadmin**
- **worklightdeployer**
- **worklightmonitor**
- **worklightoperator**

Method

PUT

Path

/management-apis/1.0/runtimes/runtime-name/notifications/applications/application-name/wnsConf/application-env/application-version/

Example

<https://www.example.com/worklightadmin/management-apis/1.0/runtimes/myruntime/notifications/applications/application-name/wnsConf/application-env/application-version/>

Path Parameters

runtime-name

The name of the runtime. This is the context root of the runtime web application, without the leading slash.

application-name

The name of the application.

application-env

The application environment.

application-version

The application version number.

Query Parameters

Query parameters are optional.

locale

The locale used for error messages.

Consumes

application/json

Produces

application/json, application/xml, text/xml

Payload

The payload in JSON format has values for packageSID and clientSecret.

JSON Example

```
{
  "clientSecret" : "82e4569er",
  "packageSID" : "ms-app://s-123-566-78910",
}
```

Payload Properties

The payload has the following properties:

clientSecret

The client secret received from WNS.

packageSID

The unique identifier of the app received from WNS.

Response

The status of set WNS credentials.

JSON Example

```
{
  "productVersion" : {
    "productVersion" : "7.1.0",
  },
  "project" : {
    "name" : "PushNotifications",
  },
  "status" : "Success",
  "type" : "SET_WNS_CREDENTIALS",
}
```

XML Example

```
<?xml version="1.0" encoding="UTF-8"?>
<setWNSCredentialsStatus
  status="Success"
  type="SET_WNS_CREDENTIALS">
  <productVersion productVersion="7.1.0"/>
  <project name="PushNotifications"/>
</setWNSCredentialsStatus>
```

Response Properties

The response has the following properties:

productVersion

The exact product version.

project

Project name.

status

The WNS credentials are saved successfully.

type

Transaction type.

The *productVersion* has the following properties:

productVersion

The exact product version

The *project* has the following properties:

name

Name of the project

Errors

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

REST API Runtime Services

The REST API for Push in the MobileFirst runtime environment enables back-end server applications that were deployed outside of the MobileFirst Server to access Push functions from a REST API endpoint.

The Push service on the MobileFirst Server is exposed over a REST API endpoint that can be directly accessed by non-mobile clients. You can use the REST API runtime services for Push for registrations, subscriptions, messages, and retrieving tags. Paging and filtering is supported for database persistence in both Cloudant and SQL.

This REST API endpoint is protected by OAuth which requires the clients to be confidential clients and also possess the required access scopes in their OAuth access tokens that is passed by a designated HTTP header.

Push Device Registration (DELETE)

Deletes(Unregisters) an existing device registration of Push

Description

The device registrations of push service is deleted for the given deviceId. The call returns HTTP response code 204 with no content on successful deletion of the device registration.

Method

DELETE

Path

/apps/applicationId/devices/deviceId

Example

`https://example.com:443/myproject/imfpush/v1/apps/myapp/devices/12345-6789`

Path Parameters

deviceId

The device identifier

applicationId

The name or identifier of the application

Header Parameters

Some header parameters are optional.

Accept-Language

(Optional) The preferred language to use for error messages.. Default:en-US

Authorization

The token with the scope "unregister-device" obtained using the confidential client in the format Bearer *token*.. This parameter has to be mandatorily set.

mfpEnvironmentName

(Optional) The environment name to use while executing the request..

mfpEnvironmentVersion

(Optional) The application version to use while executing the request..

Produces

application/json

Errors

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

A device registration with the specified deviceId is not found.

406

Unsupported Accept type - The content type specified in Accept header is not application/json.

500

An internal error occurred.

Push Device Registration (GET)

Retrieves all or a subset of existing device registration(s) of Push.

Description

The device registrations of push service is retrieved for the given criteria.

Method

GET

Path

/apps/applicationId/devices

Example

<https://example.com:443/myproject/imfpush/v1/apps/myapp/devices?expand=true&filter=platform=A&offset=0>

Path Parameters

applicationId

The name or identifier of the application

Query Parameters

Query parameters are optional.

expand

Retrieves additional metadata for every device registration that is returned in the response.

filter

The filter specifies the search criteria. Refer to the filter section for detailed syntax.

offset

Pagination offset that is normally used along with the size.

size

Pagination size that is normally used along with the offset to retrieve a subset.

userId

Retrieves subscriptions only for the specified userId.

Header Parameters

Some header parameters are optional.

Accept-Language

(Optional) The preferred language to use for error messages.. Default:en-US

Authorization

The token with the scope "get-devices" obtained using the confidential client in the format Bearer *token*.. This parameter has to be mandatorily set.

mfpEnvironmentName

(Optional) The environment name to use while executing the request..

mfpEnvironmentVersion

(Optional) The application version to use while executing the request..

Produces

application/json

Response

The details of the device registration that is retrieved.

JSON Example

```
{
  "devices" : [
    {
      "deviceId" : "12345-6789",
      "platform" : "A",
      "token" : "12345-6789",
      "userId" : "admin",
    },
    ...
  ],
  "pageInfo" : {
    "count" : "2",
    "next" : "",
    "previous" : "",
    "totalCount" : "10",
  },
}
```

Response Properties

The response has the following properties:

devices

The array of device registrations with Push.

pageInfo

The pagination information

The *devices* has the following properties:

deviceId

The unique id of the device.

platform

The device platform.

token

The unique push token of the device.

userId

The userId of the device.

The *pageInfo* has the following properties:

count

The number of device registration that are retrieved

next

A hyperlink to the next page

previous

A hyperlink to the previous page

totalCount

The total number of device registration present for the given search criteria

Errors

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

406

Unsupported Accept type - The content type specified in Accept header is not application/json.

500

An internal error occurred.

Push Device Subscription (DELETE)

Unsubscribes the specified device from a tag.

Description

Given the deviceId and the tag name, the request deletes an existing subscription from a tag specified. It will return HTTP response code 204 with no content on successfully unsubscribing.

Method

DELETE

Path

/apps/applicationId/subscriptions

Example

<https://example.com:443/myproject/imfpush/v1/apps/myapp/subscriptions?deviceId=12345-6789&tagName=>

Path Parameters

applicationId

The name or identifier of the application

Query Parameters

Query parameters are optional.

deviceId

The unique identifier for the device

tagName

The tag name to unsubscribe

Header Parameters

Some header parameters are optional.

Accept-Language

(Optional) The preferred language to use for error messages. Default:en-US

Authorization

The token with the scope "unsubscribe-tag" obtained using the confidential client in the format Bearer *token*.. This parameter has to be mandatorily set.

mfpEnvironmentName

(Optional) The environment name to use while executing the request.

mfpEnvironmentVersion

(Optional) The application version to use while executing the request.

Produces

application/json

Errors

400

A device registraion has userId longer than 254 characters.

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

A device registraion with the specified deviceId is not found.

405

Unsupported Content type - The content type specified in Content-Type header is not application/json

406

Unsupported Accept type - The content type specified in Accept header is not application/json.

500

An internal error occurred.

Push Device Subscription (GET)

Retrieves all or a subset of existing subscriptions

Description

The subscriptions of push service is retrieved for the given criteria.

Method

GET

Path

/apps/applicationId/subscriptions

Example

<https://example.com:443/myproject/imfpush/v1/apps/myapp/subscriptions?deviceId=12345-6789&expand=true>

Path Parameters**applicationId**

The name or identifier of the application

Query Parameters

Query parameters are optional.

deviceId

Retrives subscriptions only for the specified deviceId

expand

Retrives additional metadata for every subscription that is returned in the response

filter

The filter specifies the search criteria. Refer to the filter section for detailed syntax

offset

Pagination offset that is normally used along with the size

size

Pagination size that is normally used along with the offset to retrieve a subset

tagName

Retrives subscriptions only for the specified tagName

userId

Retrives subscriptions only for the specified userId

Header Parameters

Some header parameters are optional.

Accept-Language

(Optional) The preferred language to use for error messages. Default:en-US

Authorization

The token with the scope "get-subscriptions" obtained using the confidential client in the format Bearer *token*.. This parameter has to be mandatorily set.

mfpEnvironmentName

(Optional) The environment name to use while executing the request.

mfpEnvironmentVersion

(Optional) The application version to use while executing the request.

Produces

application/json

Response

The details of the device registration that is retrieved.

JSON Example

```
{
  "devices" : [
    {
      "deviceId" : "12345-6789",
      "platform" : "A",
      "token" : "12345-6789",
      "userId" : "admin",
    },
    ...
  ],
}
```

```
"pageInfo" : {  
  "count" : "2",  
  "next" : "",  
  "previous" : "",  
  "totalCount" : "10",  
},  
}
```

Response Properties

The response has the following properties:

devices

The array of device registrations with Push.

pageInfo

The pagination information

The *devices* has the following properties:

deviceId

The unique id of the device.

platform

The device platform.

token

The unique push token of the device.

userId

The userId of the device.

The *pageInfo* has the following properties:

count

The number of device registration that are retrieved

next

A hyperlink to the next page

previous

A hyperlink to the previous page

totalCount

The total number of device registration present for the given search criteria

Errors

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

406

Unsupported Accept type - The content type specified in Accept header is not application/json.

500

An internal error occurred.

Push Device Subscription (POST)

Creates a new subscription for a tag.

Description

Given the deviceId and the tag name, the request creates a new subscription which subscribes the device to the tag specified

Method

POST

Path

/apps/applicationId/subscriptions

Example

`https://example.com:443/myproject/imfpush/v1/apps/myapp/subscriptions`

Path Parameters

applicationId

The name or identifier of the application

Header Parameters

Some header parameters are optional.

Accept-Language

(Optional) The preferred language to use for error messages. Default:en-US

Authorization

The token with the scope "subscribe-tag" obtained using the confidential client in the format Bearer *token*.. This parameter has to be mandatorily set.

Content-Type

Specify the JSON content type. This parameter has to be mandatorily set.

mfpEnvironmentName

(Optional) The environment name to use while executing the request.

mfpEnvironmentVersion

(Optional) The application version to use while executing the request.

Consumes

application/json

Produces

application/json

Payload

The details of the device and the tag name to which it has to subscribe.

JSON Example

```
{
  "deviceId" : "12345-6789",
  "tagName" : "testTag",
}
```

Payload Properties

The payload has the following properties:

deviceId

The unique id of the device.

tagName

The tag name to subscribe.

Response

The details of the device registration that is updated.

JSON Example

```
{
  "deviceId" : "12345-6789",
  "tagName" : "testTag",
}
```

Response Properties

The response has the following properties:

deviceId

The unique id of the device.

tagName

The tag name to subscribe.

Errors

400

A device registraion has userId longer than 254 characters.

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

A device registraion with the specified deviceId is not found.

405

Unsupported Content type - The content type specified in Content-Type header is not application/json

406

Unsupported Accept type - The content type specified in Accept header is not application/json.

500

An internal error occurred.

Push Tags (GET)

Retrieves an existing tag of Push

Method

GET

Path

/apps/applicationId/tags/tagName

Example

`https://example.com:443/myproject/imfpush/v1/apps/myapp/tags/sports`

Path Parameters

applicationId

The name or identifier of the application

tagName

The name of the tag

Header Parameters

Some header parameters are optional.

Accept-Language

(Optional) The preferred language to use for error messages. Default:en-US

Authorization

The token with the scope "get-tags" obtained using the confidential client in the format Bearer *token*.. This parameter has to be mandatorily set.

Produces

application/json

Response

The details of the tag that is retrieved.

JSON Example

```
{
  "createdMode" : "API",
  "createdTime" : "2015-05-20T11:42:11Z",
  "lastUpdatedTime" : "2015-05-20T11:42:11Z",
  "name" : "sports",
}
```

Response Properties

The response has the following properties:

createdMode

The mode of creation.

createdTime

The date and time when the push device registration was created on the server in ISO 8601 format.

lastUpdatedTime

The date and time when the push device registration was last updated on the server in ISO 8601 format.

name

The name of the tag.

Errors

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

A device registration with the specified deviceId is not found.

406

Unsupported Accept type - The content type specified in Accept header is not application/json.

500

An internal error occurred.

Retrieve a Device Registration (GET)

Retrieves an existing device registration of Push

Description

The device registrations of push service is retrieved for the given deviceId.

Method

GET

Path

/apps/applicationId/devices/deviceId

Example

<https://example.com:443/myproject/imfpush/v1/apps/myapp/devices/12345-6789>

Path Parameters

deviceId

The device identifier

applicationId

The name or identifier of the application

Header Parameters

Some header parameters are optional.

Accept-Language

(Optional) The preferred language to use for error messages. Default:en-US

Authorization

The token with the scope "get-devices" obtained using the confidential client in the format Bearer *token*.. This parameter has to be mandatorily set.

mfpEnvironmentName

(Optional) The environment name to use while executing the request.

mfpEnvironmentVersion

(Optional) The application version to use while executing the request.

Produces

application/json

Response

The details of the device registration that is retrieved.

JSON Example

```
{
  "createdMode" : "API",
  "createdTime" : "2015-05-20T11:42:11Z",
  "deviceId" : "12345-6789",
  "lastUpdatedTime" : "2015-05-20T11:42:11Z",
  "platform" : "A",
  "token" : "12345-6789",
  "userId" : "admin",
}
```

Response Properties

The response has the following properties:

createdMode

The mode of creation.

createdTime

The date and time when the push device registration was created on the server in ISO 8601 format.

deviceId

The unique id of the device.

lastUpdatedTime

The date and time when the push device registration was last updated on the server in ISO 8601 format.

platform

The device platform.

token

The unique push token of the device.

userId

The userId of the device.

Errors

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

A device registration with the specified deviceId is not found.

406

Unsupported Accept type - The content type specified in Accept header is not application/json.

500

An internal error occurred.

Send Bulk Messages (POST)

Send bulk messages with different options to be specified.

Method

POST

Path

/apps/applicationId/messages/bulk

Example

<https://example.com:443/myproject/imfpush/v1/apps/myapp/messages/bulk>

Path Parameters

applicationId

The name or identifier of the application

Header Parameters

Some header parameters are optional.

Accept-Language

(Optional) The preferred language to use for error messages. Default:en-US

Authorization

The token with the scope "send-bulk-messages" obtained using the confidential client in the format Bearer *token*.. This parameter has to be mandatorily set.

Consumes

application/json

Produces

application/json

Payload

The payload in JSON format has values for array of messages, target, and settings.

JSON Example

```
{
  "//ArrayOfMessageBody" : [
    {
      "messages" : {
        "alert" : "Test message",
      },
      "settings" : {
        "apns" : {
          "badge" : 1,
          "iosActionKey" : "Ok",
          "payload" : "",
          "sound" : "song.mp3",
          "type" : "SILENT",
        },
        "gcm" : {
          "delayWhileIdle" : ,

```

mpns

Attributes for sending message to an MPNS device.

The *apns* has the following properties:

badge

An integer value to be displayed in a badge on the application icon.

iosActionKey

The label of the dialog box button that allows the user to open the app upon receiving the notification.

payload

A JSON block that is transferred to the application if the application is opened by the user when the notification is received, or if the application is already open.

sound

The name of a file to play when the notification arrives.

type

Specify the type of APNS notification. It should be either DEFAULT, MIXED or SILENT

The *gcm* has the following properties:

delayWhileIdle

A Boolean value that indicates that the message must not be sent if the device is idle. The server waits for the device to become active before the message is sent.

payload

A JSON block that is transferred to the application if the application is opened by the user when the notification is received, or if the application is already open.

sound

The name of a sound file on the device to play when the notification arrives to the device.

timeToLive

The duration (in seconds) that the message is kept on GCM storage if the device is offline. Default value is 4 weeks, and must be set as a JSON number.

The *mpns* has the following properties:

raw

Raw.

title

Title.

toast

Toast.

The *raw* has the following properties:

payload

A JSON block that is transferred to the application if the application is opened by the user when the notification is received, or if the application is already open.

The *title* has the following properties:

backBackgroundImage

URL of the back image on a medium flip Tile.

backContent

Content that displays on the back of a medium flip Tile.

backTitle

Title that displays on the back of a flip Tile.

backgroundImage

URL of the front image on a medium flip Tile.

count

An integer value from 1 to 99. If the value of count is not set or it is set to 0, the circle image and value do not display in the Tile. This property is also known as badge.

title

A string that indicates the title of the application. The title fits on a single line of text and must not be wider than the Tile. Approximately 15 characters can fit in the title before it is truncated.

The *toast* has the following properties:

param

Toast notification content.

title

Toast notification title.

The *target* has the following properties:

deviceIds

An array of the devices represented by the device identifiers. Devices with these ids receive the notification. This is a unicast notification

platforms

An array of device platforms. Devices running on these platforms receive the notification. Supported values are A (Apple/iOS), G (Google/Android) and M (Microsoft/Windows).

tagNames

An array of tags specified as tagNames. Devices that are subscribed to these tags receive the notification. Use this type of target for tag based notifications

userIds

An array of users represented by their userIds to send the notification. This is a unicast notification.

Errors

400

Invalid JSON.

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Send Message (POST)

Send message with different options.

Description

Sends a push notifications to the specified targets and returns HTTP return code 202 when the request to send the message is accepted.

Method

POST

Path

/apps/applicationId/messages

Example

<https://example.com:443/myproject/imfpush/v1/apps/myapp/messages>

Path Parameters

applicationId

The name or identifier of the application

Header Parameters

Some header parameters are optional.

Accept-Language

(Optional) The preferred language to use for error messages. Default:en-US

Authorization

The token with the scope "send-message" obtained using the confidential client in the format Bearer *token*.. This parameter has to be mandatorily set.

Consumes

application/json

Produces

application/json

Payload

The payload in JSON format has values for message, target, and settings.

JSON Example

```
{
  "message" : {
    "alert" : "Test message",
  },
  "settings" : {
    "apns" : {
```

```

        "badge" : 1,
        "iosActionKey" : "Ok",
        "payload" : "",
        "sound" : "song.mp3",
        "type" : "SILENT",
    },
    "gcm" : {
        "delayWhileIdle" : ,
        "payload" : "",
        "sound" : "song.mp3",
        "timeToLive" : ,
    },
    "mpns" : {
        "raw" : {
            "payload" : {
            },
        },
        "title" : {
            "backBackgroundImage" : "Blue.jpg",
            "backContent" : "Back Title Content",
            "backTitle" : "Back Title",
            "backgroundImage" : "Red.jpg",
            "count" : 1,
            "title" : "Push Notification",
        },
        "toast" : {
            "param" : "/Page2.xaml?NavigatedFrom=Toast Notification",
            "title" : "Hello",
        },
    },
},
"target" : {
    "deviceIds" : [ "MyDeviceId1", ... ],
    "platforms" : [ "A,G", ... ],
    "tagNames" : [ "Gold", ... ],
    "userIds" : [ "MyUserId", ... ],
},
}

```

Payload Properties

The payload has the following properties:

message

The alert message to be sent

settings

The settings are the different attributes of the notification.

target

Set of targets can be user Ids, devices, platforms, or tags. Only one of the targets can be set.

The *message* has the following properties:

alert

A string to be displayed in the alert.

The *settings* has the following properties:

apns

Attributes for sending message to an iOS device.

gcm

Attributes for sending message to an Android device.

mpns

Attributes for sending message to an MPNS (Windows) device.

The *apns* has the following properties:

badge

An integer value to be displayed in a badge on the application icon.

iosActionKey

The label of the dialog box button that allows the user to open the app upon receiving the notification.

payload

A JSON block that is transferred to the application if the application is opened by the user when the notification is received, or if the application is already open.

sound

The name of a file to play when the notification arrives.

type

Specify the type of APNS notification. It should be either DEFAULT, MIXED or SILENT

The *gcm* has the following properties:

delayWhileIdle

A Boolean value that indicates that the message must not be sent if the device is idle. The server waits for the device to become active before the message is sent.

payload

A JSON block that is transferred to the application if the application is opened by the user when the notification is received, or if the application is already open.

sound

The name of a sound file on the device to play when the notification arrives to the device.

timeToLive

The duration (in seconds) that the message is kept on GCM storage if the device is offline. Default value is 4 weeks, and must be set as a JSON number.

The *mpns* has the following properties:

raw

Raw.

title

Title.

toast

Toast.

The *raw* has the following properties:

payload

A JSON block that is transferred to the application if the application is opened by the user when the notification is received, or if the application is already open.

The *title* has the following properties:

backBackgroundImage

URL of the back image on a medium flip Tile.

backContent

Content that displays on the back of a medium flip Tile.

backTitle

Title that displays on the back of a flip Tile.

backgroundImage

URL of the front image on a medium flip Tile.

count

An integer value from 1 to 99. If the value of count is not set or it is set to 0, the circle image and value do not display in the Tile. This property is also known as badge.

title

A string that indicates the title of the application. The title fits on a single line of text and must not be wider than the Tile. Approximately 15 characters can fit in the title before it is truncated.

The *toast* has the following properties:

param

Toast notification content.

title

Toast notification title.

The *target* has the following properties:

deviceIds

An array of the devices represented by the device identifiers. Devices with these ids receive the notification. This is a unicast notification

platforms

An array of device platforms. Devices running on these platforms receive the notification. Supported values are A (Apple/iOS), G (Google/Android) and M (Microsoft/Windows).

tagNames

An array of tags specified as tagNames. Devices that are subscribed to these tags receive the notification. Use this type of target for tag based notifications

userIds

An array of users represented by their userIds to send the notification. This is a unicast notification.

Errors

400

Invalid JSON.

403

The user is not authorized to call this service.

404

The corresponding runtime is not found or not running.

500

An internal error occurred.

Update Device Registrations (PUT)

Updates an existing device registration of Push.

Description

The push device registration is updated with the new user identifier or the token specified. In most use cases this call is used to update the `userId` only.

Method

PUT

Path

/apps/applicationId/devices/deviceId

Example

<https://example.com:443/myproject/imfpush/v1/apps/myapp/devices/12345-6789>

Path Parameters

deviceId

The device identifier

applicationId

The name or identifier of the application

Header Parameters

Some header parameters are optional.

Accept-Language

(Optional) The preferred language to use for error messages. Default:en-US

Authorization

The token with the scope "update-device" obtained using the confidential client in the format Bearer *token*.. This parameter has to be mandatorily set.

Content-Type

Specify the JSON content type. For example: application/json. This parameter has to be mandatorily set.

mfpEnvironmentName

(Optional) The environment name to use while executing the request.

mfpEnvironmentVersion

(Optional) The application version to use while executing the request.

Consumes

application/json

Produces

application/json

Payload

The details of the device registration will be updated.

JSON Example

```
{
  "deviceId" : "12345-6789",
  "token" : "xyz",
  "userId" : "admin",
}
```

Payload Properties

The payload has the following properties:

deviceId

The unique id of the device.

token

The token of the device. Its optional to set this.

userId

The userId of the device. Its optional to set this.

Response

The details of the device registration that is updated.

JSON Example

```
{
  "createdMode" : "API",
  "createdTime" : "2015-05-20T11:42:11Z",
  "deviceId" : "12345-6789",
  "lastUpdatedTime" : "2015-05-20T11:42:11Z",
  "platform" : "A",
  "token" : "12345-6789",
  "userId" : "admin",
}
```

Response Properties

The response has the following properties:

createdMode

The mode of creation.

createdTime

The date and time when the push device registration was created on the server in ISO 8601 format.

deviceId

The unique id of the device.

lastUpdatedTime

The date and time when the push device registration was last updated on the server in ISO 8601 format.

platform

The device platform.

token

The unique push token of the device.

userId

The userId of the device.

Errors

400

A device registration has userId longer than 254 characters.

401

Unauthorized - The caller is either not authenticated or not authorized to make this request.

404

A device registration with the specified deviceId is not found.

405

Unsupported Content type - The content type specified in Content-Type header is not application/json

406

Unsupported Accept type - The content type specified in Accept header is not application/json.

500

An internal error occurred.

Filter syntax

The filter has the following syntax: `name operator expression`

name The field name on which the filter is being applied.

operator

Either == (Exact Match) or =@ (Contains Substring) that describes filter match to use.

expression

The values to include in the result.

For Cloudant data persistence, do not use the @ character in a filter expression when the operator is *Contains Substring*.

When a comma and a backslash are displayed in an expression, they must be backslash-escaped.

When using multiple filters, they can be combined using AND and OR logic.

For AND logic, use multiple filters in the query.

For OR logic, use a comma(,) inside of the filter expression.

For both AND and OR logic, a single query can have both however each filter is evaluated individually before combining them in an AND expression.

For the device GET API the following combinations are supported:

- The name can be one of these fields: **userId** or **platform**
- Except for the platform, the operator can be == or =@
- For the platform, the operator must be ==
- If operator =@ is used, the value can be a sub string. If == is used, the value must be an exact matching string.

For the subscription GET API the following combinations are supported:

- The name can be one of these fields: **tagName** or **deviceId 2**
- Except for the platform, the operator can be == or =@
- For the platform, the operator must be ==
- If operator =@ is used, the value can be a sub string. If == is used, the value must be an exact matching string.

MobileFirst Cloudant API reference

Cloudant is an advanced NoSQL database that is capable of handling a wide variety of data types, such as JSON, full-text, and geospatial data. You can use the Cloudant APIs to access a Cloudant database from your mobile application.

For more information about the SDK and Cloudant, see “Storing mobile data in Cloudant” on page 8-471.

Java API for MobileFirst Cloudant extensions

Use the Java API reference if you are developing a native Android application that accesses a Cloudant database.

You can find the description of the API in the following file: Java API for MobileFirst Cloudant extensions.

Objective-C API for MobileFirst Cloudant extensions

Use the Objective-C API reference if you are developing a native iOS application in Swift or Objective-C that accesses a Cloudant database.

You can use the IMFData Framework for iOS and the CloudantToolkit Framework for iOS to make your data persistent in the cloud.

- You can find description of the API of the IMFData Framework for iOS in the following file: Objective-C API for MobileFirst Cloudant extensions: IMFData
- You can find description of the API of the CloudantToolkit Framework for iOS in the following file: Objective-C API for MobileFirst Cloudant extensions: Cloudant Toolkit

Deploying MobileFirst projects

After you have created projects and apps with MobileFirst Studio, you must deploy them to the production environment.

Note: Before you can deploy the project to the production environment, you must install the MobileFirst Administration Components as described in “Installing the MobileFirst Server administration” on page 6-58.

You can deploy several MobileFirst runtime environments (that is, several project WAR files) to an application server just as you would deploy any Java EE application. Each deployed project must have a unique name and a unique context path.

Note: An Administration Service must be installed on the application server for one of the topologies that are listed at “Planning deployment of administration components and runtimes” on page 6-19. Otherwise, the runtime environment cannot download its applications and adapters, and cannot start.

You can choose between having several projects use the same database server, or making each project use a different database server. If you configure several projects to use the same relational database, you must configure each data source to connect to an independent data storage structure (for example, different schemas on DB2, or different user names on Oracle). Database sharing is not relevant for MySQL and Apache Derby. For Cloudant, the project name is included in the database name so every project uses a different database.

Several instances of MobileFirst Server with different versions of IBM MobileFirst Platform Foundation installed can share the same application server and the same MobileFirst Administration Service. However, they must be migrated to be compatible with the current version of the Administration Service. For more information about migration, see “Migrating a project WAR file for use with a new MobileFirst Server” on page 12-38.

For more information, see “Separation of lifecycle between MobileFirst Server and MobileFirst Studio” on page 7-4.

Read this series of topics to learn how to deploy your MobileFirst projects and apps to the production environment.

Deploying MobileFirst applications to test and production environments

When you have developed an application, deploy it to a separate test and production environment.

About this task

When you finish a development cycle of your application, you usually deploy it to a testing environment, and then to a production environment.

The tools that you can use to deploy apps and adapters across development, QA, and production environments are described in the following topics.

Deploying an application from development to a test or production environment

After you have developed an application, you want to move from your development environment and deploy a MobileFirst project to a test or production environment.

Before you begin

You have built a MobileFirst project that contains one or more applications in MobileFirst tools. A WAR file and a set of `.wlap` files are created in the `bin` folder of your MobileFirst project. You now want to deploy the project and the applications to a test or production environment.

- A WAR file is created by MobileFirst tools for every MobileFirst project, regardless of the number of apps it contains.
- If you build an entire app, a file that is called `app-name.wlap` is created, containing the code and resources of all environments that are supported by your app. For example: `myApp-all.wlap`.
- If you build an app only for specific environments, a file that is called `app-name-env-version.wlap` is created per environment. For example: `myApp-iphone-1.0.wlap`.

About this task

First, you prepare the application or applications for deployment, and then you deploy them. You can deploy many apps within the same project. The following instructions lead you through this process.

Procedure

1. Install the MobileFirst Server administration components as described in “Installing the MobileFirst Server administration” on page 6-58.

You can have several MobileFirst runtime environments that are managed by the same MobileFirst Operations Console. Verify that you have deployment rights for IBM MobileFirst Platform Foundation, such as the role of **worklightdeployer** or **worklightadmin**. For more information, see “Configuring user authentication for MobileFirst Server administration” on page 6-106.

2. For each application in the project, change the settings in the `application-descriptor.xml` file to match your production environment. If necessary, depending on the functions and licensing provisions of the app, change the following settings.

- Settings screen
- Device provisioning
- Application license type. (Only applicable if IBM MobileFirst Platform Foundation version 7.1, Fix Pack 1 or later is installed, and token licensing is activated on the MobileFirst Server.) For more information, see “Token licensing: setting the license app type” on page 8-229.
- Application authenticity
- User authentication
- The Android shared user ID

For more information about each setting, see the application descriptor file documentation for your target mobile environment or application type.

3. You might want to look at the settings in the `worklight.properties` file, which is in `server/conf`. Those settings define the default values for the configuration properties on the server. When you deploy your MobileFirst project on the server, you can replace the default settings that are in the `worklight.properties` file with values that are relevant for the production environment. For more information, see “Configuring a MobileFirst project in production by using JNDI environment entries” on page 12-66.

4. Create the project WAR file in either of two ways:

- Right-click the application and click **Run As > Run on MobileFirst Development Server**.
- Use the Ant script tool that is described in “Ant tasks for building and deploying applications and adapters” on page 12-79.

The project WAR file is created in the `bin` folder.

5. Configure a database and deploy the project WAR to the application server with one of these two methods:

- With the MobileFirst Server Configuration Tool. For more information, see “Deploying, updating, undeploying, or upgrading MobileFirst Server by using the Server Configuration Tool” on page 12-11.
- With Ant tasks for configuring a database for a MobileFirst project and deploying a MobileFirst project WAR file to an application server. With this method, you can also configure the project on the server by using JNDI environment entries.
 - The documentation of the Ant tasks for configuring a database is at “Creating and configuring the databases with Ant tasks” on page 12-15.
 - The documentation of the Ant tasks for deploying a project WAR file is at “Deploying a project WAR file and configuring the application server with Ant tasks” on page 12-16.
 - The list of JNDI environment entries that can be configured is at “JNDI environment entries for MobileFirst projects in production” on page 12-68.
 - You can find sample Ant files that use these Ant tasks in the MobileFirst distribution in `product_install_dir/WorklightServer/configuration-samples`. Their file names use the naming convention `configure-appServer-database.xml`. For more information, see “Sample configuration files” on page 16-77.
 - a. First call **configuredatabase**, the **databases** target in the sample Ant files.
 - b. Then call **configureapplicationserver**, the **install** target in the sample Ant files.

6. If you want to enable extended authenticity checking, follow the steps in “Configuring extended app authenticity checking” on page 12-56.

7. Open the MobileFirst Operations Console of the target environment.

If the MobileFirst Operations Console is installed with the default context root, its URL is of the form `https://your-remote-server:server-port/worklightconsole`. If HTTPS is not supported in your application server, it is the unsecured URL `http://your-remote-server:server-port/worklightconsole`.

Important: If you access the MobileFirst Operations Console through HTTP instead of HTTPS, your MobileFirst administration user password is compromised.

8. From the MobileFirst Operations Console, deploy the relevant .wla files from the bin folder of your MobileFirst project. If you enabled extended authenticity checking in step 6 on page 12-3, deploy the .wla files that resulted from that procedure, instead.
 - For more information about how to deploy an application by using MobileFirst Operations Console, see “Deploying apps” on page 12-88.
 - You can also deploy the app to the target environment by using the MobileFirst Server administration command-line tools. For more information about how to deploy an app by using the provided command-line tools, see “Administering MobileFirst applications through Ant” on page 13-12 and “Administering MobileFirst applications through the command line” on page 13-37.
9. Deploy the adapters from the development environment.
 - a. Navigate to the bin folder in your project.
 - b. Copy the .adapter file or files.
 - c. From the MobileFirst Operations Console, deploy the .adapter files from the bin folder of your project.
 - For more information about how to deploy an adapter by using MobileFirst Operations Console, see “Deploying adapters” on page 12-89.
 - You can also deploy the adapter to the target environment by using the MobileFirst Server administration command-line tools. For more information about how to deploy an app by using the provided command-line tools, see “Administering MobileFirst applications through Ant” on page 13-12 and “Administering MobileFirst applications through the command line” on page 13-37.

Results

A message is displayed, indicating whether the deployment action succeeded or failed.

Building a project WAR file with Ant

You can build the project WAR file by using Ant tasks.

Before you can run Ant tasks, make sure that Apache Ant is installed. The minimum supported version of Ant is listed in “System requirements” on page 2-15.

Apache Ant 1.8.4 is included in MobileFirst Server. In the *product_install_dir/shortcuts/* directory, the following scripts are provided:

- For UNIX / Linux: ant
- For Windows: ant.bat

These scripts are ready to run, which means that they do not require specific environment variables. If the JAVA_HOME environment variable is set, the scripts accept it.

Note: Since IBM Worklight Foundation V6.2.0, the *worklight-ant-builder.jar* file is included in the IBM MobileFirst Platform Command Line Interface, whereas in earlier versions, it was included in MobileFirst Server. By default,

worklight-ant-builder.jar is installed in the following location: *<CLI Install Path>/public/worklight-ant-builder.jar*. For example, on OSX, the default CLI Install Path is */Applications/IBM/Worklight-CLI*. If you use the default installation path, the Ant task is installed here: */Applications/IBM/Worklight-CLI/public/worklight-ant-builder.jar*.

The Ant task for building a MobileFirst project WAR file has the following structure:

```
<?xml version="1.0" encoding="UTF-8"?>
<project name="myProject" default="all">
  <taskdef resource="com/worklight/ant/defaults.properties">
    <classpath>
      <pathelement location="cli_install_dir/public/worklight-ant-builder.jar"/>
    </classpath>
  </taskdef>
  <target name="all">
    <war-builder projectfolder="."
      destinationfolder="bin/war"
      warfile="bin/project.war"
      classesFolder="classes-folder"/>
  </target>
</project>
```

The `<war-builder>` element has the following attributes:

- The `projectfolder` attribute specifies the path to your project.
- The `destinationfolder` attribute specifies a folder for holding temporary files.
- The `warfile` attribute specifies the destination and file name of the generated `.war` file
- The `classesFolder` attribute specifies a folder with compiled Java classes to add to the `.war` file. `.jar` files in the `projectfolder\server\lib` directory are added automatically

Deploying the project WAR file

For the MobileFirst runtime environment to start, you must deploy it to the server where the Administration Services application is installed. If you use WebSphere Application Server Network Deployment, you can alternatively install the MobileFirst runtime environment in a server or cluster of the cell other than the one where the Administration Services application that manages this runtime is installed. If you do so, you must start the server or cluster where the Administration Services application is installed before the one where the MobileFirst runtime environment is installed.

Before you start

See “Planning deployment of administration components and runtimes” on page 6-19 for the supported deployment topologies.

Install the MobileFirst Server by following the procedure in “Installing MobileFirst Server” on page 6-14.

If you have a farm topology, configure the server farm by following the procedure in “Installing a server farm” on page 6-138.

To serve users who are using the new session independent mode, as well as existing users whose apps work in session-dependent mode, you must deploy the new V7.1.0 WAR with its V7.1.0 artifacts, but **WITHOUT** removing the old WAR. For more information, see “Upgrading projects to work in session-independent mode” on page 7-19.

The database and application server prerequisites for this task are described in “Installation prerequisites” on page 6-15.

You must build a MobileFirst project WAR file by using MobileFirst Studio, or by following the instructions in “Building a project WAR file with Ant” on page 12-4. The WAR file contains the default configuration values for the server, and some resources for the MobileFirst applications and adapters.

- For project WAR files built with earlier versions than V6.2.0.x: The project WAR file must be built with the same version of Worklight Studio as the version used to build the apps that are deployed on the Worklight Server.
- For project WAR files that were built with V6.2.0 and later, and deployed to Worklight Server V6.2.0.1 and later, apps and adapters that were built with any version, 5.0.6.x and above (but not later than the project WAR version itself), can be deployed.
- Before deploying WAR files to support session-independent mode, see “Session-independent mode” on page 8-324.

You can deploy a MobileFirst project in one the following ways:

- By using the Server Configuration Tool.
- By using a set of Ant tasks that are supplied with MobileFirst Server to deploy a project WAR file and configure your databases and application servers.
- By creating and configuring the databases manually, and deploying the project WAR file manually.

Optional creation of databases

If you want to activate the option to install the project runtime relational databases when you run the Ant tasks or the Server Configuration Tool, you must have certain database access rights that entitle you to create the databases, or the users, or both, that are required by the project runtime component.

If you have sufficient database administration credentials, and if you enter the administrator user name and password in the installer when prompted, the installation tools can create the databases for you. Otherwise, you must ask your database administrator to create the required database for you. In this case, the database must be created before you start the installation tools.

If you want to use Cloudant for the project runtime database, ensure that you have access to a valid Cloudant account and a user with basic authentication credentials is defined to create the databases. Contrary to relational databases, the installation tools do not create Cloudant databases. They are automatically created when the project runtime is launched on the application server where it is deployed with the Cloudant account URL and user credentials.

The following topics describe the procedure for the supported database management systems.

Important: The manual creation of databases is optional if you install MobileFirst Server with the Server Configuration Tool or the Ant tasks because the Server Configuration Tool and the Ant tasks can create the databases automatically.

Creating the DB2 database:

This section explains the procedures used to create the DB2 databases.

Before you begin

You perform this procedure to create the databases before you run Ant tasks or the Server Configuration Tool to populate them. For a fully manual database installation, see “Configuring the DB2 databases manually” on page 12-20 instead.

About this task

The <configureDatabase> Ant task can create the databases for you if you enter the name and password of a user account on the database server that has the DB2 SYSADM or SYSCTRL privilege, and the account can be accessed through SSH. Otherwise, the database administrator can create the databases for you. For more information, see the DB2 Solution user documentation.

You can replace the database name (here WRKLGHT) and password with a database name and password of your choosing.

Important: You can name your database and user differently, or set a different password, but ensure that you enter the appropriate database name, user name, and password correctly across the DB2 database setup. DB2 has a database name limit of 8 characters on all platforms, and has a user name and password length limit of 8 characters for Unix and Linux systems, and 30 characters for Windows.

Procedure

1. Create a system user, for example, named `wluser` in a DB2 admin group such as `DB2USERS`, using the appropriate commands for your operating system. Give it a password, for example, `wluser`. If you want multiple MobileFirst projects to connect to the same database, use a different user name for each connection. Each database user has a separate default schema. For more information about database users, see the DB2 documentation and the documentation for your operating system.
2. Open a DB2 command line processor, with a user that has SYSADM or SYSCTRL permissions:
 - On Windows systems, click **Start > IBM DB2 > Command Line Processor**
 - On Linux or UNIX systems, navigate to `~/sqlllib/bin` and enter `./db2`.
 - Enter database manager and SQL statements similar to the following example to create the database:

```
CREATE DATABASE WRKLGHT COLLATE USING SYSTEM PAGESIZE 32768
CONNECT TO WRKLGHT
GRANT CONNECT ON DATABASE TO USER wluser
DISCONNECT WRKLGHT
QUIT
```

Where *wluser* is the name of the system user that you previously created. If you defined a different user name, replace *wluser* accordingly.
3. It is also possible to use only one database (with pagesize settings compatible with what is previously listed), and to create the databases for IBM MobileFirst Platform Foundation in different schemas. In that case, only one database is required. If the `IMPLICIT_SCHEMA` authority is granted to the user created in step 1 (the default in the database creation script in step 2), no further action is required. If the user does not have the `IMPLICIT_SCHEMA` authority, you need to create a `SCHEMA` for the runtime database tables and objects and a `SCHEMA` for the reports database tables and objects.

Creating the MySQL database:

This section explains the procedures used to create the MySQL databases.

Before you begin

You perform this procedure to create the databases before you run Ant tasks or the Server Configuration Tool to populate them. For a fully manual database installation, see “Configuring the MySQL databases manually” on page 12-28 instead.

About this task

The <configureDatabase> Ant task can create the database for you if you enter the name and password of the superuser account. For more information, see Securing the Initial MySQL Accounts on your MySQL database server. Your database administrator can also create the database for you. When you manually create the database, you can replace the database name (here WRKLGHT) and the password with a database name and a password of your choosing. Note that MySQL database names are case-sensitive on Unix.

Procedure

1. Start the MySQL command-line tool.
2. Enter the following commands:

```
CREATE DATABASE WRKLGHT CHARACTER SET utf8 COLLATE utf8_general_ci;  
GRANT ALL PRIVILEGES ON WRKLGHT.* TO 'worklight'@'Worklight-host' IDENTIFIED BY 'password';  
GRANT ALL PRIVILEGES ON WRKLGHT.* TO 'worklight'@'localhost' IDENTIFIED BY 'password';  
FLUSH PRIVILEGES;
```

Where *worklight* before the @ sign is the user name, *password* after IDENTIFIED BY is the user password, and *Worklight-host* is the name of the host on which IBM MobileFirst Platform Foundation runs.

Creating the Oracle database:

You can use the <configureDatabase> Ant task to create the Oracle database, except for the Oracle 12c database type.

Before you begin

You perform this procedure to create the databases before you run Ant tasks or the Server Configuration Tool to populate them. For a fully manual database installation, see “Configuring the Oracle databases manually” on page 12-32 instead.

About this task

The <configureDatabase> Ant task can create the databases, except for the Oracle 12c database type, or the users and schemas inside an existing database if you enter the name and password of the Oracle administrator on the database server, and the account can be accessed through SSH. Otherwise, the database administrator can create the databases or users and schemas for you. When you manually create the databases or users, you can use database names, user names, and a password of your choosing. Note that lowercase characters in Oracle user names might not be supported.

Procedure

1. If you do not already have a database named ORCL, use the Oracle Database Configuration Assistant (DBCA) and follow the steps in the wizard to create a new database named ORCL:
 - a. Use global database name *ORCL_your_domain*, and system identifier (SID) ORCL.
 - b. On the **Custom Scripts** tab of the step **Database Content**, do not run the SQL scripts, because you must first create a user account.
 - c. On the **Character Sets** tab of the step **Initialization Parameters**, select **Use Unicode (AL32UTF8) character set and UTF8 - Unicode 3.0 UTF-8 national character set**.
 - d. Complete the procedure, accepting the default values.

If the Oracle installation is on a UNIX or Linux machine, make sure that the database will be started the next time the Oracle installation is restarted. To this effect, make sure the line in */etc/oratab* that corresponds to the database ends with a Y, not with an N.

2. Create database users either by using Oracle Database Control, or by using the Oracle SQLPlus command-line interpreter.
 - Using Oracle Database Control.
 - a. Create the user for the runtime database:
 - 1) Connect as SYSDBA.
 - 2) Go to the **Users** page: click **Server**, then **Users** in the **Security** section.
 - 3) Create a user, for example, named *WORKLIGHT*. If you want multiple MobileFirst projects to connect to the same general-purpose database you created in step 1, use a different user name for each connection. Each database user has a separate default schema.
 - 4) Assign the following attributes:
 - Profile: **DEFAULT**
 - Authentication: **password**
 - Default tablespace: **USERS**
 - Temporary tablespace: **TEMP**
 - Status: **Unlocked**
 - Add system privilege: **CREATE SESSION**
 - Add system privilege: **CREATE SEQUENCE**
 - Add system privilege: **CREATE TABLE**
 - Add quota: **Unlimited for tablespace USERS**
 - Using the Oracle SQLPlus command-line interpreter.

The commands in the following example create a user named *WORKLIGHT*:

```
CONNECT SYSTEM/<SYSTEM_password>@ORCL
CREATE USER WORKLIGHT IDENTIFIED BY 'WORKLIGHT_password' DEFAULT TABLESPACE USERS QUOTA UNLIMITED ON USERS;
GRANT CREATE SESSION, CREATE SEQUENCE, CREATE TABLE TO WORKLIGHT;
DISCONNECT;
```

Creating the Cloudant database:

Before a project runtime can create or access a Cloudant database, you need to configure Cloudant accounts and users. You might also need to specify database prefixes to distinguish projects that have the same name.

General requirements

To use the Cloudant database, you need either an account at Cloudant.com using the Cloudant database in the Cloud, or you need to install Cloudant Local on your own hardware, as described in IBM Cloudant Data Layer Local Edition documentation.

Whether you use Cloudant.com or Cloudant Local, the Cloudant database is accessible via HTTP or HTTPS, and you need the URL to access it and a user name and password.

Cloudant account

Before a project runtime can create or access a Cloudant database at Cloudant.com, you must register a valid account for Cloudant.com. The account registration provides you with the following things:

Account name

The Cloudant account is implicitly also the URL; for example, the account `exampleaccount` corresponds to the URL `https://exampleaccount.cloudant.com`.

User name

By default, the account name serves also as administrator user name of the databases created in your account. Access is granted per database. By default, all databases that you create are only accessible to your account. If you are using a shared database that is accessible to multiple users, you need a user name that has sufficient permissions to write and read documents of the database.

Password

A password to access the account at Cloudant.com.

See [Sign Up for a Free Account](#) for information about how to create an account on Cloudant.com.

Cloudant Local

If you use a Cloudant Local installation instead of Cloudant.com, you must configure the following things:

- The URL to access your Cloudant Local installation.
- A user name to access your Cloudant Local installation, which has sufficient permissions to write and read documents in the database.
- A password for this user in your Cloudant Local installation.

For more information about how to create and administer users for Cloudant Local, see [Configuring database-level security](#).

Permissions

The default permissions for a new account at Cloudant.com or at Cloudant Local are sufficient for the project runtime.

The database can be created through the Cloudant dashboard. The user must have at least the following roles set for your database:

_reader

Gives the user permission to read documents from the database.

_writer

Gives the user permission to create and modify documents in the database.

_admin

Gives the user permission to install and update design documents in the database.

Unlike relational databases, there is no concept of “tables” in Cloudant, hence there is no need to create any tables ahead of time or to set any permissions on tables. If the database is not yet created, it will be automatically created when the project runtime is launched on the application server. In this case, the user name must be set to the administrator user name of the Cloudant account, because only the administrator has permission to create new databases.

Default database name for project runtimes

Each deployed project needs to have a separate database. By default, the name of this database is in the following form:

```
{project_name}_runtime_db
```

where {project_name} is the context root of the project without the leading forward slash.

If multiple teams use the same database with projects that have the same names, they can specify a prefix through a "**dbNamePrefix**" at deployment time to distinguish each project either manually or with Ant tasks. For more information about how to use this prefix manually for the application server to which you plan to deploy your MobileFirst runtime, see the relevant subsection in “Deploying a project WAR file and configuring the application server manually” on page 12-37. For more information about how to use this prefix with Ant tasks, see “Ant tasks for installation of MobileFirst runtime environments” on page 16-42, Table 16-60 on page 16-55.

Note:

Databases for projects are created if needed after deployment when the project is launched.

Deploying, updating, undeploying, or upgrading MobileFirst Server by using the Server Configuration Tool

The Server Configuration Tool is a graphical tool that you can use to deploy, update, undeploy, or upgrade a MobileFirst Server instance to or from an application server and database.

If you use this tool in production to upgrade a MobileFirst Server, you must complete more actions to upgrade the server, as described in “Upgrading to MobileFirst Server V7.1.0 in a production environment” on page 7-22.

Before you use this tool, verify that the user who runs the Server Configuration Tool has the privileges that are described in “File system prerequisites” on page 6-16.

The Server Configuration Tool provides the same capabilities as the Ant tasks that are described in “Ant tasks for installation of MobileFirst Operations Console and

Administration Services” on page 16-34 and “Ant tasks for installation of MobileFirst runtime environments” on page 16-42. Compared to Ant tasks, the Server Configuration Tool is limited to a set of operations that are described in the following list:

- The supported databases are IBM DB2, Oracle, MySQL, and Cloudant.

Restriction: The Derby database is not supported.

- It is not possible to define JNDI deployment properties, such as **publicWorkLightHostname** or other properties that are listed in “JNDI environment entries for MobileFirst projects in production” on page 12-68. To define those properties, use Ant files. You can use the Server Configuration Tool to export an Ant file from a server configuration and then add JNDI deployment properties to it manually. (See “Other operations available in the Server Configuration Tool” on page 12-14.)
- The Server Configuration Tool must be started on the computer where your application server is installed.
- The Server Configuration Tool maintains a deployment status of configuration server components, whether they are deployed or not. This status is not accurate if the MobileFirst Server components are modified outside the Server Configuration Tool.
- The Server Configuration Tool is available only on Windows and Linux (x86). It is also available on Mac OS for test or demonstration purposes, but the MobileFirst Server is not supported for production in this environment.
- You can use the Server Configuration Tool to install MobileFirst Server to WebSphere Application Server Network Deployment (clusters, servers), to a stand-alone WebSphere Application Server instance, or to a Liberty or Tomcat server. However, you cannot use the Server Configuration Tool to install MobileFirst Server to a server farm.
- You cannot use the Server Configuration Tool to add a runtime to an Administration Service that was installed or upgraded with Ant tasks and not with the Server Configuration Tool.

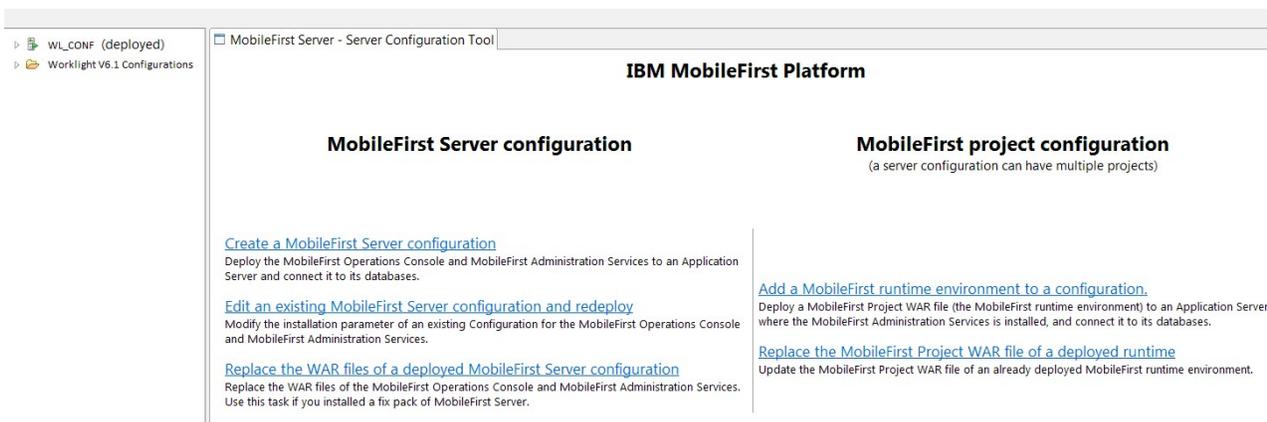

Figure 12-1. Server Configuration Tool main window

Running the Server Configuration Tool

You can start the Server Configuration Tool in the following ways:

On Linux

- By using the desktop menu shortcut **Server Configuration Tool**.

- In a File Manager, click the file *mf_server_install_dir/shortcuts/configuration-tool.sh*.

Note: *mf_server_install_dir* is the directory where you install MobileFirst Server. *mf_server* is the shortcut for MobileFirst Server.

- From a shell command line, run the command *mf_server_install_dir/shortcuts/configuration-tool.sh*.

On Windows

- By using the **Start > IBM MobileFirst Platform Server > Server Configuration Tool** menu command.
- In Windows Explorer, double-click the file *mf_server_install_dir/shortcuts/configuration-tool.bat*.
- In a console window, run *mf_server_install_dir/shortcuts/configuration-tool.bat*.

On Mac OS X

Restriction: MobileFirst Server is not supported for production in this environment.

- In the Finder, double-click the file *mf_server_install_dir/shortcuts/configuration-tool.sh*.
- In a Terminal window, run *mf_server_install_dir/shortcuts/configuration-tool.sh*.

Main tasks

Create a MobileFirst Server configuration

For more information, see “Installing MobileFirst Server administration with the Server Configuration Tool” on page 6-70.

After a MobileFirst Server configuration is created, you can do the following tasks:

Edit an existing MobileFirst Server configuration and redeploy

Use this task to edit and modify an existing MobileFirst Server configuration. If you select this action, the work flow is as follows:

1. You are prompted to select one of the configurations visible in the Navigation view.
2. If passwords are required to redeploy the configuration, you are prompted to enter them.
3. After you enter the passwords, the configuration is checked for errors.
4. If errors are found, a report is displayed.
5. You can then edit the configuration.
6. If the configuration contains no errors, the **Redeploy** button is enabled.
7. When you click **Redeploy**, the MobileFirst administration components are uninstalled from the application server, and reinstalled with the new parameters.

Add a MobileFirst runtime environment to a configuration

Use this task to add a MobileFirst runtime environment to a MobileFirst Server configuration.

To create a new MobileFirst runtime environment, complete the following steps:

1. Select a MobileFirst Server configuration.

2. Select **File > Add MobileFirst runtime environment**.
3. Enter a descriptive name for the MobileFirst runtime environment.
4. Select the path for the MobileFirst project WAR file to be deployed.
5. Step through the wizard to describe the target database management system.

If you need to create a relational database for your MobileFirst runtime environment, the Server Configuration Tool can create it for you. If you provide the requested administrator password when you are prompted in the Database Creation Request panel, the database for MobileFirst runtime environment is created. Alternatively, you can ask your database administrator to create the database manually by following the instructions in “Optional creation of databases” on page 12-6.

Note: The Server Configuration Tool does not create a database if you select Cloudant as the database management system for your MobileFirst runtime environment. The database name depends on values that you are prompted for, and is displayed on the **Database Creation Request** panel.

6. After you provide all the necessary information, the **Deploy** button is enabled. When you click **Deploy**, the following effects take place:
 - a. The configuration file is saved.
 - b. If the database contains no MobileFirst tables, these tables are created.
 - c. If the database contains MobileFirst tables for an older version of the product, the tables are upgraded to the current version.
 - d. If the database operations succeed, the MobileFirst Server is deployed to the application server.
 - e. If the WAR file needs to be migrated to the current version, it is migrated.

Replace the project WAR file of a deployed runtime

Use this task to update the WAR files and libraries of the MobileFirst administration components. For example, apply a fix pack to the installation directory of MobileFirst Server.

Replace the WAR file of a deployed MobileFirst Server configuration

If you applied a fix pack to your installation of MobileFirst Server, use this task to update the console and administration WAR files of a deployed configuration.

Other operations available in the Server Configuration Tool

Export a Configuration

When you click **File > Export Configuration as Ant files**, Ant files are exported. These Ant files contain tasks that take the following actions for the MobileFirst Operations Console and Administration Services, and for each MobileFirst runtime environment of the configuration:

- Create or update the databases
- Deploy the WAR file
- Update the WAR file
- Undeploy the WAR file

A **help** target, the default target of the Ant project, describes the different targets available. You might want to export a configuration for the following reasons:

- To add deployment JNDI properties, then run the Ant file in command-line mode with Apache Ant.
- To run the Ant file on a computer without a graphical user interface.
- To perform the MobileFirst Server operations in batch mode (from the command line and without using a graphical user interface).

If you modify the MobileFirst Server status outside the Server Configuration Tool, the status for this configuration is no longer accurate.

Migrate a V6.1.0 Configuration

Configurations that were created with IBM Worklight V6.1.0 are displayed in a folder called **Worklight 6.1 Configurations**. To migrate such configurations to IBM MobileFirst Platform Foundation V7.1.0, complete the following steps:

1. Select the configuration.
2. Right-click to open a contextual menu.
3. Select **Migrate a V6.1 configuration**. An IBM MobileFirst Platform Foundation V7.1.0 configuration is created.
4. Review all the pages of the wizard. In Database Additional Settings, you must enter information for the new administration database.
5. When all the pages are reviewed, click **Migrate**.

The IBM Worklight runtime environment V6.1.0 is removed from the application server. The databases are migrated, the MobileFirst Operations Console and Administration Services are deployed, and the MobileFirst runtime environment is deployed.

Upgrade a MobileFirst configuration to the current version with the Server Configuration Tool

Since IBM MobileFirst Platform Foundation V7.1.0, you can use the Server Configuration Tool to upgrade an older configuration already deployed, in a single action. For more information, see “Upgrading with the Server Configuration Tool” on page 7-81.

Change the working directory where the configurations are stored

Click **File > Preferences** and select a different working directory.

Using Ant tasks to deploy the project WAR file

Creating and configuring the databases with Ant tasks:

If you did not manually create databases, you can use Ant tasks to create and configure your databases.

About this task

If you did not use the procedure in “Optional creation of databases” on page 12-6 to create the databases manually, complete the following steps.

Important: You use this procedure to create a relational database, if needed, and to populate it with the required tables. If you deploy with Cloudant as a database, you do not need to perform this procedure.

Procedure

1. Review the sample configuration files in “Sample configuration files” on page 16-77, and copy the Ant file that corresponds to your database. The files for creating a database are named after the following pattern:

```
create-database-database.xml
```

For more information, see table 1, Table 16-83 on page 16-78, in “Sample configuration files” on page 16-77.

2. Follow step 4 of the page “Sample configuration files” on page 16-77 to edit the Ant file and replace the placeholder values for the properties at the beginning of the file.
3. Run the following commands to create the databases.

```
ant -f create-database-database.xml databases
```

You can find the Ant command in *product_install_dir*/shortcuts.

If the databases are created, and you must create only the databaseTABLES.

4. Edit the Ant script that you use later to create and configure the databases.
5. Review the sample configuration files in “Sample configuration files” on page 16-77, and copy the Ant file that corresponds to your database. The files for configuring an existing database are named after this pattern:

```
configure-appServer-database.xml
```

For more information, see table 1, Table 16-83 on page 16-78, in “Sample configuration files” on page 16-77.

6. See step 4 of the page “Sample configuration files” on page 16-77 to edit the Ant file and replace the placeholder values for the properties at the beginning of the file.
7. Run the following commands to create the databases.

```
ant -f configure-appServer-database.xml databases
```

You can find the Ant command in *product_install_dir*/shortcuts.

What to do next

See also:

- “Ant **configuredatabase** task reference” on page 16-25
- “Sample configuration files” on page 16-77

Deploying a project WAR file and configuring the application server with Ant tasks:

Use Ant tasks to deploy the project WAR file to an application server, and configure data sources, properties, and database drivers that are used by IBM MobileFirst Platform Foundation. A set of Ant tasks is supplied with IBM MobileFirst Platform Server.

Before you begin

See “Planning deployment of administration components and runtimes” on page 6-19 for the supported deployment topologies.

Before you deploy your project WAR file and configure the application server, you must complete the following procedures:

- “Installing MobileFirst Server” on page 6-14.
- “Installing a server farm” on page 6-138, to configure the server farm if you have a farm topology.
- “Creating and configuring the databases with Ant tasks” on page 12-15 (only for relational databases)

If you use Cloudant via https as a database, and WebSphere Application Server full profile as an application server, declare the Cloudant signer certificate, as described in “Configuring WebSphere Application Server for use with Cloudant” on page 6-68.

If you deploy different project WAR files with relational databases, each WAR file must have its own set of tables. Likewise, if you deploy different project WAR files with Cloudant, each WAR file must have its own database to store the JSON documents. Each supported database type has the following guidelines:

- For DB2, each WAR file must have different databases, or schema to store the tables.
- For MySQL, each WAR file must have different databases to store the tables.
- For Oracle, each WAR file must have different database users to store the tables.
- For Derby, each WAR file must have different databases to store the tables.
- For Cloudant, each WAR file must have different databases, unless a prefix is specified for the database name, so that several teams use the same database. For more information, see “Creating the Cloudant database” on page 12-9.

You must run the Ant task on the computer where the application server is installed, or the Network Deployment Manager for WebSphere Application Server Network Deployment. If you want to start the Ant task from a computer on which Worklight Server is not installed, you must copy the file *mf_server_install_dir/WorklightServer/worklight-ant-deployer.jar* to that computer.

The *mf_server_install_dir* placeholder is the directory where you installed IBM MobileFirst Platform Server.

Note: If your application server is WebSphere Application Server V7.0, you must add the configuration property “*com.ibm.ws.webcontainer.invokerequestlistenerforfilter = true*”. For more information about how to add this property, see “Configuring WebSphere Application Server V7.0” on page 6-70.

Procedure

1. Review the environment ID that you used to install the MobileFirst Server administration. This environment ID is installed as a JNDI property. For more information about the list of JNDI properties, see “List of JNDI properties for MobileFirst Server administration” on page 6-111.

Important: If the MobileFirst Server administration used an environment ID, install the project WAR file with the same environment ID. Otherwise, that project WAR file cannot be managed by the MobileFirst Server administration.

2. Edit the Ant script that you use later to deploy the Project WAR File.
 - a. Review the sample configuration files in “Sample configuration files” on page 16-77, and copy the Ant file that corresponds to your database. The files for deploying a project WAR file are named after the following pattern:
`configure-appServer-database.xml`

For more information, see table 1, Table 16-83 on page 16-78, in “Sample configuration files” on page 16-77.

Note: If your file name follows the pattern `configure-appServer-database.xml`, you can reuse it for “Creating and configuring the databases with Ant tasks” on page 12-15,

- b. Follow step 4 of the page “Sample configuration files” on page 16-77 to edit the Ant file and replace the placeholder values for the properties at the beginning of the file.
 - c. Each project WAR file that uses Cloudant as a database must have its own database. By default, the database includes the project name. If several teams use the same Cloudant database with projects that have the same names, make the distinction by using the `dbNamePrefix` of the `<cloudant>` element in the Ant task **configureapplicationserver**.
3. If the MobileFirst Server administration uses an environment ID, and you run an Ant task for the installation, add an `environmentID` attribute to the following Ant tasks, which are used for the administration installation:
 - **installworklightadmin**
 - **updateworklightadmin**
 - **uninstallworklightadmin**
 - **configureapplicationserver**
 - **updateapplicationserver**
 - **unconfigureapplicationserver**

For more information, see “Ant tasks for installation of MobileFirst runtime environments” on page 16-42 and “Ant tasks for installation of MobileFirst Operations Console and Administration Services” on page 16-34.

Important: The value of the attribute must be the same as the one used for the MobileFirst Server administration.

4. To deploy the project WAR file, run the following command:

```
ant -f configure-appServer-database.xml install
```

You can find the Ant command in `mf_server_install_dir/shortcuts`

5. Save the Ant file. You might need it later to apply a fix pack or perform an upgrade. For more information, see “Identify the MobileFirst WAR file and prepare the Ant deployment script” on page 7-30. If you do not want to save the passwords, you can replace them by “*****” (12 stars) for interactive prompting.

What to do next

See also:

- “Ant tasks for installation of MobileFirst runtime environments” on page 16-42
- “Sample configuration files” on page 16-77
- “Using Ant tasks to install MobileFirst Server administration” on page 6-73
- “Encrypting database password with Ant tasks for Liberty” on page 16-33

Configuring WebSphere Application Server Network Deployment servers:

Specific considerations when you configure WebSphere Application Server Network Deployment servers through Ant tasks are documented in this section.

To install a MobileFirst project into a set of WebSphere Application Server Network Deployment servers, run the <configureapplicationserver> Ant task on the computer where the deployment manager is running.

Procedure

1. Specify a database type other than Apache Derby. IBM MobileFirst Platform Foundation supports Apache Derby only in embedded mode, and this choice is incompatible with deployment through WebSphere Application Server Network Deployment.
2. As value of the profile attribute, specify the deployment manager profile.
Attention: Do not specify an application server profile and then a single managed server. Doing so causes the deployment manager to overwrite the configuration of the server. This is true whether you install on the computer on which the deployment manager is running or on a different computer.
3. Specify an inner element, depending on where you want the MobileFirst Runtime Component to be installed. The following table lists the available elements:

Note: You must choose the same inner element to install the MobileFirst Administration Services. You must install an instance of the MobileFirst Administration Service on each server where the MobileFirst Runtime Component is installed.

Table 12-1. Inner elements of <was> for network deployment

Element	Explanation
cell	Install the MobileFirst project into all application servers of the cell.
cluster	Install the MobileFirst project into all application servers of the specified cluster.
node	Install the MobileFirst project into all application servers of the specified node that are not in a cluster.
server	Install the MobileFirst project into the specified server, which is not in a cluster.

4. After starting the <configureapplicationserver> Ant task, restart the affected servers:
 - You must restart the servers that were running and on which the MobileFirst project application was installed. To restart these servers with the deployment manager console, select **Applications > Application Types > WebSphere enterprise applications > IBM_Worklight_Console > Target specific application status**.
 - You do not have to restart the deployment manager or the node agents.

Results

The configuration has no effect outside the set of servers in the specified scope. The JDBC providers, JDBC data sources, and shared libraries are defined with the specified scope. The entities that have a cell-wide scope (the applications and, for DB2, the authentication alias) use the specified id attribute as a suffix in their name; it makes their name unique. So, you can install MobileFirst Server in different configurations or even different versions of MobileFirst Server, in different clusters of the same cell.

Note: Because the JDBC driver is installed only in the specified set of application servers, the **Test connection** button for the JDBC data sources in the WebSphere Application Server administrative console of the deployment manager might not work.

Adding a server to a cluster

When you add a server to a cluster that has a MobileFirst project installed on it, you must repeat some configuration manually. For each affected server, add a specific web container custom property:

1. Click **Servers > Server Types > Application Servers**, and select the server.
2. Click **Web Container Settings > Web container**.
3. Click **Custom properties**.
4. Click **New**.
5. Enter the property values listed in the following table:

Table 12-2. Web container custom property values

Property	Value
Name	com.ibm.ws.webcontainer.invokeFlushAfterService
Value	false
Description	See http://www.ibm.com/support/docview.wss?uid=swg1PM50111 .

6. Click **OK**.
7. Click **Save**.

Deploying the project WAR file manually

Creating and configuring the databases manually:

You can manually create and configure the IBM MobileFirst Platform Foundation databases.

Note: The reports database and the sample BIRT Reports are deprecated since IBM MobileFirst Platform Foundation V7.0.0. However, if you need it, you can still manually create and configure the reports database. For more information about this procedure, see “Manually creating and configuring the reports database” on page 14-122.

Configuring the DB2 databases manually:

You configure the DB2 databases manually by creating the databases, creating the database tables, and then configuring the relevant application server to use this database setup.

Procedure

1. Create the databases. This step is described in “Creating the DB2 database” on page 12-6.
2. Create the tables in the databases. This step is described in “Setting up your DB2 database manually” on page 12-21.
3. Perform the application server-specific setup as the following list shows.

Note: At this stage, you can choose to provide a database user with limited privileges to better secure access to the Application Server database during runtime operations. To create a database user with restricted privileges, see “Restricting database user permissions for IBM MobileFirst Platform Server runtime operations” on page 6-31.

Setting up your DB2 database manually:

You can set up the database manually instead of using Ant tasks.

About this task

Set up your DB2 database by creating the database schema. The following procedure creates the schemas for WRKLGHT.

Procedure

1. Create a system user, **worklight**, in a DB2 admin group such as **DB2USERS**, by using the appropriate commands for your operating system. Give it the password **password**. For more information, see the DB2 documentation and the documentation for your operating system.

Important: You can name your user differently, or set a different password, but ensure that you enter the appropriate user name and password correctly across the DB2 database setup. DB2 has a user name and password length limit of 8 characters for UNIX and Linux systems, and 30 characters for Windows.

Note: If you want multiple instances of IBM MobileFirst Platform Server to connect to the same database, use a different user name for each connection. Each database user has a separate default schema.

2. Open a DB2 command line processor, with a user that has **SYSADM** or **SYSCTRL** permissions:
 - On Windows systems, click **Start > IBM DB2 > Command Line Processor**.
 - On Linux or UNIX systems, go to `~/sql11ib/bin` and enter `./db2`.
3. Enter the following database manager and SQL statements to create a database that is called **WRKLGHT**:

```
CREATE DATABASE WRKLGHT COLLATE USING SYSTEM PAGESIZE 32768
CONNECT TO WRKLGHT
GRANT CONNECT ON DATABASE TO USER worklight
QUIT
```

Where **worklight** is the name of the system user that you previously created. If you defined a different user name, replace **worklight** with the user name.

4. Run DB2 with the following commands to create the **WRKLGHT** tables:

```
db2 CONNECT TO WRKLGHT USER worklight USING password
db2 SET CURRENT SCHEMA = 'WRKSCHM'
db2 -vf product_install_dir/WorklightServer/databases/create-worklight-db2.sql -t
```

Where **worklight** after **USER** is the name of the system user with "CONNECT" access to the **WRKLGHT** database that you previously created, and **password** after **USING** is this user's password. If you defined either a different user name, or a different password, or both, replace **worklight**, or **password**, or both.

DB2 has a user name and password length limit of 8 characters for UNIX and Linux systems, and 30 characters for Windows.

Important: If you do not specify the user name and password, DB2 assumes that the user is the current user, and creates the tables by using this current

user's schema. If the current user differs from the settings in **Worklight**, then the current user is denied access to the tables in the database.

Configuring Liberty profile for DB2 manually:

If you want to manually set up and configure your DB2 database with WebSphere Application Server Liberty profile, use the following procedure.

Before you begin

Complete the DB2 Database Setup procedure before continuing.

Procedure

1. Add the DB2 JDBC driver JAR file (download it from DB2 JDBC Driver Versions, or fetch it from the directory DB2_INSTALL_DIR/java on the DB2 server) to \$LIBERTY_HOME/wlp/usr/shared/resources/db2. If that directory does not exist, create it.
2. Configure the data source in the \$LIBERTY_HOME/wlp/usr/servers/worklightServer/server.xml file (worklightServer can be replaced in this path by the name of your server) as follows:

```
<!-- Declare the jar files for DB2 access through JDBC. -->
<library id="DB2Lib">
  <fileset dir="{shared.resource.dir}/db2" includes="*.jar"/>
</library>

<!-- Declare the runtime database -->
<dataSource jndiName="worklight/jdbc/WorklightDS" transactional="false">
  <jdbcDriver libraryRef="DB2Lib"/>
  <properties.db2.jcc databaseName="WRKLGHT" currentSchema="WRKSCHM"
    serverName="db2server" portNumber="50000"
    user="worklight" password="password"/>
</dataSource>
```

Where **worklight** after **user=** is the name of the system user with "CONNECT" access to the **WRKLGHT** database that you previously created, and **password** after **password=** is this user's password. If you defined either a different user name, or a different password, or both, replace these entries accordingly. Also, replace **db2server** with the host name of your DB2 server (for example, localhost, if it is on the same machine).

Note: The database user that is provided in step 2 does not need extended privileges on the databases. If you need to implement restrictions on the database, you can set here a user that has the restricted privileges that are listed in "Restricting database user permissions for IBM MobileFirst Platform Server runtime operations" on page 6-31.

DB2 has a user name and password length limit of 8 characters for UNIX and Linux systems, and 30 characters for Windows.

The `jndiName` attributes must depend on the context root that you select for the MobileFirst Server application, following the instructions in "Configuring the Liberty profile manually" on page 12-38. If the context root is `/app_context`, use `jndiName="app_context/jdbc/WorklightDS"`.

3. You can encrypt the database password with the securityUtility program in `<liberty_install_dir>/bin`.

Configuring WebSphere Application Server for DB2 manually:

If you want to manually set up and configure your DB2 database with WebSphere Application Server, use the following procedure.

About this task

Complete the DB2 database Setup procedure before continuing.

Procedure

1. Determine a suitable directory for the JDBC driver JAR file in the WebSphere Application Server installation directory.
 - For a standalone server, you can use a directory such as `WAS_INSTALL_DIR/optionalLibraries/IBM/project-name/db2`.
 - For deployment to a WebSphere Application Server Network Deployment cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/project-name/db2`.
 - For deployment to a WebSphere Application Server Network Deployment cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/project-name/db2`.
 - For deployment to a WebSphere Application Server Network Deployment node, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/project-name/db2`.
 - For deployment to a WebSphere Application Server Network Deployment server, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/project-name/db2`.

If the directory for the JDBC driver JAR file does not exist, you must create it.

2. Add the DB2 JDBC driver JAR file to the directory that you determined in step 1.

You can retrieve the file in one of two ways:

- Download it from DB2 JDBC Driver Versions.
- Fetch it from the `db2_install_dir/java` on the DB2 server directory.

3. Set up the JDBC provider:
 - a. In the WebSphere Application Server console, click **Resources > JDBC > JDBC Providers**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Set **Database type** to **DB2**.
 - e. Set **Provider type** to **DB2 Using IBM JCC Driver**.
 - f. Set **Implementation Type** to **Connection pool data source**.
 - g. Set **Name** to **DB2 Using IBM JCC Driver**.
 - h. Click **Next**.
 - i. Set the **Class path** to the set of JAR files in the directory that you determined in step 1, one per line, replacing `WAS_INSTALL_DIR/profiles/profile-name` with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.
 - j. Do not set **Native library path**.
 - k. Click **Next**.
 - l. Click **Finish**.
 - m. The JDBC provider is created.

- n. Click **Save**.
4. Create a data source for the runtime database:
 - a. Click **Resources > JDBC > Data Sources**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New** to create a data source.
 - d. Set the **Data source name** to **Worklight Database**.
 - e. Set **JNDI Name** to **jdbc/WorklightDS**.
 - f. Click **Next**.
 - g. Enter properties for the data source, for example:
 - **Driver type:** 4
 - **Database Name:** WRKLGHT
 - **Server name:** localhost
 - **Port number:** 50000 (default)
 Leave **Use this data source in (CMP)** selected.
 - h. Click **Next**.
 - i. Create **JAAS-J2C** authentication data, specifying the DB2 user name and password as its properties. If necessary, go back to the data source creation wizard, by repeating steps 4a to 4h.
 - j. Select the authentication alias that you created in the **Component-managed authentication alias** combination box (not in the **Container-managed authentication alias** combination box).
 - k. Click **Next** and **Finish**.
 - l. Click **Save**.
 - m. In **Resources > JDBC > Data sources**, select the new data source.
 - n. Click **WebSphere Application Server data source properties**.
 - o. Select the **Non-transactional data source** check box.
 - p. Click **OK**.
 - q. Click **Save**.
 - r. Click **Custom properties** for the data source, select property **currentSchema**, and set the value to the schema used to create the data source tables (WRKSCHM and WLRESCHM in this example).
5. Test the data source connection by selecting each **Data Source** and clicking **Test Connection**.
6. For WebSphere Application Server Network Deployment, click **System administration > Nodes**, select the nodes, and click **Full Synchronize**.

Configuring Apache Tomcat for DB2 manually:

If you want to manually set up and configure your DB2 database with Apache Tomcat server, use the following procedure.

About this task

Complete the DB2 Database Setup procedure before continuing.

Procedure

1. Add the DB2 JDBC driver JAR file to \$TOMCAT_HOME/lib.

You can retrieve the file in one of two ways:

 - Download it from DB2 JDBC Driver Versions

- Fetch it from the `db2_install_dir/java` directory on the DB2 server.
2. Prepare an XML statement that defines the data source, as shown in the following code example. Insert this statement in the `server.xml` file, as indicated in “Configuring Apache Tomcat manually” on page 12-46.

```
<Resource auth="Container"
  driverClassName="com.ibm.db2.jcc.DB2Driver"
  name="jdbc/WorklightDS"
  username="worklight"
  password="password"
  type="javax.sql.DataSource"
  url="jdbc:db2://db2server:50000/WRKLGHT:currentSchema=WRKSCHM;"/>
```

Where **worklight** after **username=** is the name of the system user with "CONNECT" access to the **WRKLGHT** database that you previously created, and **password** after **password=** is this user's password. If you have defined either a different user name, or a different password, or both, replace **worklight** accordingly. Also, replace **db2server** with the host name of your DB2 server (for example, `localhost`, if it is on the same machine).

Note: The database user that is provided in this step does not need extended privileges on the databases. If you need to implement restrictions on the database, you can set here a user that has the restricted privileges that are listed in “Restricting database user permissions for IBM MobileFirst Platform Server runtime operations” on page 6-31.

DB2 has a user name and password length limit of 8 characters for UNIX and Linux systems, and 30 characters for Windows.

Configuring the Apache Derby databases manually:

You configure the Apache Derby databases manually by creating the databases and database tables, and then configuring the relevant application server to use this database setup.

Procedure

1. Create the databases and the tables within them. This step is described in “Setting up your Apache Derby database manually.”
2. Configure the application server to use this database setup. Go to one of the following topics:
 - “Configuring Liberty Profile for Derby manually” on page 12-26
 - “Configuring WebSphere Application Server for Derby manually” on page 12-26
 - “Configuring Apache Tomcat for Derby manually” on page 12-28

Setting up your Apache Derby database manually:

You can set up your Apache Derby database manually instead of by running Ant tasks.

About this task

Set up your Apache Derby database by creating the database schema.

Procedure

1. In the location where you want the database to be created, run `ij.bat` on Windows systems or `ij.sh` on UNIX and Linux systems.

Note: The ij program is part of Apache Derby. If you do not already have it installed, you can download it from Apache Derby: Downloads.

For supported versions of Apache Derby, see “System requirements” on page 2-15.

The script displays ij version number.

2. At the command prompt, enter the following commands:

```
connect 'jdbc:derby:WRKLGHT;user=WORKLIGHT;create=true';
run 'product_install_dir/WorklightServer/databases/create-worklight-derby.sql';
quit;
```

Configuring Liberty Profile for Derby manually:

If you want to manually set up and configure your Apache Derby database with WebSphere Application Server Liberty Profile, use the following procedure.

About this task

Complete the Apache Derby database setup procedure before continuing.

Procedure

Configure the data source in the \$LIBERTY_HOME/usr/servers/worklightServer/server.xml file (worklightServer may be replaced in this path by the name of your server) as follows:

```
<!-- Declare the jar files for Derby access through JDBC. -->
<library id="derbyLib">
  <fileset dir="C:/Drivers/derby" includes="derby.jar" />
</library>

<!-- Declare the runtime database -->
<dataSource jndiName="worklight/jdbc/WorklightDS" transactional="false" statementCacheSize="10">
  <jdbcDriver libraryRef="derbyLib"
    javax.sql.ConnectionPoolDataSource="org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource40"/>
  <properties.derby.embedded databaseName="DERBY_DATABASES_DIR/WRKLGHT" user="WORKLIGHT"
    shutdownDatabase="false" connectionAttributes="upgrade=true"/>
  <connectionManager connectionTimeout="180"
    maxPoolSize="10" minPoolSize="1"
    reapTime="180" maxIdleTime="1800"
    agedTimeout="7200" purgePolicy="EntirePool" />
</dataSource>
```

The jndiName attributes must depend on the context root that you select for the MobileFirst Server application, following the instructions in “Configuring the Liberty profile manually” on page 12-38. If the context root is /app_context, use jndiName="app_context/jdbc/WorklightDS".

Configuring WebSphere Application Server for Derby manually:

You can set up and configure your Apache Derby database manually with WebSphere Application Server.

About this task

Complete the Apache Derby database setup procedure before continuing.

Procedure

1. Determine a suitable directory for the JDBC driver JAR file in the WebSphere Application Server installation directory.
 - For a standalone server, you can use a directory such as `WAS_INSTALL_DIR/optionalLibraries/IBM/project-name/derby`.
 - For deployment to a WebSphere Application Server Network Deployment cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/project-name/derby`.
 - For deployment to a WebSphere Application Server Network Deployment cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/project-name/derby`.
 - For deployment to a WebSphere Application Server Network Deployment node, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/project-name/derby`.
 - For deployment to a WebSphere Application Server Network Deployment server, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/project-name/derby`.

If the directory for the JDBC driver JAR file does not exist, you must create it.

2. Add the Derby JAR file from `product_install_dir/ApplicationCenter/tools/lib/derby.jar` to the directory that you determined in step 1.
3. Set up the JDBC provider.
 - a. In the WebSphere Application Server console, click **Resources > JDBC > JDBC Providers**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Set **Database type** to **User-defined**.
 - e. Set **Class Implementation name** to `org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource40`.
 - f. Set **Name** to **Worklight - Derby JDBC Provider**.
 - g. Set **Description** to **Derby JDBC provider for Worklight**.
 - h. Click **Next**.
 - i. Set the **Class path** to the JAR file in the directory that you determined in step 1, replacing `WAS_INSTALL_DIR/profiles/profile-name` with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.
 - j. Click **Finish**.
4. Create the data source for the runtime database.
 - a. In the WebSphere Application Server console, click **Resources > JDBC > Data sources**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Set **Data source Name** to **Worklight Database**.
 - e. Set **JNDI name** to `jdbc/WorklightDS`.
 - f. Click **Next**.
 - g. Select the existing JDBC provider that is named **Worklight - Derby JDBC Provider**.
 - h. Click **Next**.
 - i. Click **Next**.
 - j. Click **Finish**.

- k. Click **Save**.
 - l. In the table, click the **Worklight Database** data source that you created.
 - m. Under **Additional Properties**, click **Custom properties**.
 - n. Click **databaseName**.
 - o. Set **Value** to the path to the WRKLGHT database that is created by the configuredatabase ant task.
 - p. Click **OK**.
 - q. Click **Save**.
 - r. At the top of the page, click **Worklight Database**.
 - s. Under **Additional Properties**, click **WebSphere Application Server data source properties**.
 - t. Select **Non-transactional datasource**.
 - u. Click **OK**.
 - v. Click **Save**.
 - w. In the table, select the **Worklight Database** data source that you created.
 - x. Click **test connection** (only if you are not on the console of a WAS Deployment Manager).
5. For WebSphere Application Server Network Deployment, click **System administration > Nodes**, select the nodes, and click **Full Synchronize**.

Configuring Apache Tomcat for Derby manually:

If you want to manually set up and configure your Apache Derby database with the Apache Tomcat server, use the following procedure.

About this task

Complete the Apache Derby database setup procedure before continuing.

Procedure

1. Add the Derby JAR file from *product_install_dir*/ApplicationCenter/tools/lib/derby.jar to the directory \$TOMCAT_HOME/lib.
2. Prepare an XML statement that defines the data source, as shown in the following code example. Insert this statement in the server.xml file, as indicated in “Configuring Apache Tomcat manually” on page 12-46.

```
<Resource auth="Container"
  driverClassName="org.apache.derby.jdbc.EmbeddedDriver"
  name="jdbc/WorklightDS"
  username="WORKLIGHT"
  password=""
  type="javax.sql.DataSource"
  url="jdbc:derby:DERBY_DATABASES_DIR/WRKLGHT"/>
```

Configuring the MySQL databases manually:

You configure the MySQL databases manually by creating the databases, creating the database tables, and then configuring the relevant application server to use this database setup.

Procedure

1. Create the databases. This step is described in “Creating the MySQL database” on page 12-8.

2. Create the tables in the databases. This step is described in “Setting up your MySQL database manually.”
3. Perform the application server-specific setup as the following list shows.

Setting up your MySQL database manually:

You can set up the database manually instead of using the Ant tasks.

About this task

Complete the following procedure to set up your MySQL databases.

Procedure

1. Create the database schema.
 - a. Run a MySQL command line client with the option `-u root`.
 - b. Enter the following commands:

```
CREATE DATABASE WRKLGHT CHARACTER SET utf8 COLLATE utf8_general_ci;
GRANT ALL PRIVILEGES ON WRKLGHT.* TO 'worklight'@'Worklight-host' IDENTIFIED BY 'worklight';
GRANT ALL PRIVILEGES ON WRKLGHT.* TO 'worklight'@'localhost' IDENTIFIED BY 'worklight';
FLUSH PRIVILEGES;
```

```
USE WRKLGHT;
SOURCE product_install_dir/WorklightServer/databases/create-worklight-mysql.sql;
```

Where **worklight** before the "at" sign (@) is the user name, **worklight** after **IDENTIFIED BY** is its password, and **Worklight-host** is the name of the host on which IBM MobileFirst Platform Foundation runs.

2. Add the following property to your MySQL option file:

```
max_allowed_packet=256M
```

 For more information about `max_allowed_packet`, see the MySQL documentation, section Packet Too Large.
3. Add the following property to your MySQL option file:

```
innodb_log_file_size
=      250M
```

 For more information about `innodb_log_file_size`, see the MySQL documentation, section `innodb_log_file_size`.
 For more information about option files, see the MySQL documentation.

Configuring Liberty profile for MySQL manually:

If you want to manually set up and configure your MySQL database with WebSphere Application Server Liberty profile, use the following procedure.

Before you begin

Complete the MySQL database setup procedure before continuing.

Procedure

1. Add the MySQL JDBC driver JAR file to `$LIBERTY_HOME/wlp/usr/shared/resources/mysql`. If that directory does not exist, create it.
2. Configure the data source in the `$LIBERTY_HOME/usr/servers/worklightServer/server.xml` file (`worklightServer` may be replaced in this path by the name of your server) as follows:

```
<!-- Declare the jar files for MySQL access through JDBC. -->
<library id="MySQLLib">
  <fileset dir="${shared.resource.dir}/mysql" includes="*.jar"/>
```

```

</library>

<!-- Declare the runtime database -->
<dataSource jndiName="worklight/jdbc/WorklightDS" transactional="false">
  <jdbcDriver libraryRef="MySQLLib"/>
  <properties databaseName="WRKLGHT"
    serverName="mysqlserver" portNumber="3306"
    user="worklight" password="password"/>
</dataSource>

```

Where **worklight** after **user=** is the user name, **password** after **password=** is this user's password, and **mysqlserver** is the host name of your MySQL server. If you have defined either a different user name, or a different password, or both, replace these entries accordingly. Also, replace **mysqlserver** with the host name of your MySQL server (for example, localhost, if it is on the same machine).

Note: The database user that is provided in this step does not need extended privileges on the databases. If you need to implement restrictions on the database, you can set here a user that has the restricted privileges that are listed in “Restricting database user permissions for IBM MobileFirst Platform Server runtime operations” on page 6-31.

The `jndiName` attributes must depend on the context root that you select for the MobileFirst Server application, following the instructions in “Configuring the Liberty profile manually” on page 12-38. If the context root is `/app_context`, use `jndiName="app_context/jdbc/WorklightDS"`.

3. You can encrypt the database password with the `securityUtility` program in `<liberty_install_dir>/bin`.

Configuring WebSphere Application Server for MySQL manually:

If you want to manually set up and configure your MySQL database for Application Center with WebSphere Application Server, use the following procedure.

About this task

Complete the MySQL database setup procedure before continuing.

Note: MySQL in combination with WebSphere Application Server Liberty profile or WebSphere Application Server full profile is not classified as a supported configuration. For more information, see WebSphere Application Server Support Statement. We suggest that you use IBM DB2 or another database supported by WebSphere Application Server to benefit from a configuration that is fully supported by IBM Support.

Procedure

1. Determine a suitable directory for the JDBC driver JAR file in the WebSphere Application Server installation directory.
 - For a standalone server, you can use a directory such as `WAS_INSTALL_DIR/optionalLibraries/IBM/project-name/mysql`.
 - For deployment to a WebSphere Application Server Network Deployment cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/project-name/mysql`.
 - For deployment to a WebSphere Application Server Network Deployment cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/project-name/mysql`.

- For deployment to a WebSphere Application Server Network Deployment node, use *WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/project-name/mysql*.
- For deployment to a WebSphere Application Server Network Deployment server, use *WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/project-name/mysql*.

If the directory for the JDBC driver JAR file does not exist, you must create it.

2. Add the MySQL JDBC driver JAR file that you downloaded from Download Connector/J to the directory determined in step 1.
3. Set up the JDBC provider:
 - a. In the WebSphere Application Server console, click **Resources > JDBC > JDBC Providers**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Create a **JDBC provider** named **MySQL**.
 - e. Set **Database type** to **User defined**.
 - f. Set **Scope** to **Cell**.
 - g. Set **Implementation class** to **com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource**.
 - h. Set the **Class path** to the JAR file in the directory that you determined in step 1, replacing *WAS_INSTALL_DIR/profiles/profile-name* with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.
 - i. Save your changes.
4. Create a data source for the runtime database:
 - a. Click **Resources > JDBC > Data sources**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New** to create a data source.
 - d. Type any name (for example, Worklight Database).
 - e. Set **JNDI Name** to `jdbc/WorklightDS`.
 - f. Use the existing **JDBC Provider MySQL**, defined in the previous step.
 - g. Set **Scope** to **New**.
 - h. On the **Configuration** tab, select **Non-transactional data source**.
 - i. Click **Next** a number of times, leaving all other settings as defaults.
 - j. Save your changes.
5. Set the custom properties of each new data source.
 - a. Select the new data source.
 - b. Click **Custom properties**.
 - c. Set the following properties:

```
portNumber = 3306
relaxAutoCommit=true
databaseName = WRKLGHT
serverName = the host name of the MySQL server
user = the user name of the MySQL server
password = the password associated with the user name
```

Note: The database user that is listed in this step does not need extended privileges on the databases. If you need to implement restrictions on the database, you can set here a user that has the restricted privileges that are listed in “Restricting database user permissions for IBM MobileFirst Platform Server runtime operations” on page 6-31.

6. Set the WAS custom properties of each new data source.
 - a. In **Resources > JDBC > Data sources**, select the new data source.
 - b. Click **WebSphere Application Server data source properties**.
 - c. Select the **Non-transactional data source** check box.
 - d. Click **OK**.
 - e. Click **Save**.
7. For WebSphere Application Server Network Deployment, click **System administration > Nodes**, select the nodes, and click **Full Synchronize**.

Configuring Apache Tomcat for MySQL manually:

If you want to manually set up and configure your MySQL database with the Apache Tomcat server, use the following procedure.

About this task

Complete the MySQL database setup procedure before continuing.

Procedure

1. Add the MySQL Connector/J JAR file to the \$TOMCAT_HOME/lib directory.
2. Prepare an XML statement that defines the data source, as shown in the following code example. Insert this statement in the server.xml file, as indicated in “Configuring Apache Tomcat manually” on page 12-46.

```
<Resource name="jdbc/WorklightDS"
  auth="Container"
  type="javax.sql.DataSource"
  maxActive="100"
  maxIdle="30"
  maxWait="10000"
  username="worklight"
  password="worklight"
  driverClassName="com.mysql.jdbc.Driver"
  url="jdbc:mysql://mysqlserver:3306/WRKLGHT"/>
```

Where **worklight** after **username=** is the user name of the MySQL server, **worklight** after **password=** is this user's password, and **mysqlserver** is the host name of your MySQL server (for example, localhost, if it is on the same machine).

Note: The database user that is listed in this step does not need extended privileges on the databases. If you need to implement restrictions on the database, you can set here a user that has the restricted privileges that are listed in “Restricting database user permissions for IBM MobileFirst Platform Server runtime operations” on page 6-31.

Configuring the Oracle databases manually:

You configure the Oracle databases manually by creating the databases, creating the database tables, and then configuring the relevant application server to use this database setup.

Procedure

1. Create the databases. This step is described in “Creating the Oracle database” on page 12-8.
2. Create the tables in the databases. This step is described in “Setting up your Oracle database manually” on page 12-33.

3. Perform the application server-specific setup as the following list shows.

Setting up your Oracle database manually:

You can set up the database manually instead of using Ant tasks.

About this task

Complete the following procedure to set up your Oracle databases.

Procedure

1. Ensure that you have at least one Oracle database.

In many Oracle installations, the default database has the SID (name) ORCL. For best results, set the character set of the database to **Unicode (AL32UTF8)**.

If the Oracle installation is on a UNIX or Linux computer, make sure that the database is started the next time the Oracle installation is restarted. To this effect, make sure that the line in `/etc/oratab` that corresponds to the database ends with a `Y`, not with an `N`.

2. Create the user `WORKLIGHT`, either by using Oracle Database Control, or by using the Oracle SQLPlus command-line interpreter.

- To create the user for the runtime database/schema (by default `Worklight`), by using Oracle Database Control, proceed as follows:

- a. Connect as `SYSDBA`.
- b. Go to the Users page.
- c. Click **Server**, then **Users** in the Security section.
- d. Create a user, named `WORKLIGHT` with the following attributes:

```
Profile: DEFAULT
Authentication: password
Default tablespace: USERS
Temporary tablespace: TEMP
Status: Unlocked
Add system privilege: CREATE SESSION
Add system privilege: CREATE SEQUENCE
Add system privilege: CREATE TABLE
Add quota: Unlimited for tablespace USERS
```

•

To create the user by using Oracle SQLPlus, enter the following commands:

```
CONNECT SYSTEM/SYSTEM_password@ORCL
CREATE USER WORKLIGHT IDENTIFIED BY WORKLIGHT_password DEFAULT TABLESPACE USERS QUOTA UNLIMITED ON USERS;
GRANT CREATE SESSION, CREATE SEQUENCE, CREATE TABLE TO WORKLIGHT;
DISCONNECT;
```

3. Create the database tables for the runtime database:

- a. Using the Oracle SQLPlus command-line interpreter, create the tables for the runtime database by running the `create-worklight-oracle.sql` file:

```
CONNECT WORKLIGHT/product_password@ORCL
@product_install_dir/WorklightServer/databases/create-worklight-oracle.sql
DISCONNECT;
```

4. Download and configure the Oracle JDBC driver:

- a. Download the JDBC driver from the Oracle website at Oracle: JDBC, SQLJ, Oracle JPublisher and Universal Connection Pool (UCP).
- b. Ensure that the Oracle JDBC driver is in the system path. The driver file is `ojdbc6.jar`.

Configuring Liberty Profile for Oracle manually:

If you want to manually set up and configure your Oracle database with WebSphere Application Server Liberty profile, use the following procedure.

Before you begin

Complete the Oracle database setup procedure before continuing.

Procedure

1. Add the Oracle JDBC Driver JAR file to \$LIBERTY_HOME/wlp/usr/shared/resources/oracle. If that directory does not exist, create it.
2. If you are using JNDI, configure the data sources in the \$LIBERTY_HOME/wlp/usr/servers/worklightServer/server.xml file (worklightServer may be replaced in this path by the name of your server) as shown in the following JNDI code example:

```
<!-- Declare the jar files for Oracle access through JDBC. -->
<library id="OracleLib">
  <fileset dir="{shared.resource.dir}/oracle" includes="*.jar"/>
</library>

<!-- Declare the runtime database -->
<dataSource jndiName="worklight/jdbc/WorklightDS" transactional="false">
  <jdbcDriver libraryRef="OracleLib"/>
  <properties.oracle driverType="thin" databaseName="ORCL"
    serverName="oserver" portNumber="1521"
    user="WORKLIGHT" password="WORKLIGHT_password"/>
</dataSource>
```

Where **WORKLIGHT** after **user=** is the name of the user with "CONNECT" access to the **WRKLGHT** database that you previously created, and **password** after **password=** is this user's password. If you defined either a different user name, or a different password, or both, replace these entries accordingly. Also, replace **oserver** with the host name of your Oracle server (for example, localhost, if it is on the same machine).

Note:

- For more information on how to connect the Liberty server to the Oracle database with a service name, or with a URL, see the WebSphere Application Server Liberty Core 8.5.5 documentation, section **properties.oracle**.
- The database users that are provided in this step do not need extended privileges on the databases. If you need to implement restrictions on the database, you can set here a user that has the restricted privileges that are listed in "Restricting database user permissions for IBM MobileFirst Platform Server runtime operations" on page 6-31.

The jndiName attributes must depend on the context root that you select for the MobileFirst Server application, following the instructions in "Configuring the Liberty profile manually" on page 12-38. If the context root is /app_context, use jndiName="app_context/jdbc/WorklightDS".

3. You can encrypt the database password with the securityUtility program in <liberty_install_dir>/bin.

Configuring WebSphere Application Server for Oracle manually:

If you want to manually set up and configure your Oracle database with WebSphere Application Server, use the following procedure.

About this task

Complete the Oracle database setup procedure before continuing.

Procedure

1. Determine a suitable directory for the JDBC driver JAR file in the WebSphere Application Server installation directory.
 - For a standalone server, you can use a directory such as `WAS_INSTALL_DIR/optionalLibraries/IBM/project-name/oracle`.
 - For deployment to a WebSphere Application Server Network Deployment cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/project-name/oracle`.
 - For deployment to a WebSphere Application Server Network Deployment cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/project-name/oracle`.
 - For deployment to a WebSphere Application Server Network Deployment node, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/project-name/oracle`.
 - For deployment to a WebSphere Application Server Network Deployment server, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/project-name/oracle`.

If the directory for the JDBC driver JAR file does not exist, you must create it.

2. Add the Oracle `ojdbc6.jar` file downloaded from JDBC and Universal Connection Pool (UCP) to the directory that you determined in step 1.
3. Set up the JDBC provider:
 - a. In the WebSphere Application Server console, click **Resources > JDBC > JDBC Providers**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Complete the JDBC Provider fields as indicated in the following table:

Table 12-3. JDBC Provider field values

Field	Value
Database type	Oracle
Provider type	Oracle JDBC Driver
Implementation type	Connection pool data source
Name	Oracle JDBC Driver

- e. Click **Next**.
 - f. Set the **Class path** to the JAR file in the directory that you determined in step 1, replacing `WAS_INSTALL_DIR/profiles/profile-name` with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.
 - g. Click **Next**.

The JDBC provider is created.
4. Create a data source for the runtime database:
 - a. Click **Resources > JDBC > Data sources**.
 - b. Select the appropriate scope from the **Scope** combination box.
 - c. Click **New**.
 - d. Set **Data source name** to **Oracle JDBC Driver DataSource**.

- e. Set **JNDI name** to `jdbc/WorklightDS`.
 - f. Click **Next**.
 - g. Click **Select an existing JDBC provider** and select **Oracle JDBC driver** from the list.
 - h. Click **Next**.
 - i. Set the URL value to `jdbc:oracle:thin:@oserver:1521:ORCL`, where **oserver** is the host name of your Oracle server (for example, localhost, if it is on the same machine).
 - j. Click **Next** twice.
 - k. Click **Resources > JDBC > Data sources > Oracle JDBC Driver DataSource > Custom properties**.
 - l. Set `oracleLogPackageName` to `oracle.jdbc.driver`.
 - m. Set `user` = `WORKLIGHT`.
 - n. Set `password` = `WORKLIGHT_password`.
 - o. Click **OK** and save the changes.
 - p. In **Resources > JDBC > Data sources**, select the new data source.
 - q. Click **WebSphere Application Server data source properties**.
 - r. Select **Non-transactional data source**.
 - s. Click **OK**.
 - t. Click **Save**.
5. For WebSphere Application Server Network Deployment, click **System administration > Nodes**, select the nodes, and click **Full Synchronize**.

What to do next

Note: The database user **WORKLIGHT** that is provided in this step does not need extended privileges on the databases. If you need to implement restrictions on the database, you can set here a user that has the restricted privileges that are listed in “Restricting database user permissions for IBM MobileFirst Platform Server runtime operations” on page 6-31.

Configuring Apache Tomcat for Oracle manually:

If you want to manually set up and configure your Oracle database with the Apache Tomcat server, use the following procedure.

About this task

Complete the Oracle database setup procedure before continuing.

Procedure

1. Add the Oracle JDBC driver JAR file to the directory `$TOMCAT_HOME/lib`.
2. Prepare an XML statement that defines the data source, as shown in the following code example. Insert this statement in the `server.xml` file, as indicated in “Configuring Apache Tomcat manually” on page 12-46.

```
<Resource name="jdbc/WorklightDS"
  auth="Container"
  type="javax.sql.DataSource"
  driverClassName="oracle.jdbc.driver.OracleDriver"
  url="jdbc:oracle:thin:@oserver:1521:ORCL"
  username="WORKLIGHT"
  password="WORKLIGHT_password"/>
```

Where **WORKLIGHT** after **username=** is the name of the user with "CONNECT" access to the **WRKLGHT** database that you previously created, and **password** after **password=** is this user's password. If you defined either a different user name, or a different password, or both, replace these entries accordingly. Also, replace **oserver** with the host name of your Oracle server (for example, localhost, if it is on the same machine).

Note: The database users that are provided in this step do not need extended privileges on the databases. If you need to implement restrictions on the database, you can set here a user that has the restricted privileges that are listed in "Restricting database user permissions for IBM MobileFirst Platform Server runtime operations" on page 6-31.

Configuring the Cloudant databases manually:

Use JNDI properties to configure the Cloudant databases.

Procedure

Configure the Cloudant database by setting JNDI properties in the relevant application server.

No manual configuration is necessary from the Cloudant perspective. If the database for the project runtime does not exist, and if the Cloudant user that is provided to the project runtime is the Cloudant administrator, then the database is automatically created when the MobileFirst project environment is started. If the user that is provided to the project runtime is not allowed to create a database, you must create a database with the names that are documented at "Creating the Cloudant database" on page 12-9.

What to do next

For more information about MobileFirst runtime configuration with Cloudant, see "Deploying a project WAR file and configuring the application server manually."

Deploying a project WAR file and configuring the application server manually:

The procedure to manually deploy your app to an application server depends on the type of application server being configured, as detailed here. Depending on the version of the product that was used to build the project WAR file and the version of MobileFirst Server, you might need to migrate the WAR file first.

When the version of IBM MobileFirst Platform Foundation produces a WAR file that is not compatible with the version of MobileFirst Server, you must migrate the project WAR file to the current MobileFirst Server version to ensure a successful manual deployment. All fix packs of a product version are compatible in that sense, and so you do not need to migrate associated project WAR files. For example, if you build a project WAR file by using MobileFirst Studio V6.0.0 and want to deploy it manually to MobileFirst Server V6.0.0.1, you do not need to migrate the WAR file. WAR file migration is necessary if MobileFirst Studio and MobileFirst Server are of different versions. For example, if you build a project WAR file by using MobileFirst Studio V6.0.0 and want to deploy it to MobileFirst Server V6.1.0, you must migrate the WAR file before you deploy it manually. Project WAR files need to be migrated because they contain information that is specific to the MobileFirst Server version. The migration updates the version-specific information in the WAR file, thus making it suitable to run on the new version of MobileFirst Server.

Only WAR files produced by MobileFirst Studio from V5.0.6 and later can be migrated: earlier versions are not supported.

These manual configuration instructions assume that you are familiar with your application server.

Note: Using the Ant task to deploy the project WAR file and configure the application server is more reliable than installing and configuring manually, and should be used whenever possible.

Migrating a project WAR file for use with a new MobileFirst Server:

Use Ant tasks to migrate a project WAR file so that you can deploy it manually to a new version of MobileFirst Server.

You migrate a project WAR file by running a `<migrate>` Ant task, which is included in the `worklight-ant-deployer.jar` library. You can migrate `.war` files that are developed in V5.0.6 of this product and later. To run the Ant task, you invoke it from an Ant XML file similar to the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<project name="MigrateWarFile" default="migrate" basedir=".">
  <target name="migrate">
    <echo message="Loading Ant Tool" />
    <taskdef resource="com/worklight/ant/defaults.properties">
      <classpath>
        <pathelement location="worklight-ant-deployer.jar" />
      </classpath>
    </taskdef>
    <migrate sourceWarFile="d:/myOldWarFolder/myProject.war" destWarFile="d:/myNewWarFolder/myMigratedProject.war"/>
  </target>
</project>
```

The `<migrate>` task accepts the following input parameters:

sourceWarFile

(mandatory) The path to the source project WAR file. The path must not contain spaces.

destWarFile

(optional) The destination file for the migrated WAR file. Default value: `<source-war-folder>/migrated-to-<new version number>/<source-war-filename>`.

Configuring the Liberty profile manually:

To configure the WebSphere Application Server Liberty profile manually, you must modify the `server.xml` file and declarations for the runtime and the IBM MobileFirst Platform Operations Console.

Before you begin

See “Planning deployment of administration components and runtimes” on page 6-19 for the supported deployment topologies.

Review the environment IDs. Environment IDs are optional, but if you do specify one, the identifier must meet the following two conditions:

- Its value must be the same for each MobileFirst runtime environment that is managed by the same MobileFirst Server administration component.

- Its value must match the environment ID that is used when the MobileFirst Server administration component is installed.

The environment ID is defined as an application JNDI variable, prefixed by the context root of the application. See step 7 on page 12-40.

About this task

In addition to modifications for the databases that are described in “Creating and configuring the databases manually” on page 12-20, you must make the following modifications to the `server.xml` file.

Note: In the following procedure, when the example uses the `worklight.war` project file, use the name of your MobileFirst project, for example, `myProject.war`.

Procedure

1. In the installation directory of Liberty, open the *user data* directory.
 - If the installation directory of Liberty contains a `etc/server.env` file and if this file defines a `WLP_USER_DIR` variable, the *user data* directory is the value of this variable.
 - Otherwise, it is the `usr` directory in the installation directory of Liberty.
2. Copy the MobileFirst JAR file into the `shared/resources/lib/` directory that is in the *user data* directory.

If there is no `etc/server.env` file in the installation directory of Liberty, enter the following commands, according to your operating system:

- On UNIX and Linux:

```
mkdir -p WLP_DIR/usr/shared/resources/lib
cp product_install_dir/WorklightServer/worklight-jee-library.jar WLP_DIR/usr/shared/resources/lib
```

- On Windows:

```
mkdir WLP_DIR\usr\shared\resources\lib
copy /B product_install_dir\WorklightServer\worklight-jee-library.jar WLP_DIR\usr\shared\resources\lib\worklight-jee-library.jar
```

3. Ensure that the `<featureManager>` element contains at least the following `<feature>` elements:
 - For WebSphere Application Server Liberty profile V8.5.0.x:

```
<feature>ssl-1.0</feature>
<feature>servlet-3.0</feature>
<feature>jdbc-4.0</feature>
```

- For WebSphere Application Server Liberty profile V8.5.5.0 and later:

```
<feature>jdbc-4.0</feature>
<feature>servlet-3.0</feature>
<feature>ssl-1.0</feature>
```

4. Copy the `worklight.war` file to the `apps` directory of the Liberty server.

Note: The `apps` directory is in the same directory as the `server.xml` file.

5. Add the following declarations in the `<server>` element for the MobileFirst runtime.

Important:

- The `id` attribute of the `privateLibrary` tag must identify a unique MobileFirst runtime. By convention, it takes this form: `<privateLibrary id="worklightlib_<context root">`

- The version number of the `com.ibm.ws.crypto.passwordutil_*.jar` cryptographic JAR file might change according to the version of WebSphere Application Server Liberty profile or its fix packs.

```
<!-- Declare the MobileFirst Server application. -->
<application id="worklight" name="worklight" location="worklight.war" type="war">
  <classloader delegation="parentLast">
    <privateLibrary id="worklightlib_worklight">
      <fileset dir="{shared.resource.dir}/lib" includes="worklight-jee-library.jar"/>
      <fileset dir="{wlp.install.dir}/lib" includes="com.ibm.ws.crypto.passwordutil_*.jar"/>
    </privateLibrary>
  </classloader>
</application>
```

```
<!-- Declare web container custom properties for the MobileFirst Server application. -->
<webContainer invokeFlushAfterService="false"/>
```

This declaration installs the MobileFirst Server application with the context root `/worklight`. If you want to assign a different context root `/app_context`, start the declaration with one of the following code snippets:

```
<application id="app_context" name="app_context" location="worklight.war" type="war">
```

Or:

```
<application id="worklight" name="worklight" location="worklight.war" context-root="/app_context" type="war">
```

In either case, also change the `privateLibrary` tag accordingly: `<privateLibrary id="worklightlib_app_context">`

6. If the database is Oracle, add the `commonLibraryRef` attribute to the class loader of the worklight runtime application.

```
...
<classloader delegation="parentLast" commonLibraryRef="OracleLib">
...
```

The name of the library reference (`OracleLib` in this example) must be the ID of the library that contains the JDBC JAR file. This ID is declared in the procedure that is documented in “Configuring Liberty profile for Oracle manually for MobileFirst Server administration” on page 6-89.

7. If the MobileFirst Server administration component uses an environment ID, declare that environment ID for MobileFirst Server application:

```
<jndiEntry jndiName="worklight/ibm.worklight.admin.environmentid" value="ValueOfEnvironmentID"/>
```

- `worklight` is the context root of the MobileFirst Server application. If you choose another value in previous step, replace `worklight` with that value.
- Replace `ValueOfEnvironmentID` with the value that is used for the MobileFirst Server administration component.

8. If you want to use Cloudant as the database for the MobileFirst runtime you defined in step 5 on page 12-39, then add the following JNDI properties:

```
<!-- Declare the JNDI properties for the IBM Worklight project runtime for Cloudant. -->
<jndiEntry jndiName="worklight/mfp.db.cloudant.url" value="https://cloudant.com:443"/>
<jndiEntry jndiName="worklight/mfp.db.cloudant.username" value="wuser"/>
<jndiEntry jndiName="worklight/mfp.db.cloudant.password" value="password"/>
```

- `worklight` is the context root of the MobileFirst Server application. If you choose another value in previous step, replace `worklight` with that value.
- Replace `https://cloudant.com:443` with the URL to connect to Cloudant.
- Replace `wuser` with the name of the user that has access the MobileFirst runtime database. If this user is not allowed to create a database, you must create a database manually, with the names that are documented in “Creating the Cloudant database” on page 12-9.

- Replace password with the password associated with this user.

Note: Each project using Cloudant as a database needs its own database. By default, the database includes the project name. But if several teams use the same Cloudant database with projects that have same names, add JNDI property `mfp.db.cloudant.dbNamePrefix` to distinguish the projects as indicated below, and replace *your_prefix* with a value of your choosing.

```
<jndiEntry jndiName="worklight/mfp.db.cloudant.dbNamePrefix" value="your_prefix" />
```

Important: The Cloudant database name must start with a lowercase letter, and can contain only lowercase characters (a-z), digits (0-9), and any of the following characters: `_`, `$`, `-`.

The value that you specify for the variable `mfp.db.cloudant.dbNamePrefix` must comply with this rule.

9. If you installed MobileFirst Operational Analytics, and you want it to collect data from the MobileFirst runtime, add the following JNDI properties:

```
<jndiEntry jndiName ="worklight/wl.analytics.url" value = "http://analytics.host:port/analytics-service/data" />
<jndiEntry jndiName ="worklight/wl.analytics.console.url" value = "http://analytics.host:port/analytics/console" />
<jndiEntry jndiName ="worklight/wl.analytics.username" value = "wlanalyticsuser" />
<jndiEntry jndiName ="worklight/wl.analytics.password" value = "wlanalyticspassword" />
```

- `worklight` is the context root of the MobileFirst Server application. If you select another value in the previous step, replace `worklight` with that value.
- Replace `analytics.host:port` with the host name and port of the server where you installed MobileFirst Operational Analytics.
- Replace `wlanalyticsuser` with the name of the user who has access to MobileFirst Operational Analytics.
- Replace `wlanalyticspassword` with the password that is associated with this user.

Note: The user name and password that you provide in replacement of `wlanalyticsuser` and `wlanalyticspassword` must match the credentials of the user that you defined in the server where MobileFirst Operational Analytics is installed.

Related reference:

“JNDI environment entries for MobileFirst projects in production” on page 12-68
JNDI environment entries cover all the properties that you can set in a production environment. Set production environment properties by configuring your project WAR file with JNDI environment entries.

Related information:

 [WebSphere Application Server documentation about Deploying application to the Liberty Profile](#)

Configuring WebSphere Application Server manually:

To configure WebSphere Application Server manually, you must configure variables, custom properties, and class loader policies.

Before you begin

See “Planning deployment of administration components and runtimes” on page 6-19 for the supported deployment topologies.

If you use Cloudant via https as a database, and WebSphere Application Server full profile as an application server, declare the Cloudant signer certificate, as described in “Configuring WebSphere Application Server for use with Cloudant” on page 6-68.

Find the SOAP port of the deployment manager (WebSphere Application Server Network Deployment only)

These instructions assume that a stand-alone profile exists with an application server named “Worklight” and that the server is using the default ports.

For WebSphere Application Server Network Deployment, find the SOAP port of the deployment manager:

1. Open the System Administration/Deployment manager.
2. In Additional properties, open **Ports**.
3. Note the value of **SOAP_CONNECTOR_ADDRESS**. This value is needed to set the value of the **ibm.worklight.admin.jmx.dmgr.port** environment entry for the MobileFirst Administration Services.

Review the environment IDs

Specifying an environment ID is optional. However, if you specify an ID, use the same value for each MobileFirst runtime environment that is managed by the same MobileFirst Server administration component. Moreover, this value must match the environment ID that is used when the MobileFirst Server administration component is installed. For more information about the **ibm.worklight.admin.environmentid** JNDI property, see “JNDI environment entries for MobileFirst projects in production” on page 12-68.

Note: If you use WebSphere Application Server V7.0, you must add the configuration property “com.ibm.ws.webcontainer.invokerequestlistenerforfilter = true”. For more information about how to add this property, see “Configuring WebSphere Application Server V7.0” on page 6-70.

Procedure

1. Determine a suitable file name for the MobileFirst shared library in the WebSphere Application Server installation directory.
 - For a standalone server, you can use a file name such as `WAS_INSTALL_DIR/optionalLibraries/IBM/project-name/worklight-jee-library.jar`.
 - For deployment to a WebSphere Application Server Network Deployment cell, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/project-name/worklight-jee-library.jar`.
 - For deployment to a WebSphere Application Server Network Deployment cluster, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/clusters/cluster-name/project-name/worklight-jee-library.jar`.
 - For deployment to a WebSphere Application Server Network Deployment node, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/project-name/worklight-jee-library.jar`.
 - For deployment to a WebSphere Application Server Network Deployment server, use `WAS_INSTALL_DIR/profiles/profile-name/config/cells/cell-name/nodes/node-name/servers/server-name/project-name/worklight-jee-library.jar`.

If the directory does not exist, you must create it.

2. Copy the file *product_install_dir/WorklightServer/worklight-jee-library.jar* to the location that you determined in step 1.
3. Log on to the WebSphere Application Server administration console for your MobileFirst Server.
The address is of the form `http://server.com:9060/ibm/console`, where *server* is the name of the server.
4. Create the MobileFirst shared library definition:
 - a. Click **Environment > Shared libraries**.
 - b. From the **Scope** list, select **Worklight server**.
 - c. Click **New**. The Configuration pane is displayed.
 - d. In the **Name** field, type `WL_PLATFORM_LIB`.
 - e. Optional: In the **Description** field, type a description of the library.
 - f. In the **Classpath** field, enter the file name that you determined in step 1, replacing `WAS_INSTALL_DIR/profiles/profile-name` with the WebSphere Application Server variable reference `${USER_INSTALL_ROOT}`.
 - g. In **Class Loading**, select the check box **Use an isolated class loader for this shared library**.
5. Create the MobileFirst JDBC data source and provider.

Note: You do not need to perform this step if you use Cloudant as a database. See the instructions for the appropriate DBMS in “Creating and configuring the databases manually” on page 12-20.

6. Add a specific web container custom property.
 - a. Click **Servers > Server Types > Application Servers**, and select the server for IBM MobileFirst Platform Foundation.
 - b. Click **Web Container Settings > Web container**.
 - c. Click **Custom properties**.
 - d. Click **New**.
 - e. Enter the property values listed in the following table.

Table 12-4. Values for the web container custom property.

Property	Value
Name	<code>com.ibm.ws.webcontainer.invokeFlushAfterService</code>
Value	<code>false</code>
Description	See http://www.ibm.com/support/docview.wss?uid=swg1PM50111

- f. Click **OK**.
 - g. Click **Save**.
7. Install a MobileFirst project WAR file.
Note: In the following procedure, when the example uses `worklight.war`, use the name of your MobileFirst project, for example, `myProject.war`.
 - a. Depending on your version of WebSphere Application Server, click one of the following options:
 - **Applications > New > New Enterprise Application**
 - **Applications > New Application > New Enterprise Application**
 - b. Navigate to the MobileFirst Server installation directory *product_install_dir/WorklightServer*.

- c. Select `worklight.war`, and then click **Next**.
- d. On the "How do you want to install the application?" page, select **Detailed**, and then click **Next**.
- e. On the Application Security Warnings page, click **Continue**.
- f. Click **Continue** repeatedly until you reach Step 4 of the wizard: Map Shared Libraries.
- g. Select **Select** for `worklight_war` and click **Reference shared libraries**.
- h. From the Available list, select `WL_PLATFORM_LIB` and click **>**.
- i. Click **OK**.
- j. Click **Next** until you reach the "Map resource references to resources" page.
- k. If you use a relational database, enter the JNDI name you created in step 5 on page 12-43 for the `jdbc/WorklightDS` data source.
- l. You must also enter a default data source in the following cases:
 - You do not use the reports database, whose resource reference is `jdbc/WorklightReportsDS`. The reports database is not used by default. For more information, see "(deprecated) Reports database" on page 14-99.
 - You do not need any relational database because you use Cloudant. The data source is not used in this case.

To enter a default data source, enter `DefaultDatasource` in the **Target Resource JNDI Name** field. If the `DefaultDatasource` does not exist in your application server, a message displays **Application Resource Warning** when you quit the page. Ignore the warning and click **Continue**.

- m. Click **Next** until you reach the "Map context roots for web modules" page.
- n. In the **Context Root** field, type `/worklight`.
- o. Click **Next**.
- p. In **Map environment Entries for Web Module**, you can assign the JNDI variables according to your configuration.
 - Set the variable `ibm.worklight.topology.platform` to WAS
 - Set the variable `ibm.worklight.admin.jmx.connector` to SOAP
 - If the environment ID is set for the Administration Services, set the variable `ibm.worklight.admin.environmentid` to the same value.
 - On a stand-alone WebSphere Application Server, set the value of `ibm.worklight.topology.clustermode` to Standalone
 - On WebSphere Application Server Network Deployment, set the variables as follows:
 - `ibm.worklight.topology.clustermode`: Cluster
 - `ibm.worklight.admin.jmx.dmgr.host`: the host name of the deployment manager
 - `ibm.worklight.admin.jmx.dmgr.port`: the SOAP port of the deployment manager
 - If you want to use Cloudant as the database for the MobileFirst runtime, set the variables as follows:
 - `mfp.db.cloudant.url`: the URL to connect to Cloudant
 - `mfp.db.cloudant.username`: the Cloudant account user name
 - `mfp.db.cloudant.password`: the Cloudant account password

Notes:

- If this user is not allowed to create a database, you must create a database manually with the names that are documented in “Creating the Cloudant database” on page 12-9.
- Each project that uses Cloudant as a database must have its own database. By default, the database includes the project name. But if several teams use the same Cloudant database with projects that have same names, add the JNDI property **mfp.db.cloudant.dbNamePrefix** to distinguish the projects.

Important: The Cloudant database name must start with a lowercase letter, and can contain only lowercase characters (a-z), digits (0-9), and any of the following characters: `_`, `$`, `-`.

The value that you specify for the variable `mfp.db.cloudant.dbNamePrefix` must comply with this rule.

- If you installed MobileFirst Operational Analytics, and you want it to collect data from the MobileFirst runtime, set the variables as follows:
 - `wl.analytics.url` is the URL to connect to a server where MobileFirst Operational Analytics Services is installed.
 - `wl.analytics.console.url` is the URL to connect to a server where MobileFirst Operational Analytics Console is installed.
 - `wl.analytics.username` is the user name used for a basic authentication to access the URL that you entered in `wl.analytics.url`.
 - `wl.analytics.password` is the password for the user that you entered in `wl.analytics.username`.

Note: The user name and password that you provide in `wl.analytics.username` and `wl.analytics.password` must match the credentials of the user that you defined in the server where MobileFirst Operational Analytics is installed.

- q. Click **Finish**.
8. Optional: As an alternative to step 6, you can map the shared libraries as follows:
 - a. Click **Applications > Application Types > WebSphere enterprise applications > worklight_war**.
 - b. In the References section, click **Shared library references**.
 - c. Select **Select** for `worklight_war` and click **Reference shared libraries**.
 - d. From the Available list, select `WL_PLATFORM_LIB` and click **>**.
 - e. Click **OK** twice to return to the `worklight_war` configuration page.
 - f. Click the **Save** link.
9. Define the startup behavior.
 - a. Click **Applications > Application Types > WebSphere enterprise applications > worklight_war**.
 - b. Click **Startup behavior**.
 - c. In **Startup Order**, enter 2.

Note: The MobileFirst Administration service must already be available when the MobileFirst runtime starts.

10. Configure the class loader policies and then start the application:

- a. Click the **Manage Applications** link, or click **Applications > WebSphere Enterprise Applications**.
 - b. From the list of applications, click **worklight_war**.
 - c. In the “Detail Properties” section, click the **Class loading and update detection** link.
 - d. In the “Class loader order” pane, click **Classes loaded with local class loader first (parent last)**.
 - e. Click **OK**.
 - f. In the Modules section, click **Manage Modules**.
 - g. From the list of modules, click the MobileFirst module.
 - h. In the “Class loader order” pane, click **Classes loaded with local class loader first (parent last)**.
 - i. Click **OK** twice.
 - j. Click **Save**.
 - k. Select **Select** for **worklight_war** and click **Start**.
11. Review the server class loader policy: Click **Servers > Server Types > Application Servers > Worklight**
 - If the class loader policy is set to **Multiple**, do nothing.
 - If the class loader policy is set to **Single** and the class loading mode is set to **parent-last**, do nothing.
 - If the class loader policy is set to **Single** and the class loading mode is set to **parent-first**, change the class loader policy to **Multiple**, and set the class loader order of all applications other than MobileFirst applications to **parent-first**.
 12. For WebSphere Application Server Network Deployment, click **System administration > Nodes**, select the nodes, and click **Full Synchronize**.

Results

You can now view the runtime component from the MobileFirst Administration Console that is installed in “Installing the MobileFirst Server administration” on page 6-58. The default URL of the MobileFirst Administration Console is `http://<server>:<port>/worklightconsole`, where *server* is the host name of your server and *port* is the port number (default value 9080).

Configuring Apache Tomcat manually:

To configure Apache Tomcat manually, you must copy JAR and WAR files to Tomcat, add database drivers, edit the `server.xml` file, and then start Tomcat.

Before you begin

See “Planning deployment of administration components and runtimes” on page 6-19 for the supported deployment topologies.

Review the environment IDs. Specifying an environment ID is optional. However, if you specify an ID, use the same value for each MobileFirst runtime environment that is managed by the same MobileFirst Server administration component. Moreover, this value must match the environment ID that is used when the MobileFirst Server administration component is installed. For more information about the `ibm.worklight.admin.environmentid` JNDI property, see “JNDI environment entries for MobileFirst projects in production” on page 12-68.

Procedure

1. Copy the MobileFirst JAR file to the Tomcat lib directory:
 - On UNIX and Linux systems: `cp product_install_dir/WorklightServer/worklight-jee-library.jar tomcat_install_dir/lib`
 - On Windows systems: `copy /B product_install_dir\WorklightServer\worklight-jee-library.jar tomcat_install_dir\lib\worklight-jee-library.jar`
2. Add the database drivers to the Tomcat lib directory. See the instructions for the appropriate DBMS in “Creating and configuring the databases manually” on page 12-20.
3. Copy the MobileFirst project WAR file to the Tomcat web application directory, `tomcat_install_dir/webapps`, and rename it according to the context root. For example:
 - If the context root is `/worklight`, rename it to `worklight.war`.
 - If the context root is `/`, rename it to `R00T.war`.
4. Edit `tomcat_install_dir/conf/server.xml` to declare the context and properties of the MobileFirst application:

```
<!-- Declare the MobileFirst runtime environment. -->
<Context path="/worklight" docBase="worklight">
  <Environment name="ibm.worklight.topology.platform" value="Tomcat" type="java.lang.String" override="false"/>
  <Environment name="ibm.worklight.topology.clusterMode" value="Standalone" type="java.lang.String" override="false"/>
  <!-- Declare the worklight and worklight reports databases. -->
  <!-- <Resource name="jdbc/WorklightDS" type="javax.sql.DataSource" ... /> -->
  <!-- <Resource name="jdbc/WorklightReportsDS" type="javax.sql.DataSource" ... /> -->
</Context>
```

Where you must uncomment and complete the `<Resource>` element to declare the administration database as described in the following sections:

- “Configuring Apache Tomcat for DB2 manually” on page 12-24
- “Configuring Apache Tomcat for Derby manually” on page 12-28
- “Configuring Apache Tomcat for MySQL manually” on page 12-32
- “Configuring Apache Tomcat for Oracle manually” on page 12-36

Make sure that the path and docBase attributes are both consistent with the WAR file name. That is, if the WAR file name is `worklight.war`, set the path to `/worklight` and the docBase to `worklight`. Whereas if the WAR file name is `R00T.war`, set the path to `"` and the docBase to `"R00T"`.

If the environment ID is set for the Administration Services, set the variable `ibm.worklight.admin.environmentid` to the same value.

5. If you want to use Cloudant as the database for the MobileFirst runtime that you defined in step 4, add the following JNDI properties inside the `<Context path="/worklight" docBase="worklight">` element.

```
<Environment name="https://cloudant.com:443" type="java.lang.String" override="false"/>
<Environment name="mfp.db.cloudant.username" value="wuser" type="java.lang.String" override="false"/>
<Environment name="mfp.db.cloudant.password" value="password" type="java.lang.String" override="false"/>
```

- Replace `https://cloudant.com:443` with the URL to connect to Cloudant.
- Replace `wuser` with the name of the user who has access to the MobileFirst runtime database. If this user is not allowed to create a database, you must create a database manually, with the names that are documented in “Creating the Cloudant database” on page 12-9.
- Replace `password` with the password associated with this user.

Note: Each project using Cloudant as a database needs its own database. By default, the database includes the project name. But if several teams use the same Cloudant database with projects that have same names, add JNDI

property `mfp.db.cloudant.dbNamePrefix` to distinguish the projects as indicated below, and replace `your_prefix` with a value of your choosing.

```
<Environment name="mfp.db.cloudant.dbNamePrefix" value="your_prefix" type="java.lang.String" override="false"/>
```

Important: The Cloudant database name must start with a lowercase letter, and can contain only lowercase characters (a-z), digits (0-9), and any of the following characters: `_`, `$`, `-`.

The value that you specify for the variable `mfp.db.cloudant.dbNamePrefix` must comply with this rule.

6. If you installed MobileFirst Operational Analytics, and you want it to collect data from the MobileFirst runtime, add the following JNDI properties:

```
<Context docBase ="worklight" path ="/worklight">
...
<Environment name ="wl.analytics.url" value ="http://analytics.host:port/analytics-service/data" type ="java.lang.String" over
<Environment name ="wl.analytics.console.url" value ="http://analytics.host:port/analytics/console" type ="java.lang.String" o
<Environment name ="wl.analytics.username" value ="wlanalyticsuser" type ="java.lang.String" override ="false"/>
<Environment name ="wl.analytics.password" value ="wlanalyticspassword" type ="java.lang.String" override ="false"/>
...
</Context>
```

- `worklight` is the context root of the MobileFirst Server application. If you select another value in the previous step, replace `worklight` with that value.
- Replace `analytics.host:port` with the host name and port of the server where you installed MobileFirst Operational Analytics.
- Replace `wlanalyticsuser` with the name of the user who has access to MobileFirst Operational Analytics.
- Replace `wlanalyticspassword` with the password that is associated with this user.

Note: The user name and password that you provide in replacement of `wlanalyticsuser` and `wlanalyticspassword` must match the credentials of the user that you defined in the server where MobileFirst Operational Analytics is installed.

7. Start Tomcat.

Related reference:

“JNDI environment entries for MobileFirst projects in production” on page 12-68
JNDI environment entries cover all the properties that you can set in a production environment. Set production environment properties by configuring your project WAR file with JNDI environment entries.

Related information:

 [WebSphere Application Server documentation about Deploying application to the Liberty Profile](#)

Completing the deployment of a project WAR file:

To complete the deployment, you may need to restart the application server.

When the project WAR file is deployed on the application server, you must restart the application server in the following circumstances:

- When you used the `<configureApplicationServer>` Ant task or the manual instructions for deploying the project WAR file:
 - If you are using WebSphere Application Server with DB2 as database type for one or both of the databases.

- If you are using WebSphere Application Server Liberty profile or Apache Tomcat.
- When you used the <updateApplicationServer> Ant task:
 - If you are using WebSphere Application Server (full profile or Liberty profile) and the MobileFirst runtime library (worklight-jee-library.jar) is changed.
 - If you are using Apache Tomcat.

If you are using WebSphere Application Server Network Deployment and you deployed to managed servers through the deployment manager:

- You must restart the servers that were running during the deployment and on which the MobileFirst project web application has been installed.
To restart these servers with the deployment manager console, select **Applications > Application Types > WebSphere enterprise applications > IBM_Worklight_Console > Target specific application status**.
- You do not have to restart the deployment manager or the node agents.

Declaring the Cloudant SSL configuration for a project WAR file

If you deploy a project WAR file into WebSphere Application Server or WebSphere Application Server Network Deployment, you use a Cloudant database, and meet specific criteria described in this topic, you must declare the Cloudant SSL configuration.

About this task

You must perform this procedure if you meet all of the following criteria:

- You are deploying a project WAR file into WebSphere Application Server or WebSphere Application Server Network Deployment.
- You use a Cloudant database for this web application.
- The Cloudant database server URL uses the https protocol.
- You created a separate SSL configuration for Cloudant, as described in “Configuring WebSphere Application Server for use with Cloudant” on page 6-68, but did not create a dynamic outbound configuration for it.

Procedure

1. Log in to the WebSphere Application Server console.
2. Select **Applications > Application Types > WebSphere enterprise applications**.
3. Click the web application that corresponds to the project WAR file.
4. In the **Web Module Properties** section, select **Environment entries for Web modules**.
5. Set the value of the property `mfp.db.cloudant.ssl.configuration` to the name of the SSL configuration that you created.
6. Click **OK**.
7. Click **Save**.

Configuring multiple MobileFirst projects in different environments

Different environments operate independently. For example, with this approach you can host a test environment, a pre-production environment, and a production environment on the same server or in the same WebSphere Application Server Network Deployment cell.

You can configure multiple projects, either with the same Administration Services and MobileFirst Operations Console, or with separate MobileFirst environments. An environment consists of the following web applications:

- The Administration Services web application,
- Optionally, the MobileFirst Operations Console web application,
- Some MobileFirst runtime environments or project web applications, each with the appropriate database schemas.

According to your installation method, you specify the environment as follows:

- If you install with Ant tasks, specify it through the attribute `environmentId` in the `<installworklightadmin>` and `<configureapplicationserver>` invocations.
- If you install manually, specify it through the JNDI property `ibm.worklight.admin.environmentid` of the Administration Services application, and of the project WAR file.

If you use this approach, you must respect the following constraints:

- Each Administration Services application must use a different administration database or schema.
- Each configuration for a MobileFirst runtime environment must use a different runtime database or schema, and its own reports database or schema.
- Each configuration for a MobileFirst runtime environment must be deployed with the same `environmentId` attribute as the corresponding Administration Services.
- If the application server is WebSphere Application Server Liberty profile, each MobileFirst project must use a different `contextroot` attribute and have a different base name for the `.war` file. But you can rename a `.war` file before you install it. The `id` attribute of the Ant tasks is not used in this case.
- If the application server is WebSphere Application Server full profile or WebSphere Application Server Network Deployment, each MobileFirst project must use either a different `environmentId` attribute or, when installed with Ant tasks and with the same `environmentId`, a different `id` attribute. Different deployments with the same `contextroot` attribute are possible, if they are deployed to separate sets of servers (for example, to different clusters or to different nodes).
- If the application server is Apache Tomcat, each MobileFirst project must use a different `contextroot` attribute. In addition, the versions of the JDBC drivers must be suitable for all declared data sources of the particular database type.

Configuration of MobileFirst applications on the server

You can configure each MobileFirst application by specifying a set of configuration parameters on the server side.

MobileFirst application configuration parameters configure the database, push notifications, the use of SSL to secure communications between the server and the client application, and other settings.

When you develop a MobileFirst application, you use the `worklight.properties` file to specify most of the configuration parameters. This file is in the `server/conf` folder in the project. You use the `worklight.properties` file during development to test a particular configuration. For example, if you want to use the analytics features during development, you might set the `wl.analytics.url` property to a valid URL in the `worklight.properties` file.

When your MobileFirst project is built by MobileFirst Studio, the project WAR file that is created in the project bin folder contains the configuration that is specified in the `worklight.properties` file. The values for the parameters that are specified in the `worklight.properties` file then define the default configuration of your application.

When you deploy your project (your WAR file) to the production or test environment, your configuration is certain to be different from the development environment. It is easy to modify the configuration to fit the new environment because the project WAR file defines JNDI environment entries for each parameter that can be configured in a production environment. You leave the values in the `worklight.properties` file unchanged; instead, you specify the configuration during the deployment to the application server.

See “JNDI environment entries for MobileFirst projects in production” on page 12-68 to learn about the JNDI environment entries that you can specify in a production environment. Properties that are relevant only in development environments are not available as JNDI entries.

Within the `worklight.properties` file, you can define some application-specific configuration properties; for example, to configure the URL of a service that is called from the mobile application and the URL is different in production, development, and test environments. See “Declaring and using application-specific configuration properties” on page 12-64 to learn how to create such configuration properties.

Configuring the IBM MobileFirst Platform Server location

You can configure the MobileFirst Server location by specifying configuration properties.

In production, you must configure your server location in the following circumstances:

- You are using relative path for the `onLoginUrl` parameter in the `authenticationConfig.xml` file.
- You are generating the URL for mobile web and desktop browser apps from the console.

In most cases, production servers sit behind a reverse proxy; therefore, their machine IP address (which is the default value of `publicWorkLightHostname`) is not used for accessing them from the outside world.

To configure the MobileFirst Server location, set the values of the following properties:

Table 12-5. MobileFirst Server location properties

Property name	Description
publicWorkLightHostname	<p>The IP address or host name of the computer running IBM MobileFirst Platform Foundation.</p> <p>If the MobileFirst Server is behind a reverse proxy, the value is the IP address or host name of the reverse proxy.</p> <p>This property must be identical for nodes within the same cluster.</p> <p>Default: IP address of current server.</p>
publicWorkLightPort	<p>The port for accessing the MobileFirst Server.</p> <p>If the MobileFirst Server is behind a reverse proxy, the value is the port for accessing the reverse proxy.</p> <p>This property must be identical for nodes within the same cluster.</p> <p>Default: 10080.</p> <p>The <configureApplicationServer> Ant task sets a default value that depends on the application server.</p>
publicWorkLightProtocol	<p>The protocol for accessing the MobileFirst Server.</p> <p>The valid values are HTTP and HTTPS. If the MobileFirst Server is behind a reverse proxy, the value is the protocol for accessing the reverse proxy.</p> <p>This property must be identical for nodes within the same cluster.</p> <p>Default: HTTP.</p> <p>The <configureApplicationServer> Ant task sets a default value that depends on the application server.</p>

For descriptions of other configuration properties, see “JNDI environment entries for MobileFirst projects in production” on page 12-68.

For information about how to specify configuration properties, see “Configuration of MobileFirst applications on the server” on page 12-50.

Runtime database setup for development mode

IBM MobileFirst Platform Foundation uses defaults to access the runtime database, which kind is WRKLGHT by default. When you work in a development environment and use JDBC to connect to a database, you can use a set of property keys to change the settings. You can also use a set of properties to configure Cloudant as the runtime database.

Attention:

This method of declaring data sources is deprecated in a production environment and is only suitable when working in a development environment and using JDBC for database connections. To configure data sources when working in a production environment, see “Creating and configuring the databases manually” on page 12-20.

Property keys and values for JDBC-based properties

Property Key	Property Value
<code>wl.db.url</code>	JDBC path to the runtime database.
<code>wl.db.username</code>	Runtime database user name. Default: Worklight
<code>wl.db.password</code>	Runtime database password. Default: Worklight
<code>wl.db.driver</code>	The class that implements a JDBC driver for each vendor. For example: MySQL: <code>com.mysql.jdbc.Driver</code> Oracle: <code>oracle.jdbc.OracleDriver</code> DB2: <code>com.ibm.db2.jcc.DB2Driver</code> Derby: <code>org.apache.derby.jdbc.EmbeddedDriver</code>
<code>wl.reports.db.url (*)</code>	JDBC path to the reports database Default: refers to runtime database. Note: Deprecated in V7.1.0. Use “Operational analytics” on page 14-9 instead.
<code>wl.reports.db.username (*)</code>	Reports database user name. Default: refers to Worklight database. Note: Deprecated in V7.1.0. Use “Operational analytics” on page 14-9 instead.
<code>wl.reports.db.password (*)</code>	Reports database password Default: refers to runtime database. Note: Deprecated in V7.1.0. Use “Operational analytics” on page 14-9 instead.

Note: (*) By default all report mechanisms in MobileFirst Server use a single reports database. The reports database is set to be the same as the runtime database. For more information about how this default setting can be changed, see “Using raw data reports” on page 14-103.

To configure the MobileFirst project to use Cloudant as the runtime database configure your Cloudant credentials (user name and password). Once these credentials are configured, the server uses Cloudant as the runtime database and not the default JPA.

In addition, you can configure the following properties:

Property keys and values for Cloudant configuration

Property Key	Property Value
<code>mfp.db.cloudant.username</code>	The user name of the Cloudant account.
<code>mfp.db.cloudant.password</code>	The password of the Cloudant account.
<code>mfp.db.cloudant.url</code>	Optional. The URL of the Cloudant account.
<code>mfp.db.cloudant.dbNamePrefix</code>	Optional. The prefix that is added to the database name of the MobileFirst runtime. For example, if the value <code>department</code> is assigned to this attribute and the context root of your MobileFirst runtime is <code>/mfp</code> , the database name is <code>department_mfp_runtime_db</code> . Important: This prefix must start with a lowercase letter, and can contain only lowercase characters (a-z), digits (0-9), and any of the following characters: <code>_</code> , <code>\$</code> and <code>-</code> .
<code>mfp.db.cloudant.connectTimeout</code>	Optional. The timeout to establish a connection, in milliseconds. A value of zero means an infinite timeout.
<code>mfp.db.cloudant.socketTimeout</code>	Optional. The timeout to wait for a response, in milliseconds. A value of zero means an infinite timeout.
<code>mfp.db.cloudant.maxConnections</code>	Optional. The maximum number of connections to the database.
<code>mfp.db.cloudant.proxyHost</code>	Optional. The host name to connect through the proxy.
<code>mfp.db.cloudant.proxyPort</code>	Optional. The proxy port.

Configuring session dependency

You can control session dependency by configuring the relevant properties.

The properties described in this page became available starting from IBM MobileFirst Platform Foundation V7.1.0.

Table 12-6. MobileFirst Server session dependency properties.

Property name	Description
<code>mfp.session.independent</code>	Turns session dependency in MobileFirst Server on or off. Options are: <ul style="list-style-type: none"> • <code>true</code>: session independent • <code>false</code>: session dependent Default: <code>true</code>

Table 12-6. MobileFirst Server session dependency properties (continued).

Property name	Description
mfp.attrStore.type	<p>Specifies the attribute store type.</p> <p>Options are:</p> <ul style="list-style-type: none"> • database: the attribute store is kept on the IBM MobileFirst Platform Foundation runtime database: either a relational or Cloudant database • extremescale: the attribute store is kept on eXtreme Scale • httpsession: the attribute store is kept on the HTTP session. This value is supported only if mfp.session.independent has been set to false, otherwise, the server will not start. • datacache: the attribute store is cached in the Data Cache service on Bluemix. <p>Default: database</p>

For information about configuring attribute store cleanup, see “Configuring the attribute store cleanup task.”

For more information about session dependency, see “Session-independent mode” on page 8-324.

Configuring the attribute store cleanup task:

You can control the way IBM MobileFirst Platform Server cleans up stale data in the attribute store.

The properties described in this page became available starting from IBM MobileFirst Platform Foundation V7.1.0.

When the attribute store is configured to use the MobileFirst database, a cleanup task is run periodically to delete stale entries. Stale entries are attributes that have expired and have not been accessed for a period (the default is 30 days). The task is also applied when the attribute store is over eXtremeScale and the write-behind database is the MobileFirst database.

Attributes always have an expiration date (this is the expiration date of the realm with which the attributes are associated). An expired attribute is normally deleted the next time it is accessed. However, if the client application is no longer in use (for example, because it has been uninstalled), expired attributes that are associated with the client application are deleted by the cleanup task. Use the following properties to configure the cleanup:

Table 12-7. MobileFirst Server attribute store cleanup properties.

Property name	Description
mfp.attrStore.db.cleanupFrequency.minutes	The attribute store database cleanup task interval (in minutes). The default is 60 minutes.
mfp.attrStore.db.stalePeriod.days	The interval (in days) after which an expired attribute is considered stale, and may be deleted by the attribute store database cleanup task. The default is 30 days.

An example of stale data cleanup: if the `mfp.attrStore.db.cleanupFrequency.minutes` property has been set to 10 and the `mfp.attrStore.db.stalePeriod.days` property to 30, then every 10 minutes, the cleanup task runs and deletes data that expired more than 30 days ago.

For more information about session dependency, see “Session-independent mode” on page 8-324.

Configuring extended app authenticity checking

Checking extended application authenticity is an additional method of verifying that the MobileFirst application on the device has not been tampered with.

Enabling extended authenticity checking

Extended application authenticity checking is supported for the following environments:

- iPhone, iPad, and iOS native
- Android and Android native
- Windows Phone Silverlight 8 (but not Windows Phone Silverlight 8 native)
- Windows 8 Universal (including Windows Phone 8 Universal), Windows 8 Universal native , and Windows Phone 8 Universal native

Note:

- You cannot enable extended authenticity if you use the internal MobileFirst Development Server that is embedded in MobileFirst Studio.
- Extended application-authenticity validation is not supported for iOS apps that are installed from the Apple app store. See the Extended application authenticity for iOS known limitation.
- If your Android app uses extended authenticity, it cannot use the multiple APK feature of Google Play. See Multiple APK Support for more information about the multiple APK feature.

To enable extended authenticity checking, you must deploy a modified `.wlapp` file, instead of the original `.wlapp` file that is generated by the build process. To obtain the modified `.wlapp` file, use one of the following two facilities:

- The **enable-extended-authenticity** command of the `wladm` Ant task, as described in “Commands for apps” on page 13-19.
- The **enable extended-authenticity** command of the `wladm` program, as described in “Commands for apps” on page 13-45.

You need to specify the following files as inputs for those commands:

- The `.wlapp` file, from the `bin` folder of your MobileFirst project.
- The mobile application file for the device, that is:
 - For the iPhone, iPad, iOS native environments: the corresponding `.ipa` file. If your application must support both 32-bit and 64-bit execution, provide a single `.ipa` file that includes both 32-bit and 64-bit code.
 - For the Android and Android native environments: the corresponding `.apk` file.

Note: The `.apk` file must be signed. For more information, see Signing Your Applications.

- For the Windows Phone Silverlight 8 environment: the corresponding .xap file. If you build your application for ARM and x86 architectures, the .xap file to use for production deployment is the one for the ARM architecture; the .xap file for the x86 architecture is for use in emulators only.

Note: If an application is built in Release mode and runs on a physical device, the .xap file of the application must be signed with a certificate to be able to connect to the MobileFirst Server. The resulting .xap file must be provided as the input to the **wladm** tool after the binaries are signed. For more information about signing enterprise apps, see Preparing company apps for distribution for Windows Phone.

- For the Windows 8 Universal (including Windows Phone 8 Universal), Windows 8 Universal native, and Windows Phone 8 Universal native environments: the corresponding .appx file or the .appx file from a bundle.

The resulting, modified .wlap file is the file that you deploy to the MobileFirst Server.

Note:

- The extended application authenticity mechanism demands that there is a dedicated version of the .wlap file per each version of the native app. Before you distribute a new version of the mobile application file (.ipa, .apk, .appx, or .xap), you must perform the following actions:
 1. Update the application version number in the application-descriptor.xml file.
 2. Rebuild to create a new .wlap file.
 3. Run one of the commands described previously to enable authenticity checking on the production-ready .ipa, .apk, .appx, or .xap file and the new .wlap file.
 4. Deploy the .wlap file produced in step 3 to the MobileFirst Server.

Disabling extended authenticity checking

To revert from extended authenticity checking to basic authenticity checking, deploy the original .wlap file to the MobileFirst Server, for each of the wanted environments.

Enabling extended authenticity checking for apps that undergo app thinning

App thinning was introduced by Apple in iOS 9 for apps that are compiled with Xcode 7. App thinning reduces the size of files that are downloaded from the App Store. The feature might affect the extended authenticity features of IBM MobileFirst Platform Foundation apps because the binary file in the App Store might differ from the one that is downloaded to the client device.

Starting with the latest interim fix of IBM MobileFirst Platform Foundation V7.1.0, the new ipa file that you upload to the App Store can take advantage of app thinning, without influencing extended authenticity. To enable this capability, you must perform the following actions:

1. Configure the original .wlap file by using the `enable-extended-authenticity` command of the `wladm` program, as described earlier in this page.
2. Deploy the .wlap file to the server for testing.

Note: App thinning does not take place in apps that were developed using earlier versions of iOS and Xcode.

Push notification settings

When working with push notifications, you must use the correct proxy settings. For Android, you use GCM proxy settings, and for iOS, you use APNS proxy settings. SMS has its own set of proxy settings.

The following properties are required only when a proxy is used to route requests to APNS, GCM, or SMS push servers. When no proxy is used, it is not necessary to set the properties (the ***.enabled** property value should be set to false).

GCM proxy settings	Value
push.gcm.proxy.enabled	Shows whether Google GCM must be accessed through a proxy. Can be either true or false. The default is false.
push.gcm.proxy.protocol	GCM proxy protocol. Can be either http or https.
push.gcm.proxy.host	GCM proxy host.
push.gcm.proxy.port	GCM proxy port. Use -1 for the default port.
push.gcm.proxy.user	Proxy user name, if the proxy requires authentication. An empty user name means no authentication.
push.gcm.proxy.password	Proxy password, if the proxy requires authentication.

Note:

- For push notifications to work, you must ensure that your firewall accepts outgoing connections to `android.googleapis.com` on port 443.

APNS proxy settings	Value
push.apns.proxy.enabled	Shows whether APNS must be accessed through a proxy. Can be either true or false. The default is false.
push.apns.proxy.type	APNS proxy type. Must be SOCKS.
push.apns.proxy.host	APNS proxy host.
push.apns.proxy.port	APNS proxy port.
push.apns.proxy.user	APNS proxy user name, if the proxy requires authentication. An empty user name means no authentication.
push.apns.proxy.password	APNS proxy password, if the proxy requires authentication.

SMS proxy settings	Value
push.sms.proxy.enabled	Can be either true or false. Use true to send SMS notifications through proxy.
push.sms.proxy.protocol	SMS proxy protocol. Can be either http or https.
push.sms.proxy.host	SMS proxy host name.

SMS proxy settings	Value
<code>push.sms.proxy.port</code>	SMS proxy port. Use -1 for the default port.
<code>push.sms.proxy.user</code>	Proxy user name, for authentication. An empty user name means no authentication.
<code>push.sms.proxy.password</code>	Proxy password, if the proxy requires authentication.

Analytics

Analytics properties files contain the parameters for how IBM MobileFirst Platform Foundation creates activity logs and sends them to a server for analysis.

You can modify how the MobileFirst Server forwards analytics data to the IBM MobileFirst Platform Operational Analytics by editing the following properties files.

Table 12-8. IBM MobileFirst Platform Operational Analytics properties.

Property Name	Default Value	Description
<code>wl.analytics.console.url</code>	None.	Optional. The URL that is exposed by the IBM MobileFirst Platform Operational Analytics that links to the MobileFirst Analytics Console. Set this property if you want to access the MobileFirst Analytics Console from the MobileFirst Operations Console. Example: <code>http://<hostname>:<port>/analytics/console</code>
<code>wl.analytics.logs.forward</code>	true	When the property is set to true, server logs that are recorded on the MobileFirst Server are captured and forwarded to the IBM MobileFirst Platform Operational Analytics.
<code>wl.analytics.password</code>	None.	Required. The password that is used if the data entry point for the IBM MobileFirst Platform Operational Analytics is protected with basic authentication.
<code>wl.analytics.url</code>	None.	Required. The URL that is exposed by the IBM MobileFirst Platform Operational Analytics that receives incoming analytics data. Example: <code>http://<hostname>:<port>/analytics-service</code>

Table 12-8. IBM MobileFirst Platform Operational Analytics properties. (continued)

Property Name	Default Value	Description
wl.analytics.username	None.	Required. The user name that is used if the data entry point for the IBM MobileFirst Platform Operational Analytics is protected with basic authentication.

WebSphere Application Server SSL configuration and HTTP adapters

By setting a property, you can make HTTP adapters take benefit of the WebSphere SSL configuration.

By default, HTTP adapters do not take benefit of the WebSphere SSL configuration by concatenating the Java Runtime Environment (JRE) truststore with the Worklight truststore as referenced by the **ssl.keystore.path**, **ssl.keystore.password**, and **ssl.keystore.type** properties. See “Configuring SSL between MobileFirst adapters and back-end servers by using self-signed certificates” on page 6-192. To have HTTP adapters use the WebSphere SSL configuration, set the **ssl.websphere.config** property to true. This value has the following effects, in order of precedence:

1. If the **ssl.keystore.path**, **ssl.keystore.password**, **ssl.keystore.type** properties are set, the adapter uses the truststore that is referenced in these properties without concatenating it with the JRE truststore.
2. If the **ssl.websphere.alias** property is set, the adapter uses the SSL configuration that is associated with the alias as set in this property.
3. If the **ssl.keystore.path**, **ssl.keystore.password**, **ssl.keystore.type**, and **ssl.websphere.alias** properties are not set, the WebSphere outbound dynamic configuration is used.

SSL certificate keystore setup

Mobile applications often connect to multiple back-end systems. Some back-end systems require access through an HTTP adapter, and each back-end system can require a different SSL certificate for secure communication using HTTPS. These SSL certificates are stored in a keystore that is configured to the IBM MobileFirst Platform Server by using property keys.

IBM MobileFirst Platform Foundation provides a default keystore. You can choose to use this default keystore or replace it with your own keystore.

To configure an SSL certificate keystore, you must set the values of the property keys listed in the following table:

Table 12-9. JNDI environment entries for SSL certificate keystore

Property name	Description
ssl.keystore.path	Path to the keystore relative to the server folder in the MobileFirst project; for example: conf/my-cert.jks.
ssl.keystore.type	Type of keystore file. Valid values are jks or pkcs12.
ssl.keystore.password	Password to the keystore file.

Table 12-9. JNDI environment entries for SSL certificate keystore (continued)

Property name	Description
<code>ssl.websphere.alias</code>	WebSphere SSL configuration alias used by the HTTP adapters
<code>ssl.websphere.config</code>	Set this property to true to have HTTP adapters use WebSphere SSL configuration. Default: false.

For descriptions of other MobileFirst configuration properties, see “JNDI environment entries for MobileFirst projects in production” on page 12-68.

For information about how to specify MobileFirst configuration properties, see “Configuration of MobileFirst applications on the server” on page 12-50.

In addition to defining these three properties, configure the HTTP adapter XML file, which is located under `<Worklight Root Directory>\adapters\<HTTP adapter name>`. This file is described in “Structure of the adapter XML file” on page 8-247.

If you use SSL with mutual authentication between the MobileFirst Server and a back-end system, be aware of the following requirement:

- Define an alias and password for the private key of the keystore where the SSL certificate is stored. The alias and password are defined in the `<connectionPolicy>` element of the HTTP adapter XML file, `adaptername.xml`. The `<sslCertificateAlias>` and `<sslCertificatePassword>` subelements are described in “HTTP adapter connectionPolicy element” on page 8-252.

Note: The password that is specified in `ssl.keystore.password` is not the same password that is specified in `<sslCertificatePassword>`. `ssl.keystore.password` is used to access the keystore itself. `<sslCertificatePassword>` is used to access the correct SSL certificate within the keystore.

Miscellaneous settings

Configure the `serverSessionTimeout`, `bitly.username`, `bitly.apikey`, `compress.response.threshold`, and `adapters.saxparser.doctype.validation` parameters in the `worklight.properties` file.

Property keys and values for the `serverSessionTimeout`, `bitly.username`, `bitly.apikey`, `compress.response.threshold`, and `adapters.saxparser.doctype.validation` parameters.

Property Key	Property Value
<code>serverSessionTimeout</code>	Client inactivity timeout, after which the MobileFirst session is invalidated. Default is 10 minutes. Note: Session timeout configuration is not used in session-independent mode.
<code>bitly.username</code>	User name for accessing the bit.ly API for creating a shortened URL for mobile web apps through MobileFirst Operations Console.
<code>bitly.apikey</code>	The bit.ly API Key.

Property keys and values for the `serverSessionTimeout`, `bitly.username`, `bitly.apikey`, `compress.response.threshold`, and `adapters.saxparser.doctype.validation` parameters.

Property Key	Property Value
<code>compress.response.threshold</code>	The threshold size of the payload that is returned in response to an <code>invokeProcedure</code> call beyond which the response is compressed. The default value is 20480 bytes. Responses with payload larger than the <code>compress.response.threshold</code> are compressed by the server. To disable compression, set this value to a large value. Similarly, to compress every response, set this value to 0 (zero). If the payload is larger than the <code>compress.response.threshold</code> , the payload is compressed irrespective of whether or not compression was requested by the client through the <code>compressResponse</code> option.
<code>adapters.saxparser.doctype.validation</code>	True or False. If set to False, the adapter does not validate the XML response received from the back-end server. This might be useful in cases where the time required to validate could be expected to exceed the allowed timeout value. The default setting is True, meaning that the server validates the response.

Storing properties in encrypted format

When you configure MobileFirst applications on the server, you must encrypt the properties that are too sensitive to be written in clear text.

You can encrypt properties in two ways:

- Within the properties file: See “Encryption within the properties file.” This option is the only one for Tomcat.
- By using the application server encoding tools: `PropFilePasswordEncoder` for WebSphere Application Server and `SecurityUtility` for Liberty profile. For WebSphere Application Server and Liberty profile. See “Encoding the JNDI properties” on page 12-63.

Encryption within the properties file

The encryption facility that comes with IBM MobileFirst Platform Foundation uses the 128-bit symmetric-key algorithm that is defined by the AES specification.

Storing properties in open or encrypted format

You can keep the properties that are contained in the `worklight.properties` file either in open or in encrypted form.

An encrypted property is determined by a suffix `.enc` appended to its name. For example:

```
console.password.enc=TYakEHRba3rIU7pNjxtDxoAdqijKIEt7cy4mCr0iaEj0rY080DK00yqR
```

The MobileFirst configuration is accessed for a property. If the property is not found, but the same encrypted property (with the `.enc` suffix) is defined, MobileFirst automatically decrypts the value, and returns it to the caller.

Storing the master key

All encrypted values use the same secret key, which is stored in the special variable called **worklight_enc_password**. This variable is defined as an operating-system environment variable:

- On Windows systems: Set an environment variable under the user that runs MobileFirst Server. Under a Windows NT service, define the password as a service property by using the registry editor. For more information, see the Microsoft support website.
- On Linux systems: Set the environment variable.

Encryption

You can encrypt MobileFirst properties by using the 128-bit symmetric-key algorithm that is defined by the AES specification.

- On Windows systems, use the `encrypt.bat` utility under `product_install_dir/WorklightServer`. This utility accepts a file that contains the properties to be encrypted and the encryption password. The utility outputs the encrypted values to the same file, so that sensitive data is deleted.
- On Linux systems, use the `encrypt.sh` utility.

The input file for the encryption is called `secret.properties` and contains the following data:

```
worklight_enc_password=abc123
certificate.password=certificatepwd123
wl.db.password=edf545
```

After you run the `encrypt.sh` tool, the `secret.properties` file contains the following data:

```
#Copy the contents of this file to the worklight.properties file.
#Keep the password value in the secure system property worklight_enc_password.
#Wed Nov 28 10:10:44 CST 2012
certificate.password.enc=dR41nMQDaNEQyLQ17b2RmpdE99HKpqaSJ6mce0uJgaY\=
wl.db.password.enc=6boxojGZsUNTXw00GgI6dg\=\=
```

Encoding the JNDI properties

The preferred way to encrypt JNDI properties in WebSphere Application Server is to use the password encoding tools that are available with both application servers.

- For WebSphere Application Server: the `PropFilePasswordEncoder` tool
- For the Liberty profile: the `SecurityUtility` command. For the encoding type, only `xor` and `aes` with the default key are supported.

You can use the encoded value as the value of the JNDI properties.

For more information about how to encode properties with the application server tools, see the WebSphere Application Server documentation.

Obsolete properties

Some properties are no longer required.

Table 12-10. Categories and list of obsolete properties

Category	Properties
Proxy settings	<code>proxy.enabled</code> , <code>proxy.nonProxyHosts</code> , <code>proxy.host</code> , <code>proxy.port</code> , <code>proxy.username</code> , <code>proxy.password</code> , <code>https.proxy.host</code> , <code>https.proxy.port</code>

Table 12-10. Categories and list of obsolete properties (continued)

Category	Properties
Public resource server settings	<code>publicResourceServer.deployDestination</code> , <code>publicResourceServer.host</code> , <code>publicResourceServer.port</code> , <code>publicResourceServer.filesRootDir</code>
Environments	<code>environment.iphone</code> , <code>environment.embedded</code> , <code>environment.netvibes</code> , <code>environment.air</code> , <code>environment.android</code> , <code>environment.blackberry</code>
Certificate settings	<code>certificate.certificatesDirPath</code> , <code>certificate.keyStoreFilePath</code> , <code>certificate.keyAlias</code> , <code>certificate.keyStorePassword</code> , <code>certificate.keyAliasPassword</code> , <code>certificate.PFXFilePath</code> , <code>certificate.password</code> , <code>certificate.DERFilePath</code> , <code>certificate.P7BFilePath</code> , <code>vista.linux.oss1signcodeFilepath</code>
Push notification settings	<code>push.apns.certificatePassword</code> , <code>push.gcm.senderID</code> , <code>push.gcm.senderPassword</code>
Miscellaneous settings	<code>devmode</code> , <code>guid</code> , <code>wlclientTimeout</code> , <code>backend.request.timeout</code> , <code>reports.produceReports</code> , <code>wl.db.initialSize</code> , <code>wl.db.maxActive</code> , <code>wl.db.maxIdle</code> , <code>wl.db.testOnBorrow</code> , <code>wl.db.autodd1</code>
Tomcat settings	<code>local.bindAddress</code> , <code>local.httpPort</code>
Single identity login module security settings	<code>console.username</code> , <code>console.password</code>

Declaring and using application-specific configuration properties

Use the `${propertyName}` notation to reuse application-specific properties that are declared in the `worklight.properties` file.

As a developer, you might want to parameterize some elements in the configuration of the server side of your MobileFirst application so that an IT administrator can change the value in production. For example, a MobileFirst adapter might need to call a back-end service, and the URL of this service might be different in a production environment from its value in a development environment. In this scenario, you can create a new MobileFirst configuration property to store the URL, and the IT administrator can then set the final production value as a JNDI environment entry.

You can declare application-specific properties in the `worklight.properties` file. You can then reuse the value of those properties within the authentication configuration file (`authenticationConfig.xml`) and the adapter descriptor file (`adapter.xml`) by using the `${propertyName}` notation.

Here is an example for declaring a data source and reusing it in an adapter:

1. In the `worklight.properties` file, define a new (custom) property:
`my.adapter.db.jndi.name=jdbc/MyAdapterDS`
2. You can then include a property declaration in the `adapter.xml` file:

```
<wl:adapter>
...
<connectivity>
  <connectionPolicy xsi:type="sql:SQLConnectionPolicy">
    <dataSourceJNDIName>
```

```

        ${my.adapter.db.jndi.name}
    </dataSourceJNDIName>
</connectionPolicy>
...

```

Such properties are exposed as JNDI entries (see “JNDI environment entries for MobileFirst projects in production” on page 12-68) for the project WAR file. In this example, the JNDI name of the adapter data source becomes parametric and can be changed from the server configuration files.

In authenticationConfig.xml, you can use `${propertyName}` notation for all realm and **loginModule** parameters. Here are examples (in bold typeface) for such properties:

```

<securityTests>

  <customSecurityTest name="MySecurityTest">
    <test realm="MySecurityRealm" isInternalUserID="true"/>
  </customSecurityTest>

</securityTests>

<realms>

  <realm name="MySecurityRealm" loginModule="MySecurityLoginModule">
    <className>com.test.auth.MyAuthenticator</className>
    <parameter name="login-mode" value="${my.security.realm.mode}" />
    <parameter name="my-other-realm-param" value="${my.security.realm.param}" />
  </realm>

</realms>

<loginModules>

  <loginModule name="MySecurityLoginModule">
    <className>com.test.auth.MyLoginModule</className>
    <parameter name="roles-allowed" value="${my.security.allowed.roles}" />
    <parameter name="my-other-login-param" value="${my.security.login.param}" />
  </loginModule>

</loginModules>

```

For more information about configuring realm parameters, see “Configuring authenticators and realms” on page 8-626. For **loginModule** parameters, see “Configuring login modules” on page 8-617.

In adapter.xml, you can use the `${propertyName}` notation in the following elements:

For HTTP adapters:

```

<connectivity>
  <connectionPolicy xsi:type="http:HTTPConnectionPolicyType">
    <protocol>${my.protocol}</protocol>
    <domain>${my.domain}</domain>
    <port>${my.port}</port>

    <authentication>
      <ntlm workstation="${local.hostname}" />
      <serverIdentity>
        <username>${my.server.identity.username}</username>
        <password>${my.server.identity.password}</password>
      </serverIdentity>
    </authentication>

    <!-- Following properties used by adapter's key manager for choosing specific certificate from key store -->

```

```

    <sslCertificateAlias>${my.ssl.certificate.alias}</sslCertificateAlias>
    <sslCertificatePassword>${my.ssl.certificate.password}</sslCertificatePassword>

</connectionPolicy>

<loadConstraints maxConcurrentConnectionsPerNode="${max.connections.per.node}"/>
</connectivity>

```

For SQL adapters:

```

<connectivity>
  <connectionPolicy xsi:type="sql:SQLConnectionPolicy">

    <!-- Example for using a JNDI data source, replace with actual data source name -->
    <!-- <dataSourceJNDIName>${my.data.source.jndi.name}</dataSourceJNDIName> -->

    <!-- Example for using MySQL connector, do not forget to put the MySQL connector library in the project's lib folder -->
    <dataSourceDefinition>
      <driverClass>${my.driver.class.name}</driverClass>
      <url>${my.data.source.url}</url>
      <user>${my.data.source.username}</user>
      <password>${my.data.source.password}</password>
    </dataSourceDefinition>
  </connectionPolicy>
  <loadConstraints maxConcurrentConnectionsPerNode="${max.connections.per.node}" />
</connectivity>

```

For JMS adapters:

```

<connectivity>
  <connectionPolicy xsi:type="jms:JMSConnectionPolicyType">

    <!-- uncomment this if you want to use an external JNDI repository -->
    <!-- <namingConnection url="${my.naming.connection.url}"
      initialContextFactory="${my.initial.context.factory}"
      user="${my.naming.connection.username}"
      password="${my.naming.connection.password}"/>
    -->

    <jmsConnection connectionFactory="${my.jms.connection.factory}"
      user="${my.jms.connection.username}"
      password="${my.jms.connection.password}"
    />
  </connectionPolicy>

  <loadConstraints maxConcurrentConnectionsPerNode="${max.connections.per.node}"/>
</connectivity>

```

For more information about configuring adapters, see “HTTP adapter connectionPolicy element” on page 8-252.

Configuring a MobileFirst project in production by using JNDI environment entries

When you deploy a MobileFirst project to MobileFirst Server, you can configure the project WAR file with JNDI environment entries to set product environment properties.

About this task

JNDI environment entries cover all the properties that you can set in a production environment. For details about the JNDI entries, see “JNDI environment entries for MobileFirst projects in production” on page 12-68.

Procedure

Set the JNDI environment entries in one of the following ways:

- Edit the configuration XML file for the deployer Ant tasks.

When you deploy and configure the project with the Ant task, you can set values for MobileFirst configuration properties inside the `<configureapplicationserver>` tag. For more information, see “Deploying a project WAR file and configuring the application server with Ant tasks” on page 12-16 For example:

```
<configureapplicationserver shortcutsDir="${shortcuts.dir}">
  <property name="serverSessionTimeout" value="30"/>
  <property name="publicWorkLightHostname" value="www.example.com"/>
  <property name="publicWorkLightPort" value="80"/>
  <property name="publicWorkLightProtocol" value="http"/>
</configureapplicationserver>
```

- Configure the server environment entries. The steps to configure the server environment entries depends on which application server you use.
 - WebSphere Application Server:
 1. In the administration console, go to **Applications > Application Types > WebSphere enterprise applications > Worklight > Environment entries for Web modules**
 2. In the **Value** fields, enter values that are appropriate to your server environment. See Figure 12-2.

Web module	URI	Name	Type	Description	Value
Worklight	TestApp.war,WEB-INF/web.xml	publicWorkLightHostname	String	[REQUIRED] The IP address or host name of the computer running IBM Worklight. If the IBM Worklight Server is behind a reverse proxy, the value is the IP address or host name of the reverse proxy. This property must be identical for nodes within the same cluster. Default: IP address of current server.	<input type="text"/>
Worklight	TestApp.war,WEB-INF/web.xml	publicWorkLightPort	String	[REQUIRED] The port for accessing the IBM Worklight Server. If the IBM Worklight Server is behind a reverse proxy, the value is the port for accessing the reverse proxy. This property must be identical for nodes within the same cluster. Default: Same as local.httpPort.	<input type="text"/>
Worklight	TestApp.war,WEB-INF/web.xml	publicWorkLightProtocol	String	[REQUIRED] The protocol for accessing the IBM Worklight Server. The valid values are HTTP and HTTPS. If the IBM Worklight Server is behind a reverse proxy, the value is the protocol for accessing the reverse proxy. This property must be identical for nodes within the same cluster. Default: HTTP.	<input type="text"/>
Worklight	TestApp.war,WEB-INF/web.xml	serverSessionTimeout	String	[OPTIONAL] Idle session timeout in minutes Default is 10.	<input type="text"/>
Worklight	TestApp.war,WEB-INF/web.xml	reports.exportRawData	String	[OPTIONAL] Is reports active (true/false) default is false.	<input type="text"/>
Worklight	TestApp.war,WEB-INF/web.xml	push.gcm.proxy.enabled	String	[OPTIONAL] Shows whether Google GCM must be accessed through a proxy. Default is false.	<input type="text"/>
Worklight	TestApp.war,WEB-INF/web.xml	push.gcm.proxy.host	String	[OPTIONAL] GCM proxy host. Negative value means default port.	<input type="text"/>
Worklight	TestApp.war,WEB-INF/web.xml	push.gcm.proxy.port	String	[OPTIONAL] GCM proxy port. Use -1 for the default port. Default is -1.	<input type="text"/>
Worklight	TestApp.war,WEB-INF/web.xml	push.gcm.proxy.protocol	String	[OPTIONAL] Can be either http or https.	<input type="text"/>
Worklight	TestApp.war,WEB-INF/web.xml	push.gcm.proxy.user	String	[OPTIONAL] Proxy user name, if the proxy requires authentication. Empty user name means no authentication.	<input type="text"/>
Worklight	TestApp.war,WEB-INF/web.xml	push.gcm.proxy.password	String	[OPTIONAL] Proxy password, if the proxy requires authentication.	<input type="text"/>

Figure 12-2. Setting JNDI environment entries on WebSphere Application Server

- WebSphere Application Server Liberty profile:

Insert the following declarations in the `server.xml` file:

```
<application id="worklight" name="worklight" location="worklight.war"
  type="war" context-root="/app_context_path">
</application>
<jndiEntry value="9080" jndiName="app_context_path/publicWorkLightPort"/>
<jndiEntry value="www.example.com" jndiName="app_context_path/publicWorkLightHostname"/>
```

The context path (in the previous example: **app_context_path**) connects between the JNDI entry and a specific MobileFirst application. If multiple MobileFirst applications exist on the same server, you can define specific JNDI entries for each application by using the context path prefix. Typically, **app_context_path** is **"worklight"**.

- Apache Tomcat:

Insert the following declarations in the server.xml file:

```
<Context docBase="app_context_path" path="/app_context_path">
  <Environment name="publicWorkLightPort" override="false"
    type="java.lang.String" value="9080"/>
  <Environment name="publicWorkLightHostname" override="false"
    type="java.lang.String" value="www.example.com"/>
</Context>
```

Note: On Apache Tomcat, `override="false"` is mandatory.

With Apache Tomcat, the context path prefix is not needed because the JNDI entries are defined inside the `<Context>` element of an application.

Preconfiguring JNDI properties:

As an alternative to setting JNDI environment entries when you deploy a MobileFirst project to MobileFirst Server, you can configure all JNDI properties before you deploy by using a property file. Holding JNDI properties in a property file makes it easier to transfer the entire configuration from one web application server to another. For example, you can configure a test web server; when the configuration is stable, you can easily transfer the configuration to the production web server by copying the property file to the production server. For more information, see “Predefining MobileFirst Server configuration for several deployment environments” on page 6-315.

In some cases, when you do not want to or cannot redeploy the application, you can set values for MobileFirst configuration properties manually on the server configuration files (or console). This procedure is what the Ant task does behind the scenes. The manual configuration method is less recommended because in some cases (for example, when you upgrade or redeploy), the application server might forget the configuration and the administrator must reconfigure it.

Tip: If you choose to configure manually, be aware that if the application is upgraded or redeployed, your settings might be overwritten and then the administrator would then have to reconfigure the properties.

Related reference:

“Configuration of MobileFirst applications on the server” on page 12-50

You can configure each MobileFirst application by specifying a set of configuration parameters on the server side.

“JNDI environment entries for MobileFirst projects in production”

JNDI environment entries cover all the properties that you can set in a production environment. Set production environment properties by configuring your project WAR file with JNDI environment entries.

JNDI environment entries for MobileFirst projects in production:

JNDI environment entries cover all the properties that you can set in a production environment. Set production environment properties by configuring your project WAR file with JNDI environment entries.

JNDI environment entries cover all the properties that you can set in a production environment. You set the JNDI environment entries in one of two ways:

- Editing the configuration XML file for the deployer Ant tasks.
- Configuring the server environment entries. On WebSphere Application Server full profile and WebSphere Application Server Network Deployment, use the administration console. On WebSphere Application Server Liberty profile or Apache Tomcat, you edit the `server.xml` file.

For procedure details, see “Configuring a MobileFirst project in production by using JNDI environment entries” on page 12-66.

Many of the MobileFirst configuration properties must have different values when the project is deployed to different environments. For example, the configuration properties that are used to specify the MobileFirst Server public URL (that is, **publicWorkLightHostname**, **publicWorkLightPort**, and **publicWorkLightProtocol**) might be different when the MobileFirst project is deployed to a staging server or to a production server. You can configure the project WAR file through JNDI environment entries.

Some of the properties are relevant only in a development environment and are not available as JNDI entries.

You can encrypt the JNDI properties that are listed in the table that follows in two ways:

- You can define the property with the `.enc` suffix in the `worklight.properties` file that is packaged in the WAR file of the MobileFirst project. You can then override the encrypted value by using a JNDI property. With Apache Tomcat, this option is the only one available.
- On WebSphere Application Server full profile and Liberty profile, you can use the password encoding tools: `PropFilePasswordEncoder` for WebSphere Application Server and `SecurityUtility` for Liberty profile.

For more information, see “Storing properties in encrypted format” on page 12-62.

The following table lists the MobileFirst properties that are always available as JNDI entries:

Table 12-11. MobileFirst properties available as JNDI entries.

Property name	Description
<code>adapters.saxparser.doctype.validation</code>	Specifies whether the adapter should validate the XML response received from the back-end server. If you set this property to <code>false</code> , the adapter does not validate the response. This might be useful in cases when the time required to validate could be expected to exceed the allowed timeout value. Default: <code>true</code>
<code>cluster.data.synchronization.taskFrequencyInSeconds</code>	Interval for the synchronization of event sources data within clusters. Default: <code>2</code> .
<code>deployables.cleanup.taskFrequencyInSeconds</code>	Interval at which deployable folder are cleaned up (in seconds). Default: <code>86400</code> .

Table 12-11. MobileFirst properties available as JNDI entries (continued).

Property name	Description
ibm.worklight.admin.environmentid	Optional. Environment identifier for the registration of the MBeans. Use this identifier when different instances of the MobileFirst Server are installed on the same application server. The identifier determines which Administration Services, which console, and which runtimes belong to the same installation. The Administration Services manage only the runtimes that have the same environment identifier.
ibm.worklight.admin.jmx.connector	Mandatory. JMX connector type, by default RMI or SOAP. WebSphere Application Server profile only.
ibm.worklight.admin.jmx.dmgr.host	Mandatory. Deployment Manager host name. WebSphere Application Server Network Deployment only.
ibm.worklight.admin.jmx.dmgr.port	Mandatory. Deployment Manager RMI or SOAP port. WebSphere Application Server Network Deployment only.
ibm.worklight.admin.jmx.pwd	Optional. WebSphere Application Server Farm: the user password of the SOAP connection.
ibm.worklight.admin.jmx.user	Optional. WebSphere Application Server Farm: the user name of the SOAP connection.
ibm.worklight.admin.rmi.registryPort	Optional. RMI registry port for the JMX connection through a firewall. Tomcat only.
ibm.worklight.admin.rmi.serverPort	Optional. RMI server port for the JMX connection through a firewall. Tomcat only.
ibm.worklight.admin.serverid	Optional. Server identifier. Must be different for each server in the farm. Server farms only.
ibm.worklight.jndi.configuration	Optional. If the JNDI configuration is injected into the WAR files or provided as a shared library, the value of this property is the name of the JNDI configuration. You can also specify this value as a system property. See "Predefining MobileFirst Server configuration for several deployment environments" on page 6-315.
ibm.worklight.jndi.file	Optional. If the JNDI configuration is stored as an external file, the value of this property is the path of a file that describes the JNDI configuration. You can also specify this value as a system property. See "Predefining MobileFirst Server configuration for several deployment environments" on page 6-315.

Table 12-11. MobileFirst properties available as JNDI entries (continued).

Property name	Description
ibm.worklight.topology.clustermode	<p>In addition to the server type, you must specify the server topology. Valid values:</p> <ul style="list-style-type: none"> • Standalone • Cluster • Farm <p>The default value is Standalone.</p>
ibm.worklight.topology.platform	<p>Server type. Valid values:</p> <ul style="list-style-type: none"> • Liberty • WAS • Tomcat <p>If the default value is not set, the application tries to guess the server type.</p>
publicWorkLightHostname	<p>The IP address or host name of the computer that is running IBM MobileFirst Platform Foundation.</p> <p>If the MobileFirst Server is behind a reverse proxy, the value is the IP address or host name of the reverse proxy.</p> <p>This property must be identical for nodes within the same cluster.</p> <p>Default: IP address of current server.</p>
publicWorkLightPort	<p>The port for accessing the MobileFirst Server.</p> <p>If the MobileFirst Server is behind a reverse proxy, the value is the port for accessing the reverse proxy.</p> <p>This property must be identical for nodes within the same cluster.</p> <p>Default: 10080.</p> <p>The configureApplicationServer Ant task sets a default value that depends on the application server.</p>
publicWorkLightProtocol	<p>The protocol for accessing the MobileFirst Server.</p> <p>The valid values are HTTP and HTTPS. If the MobileFirst Server is behind a reverse proxy, the value is the protocol for accessing the reverse proxy.</p> <p>This property must be identical for nodes within the same cluster.</p> <p>Default: HTTP.</p> <p>The configureApplicationServer Ant task sets a default value that depends on the application server.</p>
push.apns.proxy.enabled	<p>Indicates whether APNS must be accessed through a proxy. Default: false.</p>

Table 12-11. MobileFirst properties available as JNDI entries (continued).

Property name	Description
push.apns.proxy.host	The hostname of the proxy server to be used to connect to APNS.
push.apns.proxy.port	The port number on the proxy server to be used to connect to APNS.
push.apns.proxy.user	The user name for authenticating with the APNS proxy server if the proxy requires authentication. An empty user name means no authentication.
push.apns.proxy.password	The password for authenticating with the APNS proxy if the proxy requires authentication.
push.clearUserOnLogout	Clear the user name from push device registration on logout. Default: false
push.gcm.proxy.enabled	Shows whether GCM must be accessed through a proxy. Default: false.
push.gcm.proxy.host	The hostname of the proxy server to be used to connect to GCM
push.gcm.proxy.password	The password for authenticating with the GCM proxy server if the proxy requires authentication.
push.gcm.proxy.port	The port number on the proxy server to be used to connect to GCM. Default port: -1.
push.gcm.proxy.protocol	Either http or https.
push.gcm.proxy.user	Proxy user name, if the proxy requires authentication. Empty user name means no authentication.
push.sms.proxy.enabled	Indicates whether push SMS proxy is enabled. Default: false.
push.sms.proxy.host	The hostname of the proxy server to be used to connect to the SMS Gateway.
push.sms.proxy.password	The password for authenticating with the proxy server if authentication is enabled on the proxy
push.sms.proxy.port	The port number on the proxy server to be used to connect to the SMS Gateway
push.sms.proxy.protocol	The protocol to be used (HTTP or HTTPS) to connect to the proxy server
push.sms.proxy.user	The user name for authenticating with the proxy server if authentication is enabled on the proxy

Table 12-11. MobileFirst properties available as JNDI entries (continued).

Property name	Description
reports.exportRawData	Indicates whether reporting is activated (true or false). Default: false. Note: Deprecated in V7.1.0. Use “Operational analytics” on page 14-9 instead.
serverSessionTimeout	Idle session timeout in minutes. Default: 10. Used in session-dependent mode only.
ssl.keystore.password	SSL certificate keystore password.
ssl.keystore.path	SSL certificate keystore location. Default: conf/mfp-default.keystore.
ssl.keystore.type	SSL certificate keystore type. Valid keystore types: jks or PKCS12. Default: jks.
ssl.websphere.alias	The WebSphere SSL configuration alias used by the HTTP adapters
ssl.websphere.config	Set this property to true to have HTTP adapters use WebSphere SSL configuration. Default: false.
sso.cleanup.taskFrequencyInSeconds	Interval (seconds) for a cleanup task that cleans the database of orphaned and expired single-sign-on login contexts. Default: 5
trusted.signer.certificate.paths	A space-separated list of trusted signer certificates for authenticating non-mobile (confidential) clients. The paths may be relative to the server folder in the MobileFirst Project (for example: conf/rootCA.crt), or absolute paths.
wl.analytics.console.url	Optional. The URL that is exposed by IBM MobileFirst Platform Operational Analytics that links to the Analytics console. Set this property if you want to access the Analytics console from the MobileFirst Operations Console. Example: http://<hostname>:<port>/<context-root>/console
wl.analytics.logs.forward	A Boolean value (true or false) that indicates whether to send all com.worklight.* logs to the operational analytics server. If this value is true, all logs that are specified in com.worklight.* settings are forwarded to the operational analytics server. The default value is true. This setting is supported only on MobileFirst production servers. It is not supported on the MobileFirst Development Server.
wl.analytics.password	The password that is used if the data entry point for the IBM MobileFirst Platform Operational Analytics is protected with basic authentication.

Table 12-11. MobileFirst properties available as JNDI entries (continued).

Property name	Description
wl.analytics.url	The URL that is exposed by the IBM MobileFirst Platform Operational Analytics that receives incoming analytics data. Example: <code>http://hostname:port/context-root/data</code> .
wl.analytics.username	The user name that is used if the data entry point for the IBM MobileFirst Platform Operational Analytics is protected with basic authentication.
wl.ca.key.alias	The alias of the entry where the private key and certificate are stored in the keystore. Default: <code>mfp-default-cert</code> .
wl.ca.key.alias.password	The password that protects the keystore entry where the private key and certificate are stored. The alias name for this entry is defined in the wl.ca.key.alias JNDI property.
wl.ca.keystore.password	The password that protects the keystore. The path to the keystore is defined in the wl.ca.keystore.path JNDI property.
wl.ca.keystore.path	The path to the keystore relative to the server folder in the MobileFirst project. Default: <code>conf/mfp-default.keystore</code> .
wl.ca.keystore.type	Type of keystore file. Valid values are <code>jks</code> or <code>pkcs12</code> . Default: <code>jks</code> .
wl.clientlogs.adapter.name	The name of the HTTP adapter that you want to use to receive client-side logs. If you do not specify this property, the default <code>WLCClientLogReceiver</code> name is used.
wl.device.archiveDecommissioned.when	A value, in days, that defines when client devices that were decommissioned will be placed in an archive file when the decommissioning task is run. The archived client devices are written to a file in the MobileFirst Server <code>home\devices_archive</code> directory. The name of the file contains the time stamp when the archive file is created. Default: 90 days.
wl.device.decommission.when	The number of days of inactivity after which a client device is decommissioned by the device decommissioning task. Default: 90 days.
wl.device.enableAccessManagement	A Boolean value (<code>true</code> or <code>false</code>) that enables the Access Management features on the MobileFirst Server. If the Access Management features are enabled, each time a device attempts to connect to the server, it is checked against the back end for its access rights.

Table 12-11. MobileFirst properties available as JNDI entries (continued).

Property name	Description
wl.device.tracking.enabled	A value that is used to enable or disable device tracking in IBM MobileFirst Platform Foundation. For performance reasons, you can disable this flag when IBM MobileFirst Platform Foundation runs only Business-to-Consumer (B2C) apps. When device tracking is disabled, the license reports are also disabled and no license metrics are generated.
mfp.adapter.invocation.url	The URL to be used for invoking adapter procedures from inside Java adapters, or JavaScript adapters that are invoked using the /rest endpoint. If this property is not set, the URL of the currently executing request will be used (this is the default behavior). This value should contain the full URL, including the context root.
mfp.attrStore.db.cleanupFrequency.minutes	The attribute store database cleanup task interval (in minutes). The default is 60 minutes.
mfp.attrStore.db.stalePeriod.days	The interval (in days) after which an expired attribute is considered stale, and may be deleted by the attribute store database cleanup task. The default is 30 days. For more information about the store database cleanup task, see "Configuring the attribute store cleanup task" on page 12-55.
mfp.attrStore.type	Specifies the cache or persistent store to save the authentication context that is kept in the attribute store of MobileFirst Server. Options: <ul style="list-style-type: none"> • database: This is the default option. Uses the same persistent store that is configured for the runtime database (either a relational or Cloudant database) • extremescale: uses eXtreme Scale as a data cache • httpsession: uses the HTTP session to store authentication context, as it was used in MobileFirst Server versions Before V7.1.0. Use this option only if mfp.session.independent has been set to false, otherwise, the server will not start. • datacache: relevant only when working in Bluemix Default: database
mfp.attrStore.xs.endpoint	A comma-separated list of host-port pairs of the WebSphere eXtreme Scale catalog servers, in the form: "host:port".
mfp.attrStore.xs.gridname	The eXtreme Scale grid that is used for caching the attribute store.
mfp.attrStore.xs.mapname	The eXtreme Scale backing map that is used for caching the attribute store.
mfp.attrStore.xs.password	The password for connecting to the eXtreme Scale server. Leave empty if authentication is not required.

Table 12-11. MobileFirst properties available as JNDI entries (continued).

Property name	Description
<code>mfp.attrStore.xs.username</code>	The user name for connecting to the eXtreme Scale server. Leave empty if authentication is not required.
<code>mfp.db.cloudant.username</code>	The user name of the Cloudant account. When this property is defined along with a Cloudant password, the runtime database is Cloudant. Otherwise, the runtime uses the relational database that is configured.
<code>mfp.db.cloudant.password</code>	The password to the Cloudant account. When this property is defined along with a Cloudant user name, the runtime database is Cloudant. Otherwise, the runtime uses the relational database that is configured.
<code>mfp.db.cloudant.url</code>	The URL of the Cloudant account that is used only if Cloudant is active, and has a defined username and password. When this property is defined, the Cloudant database is directed to this URL. Otherwise, it is redirected to the default URL: <code>https://cloudant.com</code>
<code>mfp.db.cloudant.ssl.authentication</code>	A Boolean value (true or false) that specifies whether the SSL certificate chain validation and host name verification are enabled for HTTPS connections to the Cloudant database. Default: true. Important: Setting this property to false creates security risks.
<code>mfp.db.cloudant.ssl.configuration</code>	Property that applies to WebSphere Application Server Full Profile only. For HTTPS connections to the Cloudant database, it specifies the name of an SSL configuration in the WebSphere Application Server configuration, to use when no configuration is specified for the host and port.
<code>mfp.db.cloudant.dbNamePrefix</code>	The Cloudant database prefix. When this property is configured, the prefix is added to the default database name, followed by an underscore: <code>"MobileFirst_runtime_context-root_runtime_db"</code> . The prefix string must contain lowercase letters only.
<code>mfp.db.cloudant.connectTimeout</code>	A timeout for establishing a network connection to Cloudant, in milliseconds. The zero (0) value means an infinite timeout. A negative value means the default (no override). If this property is not configured, a default value is used, which is described in the documentation for the Cloudant Java Client.
<code>mfp.db.cloudant.socketTimeout</code>	A timeout for detecting the loss of a network connection to Cloudant, in milliseconds. The zero (0) value means an infinite timeout. A negative value means the default (no override). If this property is not configured, a default value is used, which is described in the documentation for the Cloudant Java Client.

Table 12-11. MobileFirst properties available as JNDI entries (continued).

Property name	Description
<code>mfp.db.cloudant.maxConnections</code>	The maximum number of connections of the Cloudant connector. If this property is not configured, a default value is used, which is described in the documentation for the Cloudant Java Client.
<code>mfp.db.cloudant.proxyHost</code>	The proxy host of the Cloudant connector. If this property is not configured, a default value is used, which is described in the documentation for the Cloudant Java Client.
<code>mfp.db.cloudant.proxyPort</code>	The proxy port of the Cloudant connector. If this property is not configured, a default value is used, which is described in the documentation for the Cloudant Java Client.
<code>mfp.session.independent</code>	Turns session dependency in MobileFirst Server on or off. Options: <ul style="list-style-type: none"> • true: session independent • false: session dependent Default: true

Custom user properties that are defined in the `worklight.properties` file are also exposed.

The `wl.db.*` and `wl.reports.db.*` properties are not available as JNDI environment entries because they are intended for use only during the development phase.

Related tasks:

“Configuring a MobileFirst project in production by using JNDI environment entries” on page 12-66

When you deploy a MobileFirst project to MobileFirst Server, you can configure the project WAR file with JNDI environment entries to set product environment properties.

Related reference:

List of JNDI properties for MobileFirst server administration

When you configure MobileFirst Server Administration Services and MobileFirst Operations Console for your application server, you set optional or mandatory JNDI properties, in particular for Java Management Extensions (JMX).

SMS gateway configuration

An SMS gateway, or SMS aggregator, is a third-party entity which is used to forward SMS notification messages to a destination mobile phone number. IBM MobileFirst Platform Foundation routes the SMS notification messages through the SMS gateway.

To send SMS notifications from IBM MobileFirst Platform Foundation, one or more SMS gateways must be configured in the `SMSConfig.xml` file, which is in the `/server/conf` folder of your project. To configure an SMS gateway, you must set

the values of the following elements, subelements, and attributes in the SMSConfig.xml file. The MobileFirst Server must be restarted when any changes are made in the SMSConfig.xml file.

Table 12-12. SMSConfig.xml elements and subelements

Element	Element Value
gateway	<p>Mandatory. The <gateway> element is the root element of the SMS gateway definition. It includes 6 attributes:</p> <ul style="list-style-type: none"> • hostname • id • port • programName • toParamName • textParamName <p>These attributes are described in Table 12-13.</p>
parameter	<p>Optional. The <parameter> subelement is dependent on the SMS gateway. Each SMS gateway may have its own set of parameters. The number of <parameter> subelements is dependent on SMS gateway-specific parameters. If an SMS gateway requires the user name and password to be set, then these parameters can be defined as <parameter> subelements.</p> <p>Each <parameter> subelement has the following attributes:</p> <ul style="list-style-type: none"> • name • value

Table 12-13. <gateway> element attributes

Attribute	Attribute Value
hostname	Mandatory. The host name of the configured SMS gateway.
id	Mandatory. A unique ID that identifies the SMS gateway. Application developers specify the ID in the application descriptor file, application-descriptor.xml, when they develop an application.
port	Optional. The port number of the SMS gateway. The default value is 80.
programName	<p>Optional. The name of the program that the SMS gateway expects. For example, if the SMS gateway expects the following URI:</p> <p>http://<hostname>:port/sendsms</p> <p>then programName="sendsms"</p>

Table 12-13. <gateway> element attributes (continued)

Attribute	Attribute Value
toParamName	Optional. The name that is used by the SMS gateway to specify the destination mobile phone number. The default value is <i>to</i> . The destination mobile phone number is sent as a name-value pair when SMS notifications are sent; that is, <i>toParamName=destination mobile phone number</i> .
textParamName	Optional. The name that is used by the SMS gateway to specify the SMS message text. The default value is <i>text</i> .

If the SMS gateway expects an HTTP post in the following format to forward SMS messages to a mobile device:

```
http://myhost:13011/cgi-bin/sendsms?to=destination mobile phone
number&text=message text&username=fcsuser&password=fcspass
```

The SMSConfig.xml file is configured as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<sms:config xmlns:sms="http://www.worklight.com/sms/config" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <gateway hostname="myhost" id="kannelgw" port="13011" programName="cgi-bin/sendsms" toParamName="to" textParamName="text">
    <parameter name = "username" value = "fcsuser" />
    <parameter name = "password" value = "fcspass" />
  </gateway>
</sms:config>
```

Ant tasks for building and deploying applications and adapters

A set of Ant tasks is supplied with MobileFirst Server and the IBM MobileFirst Platform Command Line Interface. You can use them to build and deploy your applications, adapters, and projects.

IBM MobileFirst Platform Foundation provides a set of Ant tasks that help you build and deploy adapters and applications to your MobileFirst Server. A typical use of these Ant tasks is to integrate them with a central build service that is called manually or periodically on a central build server.

Prerequisites

Before you can run Ant tasks, make sure that Apache Ant is installed. The minimum supported version of Ant is listed in “System requirements” on page 2-15.

Apache Ant 1.8.4 is included in MobileFirst Server. In the *product_install_dir/shortcuts/* directory, the following scripts are provided.

- For UNIX / Linux: ant
- For Windows: ant.bat

These scripts are ready to run, which means that they do not require specific environment variables. If the JAVA_HOME environment variable is set, the scripts accept it.

Building applications and adapters

If you use Ant tasks, you can build both applications and adapters.

You can use the following examples of Ant XML files to build applications and adapters.

Note: Since V6.2.0, the `worklight-ant-builder.jar` file is included in the IBM MobileFirst Platform Command Line Interface as well as the MobileFirst Server, whereas in earlier versions, it was included only in Worklight Server. By default, `worklight-ant-builder.jar` is installed in the following location: `cli_install_dir/public/worklight-ant-builder.jar`. For example, on OSX, the default CLI Install Path is `/Applications/IBM/Worklight-CLI`. If you use the default installation path, the Ant task is installed here: `/Applications/IBM/Worklight-CLI/public/worklight-ant-builder.jar`.

In Worklight Server V6.2.0 and MobileFirst Server, the default location of `worklight-ant-builder.jar` is `mfp_server_install_dir/WorklightServer/worklight-ant-builder.jar`. This file has the same version as the server.

Building a hybrid application

The Ant task for building a hybrid application has the following structure:

```
<?xml version="1.0" encoding="UTF-8"?>
<project basedir="." default="target-name">
  <taskdef resource="com/worklight/ant/defaults.properties">
    <classpath>
      <pathelement location="cli_install_dir/public/worklight-ant-builder.jar"/>
    </classpath>
  </taskdef>
  <target name="target-name">
    <app-builder
      worklightserverhost="http://server-address:port"
      applicationFolder="application-source-files-folder"
      environments="list-of-environments"
      nativeProjectPrefix="project-name"
      outputFolder="output-folder"/>
  </target>
</project>
```

The `<app-builder>` element has the following attributes:

- The `worklightserverhost` attribute is mandatory and specifies the full URL of your MobileFirst Server.
- The `applicationFolder` attribute specifies the root folder for the application, which contains the `application-descriptor.xml` file and other source files for the application.
- The `environments` attribute is a comma-separated list of environments to build. This attribute is optional. The default action is to build all environments.
- The `nativeProjectPrefix` attribute is mandatory when you build iOS applications.
- The `outputFolder` attribute specifies the folder to which the resulting `.wlap` file is written.

By default, running the Ant task to build an application does not handle the Dojo Toolkit because Ant is not run with `build-dojo.xml`. You must explicitly configure the task to do so, by using the following `app-builder` setting in the Ant build file: `skinBuildExtensions=build-dojo.xml`

If you use this setting, the Dojo Toolkit files are deployed with your application.

Building a native API application

The Ant task for building a native API application has the following structure:

```
<?xml version="1.0" encoding="UTF-8"?>
<project basedir="." default="target-name">
  <taskdef resource="com/worklight/ant/defaults.properties">
    <classpath>
      <pathelement location="cli_install_dir/public/worklight-ant-builder.jar"/>
    </classpath>
  </taskdef>
  <target name="target-name">
    <native-app-builder
      sourcefolder="application-source-files-folder"
      outputFolder="output-folder"/>
  </target>
</project>
```

The `<native-app-builder>` element has the following attributes:

- The `sourceFolder` attribute specifies the root folder for the application, which contains the `application-descriptor.xml` file and other source files for the application.
- The `outputFolder` attribute specifies the folder to which the resulting `.wlap` file is written.

Building an adapter

The Ant task for building an adapter has the following structure:

```
<?xml version="1.0" encoding="UTF-8"?>
<project basedir="." default="target-name">
  <taskdef resource="com/worklight/ant/defaults.properties">
    <classpath>
      <pathelement location="cli_install_dir/public/worklight-ant-builder.jar"/>
    </classpath>
  </taskdef>

  <path id="base.path">
    <pathelement path="/Users/miguel/badjars"/>
  </path>

  <target name="target-name">
    <adapter-builder
      folder="adapter-source-files-folder"
      destinationfolder="destination-folder"
      classpathref="base.path"/>
  </target>
</project>
```

The `<adapter-builder>` element has the following attributes:

- The `folder` attribute specifies the folder that contains the source files of the adapter (its `.xml` and `.js` files).
- The `destinationfolder` attribute specifies the folder to which the resulting `.adapter` file is written.
- The `classpathref` attribute specifies a custom class path for the adapter builder. If this property is not specified, then the class path of the running Ant task is used to compile the code.

The `classpathref` attribute is required to be set for RESTful Java adapters. It is not mandatory for JavaScript adapters. You must add the `Worklight-jee-library.jar` to the class path for Java adapters. In the case of RESTful Java adapters, the task compiles the code in the `adapterRootFolder/src` directory and copies the compiled classes to the `adapterRootFolder/bin` directory. Any source files that are not Java are also copied. Error messages are printed in the console.

This Ant task requires that the `JAVA_HOME` environment variable is set to point to a JDK and not a JRE.

If you must build more than one adapter file, add an `<adapter-builder>` element for each adapter.

Example:

Building a JavaScript adapter

```
<adapter-builder
  folder="adapterRootFolder"
  destinationfolder="destination-folder"/>
```

Building a Java adapter without libs

```
<path id="my.path">
  <pathelement path="/product_install_dir/WorklightServer/worklight-jee-library.jar"/>
</path>

<adapter-builder
  folder="adapterRootFolder"
  destinationfolder="destination-folder"
  classpathref="my.path"/>
```

Building a Java adapter with the `server/lib` and the `adapter/lib` folders in the class path

```
<path id="my.path">
  <pathelement path="/product_install_dir/WorklightServer/worklight-jee-library.jar"/>
  <fileset dir="adapterRootFolder/lib">
    <include name="*.jar" />
  </fileset>
  <fileset dir="projectRootFolder/server/lib">
    <include name="*.jar" />
  </fileset>
</path>

<adapter-builder
  folder="adapterRootFolder"
  destinationfolder="destination-folder"
  classpathref="my.path"/>
```

Building the Starter project

To use the Ant script starter example, complete the following steps.

1. Download the Starter Application sample.
2. Add the `build.xml` file to the root folder of your project.
3. Complete the following properties inside the `build.xml` file with the correct values. These values depend on your computer and the location where IBM MobileFirst Platform Foundation is installed.

```
<!-- The admin console URL -->
<property name="mfp.admin.url" value="http://localhost:10080/worklightadmin"/>
<!-- The MobileFirst server host to be written in the app configuration file (wlconfig.properties or worklight.plist) -->
<property name="mfp.server.url" value="http://localhost:10080/worklight"/>
<!-- The MobileFirst builder jar - This jar contains all the builder ant tasks -->
<property name="mfp.ant.builder.jar" value="product_install_dir/WorklightServer/worklight-ant-builder.jar"/>
<!-- The MobileFirst deployer jar - This jar contains all the deployer ant tasks -->
<property name="mfp.ant.deployer.jar" value="product_install_dir/WorklightServer/worklight-ant-deployer.jar"/>
```

```
<!-- The MobileFirst server Java EE library jar - This jar is required for building the server/java folder
and for building Java adapters as well -->
<property name="mfp.jee.library.jar" value="product_install_dir/WorklightServer/worklight-jee-library-production.jar"/>
```

4. Ensure that the MobileFirst Server is running and that MobileFirst WAR is installed on it.
5. Run the **ant** command. The **ant** command builds and deploys the app and the adapter of the Starter Application project. It also builds, but does not deploy, the WAR.

```
<?xml version="1.0"?>
<project default="build-all-and-deploy" name="build-tools" basedir=".">
  <property name="mfp.runtime.name" value="worklight"/>
  <!-- The admin console URL -->
  <property name="mfp.admin.url" value="http://localhost:10080/worklightadmin"/>
  <!-- The MobileFirst server host to be written in the app configuration file (wlconfig.properties or worklight.plist) -->
  <property name="mfp.server.url" value="http://localhost:10080/worklight"/>
  <!-- The MobileFirst builder jar - This jar contains all the builder ant tasks -->
  <property name="mfp.ant.builder.jar" value="product_install_dir/WorklightServer/worklight-ant-builder.jar"/>
  <!-- The MobileFirst deployer jar - This jar contains all the deployer ant tasks -->
  <property name="mfp.ant.deployer.jar" value="product_install_dir/WorklightServer/worklight-ant-deployer.jar"/>
  <!-- The MobileFirst server Java EE library jar - This jar is required for building the server/java folder
and for building Java adapters as well -->
  <property name="mfp.jee.library.jar" value="product_install_dir/WorklightServer/worklight-jee-library-production.jar"/>
  <taskdef resource="com/worklight/ant/defaults.properties">
    <classpath>
      <pathelement location="{mfp.ant.builder.jar}"/>
    </classpath>
  </taskdef>
  <taskdef resource="com/worklight/ant/deployers/antlib.xml">
    <classpath>
      <pathelement location="{mfp.ant.deployer.jar}"/>
    </classpath>
  </taskdef>
  <target name="build-all-and-deploy">

Building applications from IBM Worklight V6.0.0 and deploying them to MobileFirst Server

Users who want to build applications and adapters from IBM Worklight V6.0.0 to their current version of MobileFirst Server must use two Ant scripts, one to build their artifacts and one to deploy them.

If you want to build apps and adapters from a IBM Worklight V6.0.0 project and deploy them to a MobileFirst Server, you might think that all you need to do is add a <taskdef> definition as shown in the following Ant task.

Note:

- *WL600_DIR* is the directory where you installed IBM Worklight V6.0.0.
- *product_install_dir* is the directory where you installed the current version of MobileFirst Server.

```

<taskdef resource="com/worklight/ant/defaults.properties">
  <classpath>
    <pathelement location="WL600_DIR/WorklightServer/worklight-ant.jar" />
  </classpath>
</taskdef>

<taskdef resource="com/worklight/ant/deployers/antlib.xml">
  <classpath>
    <pathelement location="product_install_dir/WorklightServer/worklight-ant-deployer.jar" />
  </classpath>
</taskdef>

```

However, the JAR files *worklight-ant.jar* and *worklight-ant-deployer.jar* conflict, because they contain classes with the same name in different versions. To solve this conflict, you must split the script into two different Ant files: one to build V6.0.0 artifacts and the other to deploy them to MobileFirst Server, as shown in the following examples.

Ant script to build V6.0.0 artifacts

```

<project basedir="." default="build-and-deploy">

  <property name="project.name" value="MyProject" />
  <property name="wl.server" value="http://localhost:9080/${project.name}"/ />
  <property name="wl.project.location" location="${basedir}/${project.name}"/ />
  <property name="output.location" location="${wl.project.location}/bin" />

  <property name="wl.adapter.name" location="MyAdapter" />
  <property name="wl.application.name" location="MyApplication" />

  <property name="worklight-ant" location="worklight-ant.jar" />

  <target name="init">
    <taskdef resource="com/worklight/ant/defaults.properties">
      <classpath>
        <pathelement location="${worklight-ant}"/>
      </classpath>
    </taskdef>
  </target>

  <target name="build">
    <adapter-builder folder="${wl.project.location}/adapters/${wl.adapter.name}" destinationFolder="${output.location}"/>
    <app-builder applicationFolder="${wl.project.location}/apps/${wl.application.name}" outputFolder="${output.location}"
      worklightserverhost="${wl.server}" nativeprojectprefix="${project.name}"/>
  </target>

```

```

</target>

<target name="deploy">
  <ant antfile="deploy.xml" inheritall="true" />
</target>

<target name="build-and-deploy" depends="init,build,deploy" />
</project>

```

Ant script to deploy V6.0.0. artifacts to MobileFirst Server

```

<project basedir="." default="deploy">

  <property name="worklight-ant-deployer" location="worklight-ant-deployer.jar" />

  <target name="init">
    <taskdef resource="com/worklight/ant/defaults.properties">
      <classpath>
        <pathelement location="${worklight-ant-deployer}" />
      </classpath>
    </taskdef>
  </target>

  <target name="deploy" depends="init">
    <wladm url="https://server-address:secure-port/worklightadmin" user="username" password="password">
      <deploy-app runtime="project-name" file="${output.location}/${wl.application.name}-all.wlapp"/>
      <deploy-adapter runtime="project-name" file="${output.location}/${wl.adapter.name}.adapter"/>
    </wladm>
  </target>
</project>

```

Deploying applications and adapters

You can use Ant tasks to deploy MobileFirst applications and adapters.

The following sections show examples of Ant XML files that use the **wladm** Ant task to deploy applications and adapters. You can run these Ant files locally on the MobileFirst Server host computer or remotely on a different computer. To run them remotely on a different computer, you must first copy the file *product_install_dir/WorklightServer/worklight-ant-deployer.jar* to that computer.

Deploying an application

Note: Before you use this Ant task, as a prerequisite step, you must deploy the corresponding MobileFirst project of the application. For more information, see “Deploying the project WAR file” on page 12-5.

A typical Ant script for deploying an application has the following structure:

```

<?xml version="1.0" encoding="UTF-8"?>
<project basedir="." default="target-name">
  <taskdef resource="com/worklight/ant/deployers/antlib.xml">
    <classpath>
      <pathelement location="product_install_dir/WorklightServer/worklight-ant-deployer.jar"/>
    </classpath>
  </taskdef>
  <target name="target-name">
    <wladm url="https://server-address:secure-port/worklightadmin" user="username" password="password">
      <deploy-app runtime="project-name" file="myApp.wlapp"/>
    </wladm>
  </target>
</project>

```

The `<wladm>` element has the following attributes:

Table 12-14. Attributes of the <wladm> element

Attribute	Mandatory/Optional	Description
url	Mandatory	The full URL of your MobileFirst Server web application for administration services
user and password	Mandatory	The credentials of a user in a worklightadmin or worklightdeployer role

The <deploy-app> element has the following attributes:

Table 12-15. Attributes of the <deploy-app> element

Attribute	Mandatory/Optional	Description
runtime	Mandatory	The name of the MobileFirst runtime / project.
file	Mandatory	Contains the .wlap file to deploy.

For more information about <wladm>, see “Administering MobileFirst applications through Ant” on page 13-12.

If you must deploy more than one .wlap file, either add a <deploy-app> element for each file in a single <wladm> element, or add a <wladm> element for each file.

Deploying an adapter

Note: Before you use this Ant task, as a prerequisite step, you must deploy the corresponding MobileFirst project of the adapter. For more information, see “Deploying the project WAR file” on page 12-5.

A typical Ant script for deploying an adapter has the following structure:

```
<?xml version="1.0" encoding="UTF-8"?>
<project basedir="." default="target-name">
  <taskdef resource="com/worklight/ant/deployers/antlib.xml">
    <classpath>
      <pathelement location="product_install_dir/WorklightServer/worklight-ant-deployer.jar"/>
    </classpath>
  </taskdef>
  <target name="target-name">
    <wladm url="https://server-address:secure-port/worklightadmin" user="username" password="password">
      <deploy-adapter runtime="project-name" file="myAdapter.adapter"/>
    </wladm>
  </target>
</project>
```

The <wladm> element has the following attributes:

Table 12-16. Attributes of the <wladm> element

Attribute	Mandatory/Optional	Description
url	Mandatory	The full URL of your MobileFirst Server web application for administration services
user and password	Mandatory	The credentials of a user in a worklightadmin or worklightdeployer role

The <deploy-adapter> element has the following attributes:

Table 12-17. Attributes of the <deploy-adapter> element

Attribute	Mandatory/ Optional	Description
runtime	Mandatory	The name of the MobileFirst runtime / project.
file	Mandatory	Contains the .adapter file to deploy.

For more information about <wladm>, see “Administering MobileFirst applications through Ant” on page 13-12.

If you must deploy more than one .adapter file, either add a <deploy-adapter> element for each file in a single <wladm> element, or add a <wladm> element for each file.

Deploying applications and adapters to MobileFirst Server

You can deploy customer-specific content (apps and adapters) only after the project WAR file is deployed and the server is started.

About this task

Customer-specific content includes applications that must be served by IBM MobileFirst Platform Server and their underlying integration adapters. You can create apps and adapters by building them in IBM MobileFirst Platform Studio, or with the Ant tasks provided with IBM MobileFirst Platform Foundation to build them. The result of the build action is files with extension .wlap and .adapter respectively.

There are two ways to deploy applications and adapters to IBM MobileFirst Platform Operations Console:

- Use Ant tasks that are provided with IBM MobileFirst Platform Foundation, and described in “Ant tasks for building and deploying applications and adapters” on page 12-79 and “Deploying a project WAR file and configuring the application server with Ant tasks” on page 12-16.
- Use MobileFirst Operations Console to manually deploy apps and adapters.

You can deploy customer-specific content (apps and adapters) only after the project and MobileFirst administration WAR files are deployed and the server is started.

Note: If your browser supports multiple files upload, you can select several adapters or several applications in the file chooser dialog.

Procedure

This procedure describes how to deploy applications and adapters by using MobileFirst Operations Console.

1. To deploy one or several adapters, click **Add new app or adapter**. Then, navigate to each required adapter file and select it. A message is displayed that indicates whether the deployment action succeeded or failed.
2. Click **Adapters** to display the adapter list.
3. In the adapter list, expand the deployed adapter to display connectivity details.
4. Repeat steps 1 to 3 for each adapter that you want to deploy.

5. To deploy an application, either deploy the *app_name-all.wlapp* file, or individual *app_name-environment_name-version.wlapp* files. Click **Add new app or adapter**. Then, navigate to the WLAPP files and select them. A message is displayed that indicates whether the deployment action succeeded or failed.
6. In the application list, click the deployed application **summary** link to display details of environments and versions.
7. Repeat steps 5 and 6 for each app that you want to deploy.

Administering adapters and apps in MobileFirst Operations Console

You administer adapters and apps through MobileFirst Operations Console.

About this task

Before performing any of the other tasks in this collection of topics, open MobileFirst Operations Console:

Procedure

1. Open a browser and enter a URL of the following form: `https://hostname:secure-port/worklightconsole` where *secure-port* depends on your server configuration. The defaults are 9443 for WebSphere Application Server and 8443 for Apache Tomcat.

Note: Security warning. If you access MobileFirst Operations Console through http instead of https, your MobileFirst administration user password will be compromised.

This usage is different from the MobileFirst Development Server, where no security is used. In the development environment, you use the port for the Liberty profile server in the URL: `http://localhost:10080/worklightconsole`.

2. If your MobileFirst Server is configured to require login, and you are not currently logged in, log in when prompted to do so.

Results

If only one project is deployed on the server, you see the Catalog page of MobileFirst Operations Console and you can start performing administration tasks.

If several projects are deployed on the server, you see a list of projects in MobileFirst Operations Console. Select the project to administer to navigate to the Catalog page of this project.

Deploying apps

You can select WLAPP files to deploy.

About this task

If your browser supports multiple files upload, you can select several applications in the file chooser dialog.

Procedure

To deploy an app, you deploy either the *app_name-all.wlapp* file or individual *app_name-environment_name-version.wlapp* files.

1. From the first page of MobileFirst Operations Console, click **Add new app or adapter**.
2. Select adapter files for deployment in one of the following ways
 - Select one or several WLAPP files.
 - If your browser is recent enough, drag one or several WLAPP files from the file navigator in your operating system into the first page of MobileFirst Operations Console that is open in the browser.

A message is displayed that indicates whether the deployment action succeeded or failed.

Deleting apps

You can delete an app or a version of an environment of an app.

About this task

An application can be provided in different mobile device environments, such as a tablet version and a phone version. The devices can also be distinguished by mobile operating system. Note that deleting an application from MobileFirst Operations Console will remove all push subscriptions on that application as well.

Procedure

1. From the first page of MobileFirst Operations Console, click the application name to go to the application details page.
2. Process the deletion:
 - To delete an app, click **Delete application**.
 - To delete a version of an environment of an app, click **Delete version**.

Exporting adapter configuration files

Export the configuration files for the adapter by copying them from the source folder.

Procedure

To export a deployed adapter:

Obtain the adapter from the development environment.

1. Navigate to the `/bin` folder in your project
2. Copy the `.adapter` file or files.

Deploying adapters

Deploy an adapter from the MobileFirst Operations Console.

About this task

If your browser supports multiple files upload, you can select several adapters in the file chooser dialog.

Procedure

To deploy an adapter:

1. From the first page of MobileFirst Operations Console, click **Add new app or adapter**.
2. Select adapter files for deployment in one of the following ways

- Select one or several adapter files.
- If your browser is recent enough, drag one or several adapter files from the file navigator in your operating system into the first page of MobileFirst Operations Console that is open in the browser.

A message is displayed that indicates whether the deployment action succeeded or failed.

3. Expand the deployed adapters to view the connectivity details and the list of procedures that it shows.

Modifying adapters

To modify an adapter, replace it with a new one.

Procedure

To modify an adapter:

Deploy the modified adapter file, as described in “Deploying adapters” on page 12-89.

Results

The new adapter replaces the original one.

Deleting adapters

You can delete an adapter from MobileFirst Operations Console.

Procedure

To delete an adapter:

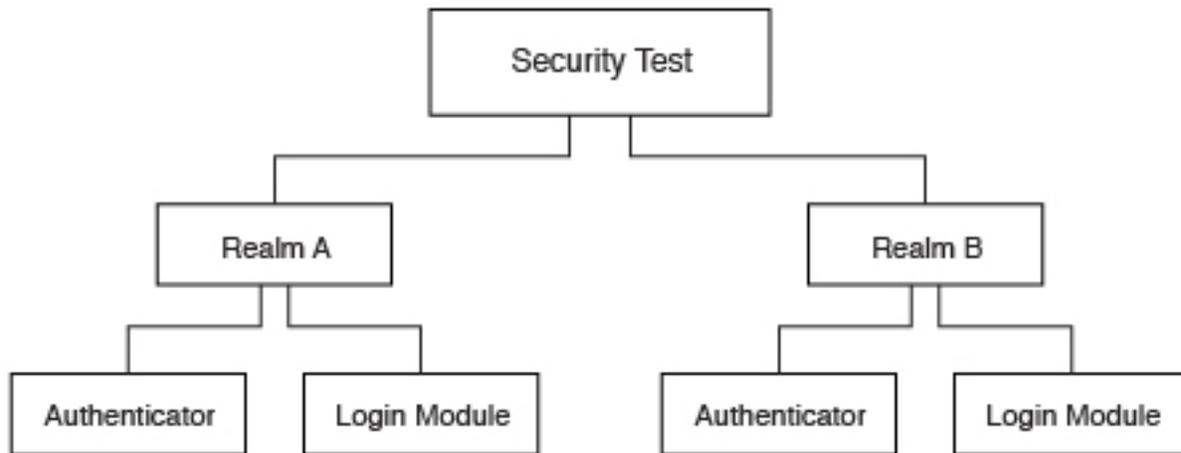

In the adapter list, click the trash icon in the adapter row.

MobileFirst security overview

IBM MobileFirst Platform Foundation has comprehensive support for various authentication and authorization methods.

MobileFirst security basics

The following image shows the authentication elements hierarchy:

Security test

A security test is a set of tests that are used to protect a resource, such as an adapter procedure or application environment. A test includes information about which realm is required to authenticate and other parameters, such as authentication order. A protected resource is accessible only after the client authenticates to all of the tests that are specified in the security test. If the client is unable to log in to all tests, the request to access the protected resource is denied. Individual adapter procedures or an entire application environment can be protected by a security test. For more information about security tests and the different types of security tests, see “Security tests” on page 8-569.

Realm A realm creates a relationship between a MobileFirst login module and a MobileFirst authenticator to provide a means of authentication. For more information about realms, see “Authentication realms” on page 8-573.

Authenticator

An authenticator parses incoming requests from a MobileFirst client to search for required credentials when a protected resource is requested. If credentials are not available in the request, the authenticator is responsible for challenging the client to authenticate. The credentials, after received correctly from the client, are formatted to the login module's predefined requirements and sent to the login module. For more information about authenticators, see “Authenticators and login modules” on page 8-603.

Login module

After an authenticator is able to parse credentials from a request, they are sent to a login module that is responsible for validating those credentials. After the credentials are considered valid and the user can be authorized, the login module creates a user identity for the realm. For more information about login modules, see “Authenticators and login modules” on page 8-603.

User identity

After a login module successfully validates a set of user credentials, it creates a user identity. A user identity contains at least a user name and a display name. It can also contain attributes that provide more details the protected resource might need.

Challenge handlers

A challenge handler is the client-side JavaScript that is included in a MobileFirst application that is created by the developer. A challenge

handler handles an authentication challenge from the server. A challenge handler can be defined for each realm, and is responsible for the following tasks:

- Determine whether a request is an authentication challenge that is specific to the realm.
- Perform necessary user interaction if it receives a challenge.
- Send the credentials to the server to complete the authentication.
- Validate that the authentication was successful.

MobileFirst security configuration

For MobileFirst Server to protect a resource, such as an adapter procedure or an application environment, the administrator must first configure the MobileFirst Server instance.

Defining a login module

A login module is the most basic security element in the MobileFirst authentication configuration. You can define a login module in the `<loginModules>` element in the `authenticationConfig.xml` file. The following example shows a login module definition:

```
<loginModules>
...
  <loginModule name="HeaderLogin"
    audit="true
    expirationInSeconds="-1">
    <className>com.worklight.core.auth.ext.HeaderLoginModule</className>
    <parameter name="user-name-header" value="userid" />
    <parameter name="display-name-header" value="username" />
  </loginModule>
...
</loginModules>
```

In this example, the login module is called `HeaderLogin` and is referred to from a realm element. The `<className>` element must contain the full Java namespace to a login module implementation. The `HeaderLoginModule` is a login module that is included by default. It checks that the user entered any, non-empty user name and password.

Defining a realm

After a login module is defined, you must specify a realm. You can add a realm to the `<realms>` element in the `authenticationConfig.xml` file. The following example shows a realm definition:

```
<realms>
...
  <realm name="RequiresUserHeaders" loginModule="HeaderLogin">
    <className>com.worklight.core.auth.ext.HeaderAuthenticator</className>
  </realm>
...
</realms>
```

Defining a security test

You can define a security test in the `<securityTests>` element in the `authenticationConfig.xml` file. The following example shows a security test definition:

```

<securityTests>
...
  <customSecurityTest name="BasicRequirements">
    <test realm="wl_antiXSRFRealm" />
    <test realm="wl_authenticityRealm" />
    <test realm="wl_remoteDisableRealm" />
    <test realm="RequiresUserHeaders" isInternalUserID="true" />
    <test realm="wl_deviceNoProvisioningRealm" isInternalDeviceID="true" />
  </customSecurityTest>
...
</securityTests>

```

This custom security test is called `BasicRequirements`, and contains a list of tests. The tests define which realms are required for authorization into the protected resource. The tests in this example are built-in realms. Built-in realms are prefixed with `wl_`.

Note: If one test fails, then the entire security test fails.

The `isInternalUserID` attributes can be set to `true` only on a single realm. This attribute is used as the default identity for a user in the security test. The `isInternalDeviceID` attribute is similar, but sets a default device identity.

This example uses the `RequiresUserHeaders` realm in the previous example.

Creating a challenge handler

You must create a challenge handler for your MobileFirst app to handle any custom challenges.

For more information about challenge handlers, see the tutorials on the following Getting Started pages of the Developer Center: Custom Authentication and Creating the client-side authentication components.

MobileFirst application environment protection

After a security test is configured with the appropriate realms, you can protect any resource. One option is to completely protect an application's environment with that security test.

To set up this protection, you must add the `securityTest` attribute to the `environment`'s element in the `applicationDescriptor.xml` file. The following example shows the environment protection definition:

```

<iPhone version="1.0" securityTest="BasicRequirements">
...
</iPhone>

```

This definition requires every iPhone device that connects to the server through your application to log in to the `BasicRequirements` security test.

MobileFirst adapter procedure protection

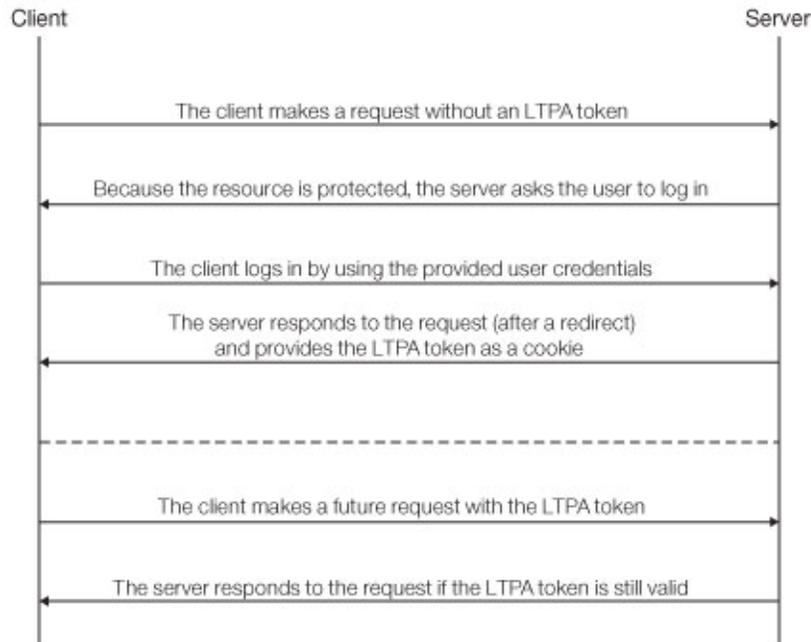

Another option is to protect a MobileFirst adapter procedure. Using the same security test, you can protect an adapter procedure. When the procedure is called and the user is not already authenticated into the security test, the client is required to authenticate. If you have an adapter procedure named `GetSecretData`, you can protect it in the adapter's XML configuration file by adding the `securityTest` attribute to the `<procedure>` element:

```
<procedure name="GetSecretData" securityTest="BasicRequirements" />
```

MobileFirst Security and LTPA

A lightweight third-party authentication (LTPA) token is a type of security token that is used by IBM WebSphere Application Server and other IBM products. LTPA can be used to send the credentials of an authenticated user to back-end services. It can also be used as a single sign-on (SSO) token between the user and multiple servers.

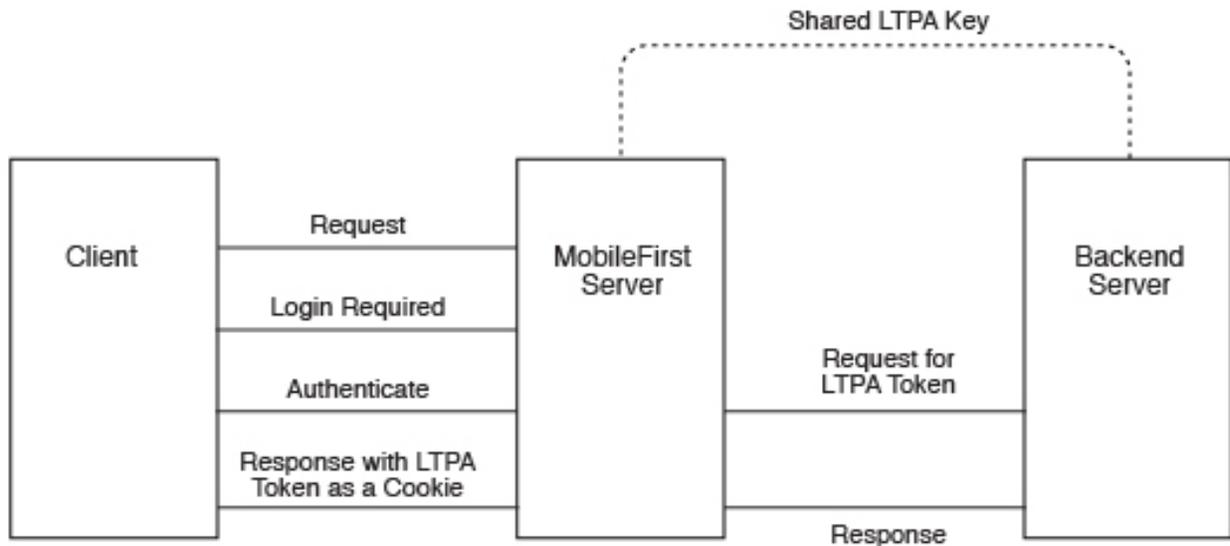

The following image shows a simple client <-> server flow with LTPA:

After a user logs in, the server generates an LTPA token, which is an encrypted hash that contains authenticated user information. The token is signed by a private key that is shared among all the servers that want to decode it. The token is usually in cookie form for HTTP services. By sending the token as a cookie, there is no need for subsequent user interaction.

LTPA tokens have a configurable expiration time to reduce the possibility for session hijacking.

The following image shows a client <-> MobileFirst Server <-> back-end server flow with LTPA:

Your infrastructure can also use the LTPA token to communicate with a back-end server to act on behalf of the user. The user cannot directly access the back-end server. Enterprise environments should use a reverse proxy, such as DataPower or IBM Security Access Manager, in the DMZ, and place the MobileFirst Server in the intranet. This configuration ensures that access to the MobileFirst Server cannot be obtained until a user authenticates. For more information, see “Reverse proxy with LTPA” on page 12-100.

Configuring the MobileFirst LTPA realm:

The IBM MobileFirst Platform Server contains the authenticator and login module that are designed to handle authentication by using LTPA through form-base authentication.

About this task

You must update the authenticationConfig.xml file to configure your server to use the MobileFirst LTPA realm.

Procedure

1. Add the login module definition to the <loginModules> element in your server’s authenticationConfig.xml file. The following example uses a login module that is called WASLTPAModule:

```

<loginModules>
...
  <loginModule name="WASLTPAModule">
    <className>com.worklight.core.auth.ext.WebSphereLoginModule</className>
  </loginModule>
...
</loginModules>
  
```

2. Add the realm definition to the <realms> element in your server’s authenticationConfig.xml file. The following example uses a realm that is called WASLTPARealm:

```

<realms>
...
  <realm name="WASLTPARealm" loginModule="WASLTPAModule">
    <className>com.worklight.core.auth.ext.WebSphereFormBasedAuthenticator</className>
  </realm>
...
</realms>
  
```

```

        <parameter name="login-page" value="/login.html" />
        <parameter name="error-page" value="/loginError.html" />
    </realm>
    ...
</realms>

```

3. Add a user test to an existing test in the authenticationConfig.xml file.

```

<customSecurityTest name="LTPASecurityTest">
    <test realm="wl_authenticityRealm" />
    <test realm="WASLTPARealm" isInternalUserID="true" />
    <test realm="wl_deviceNoProvisioningRealm" isInternalDeviceID="true" />
</customSecurityTest>

```

4. Create a login page and a login error page. The WASLTPARealm must know which HTML file to present to the client when the client must authenticate. This HTML file must be named login.html. When the client enters invalid credentials, the WASLTPARealm presents an error HTML file. This HTML file must be named loginError.html. These HTML files must be added to the root directory in the MobileFirst Server WAR file. The following example shows a sample login.html file:

```

<html>
  <head>
    <title>Login</title>
  </head>
  <body>
    <form method="post" action="j_security_check">
      <input type="text"
        id="j_username"
        name="j_username"
        placeholder="User name" />
      <input type="password"
        id="j_password"
        name="j_password"
        placeholder="Password" />
      <input type="submit" id="login" name="login" value="Log In" />
    </form>
  </body>
</html>

```

The following example shows a sample loginError.html file:

```

<html>
  <head>
    <title>Login Error</title>
  </head>
  <body>
    An error occurred while trying to log in.
  </body>
</html>

```

Supported configurations for LTPA:

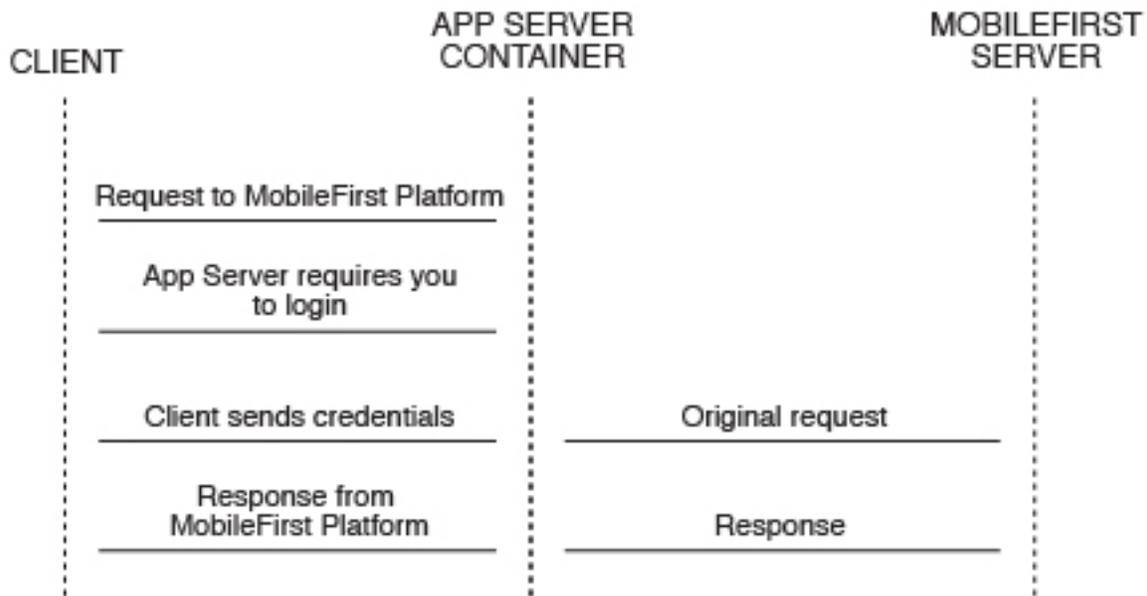

IBM MobileFirst Platform Foundation supports different configuration options to take advantage of LTPA, based on the server configuration and administrative requirements.

Protective application server (Option 1)

This configuration is formally known as Option 1 in the WebSphere LTPA-based authentication tutorial of the Developer Center. The application server is configured to protect all resources in the MobileFirst Server application, which is given specified roles. The application server sends the login page if the user does not send a valid LTPA token with the request. After the user sends valid

credentials, the original request is sent to the MobileFirst Server application with an LTPA token. The LTPA realm consumes the LTPA token and automatically logs in the user.

The following image shows a protective application server flow:

This option is not preferred for new configurations. The application server such as the WebSphere Application Server Liberty (Liberty) protects all resources and forces users to log in before any other authentication mechanism. The behavior occurs regardless of the expected authentication order for a security test.

To use this option with Liberty, you must edit the `web.xml` from the MobileFirst Server WAR file and Liberty's `server.xml` file. The following example shows the required modifications to the `web.xml` file:

```

<!-- Existing web.xml configuration here -->

<security-constraint id="worklightSecurityConstraint">
  <web-resource-collection id="worklightWebResourceCollection">
    <web-resource-name>Worklight Server</web-resource-name>
    <description>Protection area for Worklight Server.</description>
    <url-pattern>*/url-pattern>
    <http-method>GET</http-method>
    <http-method>POST</http-method>
  </web-resource-collection>
  <auth-constraint id="worklightAuthConstraint">
    <description></description>
    <role-name>allAuthenticationUsers</role-name>
  </auth-constraint>
  <user-data-constraint id="worklightUserDataConstraint">
    <transport-guarantee>NONE</transport-guarantee>
  </user-data-constraint>
</security-constraint>

<security-role id="securityRoleAllAuthenticatedUsers">
  <description>All Authenticated Users Role.</description>
  <role-name>allAuthenticationUsers</role-name>
</security-role>
  
```

```

<login-config>
  <auth-method>FORM</auth-method>
  <form-login-config>
    <form-login-page>/login.html</form-login-page>
    <form-error-page>/loginError.html</form-error-page>
  </form-login-config>
</login-config>

```

The following example shows the required modifications to the server.xml file:

```

<featureManager>
  <feature>appSecurity-1.0</feature>
  <!-- Any additional features you need go here -->
</featureManager>

<!-- Use an existing user registry instead if you have one.
      This registry is just an example. -->
<basicRegistry>
  <user name="sampleuser" password="demo" />
</basicRegistry>

<!-- Any additional settings go here -->
<application context-root="/worklight"
              location="worklight.war"
              name="worklight"
              type="war">
  <classloader commonLibraryRef="worklight-6.1.0,apps-common" />

  <!-- This is our addition: application-bnd.
        The security-role defines who is authorized into a role from web.xml -->
  <application-bnd>
    <security-role name="allAuthenticationUsers">
      <special-subject type="ALL_AUTHENTICATED_USERS" />
    </security-role>
  </application-bnd>
</classloader>
</application>

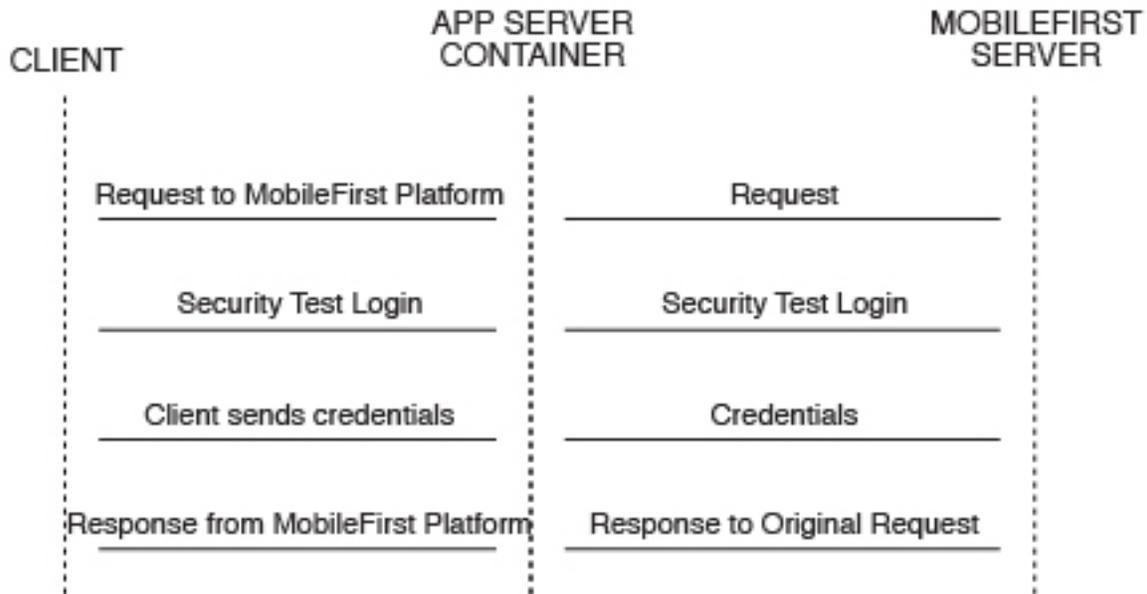

```

Note: Remember to add the login.html and loginError.html files to the root directory in the MobileFirst Server WAR file to provide a way for the user to log in. For more information, see step 4 of “Configuring the MobileFirst LTPA realm” on page 12-95.

Protective MobileFirst security test (Option 2)

An alternative configuration allows the server to use all of the MobileFirst security test configuration features. This option is preferred for new configurations. For example, Option 1 always asks the user to log in on the first request. Option 2 asks for the user to authenticate only when the MobileFirst Server deems that it is necessary.

The following image shows a protective security test flow:

You need to modify only Liberty's `server.xml` file to configure this option. The `WASLTPARealm` handles the actual authentication against the user registry that is defined in the `server.xml` file. The example configuration allows the user with the user name `sample user` and the password `demo` to authorize correctly.

The following example shows the required modifications to the `server.xml` file:

```

<featureManager>
  <feature>appSecurity-1.0</feature>
  <!-- Any additional features you need go here -->
</featureManager>

<!-- Use an existing user registry instead if you have one.
      This registry is just an example. -->
<basicRegistry>
  <user name="sampleuser" password="demo"/>
</basicRegistry>

<!-- Any additional settings go here -->
<application context-root="/worklight"
  location="worklight.war"
  name="worklight"
  type="war">
  <classloader commonLibraryRef="worklight-6.1.0,apps-common"/>
  <!-- This is our addition: application-bnd.
      The security-role defines who is authorized into a role from web.xml -->
  <application-bnd>
    <security-role name="allAuthenticationUsers">
      <special-subject type="ALL_AUTHENTICATED_USERS" />
    </security-role>
  </application-bnd>
</classloader>
</application>
  
```

Note: Remember to add the `login.html` and `loginError.html` files to the root directory in the MobileFirst Server WAR file to provide a way for the user to log in. For more information, see step 4 of "Configuring the MobileFirst LTPA realm" on page 12-95.

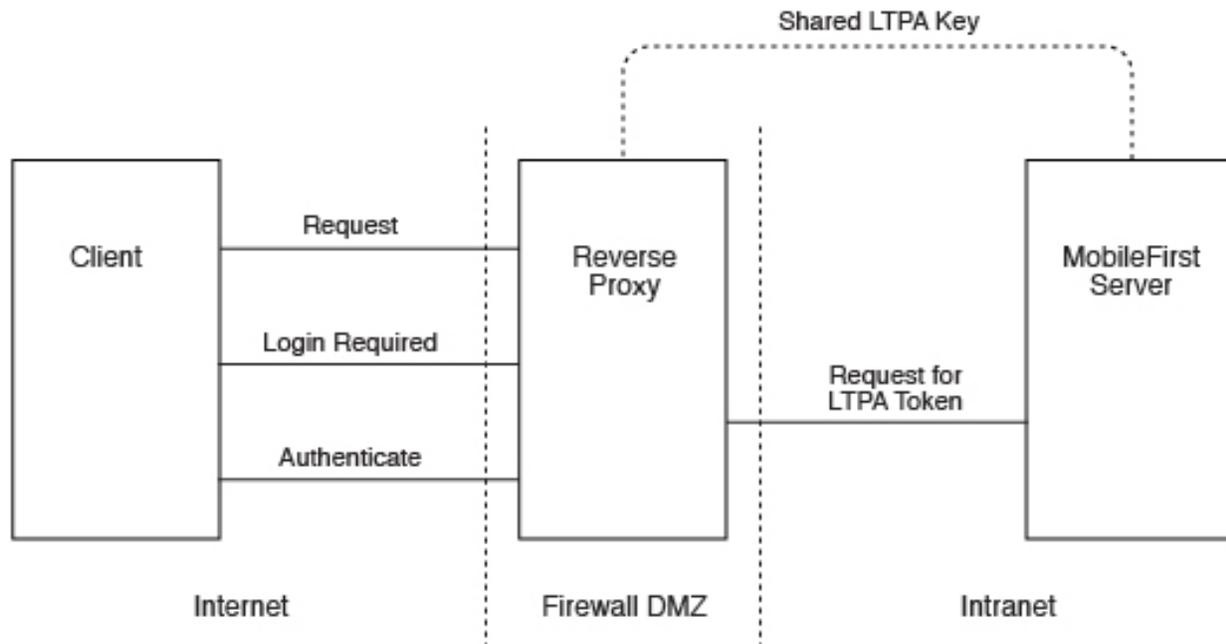

LTPA topologies and use cases:

IBM MobileFirst Platform Foundation supports various infrastructure topologies for a set of requirements that can take advantage of LTPA or MobileFirst security.

Reverse proxy with LTPA

A reverse proxy can be used to authenticate, and then send the user's LTPA token after the user is authenticated. This configuration can be useful when you want to offload IBM MobileFirst Platform Foundation from handling vital user credentials or to use an existing authentication setup. The MobileFirst Server must be configured for LTPA authentication to get the user identity. Both supported LTPA configurations log the user in automatically if the LTPA token is valid and the user is authorized. For more information about integrating IBM MobileFirst Platform Foundation with a reverse proxy, see "Integration and authentication with a reverse proxy" on page 15-3.

The following image shows a reverse proxy flow:

Related information

Integration and authentication with a reverse proxy

You can use a reverse proxy to enable enterprise connectivity within a MobileFirst environment and to provide authentication to IBM MobileFirst Platform Foundation.

Configuring the MobileFirst Server for Trusteer

Configure the IBM MobileFirst Platform Server to use Trusteer[®]-generated data to protect resources.

About this task

You must update the `authenticationConfig.xml` file to configure your server to use the MobileFirst Trusteer realm.

Note: If code that uses the Trusteer realm accesses a resource that is protected by OAuth authentication, and the client has a valid token, the MobileFirst Server is not called. As a result, the server does not check whether the device passes all of the configured Trusteer parameters. The MobileFirst Server is called when the token expires or when the Trusteer realm inside the token expires. When the realm expires, the Trusteer authenticator is invoked and the server checks whether the devices passed all of the configured Trusteer parameters. For more information about the OAuth security model, see “OAuth-based security model” on page 8-527. For a general overview of the MobileFirst security configuration, see “MobileFirst security overview” on page 12-90 and “MobileFirst security configuration” on page 12-92.

Procedure

1. Add the login module definition to the `<loginModules>` element in your server’s `authenticationConfig.xml` file. The following example uses a login module that is called `trusteerFraudDetectionLogin`:

```
<loginModules>
...
  <loginModule name="trusteerFraudDetectionLogin">
    <className>com.worklight.core.auth.ext.TrusteerLoginModule</className>
  </loginModule>
...
</loginModules>
```

2. Add the realm definition to the `<realms>` element in your server’s `authenticationConfig.xml` file. The following example uses a realm that is called `wl_basicTrusteerFraudDetectionRealm`:

```
<realms>
...
  <realm name="basicTrusteerFraudDetectionRealm" loginModule="trusteerFraudDetectionLogin">
    <className>com.worklight.core.auth.ext.TrusteerAuthenticator</className>
    <parameter name="rooted-device" value="block"/>
    <parameter name="device-with-malware" value="block"/>
    <parameter name="rooted-hiders" value="block"/>
    <parameter name="unsecured-wifi" value="alert"/>
    <parameter name="outdated-configuration" value="alert"/>
  </realm>
...
</realms>
```

The possible values for Trusteer realm parameters are described in Table 12-18.

Table 12-18. Possible values for Trusteer realm parameters.

Value	Description
block	Access fails.
alert	Access is permitted and it is recommended to issue a warning.
accept	Access is permitted.

The error codes that have been defined for Trusteer correspond to the parameters in the realm. See Table 12-19 on page 12-102.

Table 12-19. Trusteer error codes.

Code	Description	Corresponding parameter
TAS_ROOT	Indicates that the device is rooted (Android) or jailbroken (iOS).	rooted-device
TAS_MALWARE	Indicates that the device contains malware. Currently financial malware is detected, but will be expanded to all malware.	device-with-malware
TAS_ROOT_EVIDENCE	Indicate that the device contains root hider applications that hide the fact that the device is rooted/jailbroken.	rooted-hiders
TAS_WIFI	Indicates that the device is currently connected to an unsecured Wi-Fi.	unsecured-wifi
TAS_OUTDATED	Indicates that Trusteer SDK configuration has not updated for some time, meaning that it did not connect to the Trusteer server.	outdated-configuration
TAS_INVALID_HEADER	Indicates that the format of the Trusteer header is invalid.	-
TAS_NO_HEADER	Indicates that the Trusteer SDK is not installed, or has failed to initialize.	-

3. Define a security test in the <securityTest> element in the authenticationConfig.xml file. For Trusteer, it could be:

```
<customSecurityTest name="TrusteerTest">
  <test realm="wl_basicTrusteerFraudDetectionRealm" isInternalUserID="true" step="1"/>
  ...
</customSecurityTest>
```

4. Use the security test to protect a resource. For example, you can protect an application's environment completely with that security test by adding the securityTest attribute to the environment's element in the authenticationConfig.xml file:

```
<iPhone version="1.0" securityTest="TrusteerTest">
  ...
</iPhone>
```

This definition requires every iPhone device that connects to the server through your application to log in to the TrusteerTest security test.

5. Using the same security test, another option is to protect a MobileFirst adapter procedure. . If you have an adapter procedure named GetSecretData, you can protect it in the XML configuration file of the adapter by adding the <realms> attribute to the <procedure>:

```
<procedure name="GetSecretData" securityTest="TrusteerTest" />
```

6. Create a challenge handler for your MobileFirst app to handle Trusteer challenges. The following samples are samples of simple challenge handlers:

JavaScript

```
var trusteeChallengeHandler = WL.Client.createWLChallengeHandler("wl_basicTrusteerFraudDetectionRealm");

trusteeChallengeHandler.handleFailure = function(error) {
    //Note: error object includes array of alerts (same values as error.reason) from the
    //Trusteer authenticator and can be accessed via error.alerts
    WL.SimpleDialog.show("Error", "Operation failed. Please contact customer support (reason code: " + error.reason + ")",
        [{text:"OK"}]);
};

//In case authenticator succeeds, there may still be alerts that developer should notify the user about:

trusteeChallengeHandler.processSuccess = function(identity){
    var alerts = identity.attributes.alerts; //Array of alerts codes
    if(alerts.length > 0) {
        WL.SimpleDialog.show("Warning", "Please note that your device is : " + alerts, [{text:"OK"}]);
    }
}
```

Java

```
public class TrusteerChallengeHandler extends WLChallengeHandler {

    private static Logger logger = Logger.getInstance(TrusteerChallengeHandler.class.getSimpleName());
    public TrusteerChallengeHandler(String realmName) { super(realmName); }

    @Override
    public void handleSuccess(JSONObject identity) {
        try {
            JSONArray alerts = identity.getJSONObject("attributes").getJSONArray("alerts");
            if(alerts.length() > 0) {
                logger.warn ("TrusteerChallengeHandler.handleSuccess with alerts: " + alerts);
                //todo: display message to the user
            }
        } catch (Exception e) {
            logger.error("Unexpected error: " + e);
        }
    }

    @Override
    public void handleFailure(JSONObject error) {
        try {
            String errorReason = error.getString("reason");
            logger.error("TrusteerChallengeHandler.handleFailure: " + errorReason + "(" + error + ")");
            String msg = "Trusteer fraud detection failed due to " + errorReason;
            JSONArray alerts = error.getJSONArray("alerts");
            if(alerts.length() > 0) {
                logger.warn ("TrusteerChallengeHandler.handleSuccess with alerts: " + alerts);
                //todo: We also have alerts...
            }
            //todo: display error message to user
        } catch (Exception e) {
            logger.warn ("Unexpected error: " + e);
        }
    }

    @Override
    public void handleChallenge(JSONObject challenge) {
        //Nothing to do...
    }
}
```

```
// Register your newly created challenge handler for your Trusteer realm:
WLClient.getInstance().registerChallengeHandler(
    new TrusteerChallengeHandler("wl_basicTrusteerFraudDetectionRealm")
);
```

Objective-C

```
// Assuming you have added a Trusteer realm to the authentication configuration file of
// your server, you can register a challenge handler to receive the responses from
// the authenticator.

// Create a class that extends WLChallengeHandler:
#import "WLChallengeHandler.h"
@interface TrusteerChallengeHandler : WLChallengeHandler
@end

// Register your newly created challenge handler for your Trusteer realm:
[[WLClient sharedInstance] registerChallengeHandler:
[[TrusteerChallengeHandler alloc] initWithRealm:@"
wl_basicTrusteerFraudDetectionRealm"]];

// If you have set one of your realm options to block, a blocking event will trigger handleFailure.
@implementation TrusteerChallengeHandler
//...
-(void) handleFailure: (NSDictionary *)failure{
    NSLog(@"Your request could not be completed. Reason code: %@",
        failure[@"reason"]);
}
//...
@end

// If your have set one of your realm options to alert, you can catch the alert event
// by implementing the handleSuccess method.
@implementation TrusteerChallengeHandler
//...
-(void) handleSuccess:(NSDictionary *)success{
    NSArray* alerts = success[@"attributes"][@"alerts"];
    if(alerts && alerts.count){
        for(NSString* alert in alerts){
            NSLog(@"This device is %@", alert);
        }
    }
}
//...
@end
```

Accessing Trusteer risk assessment

Access Trusteer risk assessment to add Trusteer protection on the client side.

For an application that is running on a rooted device, you might want to disable the "Transfer Funds" button entirely, in addition to the server-side security tests described in "Configuring the MobileFirst Server for Trusteer" on page 12-100.

The following code samples are for JavaScript, Java, and Objective-C:

JavaScript

```
WL.Trusteer.getRiskAssessment(onSuccess);
```

Where onSuccess is a function that receives a JSON object that contains all the data processed by Trusteer. See Trusteer documentation for information on each risk item.

```
function onSuccess(result){
    //See the logs for full result
    WL.Logger.debug(JSON.stringify(result));
    //Check for a specific flag
```

```

        if(result["os.rooted"]["value"] != 0){
            alert("This device is rooted!");
        }
    }
}

```

Objective-C

```

#import "WLTrusteer.h"
NSDictionary* risks =[[WLTrusteer sharedInstance] riskAssessment];

```

This returns an NSDictionary of all the data that is processed by Trusteer. See Trusteer documentation for information on each risk item.

```

//See logs for full result
NSLog(@"%@",risks);
//Check for a specific flag
NSNumber* rooted = [[risks objectForKey:@"os.rooted"] objectForKey:@"value"];
if([rooted intValue]!= 0){
    NSLog(@"Device is jailbroken!");
}

```

Java

```

WLTrusteer trusteeer = WLTrusteer.getInstance();
JSONObject risks = trusteeer.getRiskAssessment();

```

This returns an JSONObject of all the data that is processed by Trusteer. See Trusteer documentation for information on each risk item.

```

JSONObject rooted = (JSONObject) risks.get("os.rooted");
if(rooted.getInt("value") > 0){
    //device is rooted
}

```

Advanced security features

IBM MobileFirst Platform Foundation supports more features that can use LTPA in advanced scenarios, such as user certificate authentication and role-based authentication.

Role-based authentication

In IBM Worklight V6.1 and later, role-based authentication is supported. This feature allows the MobileFirst LTPA realm to be configured to restrict access to a specific Java Platform, Enterprise Edition role. The realm denies the user if the user is not authorized to the role that is specified. This feature is optional. By not defining a required role in the realm's configuration, all users get an LTPA token and are authorized if credentials are correct.

For more information, see “WASLTPAModule login module” on page 8-620.

User certificate authentication

In IBM Worklight V6.1 and later, the User Certificate Authentication feature is supported. This form of authentication allows users to authenticate through an X.509 client certificate over SSL. The realm definition includes parameters to configure the authenticator, which includes the concept of a dependent realm. The dependent realm is a realm that is required to be authenticated before the user certificate can be generated. After the user logs in to the dependent realm, the user certificate authenticator uses the user identity to build the certificate signing request (CSR) and certificate.

For more information, see “User certificate authentication” on page 8-577.

Obfuscating Android code with ProGuard

You can obfuscate Android code to provide security against reverse engineering.

You can use the Android ProGuard tool to obfuscate, shrink, and optimize your code. Obfuscated code can be more difficult for other people to reverse engineer. ProGuard renames classes, fields, and methods with semantically obscure names and removes unused code.

IBM MobileFirst Platform Foundation provides a file that contains all of the necessary configuration information to run Android ProGuard obfuscation with a MobileFirst application. This file is called `proguard-project.txt` and is located in the MobileFirst Android native folder. Use Proguard 5.2. To change the Proguard version, replace the `proguard` folder with the new one in the `android-sdk/tools` folder.

Important: Because the tool obfuscates all Java files, consider that you will have to spend some time and resources to make it work, especially if you use libraries from other software vendors.

Related information:

 [ProGuard at developer.android.com](http://developer.android.com)

Example

Obfuscation with ProGuard results in changes to file names and to code as displayed in these examples.

The following figure shows the StarterApplication APK .jar file before and after obfuscation:

Figure 12-3. Two side-by-side images. Before obfuscation the names are longer. After obfuscation, names are shorter.

The following code is the content of the StarterApplication APK Java file before obfuscation.

```
package com.StarterApplication;

import android.app.AlertDialog;
import android.app.AlertDialog.Builder;
import android.content.DialogInterface;
import android.content.DialogInterface.OnClickListener;
import android.os.Bundle;
import com.worklight.androidgap.api.WL;
import com.worklight.androidgap.api.WLInitWebFrameworkListener;
import com.worklight.androidgap.api.WLInitWebFrameworkResult;
import org.apache.cordova.CordovaActivity;

public class StarterApplication extends CordovaActivity
    implements WLInitWebFrameworkListener
{
    private void handleWebFrameworkInitFailure(WLInitWebFrameworkResult paramWLInitWebFrameworkResult)
    {
        AlertDialog.Builder localBuilder = new AlertDialog.Builder(this);
        localBuilder.setNegativeButton(2130968579, new DialogInterface.OnClickListener()
        {
            public void onClick(DialogInterface paramAnonymousDialogInterface, int paramAnonymousInt)
            {
                StarterApplication.this.finish();
            }
        });
        localBuilder.setTitle(2130968578);
```

```

        localBuilder.setMessage(paramWlInitWebFrameworkResult.getMessage());
        localBuilder.setCancelable(false).create().show();
    }

    public void onCreate(Bundle paramBundle)
    {
        super.onCreate(paramBundle);
        WL.createInstance(this);
        WL.getInstance().showSplashScreen(this);
        WL.getInstance().initializeWebFramework(getApplicationContext(), this);
    }

    public void onInitWebFrameworkComplete(WLInitWebFrameworkResult paramWlInitWebFrameworkResult)
    {
        if (paramWlInitWebFrameworkResult.getStatusCode() == WLInitWebFrameworkResult.SUCCESS)
        {
            super.loadUrl(WL.getInstance().getMainHtmlFilePath());
            return;
        }
        handleWebFrameworkInitFailure(paramWlInitWebFrameworkResult);
    }
}

```

The following code is the content of the Java file after obfuscation:

```

package com.StarterApplication;

import android.app.AlertDialog;
import android.app.AlertDialog.Builder;
import android.os.Bundle;
import com.worklight.androidgap.b.c;
import com.worklight.androidgap.b.d;
import org.apache.cordova.CordovaActivity;

public class StarterApplication extends CordovaActivity
    implements c
{
    public final void a(d paramd)
    {
        if (paramd.a() == 0)
        {
            super.loadUrl(com.worklight.androidgap.b.a.b().c());
            return;
        }
        AlertDialog.Builder localBuilder = new AlertDialog.Builder(this);
        localBuilder.setNegativeButton(2130968579, new a(this));
        localBuilder.setTitle(2130968578);
        localBuilder.setMessage(paramd.b());
        localBuilder.setCancelable(false).create().show();
    }

    public void onCreate(Bundle paramBundle)
    {
        super.onCreate(paramBundle);
        com.worklight.androidgap.b.a.a(this);
        com.worklight.androidgap.b.a.b();
        com.worklight.androidgap.b.a.b(this);
        com.worklight.androidgap.b.a.b().a(getApplicationContext(), this);
    }
}

```

Creating an obfuscated APK file from MobileFirst Studio

To create an obfuscated application package (.apk) file in IBM MobileFirst Platform Studio, you edit the Android native project properties file, then build your application in release mode.

Before you begin

- You must be using Android API level 19 or higher.
- You must be familiar with the Android development and build process. For more information, see the Android developer website.
- You must be familiar with the ProGuard tool. See "ProGuard" at the Android developer website.
- Ensure that the ANDROID_HOME and JAVA_HOME environment variables are set.

About this task

The following steps assume that you are developing in an Eclipse integrated development environment (IDE).

Procedure

1. Complete the appropriate steps in the following table, depending on whether you are developing a native or a hybrid application:

Native Android application	Hybrid Android application
<ol style="list-style-type: none">1. Copy the file proguard-project.txt from the MobileFirst Native API for Android application to your Android project in Eclipse.2. Open the project.properties file with a text editor and add the text proguard.config=proguard-project.txt on a separate line in the file.	<ol style="list-style-type: none">1. Open the <i>project_name/apps/app_name/android/native/project.properties</i> file with a text editor.2. In the project.properties file that you just opened, uncomment the line proguard.config=proguard-project.txt.

2. Add any other configuration details that might be needed by your application to the proguard-project.txt file.
3. Build your application in release mode.
4. Save a copy of the mapping.txt file. The mapping.txt file defines how your classes are obfuscated and is needed to debug stack traces.

Important: For each build that you publish, copy the mapping.txt file or save it under a new name because subsequent builds will overwrite the file. It is important to save this file for each build for which you might need to restore a stack trace.

Creating an obfuscated APK file from a command line

You can create an obfuscated Android application package with command-line tools.

Before you begin

- You must be using Android API level 19 or higher.
- You must be familiar with the Android development and build process. For more information, see "Building and Running from the Command Line" at the Android developer website.
- You must be familiar with the ProGuard tool. See "ProGuard" at the Android developer website.
- Ensure that the ANDROID_HOME and JAVA_HOME environment variables are set.

Procedure

1. Complete the appropriate steps in the following table, depending on whether you are developing a native or a hybrid application:

Native Android application	Hybrid Android application
<ol style="list-style-type: none">1. Copy the file <code>proguard-project.txt</code> from the MobileFirst Native API for Android application to your Android project in Eclipse.2. Open the <code>project.properties</code> file with a text editor and add the text <code>proguard.config=proguard-project.txt</code> on a separate line in the file.	<ol style="list-style-type: none">1. Open the <code>project_name/apps/app_name/android/native/project.properties</code> file with a text editor.2. In the <code>project.properties</code> file that you just opened, uncomment the line <code>proguard.config=proguard-project.txt</code>.

2. Add any other configuration details that might be needed by your application to the `proguard-project.txt` file.
3. Create and add the keystore file to the Android project (in the `android/native` folder). You can use several methods to define the keystore file. The following example defines the keystore file with the **keytool** utility that is available in the Java Development Kit (JDK):

```
keytool -genkey -v -keystore release_key.keystore
-alias alias_name -keyalg RSA -keysize 2048 -validity 1000
```
4. Create and add the `ant.properties` file to the Android project.
5. In this new file, enter the following text:

```
key.alias=mykey
key.store.password=worklight
config.logging=false
key.store=release.keystore
key.alias.password=worklight
```
6. Build the application in release mode.
7. Save a copy of the `mapping.txt` file. The `mapping.txt` file defines how your classes are obfuscated and is needed to debug stack traces.

Important: For each build that you publish, copy the `mapping.txt` file or save it under a new name because subsequent builds will overwrite the file. It is important to save this file for each build for which you might need to restore a stack trace.

Results

The `release.apk` file is created in the `android/native/bin` folder.

Restoring an obfuscated stack trace

The ProGuard obfuscation process results in an obfuscated stack trace. To recover the original stack trace, you can run a `retrace` script.

Before you begin

To restore the obfuscated stack trace, you must have a copy of the `mapping.txt` file that is generated for the release build of your application. This file is created in the `proguard` directory of your project each time you build with ProGuard.

Note: For each build for which you might need to restore a stack trace, copy the `mapping.txt` file or save it under a new name because subsequent builds will overwrite the file.

Procedure

1. Navigate to the directory where ProGuard is installed. (Usually `sdk_root/tools/proguard/bin/`).
2. Run the following command, as appropriate to your operating system:
`retrace.bat|retrace.sh [-verbose] mapping.txt [stacktrace_file] > stacktrace_out.txt`

where

`stacktrace_file` is the name of the stack trace file that you want to restore to readable form.

`mapping.txt` file is the instance of this file that you saved for the specific release build.

`stacktrace_out.txt` is the file that contains the unobfuscated stack trace.

Results

A readable stack trace is written to `stacktrace_out.txt`.

Code size reduction from obfuscation

Using ProGuard can reduce the size of your code.

Because ProGuard removes unused code and performs other optimizations, using it typically reduces code size. The extent of the reduction depends on the original code. The following table shows some typical results:

Table 12-20. Example of code size reductions after use of ProGuard

Application name	Original APK size (MB)	APK size after use of ProGuard (MB)
Simple Android (without MobileFirst)	0.318	0.106
MobileFirst default application	3.4	1.9
MobileFirst StarterApplication	3.4	2.0

High availability

High availability is provided through clustering, the ability to provide multiple MobileFirst Server instances acting together.

Multiple MobileFirst Server instances enable horizontal scaling of the software as well as the prevention of a single point of failure.

Clustering

The MobileFirst Server creates a cluster by deploying multiple servers that share the database instance.

The basic setup consists of the load balancer, the cluster nodes, and a database that is shared by the cluster nodes.

All cluster nodes are identical; that is, the content of the installation folder is the same in all nodes. Cluster nodes do not synchronize with each other at run time. All management data is in the MobileFirst administration services, which verify that all cluster nodes have the same data. With WebSphere Application Server Network Deployment, you can use built in clustering support for distributing the

MobileFirst project WAR (and the MobileFirst Shared library). For more information, see the IBM WebSphere Application Server V8 user documentation.

MobileFirst Server can run on a VMware virtual machine. In such cases, one machine image is created and then deployed again and again.

IBM MobileFirst Platform Foundation is *stateful*. It caches session state within the server memory. The result is that if one MobileFirst Server is taken offline, active user sessions are lost and the client is asked to log on again.

Configuring the load balancer

You can use hardware-based or software-based load balancers.

If you do not want to use a hardware-based load balancer, you can use a simpler, software-based load balancer, or reverse proxy such as the Apache Tomcat web server. Any load balancer that can support the following features is adequate:

- Sticky session: load balancing settings should depend on session dependency:
 - When session-independent mode is on, (default) sticky session should be off.
 - When session-independent mode is off, sticky session should be on.

Note: For more information, see “Session-independent mode” on page 8-324.

- Reverse proxy capabilities: Mandatory
- SSL Acceleration: Optional

Configuration of the load balancer depends on the vendor and is not covered in this document. It is common to define the range of the node addresses so that they can be added or deleted dynamically.

Adding a node to the cluster

Follow the instructions for creating a IBM MobileFirst Platform Server to add a node to the cluster.

About this task

You can add a node to the cluster, by following the instructions for creating a MobileFirst Server:

Procedure

1. Add the IP address of the node to the load balancer or use an existing address from a range that was pre-allocated to instances of MobileFirst Server.
2. Install the MobileFirst Server.
3. Apply the project WAR.

Firewalls

Firewalls can be configured at various layers of the IBM MobileFirst Platform Foundation architecture.

Firewalls in front of a MobileFirst Server use the typical configuration.

Special attention must be given to a firewall layer between the IBM MobileFirst Platform Foundation servers and the IBM MobileFirst Platform Foundation database.

- MobileFirst Server employs database connection pooling. Firewalls may detect idle database connections and terminate them resulting in unexpected behavior.

- Firewalls limit the number of connections allowed. This is done to prevent Denial of Service (DoS) attacks. However, with multiple clustered MobileFirst Server instances, the number of connections might be higher than usual.

Disaster Recovery Site

IBM MobileFirst Platform Foundation supports the creation of a separate disaster recovery site that becomes operational if the original site goes down.

A disaster recovery site is a second, physically separate IT center on which a copy of the IT systems exists, and springs into operation if the original site is down. IBM MobileFirst Platform Foundation has such a site for some of its customers.

Within the site, IBM MobileFirst Platform Foundation provides redundancy at every level: compensating load balancers, multiple IBM MobileFirst Platform Foundation servers that scale linearly, and database redundancy through Oracle RAC. Some customers prefer to provide another level of redundancy by using a disaster recovery site.

The key administrative factors for such a site are:

- Architecture
- Data mirroring from master to backup site
- Switching to back up site on disaster

Architecture

The architecture of the backup site is a copy of the original site. Special care must be taken to:

- Provide access to all corporate back-end systems.
- Create a switch that transfers incoming requests from master to backup site.

Data mirroring

For the backup site to work, data on the master site must be mirrored to the backup regularly:

Table 12-21. Data mirroring

Component	Description	Mirror frequency
IBM MobileFirst Platform Foundation Database	All tables must be mirrored. The exceptions to this rule are cache tables (SSO_LOGIN_CONTEXTS) and report tables (which are large in size).	Highly dependent on implementation and can range from a few minutes to 24 hours. For more information, contact software support.
IBM MobileFirst Platform Foundation Software, customization, and content	Any change in IBM MobileFirst Platform Foundation software, customization, or content must also be installed on the mirror servers.	As it occurs.

Switching to back up site

When you switch to the backup site, some information might be lost:

- All clients lose context and disconnect. In the case of an authenticated app, the user is prompted to log in again.
- Report information is lost (unless previously mirrored).

- Cache is lost. If Cache was implemented for various queries, an additional server fetch is required to fill cache.

Switching back to Master Site

Before you switch back to the master site, you must mirror the database back to the master site.

Important: The success of a recovery site is in the details. To ensure the successful functioning of such a site, you must develop and follow a strict written procedure, which you test regularly.

Updating MobileFirst apps in production

There are general guidelines for upgrading your MobileFirst apps when they are already in production, on the Application Center or in app stores.

The general procedure for deploying your MobileFirst apps for the first time to MobileFirst Server and the Application Center is as follows (see “Deploying an application from development to a test or production environment” on page 12-2).

1. Build and test your app by using IBM MobileFirst Platform Foundation, and use either the MobileFirst Operations Console or the supplied Ant tasks to deploy its `.wlap` files to MobileFirst Server and the Application Center.
2. Submit the generated device app files Application Center: `.apk` for Android apps, `.ipa` for iOS apps, `.appx` for Windows 8 Universal app, and `.xap` for Windows Phone 8 Silverlight app) to their respective app stores: Google Play, Apple Store, Windows Store, and Windows Phone Store.
3. Wait for the completion of the review and approval process. Try to avoid updating your app before the review process is completed because doing so can trigger a Direct Update and can confuse the reviewers.

Procedures for upgrading your app when it is already in production are contained in this section. You can choose from several ways to perform such upgrades, depending on their nature:

- Is the upgrade a new version of the app that contains new features or native code, or is it a bug fix or security upgrade?
- Is the upgrade mandatory or optional?
- If it is optional, do you want to leave the old version of the app in place and available to users, or not?
- How and when do you want to notify users of the upgrade?

These subjects are covered in the following topics.

Deploying a new app version and leaving the old version working

The most common upgrade path, used when you introduce new features or modify native code, is to release a new version of your app. Consider following these steps:

1. Increment the app version number.
2. Build and test your project and generate new `.wlap`, `.apk`, `.ipa`, `.appx`, or `.xap` files for it.
3. Deploy the new `.wlap` files to MobileFirst Server.
4. Submit the new `.apk`, `.ipa`, `.appx`, or `.xap` files to their respective app stores.
5. Wait for review and approval, and for the apps to become available.

6. Optional - send notification message to users of the old version, announcing the new version. See “Displaying a notification message on application startup” on page 13-5 and “Defining administrator messages from MobileFirst Operations Console in multiple languages” on page 13-5.

Deploying a new app version and blocking the old version

This upgrade path is used when you want to force users to upgrade to the new version, and block their access to the old version. Consider following these steps:

1. Optional - send notification message to users of the old version, announcing a mandatory update in a few days. See “Displaying a notification message on application startup” on page 13-5 and “Defining administrator messages from MobileFirst Operations Console in multiple languages” on page 13-5.
2. Increment the app version number.
3. Build and test your project and generate new .wlapp, .apk, .ipa, .appx, or .xap files for it.
4. Deploy the new .wlapp files to MobileFirst Server.
5. Submit the new .apk, .ipa, .appx, or .xap files to their respective app stores.
6. Wait for review and approval, and for the apps to become available.
7. Copy links to the new app version.
8. Block the old version of the app in MobileFirst Operations Console, supplying a message and link to the new version. See “Locking an application” on page 13-3 and “Remotely disabling application connectivity” on page 13-3.

Note: If you disable the old app, it is no longer able to communicate with MobileFirst Server. Users can still start the app and work with it offline unless you force a server connection on app startup.

Direct Update (no native code changes)

Direct Update is a mandatory upgrade mechanism that is used to deploy fast fixes to a production app. When you redeploy an app to MobileFirst Server without changing its version, MobileFirst Server directly pushes the updated web resources to the device when the user connects to the server. It does not push updated native code. Things to keep in mind when you consider a Direct Update include:

- Direct update does **not** update the app version. The app remains at the same version, but with a different set of web resources. The unchanged version number can introduce confusion if used for the wrong purpose
- Direct update also does not go through the app store review process because it is technically not a new release. This should not be abused because vendors can become displeased if you deploy a whole new version of your app that bypasses their review. It is your responsibility to read each store's usage agreements and abide by them. Direct update is best used to fix urgent issues that cannot wait for several days.
- Direct Update is considered a security mechanism, and therefore it is mandatory, not optional. When you initiate the Direct Update, all users **must** update their app to be able to use it.
- Direct Update does not work if an application is compiled (built) with a different version of IBM MobileFirst Platform Foundation than the one that was used for the initial deployment.

The steps for initiating a Direct Update are as follows:

1. Optional - send notification message to users of the old version, announcing a mandatory update in the next few hours or days. See “Displaying a notification message on application startup” on page 13-5 or “Defining administrator messages from MobileFirst Operations Console in multiple languages” on page 13-5.

Note: Do **not** increment the app version number.

2. Build and test your project and generate new .wlapp files for it.
3. Deploy the new .wlapp files to MobileFirst Server. This initiates the Direct Update.

For more information about Direct Update, see “Direct updates of app versions to mobile devices” on page 8-379.

Application authenticity

This feature will not work properly for clients that were built with an older version of IBM MobileFirst Platform Foundation when the application deployed is of a new product version but has the same application version. Those client requests to access the authenticity-protected resources will be denied.

To keep support of old applications using app authenticity, or block them, follow these steps:

1. Upgrade the project by using the newer version of IBM MobileFirst Platform Foundation, as described above.
2. Increment the versions of the upgraded applications.
3. Deploy the new WAR file that was built.
4. Deploy the new applications to the server alongside the applications that were built with the old IBM MobileFirst Platform Foundation.
5. Normally, both applications work as expected. If you want to use the new ones only, block the old ones and refer to the new ones for upgrade.

For more information about application authenticity, see “MobileFirst application authenticity overview” on page 8-564.

Deploying to the cloud in an IBM Container

You can deploy MobileFirst applications to the cloud in IBM Containers. This type of deployment enables you to deploy what you have developed in IBM MobileFirst Platform Foundation to a cloud platform such as IBM Bluemix.

The IBM MobileFirst Platform Foundation container-related offerings use IBM Containers, which is hosted on Bluemix (IBM's cloud-hosting environment). A container is based on an image format and provides an execution environment within itself.

IBM MobileFirst Platform Foundation on IBM Containers

Using MobileFirst Platform Foundation on IBM Containers, you can run instances of MobileFirst Server and MobileFirst Operational Analytics in containers on the cloud (IBM Bluemix).

This offering enables you to build Docker images of your MobileFirst applications and runtimes and then run them using the underlying infrastructure of IBM Containers on Bluemix.

Supported operating systems include: Linux and Mac OS X.

MobileFirst Platform Foundation on IBM Containers package overview

The MobileFirst Platform Foundation on IBM Containers package contains the artifacts to create a MobileFirst Server container and a MobileFirst Operational Analytics container, and the components necessary for configuring and deploying them to Bluemix.

- The MobileFirst Server container contains the following product components:
 - IBM MobileFirst Platform Server
 - IBM MobileFirst Platform Operations Console
 - MobileFirst Data Proxy
- The MobileFirst Operational Analytics container contains the following product components:
 - IBM MobileFirst Platform Operational Analytics server
 - IBM MobileFirst Platform Operational Analytics console
- Additional components:
 - Liberty for Java runtime
 - Configuration files
 - Scripts to build and deploy the containers

You will customize your product components in the given containers before they are built and deployed to the IBM Containers service on Bluemix.

See also “Package structure and contents” on page 12-117

Note: The Reports database has been deprecated and does not work with IBM MobileFirst Platform Foundation on IBM Containers. Instead, use a MobileFirst Operational Analytics container. Ensure that the project WAR files in your containers do not have any artifacts or configurations related to the deprecated Reports database.

Using the IBM MobileFirst Platform Foundation Containers

The main steps for using MobileFirst Platform Foundation on IBM Containers are:

1. Customizing the product components included in the container.
2. Building the container image format with your customizations.
3. Deploying and running the built images on the IBM Containers service.

Prerequisites

- A Java Runtime is required. See the system requirements for version information.
- Cloud Foundry CLI plug-in for IBM Containers (**cf ic**).

Note: The prerequisite for using this plug-in is to install Cloud Foundry CLI. For details, see CLI and dev tools.

- A Docker installation
- An IBM Bluemix account

Evaluation version on developerWorks

There is an evaluation version of MobileFirst Platform Foundation on IBM Containers V7.1 available as well as a related tutorial. You can download the evaluation package from IBM developerWorks.

Also on developerWorks, learn how you can use IBM UrbanCode™ Deploy to define a DevOps deployment solution for your MobileFirst Platform Foundation artifacts.

Package structure and contents

This topic contains important information about scripts and other contents of the MobileFirst Platform Foundation on IBM Containers package (`ibm-mfpf-container-7.1.0.0`).

The MobileFirst Platform Foundation on IBM Containers package provides a means to build your custom MobileFirst applications and deploy them to IBM Containers on Bluemix.

After you download the package, extract the contents to your development environment (to the `ibm-mfpf-container-7.1.0.0` folder, also referred to in this document as *package_root*). The following tables contain descriptions of the top-level folders of the package offering.

Table 12-22. Top-level folders

Folder	Description
dependencies	Contains the IBM MobileFirst Platform Foundation runtime and IBM Java JRE 7.1.
mfpf-analytics	Contains the artifacts required to build and deploy the MobileFirst Operational Analytics container.
mfpf-libs	Contains MobileFirst product component libraries and CLI.
mfpf-server	Contains the artifacts required to build and deploy a MobileFirst Server container.

Table 12-23. MobileFirst Operational Analytics container and MobileFirst Server container folders. The sub-folder names within the MobileFirst Operational Analytics container (`mfpf-analytics`) folder and MobileFirst Server container (`mfpf-server`) folder

Folder	Description
scripts	Contains the properties files and scripts for building and deploying the containers. Other than the customizable <code>args/*.properties</code> files, do not modify any elements in this folder.
usr	Contains user-configurable elements, such as keystores, properties, registry, and projects. Elements in this folder can be modified but not deleted.

Scripts

The scripts provided build and run the MobileFirst Operational Analytics container image and MobileFirst Server container image as containers.

Scripts can only be run from within the `scripts` folder. Do not modify the given folder structure.

Configuring a database instance on IBM Cloudant:

You can configure a IBM MobileFirst Platform Foundation container to use a database instance on Cloudant.com.

Before you begin

To configure your container to use a database instance that is hosted on Cloudant.com, you need your Cloudant user name and password and the URL of the database instance.

This type of database configuration does not require that you run the `mfpf-server/scripts/prepareserverdbs.sh` script.

Procedure

1. Using the example code snippet, create an XML configuration file for the MobileFirst Server administration database and place it in the `mfpf-server/usr/config` folder. Make sure to customize the example code with your Cloudant.com account information and URL.

```
<?xml version="1.0" encoding="UTF-8"?><server description="new server">
<jndiEntry jndiName="${env.MFPF_ADMIN_ROOT}/mfp.db.cloudant.username" value="cloudant_username" />
<jndiEntry jndiName="${env.MFPF_ADMIN_ROOT}/mfp.db.cloudant.password" value="cloudant_password" />
<jndiEntry jndiName="${env.MFPF_ADMIN_ROOT}/mfp.db.cloudant.url" value="cloudant_db_url"/>
</server>
```

2. Using the example code snippet, create an XML runtime database configuration file for each runtime project to be deployed using MobileFirst Server and place the files in the `mfpf-server/usr/config` folder. Make sure to customize the example code with your project name and your Cloudant.com account information and URL.

```
<?xml version="1.0" encoding="UTF-8"?><server description="new server">
<jndiEntry jndiName="<project_name>/mfp.db.cloudant.username" value="<cloudant_username>/>
<jndiEntry jndiName="<project_name>/mfp.db.cloudant.password" value="<cloudant_password>/>
<jndiEntry jndiName="<project_name>/mfp.db.cloudant.url" value="<cloudant_db_url>/>
<application id="<project_name>" location="<project_name>.war" name="<project_name>" type="war">
<classloader delegation="parentLast">
<privateLibrary id="worklightlib_<project_name>">
<fileset dir="${shared.resource.dir}/lib" includes="worklight-jee-library.jar"/>
<fileset dir="${wlp.install.dir}/lib" includes="com.ibm.ws.crypto.passwordutil*.jar"/>
</privateLibrary>
</classloader>
</application>
</server>
```

What to do next

After the XML configuration file is in place, continue with the container set up process. The next step is to run the `mfpf-server/scripts/prepareserver.sh` script. The XML file you created gets used by the script for database configuration.

“Building and running the MobileFirst Operational Analytics container” on page 12-135

“Building and running the MobileFirst Server container” on page 12-122

Customizing MobileFirst Server containers:

You must add projects and customize the related project components before building MobileFirst Server container images.

Custom applications built using MobileFirst Studio, or using Xcode and the MobileFirst Platform Command Line Interface can be deployed in a MobileFirst Server container.

The container gets created from the artifacts that are provided in the MobileFirst Platform Foundation on IBM Containers package. For an overview of the package contents and folder structure, see “Package structure and contents” on page 12-117.

The customizable elements for the MobileFirst Server container are located in *package_root/mfpf-server/usr*. The following tables describe the sub folders and files to use for customization.

Table 12-24. Descriptions of the *mfpf-server/* sub folders

Folder	Description
<i>./usr</i>	Contains the customization template for the MobileFirst Server container.
<i>./usr/bin</i>	Contains the script file (<i>mfp-init</i>) that gets executed when the container starts. You can add custom code to the script, however, do not modify the existing code.
<i>./usr/config</i>	Contains the server configuration fragments (keystore, server properties, user registry) used by MobileFirst Server. <ul style="list-style-type: none"> <i>keystore.xml</i> - the configuration of the repository of security certificates used for SSL encryption. The files listed must be referenced in the <i>./usr/security</i> folder. <i>mfpfproperties.xml</i> - configuration properties for the MobileFirst Server. See the supported properties listed in these topics: <ul style="list-style-type: none"> “List of JNDI properties for MobileFirst Server administration” on page 6-111 “Configuration of MobileFirst applications on the server” on page 12-50 <i>registry.xml</i> - user registry configuration. The <i>basicRegistry</i> (a basic XML-based user-registry configuration is provided as the default. User names and passwords can be configured for <i>basicRegistry</i> or you can configure <i>ldapRegistry</i>.
<i>./usr/env</i>	Contains the environment properties used for server initialization (<i>server.env</i>) and custom JVM options <i>jvm.options</i> . See Table 12-25 on page 12-121 for a list of supported server environment properties.
<i>./usr/jre-security</i>	Add JRE security-related files (such as the JRE truststore, <i>policy.jar</i> files, and so forth) to be updated on the container. The files in this folder get copied to the <i>JAVA_HOME/jre/lib/security/</i> folder in the container.
<i>./usr/projects</i>	Contains the existing projects that have been deployed to MobileFirst Server. You can add MobileFirst project WAR files or add the entire folder structure of a M
<i>./usr/projects/ project_name</i>	Contains the project to deploy to MobileFirst Server.
<i>./usr/projects/ project_name/bin</i>	Contains the project WAR file. The name of the project and the name of the project WAR file must be the same.

Table 12-24. Descriptions of the *mfpf-server/* sub folders (continued)

Folder	Description
<i>./usr/projects/ project_name/ server/conf</i>	Contains authenticationConfig.xml and SMSConfig.xml . These settings override the settings provided in the project WAR file.
<i>./usr/projects/ project_name/ server/lib</i>	Contains the library (JAR) files that are required by the project.
<i>./usr/security</i>	Contains your keystore, truststore, and LTPA keys (ltpa.keys) files.
<i>./usr/ssh</i>	Contains the ssh public key file (id_rsa.pub) to enable ssh on the container.
<i>./usr/wxs</i>	Contains The WebSphere eXtreme Scale client library when the IBM Data Cache service on Bluemix is used as the attribute store for MobileFirst Server.

Table 12-25. Supported server environment properties (*server.env*)

Property	Default Value	Description
MFPF_SERVER_HTTPPORT	9080*	The port used for client HTTP requests. Use -1 to disable this port.
MFPF_SERVER_HTTPSPORT	9443*	The port used for client HTTP requests secured with SSL (HTTPS). Use -1 to disable this port.
MFPF_CLUSTER_MODE	Standalone	Configuration not required. Valid values are Standalone or Farm. The value Farm is automatically set when the container is run as a container group.
MFPF_ADMIN_ROOT	worklightadmin	The context root at which the MobileFirst Server Administration Services are made available.
MFPF_CONSOLE_ROOT	worklightconsole	The context root at which the MobileFirst Operations Console is made available.
MFPF_ADMIN_GROUP	worklightadmingroup	The name of the user group possessing the predefined role <i>worklightadmin</i> .
MFPF_DEPLOYER_GROUP	worklightdeployergroup	The name of the user group possessing the predefined role <i>worklightdeployer</i> .
MFPF_MONITOR_GROUP	worklightmonitorgroup	The name of the user group possessing the predefined role <i>worklightmonitor</i> .
MFPF_OPERATOR_GROUP	worklightoperatorgroup	The name of the user group possessing the predefined role <i>worklightoperator</i> .

Table 12-25. Supported server environment properties (*server.env*) (continued)

Property	Default Value	Description
MFPF_SERVER_ADMIN_USER	WorklightRESTUser	The Liberty server administrator user for MobileFirst Server Administration Services.
MFPF_SERVER_ADMIN_PASSWORD	Worklightadmin Ensure that you change the default value to a private password before deploying to a production environment.	The password of the Liberty server administrator user for MobileFirst Server Administration Services.
MFPF_ADMIN_USER	admin	The user name for the administrator role for MobileFirst Server operations.
MFPF_ADMIN_PASSWORD	admin	The password for the administrator role for MobileFirst Server operations.
publicKeyServerUrl		The URL to the MobileFirst runtime that runs the mobile apps with MobileFirst Data Proxy.

*Do not modify the default port number. Read more in the following section.

After you finish customizing an image, it is ready to be built and run on IBM Containers for Bluemix.

Important: If you are going to use MobileFirst Operational Analytics, you must build and run the MobileFirst Operational Analytics container before deploying and running the MobileFirst Server container.

Containers must be restarted after any configuration changes have been made (`cf ic restart containerId`). For container groups, you must restart each container instance within the group. For example, if a root certificate changes, each container instance must be restarted after the new certificate has been added.

Port number limitation

There is currently an IBM Containers limitation with the port numbers that are available for public domain. Therefore, the default port numbers given for the MobileFirst Operational Analytics container and the MobileFirst Server container (9080 for HTTP and 9443 for HTTPS) cannot be altered. Containers in a container group must use HTTP port 9080. Container groups do not support the use of multiple port numbers or HTTPS requests.

Building and running the MobileFirst Server container:

Use the scripts that are provided to build and run your customized image. You can find the scripts in the MobileFirst Platform Foundation on IBM Containers package installation directory under `mfpf-server/scripts`.

Before you begin

- You have finished customizing the image.

About this task

Scripts can only be run from within the scripts folder. Do not modify the given folder structure.

The following methods are supported for passing parameters to the scripts:

- Command-line arguments (Usage: *scriptname.sh*
[-command|--command]
ARGUMENT)
- Interactive method (By running the script with no command-line arguments.)
- Properties files (By customizing the related args/*.properties files.)
You can find information about the required and optional arguments in the properties files, such as the default values, input descriptions, and so forth. The script properties files are located in the following folders in the *package_root/*:

mfpf-analytics/scripts/args

mfpf-server/scripts/args

Example command execution usage: *prepareserver.sh*
args/prepareserver.properties

Procedure

The first step describes how to retrieve the public IP address to be bound with the container, which is a required argument when you run the *startserver.sh* script (as described in step 2).

1. Retrieve and take note of a public IP address to bind to the container.
To get IP information, use Cloud Foundry CLI plug-in for IBM Containers (**cf ic**) commands.
 - To retrieve the list of IP addresses that are potentially available to you (based on user ID), run **cf ic ip list**.
The IP addresses that are listed with no corresponding container ID are available for use.
An IP address with a corresponding container ID indicates that the IP address is already in use. If all IP addresses are already in use, you can request a new IP address.
 - To request a new IP address, run **cf ic ip request**.
2. Create a database service.

Important: Complete this step before you run the **prepareserverdbs.sh**, described in the next step.

You can create a database service instance on Bluemix in two ways:

- Using the Bluemix dashboard.
- Using the Cloud Foundry command line utility.

Use one of the following methods to create a database service instance.

Using the Bluemix dashboard:

To create a service instance of dashDB, Cloudant NoSQL DB or SQL Database on Bluemix, follow the next steps.

- a. Log in to Bluemix.

- b. Select the space name where you want to create the service instance (example: dev).
- c. Select **Data & Analytics** category.
- d. Click on the **Get started now!** icon, to go to the catalog for services under the **Data & Analytics** category.
- e. From the services catalog search for dashDB, Cloudant NoSQL DB or SQL Database.
- f. Click the desired service from the search result.
- g. Select a value of Leave unbound for the **App** field. Enter a name for the service instance in the **Service name** field. Select a suitable **Plan** for the service and click **CREATE**.

Remember: If you choose to create dashDB service instance then select a suitable service **Plan**, which supports Online Transaction Processing (OLTP) workloads, in step g.

Using the Cloud Foundry command line utility:

- a. Log in to Bluemix by using the following command:

```
cf login [-a API_URL] [-u USERNAME] [-p PASSWORD] [-o ORG] [-s SPACE]
```

Where:

-u user_name

Your user name. This parameter is optional.

-p password

Your password.

Security consideration: If you provide the password using the **-p** parameter, the password might be recorded in your command line history. If you do not want the password to be recorded, instead of using the **-p** parameter, consider entering the password when the command line interface prompts you, during the execution of the **cf login** command.

-o organization_name

The name of the organization that you want to log in to.

-s space_name

The name of the space that you want to log in to.

-a https://api.DomainName

The URL of the API endpoint of Bluemix. This parameter is optional.

- b. To create the service instance, run the following command:

```
cf create-service service_name plan_name service_instance
```

You can use one of the following examples:

```
cf create-service dashDB EnterpriseTransactional12.8.500  
mfpdashdbservice
```

```
cf create-service dashDB EnterpriseTransactional12.128.1400  
mfpdashdbservice
```

```
cf create-service cloudantNoSQLDB Shared mfpcloudantservice
```

```
cf create-service sqldb sqldb_premium mfpfsqldb-service
```

Note: The dashDB service instance can take a while before it's provisioning is completed and it is made available for use.

3. Run the scripts in the order listed:

initenv.sh

This script logs in to the container service. You must run this script before you can run any subsequent scripts.

Your Bluemix log-in credentials as well as the organization name and space name are required arguments.

prepareserverdbs.sh

This script must be run once for the administrative database and once for every project or every run time.

Your Bluemix database service instance name is a required argument.

Important: If you use Cloudant NoSQL DB to store administration and runtime data, then do not use the Shared plan. Select one of the Cloudant NoSQL DB enterprise service plans, which provides the Cloudant cluster on dedicated hardware. If you use the dashDB service to store administration and runtime data, then you need to choose only a dashDB service plan that supports OLTP (Online Transaction Processing) workloads. Other dashDB service plans are not supported.

If you are configuring a runtime database, the name of the runtime project to be deployed on the MobileFirst Server is required.

You can optionally specify a database schema name. For an administrative database, the default schema name is WLADMIN. For a runtime database, the default schema name is the runtime name.

Note: The Reports database has been deprecated and does not work with IBM MobileFirst Platform Foundation on IBM Containers. Instead, use a MobileFirst Operational Analytics container. Ensure that the project WAR files in your containers do not have any artifacts or configurations related to the deprecated Reports database.

prepareserver.sh

This script builds the server image with the mfp-server customizations and sends the image to IBM Containers.

The MobileFirst Server image name is a required argument. Use the following format: *BluemixRegistry/PrivateNamespace/ImageName:TagName*. Example: *registry.ng.bluemix.net/PrivateNamespace/mfpserver71*

startserver.sh

The script runs the MobileFirst Server image as a stand-alone container.

The MobileFirst Server image name, the container name, and the public IP address from which the container is started (from step 1) are required arguments for running the image as a container.

Tip: If you are running a **startserver.sh** or **startservergroup.sh** script interactively and configuring an analytics image (by using MFPF_PROPERTIES), you must provide the configuration information every time the script is run, and for each runtime, to avoid losing the configuration. For example, if you provided an analytics configuration (such as *MFPF_PROPERTIES=wl.analytics.url:http://127.0.0.1/analytics-service/v2,wl.analytics.console.url:http://127.0.0.1/analytics/consoleproperties* for the first runtime but did not provide it the next time that you ran the script for a different runtime, the configuration for the MobileFirst Server would be lost.

startservergroup.sh

The script runs the MobileFirst Server image as a container group.

Required arguments include: the MobileFirst Server image name, the container group name, the minimum and maximum number of container instances within the group, and the host name to which the group must be mapped.

Adding, updating, and removing projects:

This topic provides instructions for adding a project to and updating an existing project in a container, and for removing a project from an image.

Adding a project to your IBM MobileFirst Platform Foundation container

1. Run the **prepareserverdbs.sh** script by specifying the new project name. This will create the project-related schema in the database.
2. Add the new project to the `ibm-mfpf-container-7.1.0.0/mfp-server/projects` folder.
3. Run the **prepareserver.sh** script to rebuild the server image and push it to the IBM Containers service.
4. Run the script **startserver.sh** to run the image as a standalone container or **startservergroup.sh** to run the image as a container group.

Updating a project in your IBM MobileFirst Platform Foundation container

1. Update the artifacts that need to be changed in the `ibm-mfpf-container-7.1.0.0/mfp-server/projects/project_name` folder.
2. Run the **prepareserver.sh** script to rebuild the server image and push it to the IBM Containers service.
3. Run the **startserver.sh** script to run the server image as a standalone container or **startservergroup.sh** to run the server image as a container group.

Removing a project from the IBM MobileFirst Platform Foundation container image

1. Run the **removeproject.sh** script to remove the project from the IBM MobileFirst Platform Foundation container image. You can also choose to clear the project-related data from the databases.
2. After removing the project from the project folder, run the **prepareserver.sh** script to rebuild the server image and push it to the IBM Containers service.
3. Run the **startserver.sh** script to run the server image as a standalone container or **startservergroup.sh** to run the server image as a container group.

Configuring session-independent mode:

You can configure-session independent mode on MobileFirst Server.

Before you begin

You must use the IBM Data Cache service on Bluemix to configure the MobileFirst Server in session-independent mode. Learn more...

Procedure

Use the following steps to configure MobileFirst Server to use IBM Data Cache service as the attribute store.

1. Create an IBM Data Cache service instance on Bluemix and bind the service to a new or existing application.
2. Download WebSphere eXtreme Scale for Developers - Liberty Profile (`wxs-wlp_vnnn.jar`) and place it in the `package_root/mfpf-server/usr/wxs` folder.
3. Add the following code to the `.\usr\config\mfpfproperties.xml` file.

```
<featureManager>
  <feature>eXtremeScale.client-1.1</feature>
</featureManager>
<jndiEntry jndiName="project_name/mfp.session.independent" value="true"/>
<jndiEntry jndiName="project_name/mfp.attrStore.type" value="datacache"/>
```

The `project_name` value is the name of the IBM MobileFirst Platform Foundation project for which the IBM Data Cache service must be enabled as the attribute store.

4. To bind the IBM Data Cache service app to the container, use the **startserver.sh** command to start the MobileFirst Server container and then provide the application name (from step 1).

Script overview and usage:

Use the scripts for configuring, building, and deploying a MobileFirst Server container image.

The scripts are located in the `package_root/mfpf-server/scripts` folder.

initenv.sh script:

This script file creates the environment for building and running a MobileFirst Server container and performs the tasks necessary for logging into Bluemix and the IBM Containers environment. Run this script before running any other scripts for building and deploying IBM MobileFirst Platform Foundation container images.

Table 12-26. Mandatory command-line arguments

Command-line argument	Description
<code>[-u --user] BLUEMIX_USER</code>	Bluemix user ID or email address
<code>[-p --password] BLUEMIX_PASSWORD</code>	Bluemix password
<code>[-o --org] BLUEMIX_ORG</code>	Bluemix organization name
<code>[-s --space] BLUEMIX_SPACE</code>	Bluemix space name

Usage example:

```
initenv.sh
  --user Bluemix_user_ID
  --password Bluemix_password
  --org Bluemix_organization_name
  --space Bluemix_space_name
```

Table 12-27. Optional command-line arguments

Command-line argument	Description
<code>[-a --api] BLUEMIX_API_URL</code>	Bluemix API endpoint (Defaults to <code>https://api.ng.bluemix.net</code>)

prepareserverdbs.sh script:

This script configures MobileFirst Server databases (administration and runtime). This script must be run once to configure the administration database and then once for each runtime.

Table 12-28. Mandatory command-line arguments

Command-line argument	Description
<code>[-n --name] DB_SRV_NAME</code>	Bluemix database service instance name Supported database service types are dashDB, Cloudant NoSQL DB and SQL Database.

Usage example:

```
prepareserverdbs.sh
--type DB_TYPE sqldb
--name DB_SRV_NAME database_name
--plan DB_SRV_PLAN sqldb_small
--appname APP_NAME Bluemix_app_name
```

Table 12-29. Optional command-line arguments

Command-line argument	Description
<code>[-r --runtime] RUNTIME_NAME</code>	MobileFirst runtime name (Required for configuring runtime databases only.)
<code>[-sn --schema] SCHEMA_NAME</code>	Database schema name (Defaults to WLADMIN for administration databases or the

prepareserver.sh script:

This script creates the MobileFirst Server image and pushes it to IBM Containers on Bluemix. Ensure that you have run the `prepareserverdbs.sh` to configure the database before running this script.

Table 12-30. Mandatory command line arguments

Command line argument	Description
<code>[-t --tag] SERVER_IMAGE_NAME</code>	Name to be used for the customized MobileFirst Server image. Format: <code>registryUrl/namespace/imagename</code>

Usage example:

```
prepareserver.sh --tag SERVER_IMAGE_NAME registryUrl/namespace/imagename
```

Table 12-31. Optional command line arguments

Command line argument	Description
<code>[-l --loc] PROJECT_LOC</code>	The location of the MobileFirst project. Multiple project locations can be delimited by commas.

startserver.sh script:

This script runs the MobileFirst Server image as a container on IBM Containers on Bluemix. Ensure that you have run the *prepareserver.sh* script to upload the image to the IBM Containers registry before running this script.

Table 12-32. Mandatory command line arguments

Command line argument	Description
[-t --tag] SERVER_IMAGE_TAG	Name of the MobileFirst Server image.
[-n --name] SERVER_CONTAINER_NAME	Name of the MobileFirst Server container
[-i --ip] SERVER_IP	IP address that the MobileFirst Server container should be bound to. (You can provide an available public IP or request one using the cf ic ip request command.)

Usage example:

```
startserver.sh
--tag image_tag_name
--name container_name
--ip container_ip_address
```

Table 12-33. Optional command line arguments

Command line argument	Description
[-an --appName] APP_NAME	Bluemix application name that should be bound to the container
[-h --http] EXPOSE_HTTP	Expose HTTP Port. Accepted values are Y (default) or N.
[-s --https] EXPOSE_HTTPS	Expose HTTPS Port. Accepted values are Y (default) or N.
[-m --memory] SERVER_MEM	Assign a memory size limit to the container in megabytes (MB). Accepted values are 1024 MB (default) and 2048 MB.
[-se --ssh] SSH_ENABLE	Enable SSH for the container. Accepted values are Y (default) or N.
[-sk --sshkey] SSH_KEY	The SSH Key to be injected into the container. (Provide the contents of your <code>id_rsa.pub</code> file.)
[-tr --trace] TRACE_SPEC	The trace specification to be applied. Default: <code>*=info</code>
[-ml --maxlog] MAX_LOG_FILES	The maximum number of log files to maintain before they are overwritten. The default is 5 files.
[-ms --maxlogsize] MAX_LOG_FILE_SIZE	The maximum size of a log file. The default size is 20 MB.
[-v --volume] ENABLE_VOLUME	Enable mounting volume for container logs. Accepted values are Y or N (default).

Table 12-33. Optional command line arguments (continued)

Command line argument	Description
[-e --env] <i>MFPF_PROPERTIES</i>	Specify MobileFirst properties as comma-separated key:value pairs. Example: <i>wl.analytics.url:http://127.0.0.1/analytics-service/v2,wl.analytics.console.url:http://127.0.0.1/analytics/console</i> Note: If you specify properties using this script, ensure that

startservergroup.sh script:

This script runs a MobileFirst Server image as a container group on IBM Containers on Bluemix. Before running *startservergroup.sh*, ensure that you have run the *prepareserver.sh* script to upload the container image to the IBM Containers registry.

Table 12-34. Mandatory command-line arguments

Command-line argument	Description
[-t --tag] <i>SERVER_IMAGE_TAG</i>	The name of the MobileFirst Server container image in the Bluemix registry.
[-gn --name] <i>SERVER_CONTAINER_NAME</i>	The name of the MobileFirst Server container group.
[-gh --host] <i>SERVER_CONTAINER_GROUP_HOST</i>	The host name of the route.
[-gs --domain] <i>SERVER_CONTAINER_GROUP_DOMAIN</i>	The domain name of the route.

Usage example:

```
startservergroup.sh
--tag image_name
--name container_group_name
--host container_group_host_name
--domain container_group_domain_name
```

Table 12-35. Optional command-line arguments

Command-line argument	Description
[-gm --min] <i>SERVERS_CONTAINER_GROUP_MIN</i>	The minimum number of container instances. The default value is
[-gx --max] <i>SERVER_CONTAINER_GROUP_MAX</i>	The maximum number of container instances. The default value is
[-gd --desired] <i>SERVER_CONTAINER_GROUP_DESIRED</i>	The desired number of container instances. The default value is 2.
[-a --auto] <i>ENABLE_AUTORECOVERY</i>	Enable the automatic recovery option for the container instances. Accepted values are Y or N (default).
[-an --appName] <i>APP_NAME</i>	The name of the Bluemix app to be bound to the container instance.
[-tr --trace] <i>TRACE_SPEC</i>	The trace specification to be applied. Default: <i>*=info</i>
[-ml --maxlog] <i>MAX_LOG_FILES</i>	The maximum number of log files to maintain before they are overwritten. The default is 5 files.

Table 12-35. Optional command-line arguments (continued)

Command-line argument	Description
<code>[-ms --maxlogsize]</code> <code>MAX_LOG_FILE_SIZE</code>	The maximum size of a log file. The default size is 20 MB.
<code>[-e --env]</code> <code>MFPF_PROPERTIES</code>	Specify MobileFirst properties as comma-separated key:value pairs. Example: <code>wl.analytics.url:http://127.0.0.1/analytics-service/v2</code>
<code>[-m --memory]</code> <code>SERVER_MEM</code>	Assign a memory size limit to the container in megabytes (MB). Accepted values are 1024 MB (default) and 2048 MB.
<code>[-v --volume]</code> <code>ENABLE_VOLUME</code>	Enable mounting volume for container logs. Accepted values are Y or N (default).

Learn more about creating scalable container groups.

removeproject.sh script:

This script removes a project from the IBM MobileFirst Platform Foundation configuration.

After removing a project, you must run the `prepareserver.sh` script to update the image.

Table 12-36. Mandatory command-line arguments

Command-line argument	Description
<code>[-r --runtime]</code> <code>RUNTIME_NAME</code>	The name of the run time to be removed.
<code>[-i --ip]</code> <code>SERVER_IP</code>	The IP address or route to the MobileFirst Server container.
<code>[-p --port]</code> <code>SERVER_PORT</code>	The HTTPS port number exposed on the MobileFirst Server container.
<code>[-l --libertyadminusername]</code> <code>LIBERTY_ADMIN_USERNAME</code>	The Liberty administrator user name.
<code>[-lp --libertyadminpassword]</code> <code>LIBERTY_ADMIN_PASSWORD</code>	The Liberty administrator password.
<code>[-u --mfpadminusername]</code> <code>MFPF_ADMIN_USERNAME</code>	The MobileFirst Server administrator user name.
<code>[-pa --mfpadminpassword]</code> <code>MFPF_ADMIN_PASSWORD</code>	The MobileFirst Server administrator password.

Usage example:

```
removeproject.sh
--runtime runtime_name
--ip runtime_ip_address
--port port_number
--libertyadminusername liberty_administrator
--libertyadminpassword liberty_password
--mfpadminusername mfserver_administrator
--mfpadminpassword mfserver_password
```

Table 12-37. Optional command-line arguments

Command-line argument	Description
<code>[-d --deletedata] DELETE_RUNTIME_DATA</code>	Confirmation to delete the project-related data from the database. Accepted values are Y or N (default).
<code>[-an --appname] APP_NAME</code>	The Bluemix application name.
<code>[-n --servicename] DB_SRV_NAME</code>	The Bluemix database service instance name.
<code>[-sn --schema] SCHEMA_NAME</code>	Schema name (When no value is specified, defaults to the runtime name)
<code>[-ar --adminroot] MFPF_ADMIN_ROOT</code>	Admin context path of the MobileFirst Server (When no value is specified, defaults to <code>worklightadmin</code> .)
<code>[-dp --deleteproject] DELETE_RUNTIME_PROJECT</code>	Confirmation to delete the runtime project from the project folder. Accepted values are Y or N (default).
<code>[-ce --certpath] CERTIFICATE_PATH</code>	The path to the folder containing server certificates, to perform the HTTPS operations.

Using the MobileFirst Data Proxy:

The MobileFirst Data Proxy can be configured to work with your container so that your mobile app data is stored on the server side.

The MobileFirst Data Proxy works with Cloudant databases. Learn more...

Therefore, to use the MobileFirst Data Proxy with your container, you must have configured a Cloudant database instance to communicate with the MobileFirst Data Proxy component.

For example, this could be a database instance on Cloudant.com or a Cloudant NoSQL DB service on IBM Bluemix.

Using HTTPS

For MobileFirst Data Proxy to use a Cloudant database through HTTPS, you must import the Cloudant database certificate into the truststore of the Java runtime environment (JRE) that is used by the Liberty server. You can find the truststore location in `JRE_DIR/lib/security/cacerts`. Place updated certificate files in the `mfpf-server/usr/jre-security` folder. Learn more...

Using a Cloudant NoSQL DB service on Bluemix

To use the Cloudant NoSQL DB service, it must be bound to a Node.js or IBM Liberty runtime app on Bluemix.

Configuring the MobileFirst Data Proxy to work in a container:

To configure MobileFirst Data Proxy for your container, you can either specify JNDI properties or bind your container to a Bluemix app that has the Cloudant NoSQL DB service.

Before you begin

Before you begin, you must have configured the Cloudant instance that will be used to communicate with the MobileFirst Data Proxy component.

If the Cloudant database is accessed through HTTPS with a self-signed certificate, you must import the certificate to the cacerts truststore of the Java runtime environment (JRE) that is used by the Liberty server. Place updated certificate files in the `mfpf-server/usr/jre-security` folder. Learn more...

Have the following Cloudant account information ready to complete the configuration steps:

- Cloudant proxy database account
- Host name
- User name and password

If you are using the Cloudant NoSQL DB service on Bluemix, make sure that you have already done the following:

- Created an app on Bluemix with a Node.js or Liberty runtime.
- Created an instance of the Cloudant NoSQL DB service.
- Bound the Cloudant NoSQL DB service to the Bluemix app.

Procedure

1. Open `mfpf-server/usr/config/dataproxy.xml` and uncomment the MobileFirst Data Proxy configuration.
2. Specify the public key server URL for the MobileFirst Server project. To do this, open the `mfpf-server/usr/env/server.env` file and then uncomment and set the required `publicKeyServerUrl` environment variable. Example:
`publicKeyServerUrl=http://mobilefirstserver.mycompany.com:9080/MobileFirstProject`
3. The related Cloudant properties can be specified using JNDI properties in the `mfpf-server/usr/config/dataproxy.xml` file or by binding your container to a Bluemix application that has an instance of the Cloudant NoSQL DB service. Choose one of the following options:

- To specify JNDI properties, edit the `dataproxy.xml` file according to the following example.

```
<jndiEntry jndiName="datastore/CloudantProxyDbAccount" value="'hostname'"/>
<jndiEntry jndiName="datastore/CloudantProtocol" value="'http'"/>
<jndiEntry jndiName="datastore/CloudantPort" value="'80'"/>
<jndiEntry jndiName="datastore/CloudantProxyDbAccountUser" value="'cloudantuser'"/>
<jndiEntry jndiName="datastore/CloudantProxyDbAccountPassword" value="'cloudantpassword'"/>
```

Learn more...

- To bind your container to a Bluemix app that has the Cloudant NoSQL DB service, you must specify the Bluemix app name when running the `startserver.sh` or `startservergroup.sh` script.

When using this method, the environment variables are obtained automatically.

Note: Keep in mind that the `VCAP_SERVICES` environment variables in this process override any environment variables in the container that were specified manually.

MobileFirst Operational Analytics containers

This section contains the information you need to configure and run MobileFirst Operational Analytics containers.

Customizing MobileFirst Operational Analytics containers:

Use the scripts provided in the MobileFirst Platform Foundation on IBM Containers package to customize container images.

The folder where you extracted the contents of the MobileFirst Platform Foundation on IBM Containers package is referred to in this document as the *installation directory*. The customizable elements for the MobileFirst Operational Analytics container are located in *package_root/mfpf-analytics/usr*. See the following tables for details.

Table 12-38. Descriptions of the *mfpf-analytics/* sub directories

Folders and Files	Description
./usr	The root folder that contains the customization template for the MobileFirst Operational Analytics container.
./usr/bin	Contains the script file (mfp-init) that gets executed when the container starts. You can add custom code to the script, however, do not modify the existing code.
./usr/config	Contains the server configuration fragments (keystore, server properties, user registry) used by MobileFirst Server. MobileFirst Operational Analytics container.
./usr/jre-security	Add JRE security-related files (such as the JRE truststore, policy .jar files, and so forth) to be updated on the container. The files in this folder get copied to the <i>JAVA_HOME/jre/lib/security/</i> folder in the container.
./usr/config/keystore.xml	The configuration of the repository of security certificates used for SSL encryption. The keystore files referenced here should be provided as part of the <i>./usr/security</i> folder
./usr/config/mfpproperties.xml	The configuration of the MobileFirst Operational Analytics can be provided here. See the list of supported properties at "Properties and configurations" on page 14-95.
./usr/config/registry.xml	User registry configuration. By default provides the basicRegistry - a simple XML based user-registry configuration. The usernames / password for basicRegistry can be configured here. The registry can also be configured for ldapRegistry.
./usr/env/server.env	The environment properties used by the server to initialize. Supported properties
./usr/security	The keystore, truststore, and the LTPA keys (ltpa.keys) files should be placed in this folder.
./usr/ssh	The <i>id_rsa.pub</i> file - the ssh public key file to enable ssh on the container.

Table 12-39. *Server.env* supported properties

Property Name	Default Value	Description
ANALYTICS_SERVER_HTTPPORT	980*	The port used for client HTTP requests. Use -1 to disable this port.

Table 12-39. *Server.env* supported properties (continued)

Property Name	Default Value	Description
ANALYTICS_SERVER_HTTPSPORT	9443	The port used for client HTTP requests secured with SSL (HTTPS). Use -1 to disable this port.
ANALYTICS_ADMIN_GROUP	analyticsadmingroup	The name of the user group possessing the predefined role <i>worklightadmin</i> .

*Do not modify the default port number. Read more in the following section.

Port number limitation

There is currently an IBM Containers limitation with the port numbers that are available for public domain. Therefore, the default port numbers given for the MobileFirst Operational Analytics container and the MobileFirst Server container (9080 for HTTP and 9443 for HTTPS) cannot be altered. Containers in a container group must use HTTP port 9080. Container groups do not support the use of multiple port numbers or HTTPS requests.

Building and running the MobileFirst Operational Analytics container:

Use the scripts provided in the package installation directory under `mfpf-analytics/scripts` to build and run your customized image.

Before you begin

- Customization of the image has been completed.

About this task

Scripts can only be run from within the scripts folder. Do not modify the given folder structure.

The following methods are supported for passing parameters to the scripts:

- Command-line arguments (Usage: `scriptname.sh [-command|--command] ARGUMENT`)
 - Interactive method (By running the script with no command-line arguments.)
 - Properties files (By customizing the related `args/*.properties` files.)
- You can find information about the required and optional arguments in the properties files, such as the default values, input descriptions, and so forth. The script properties files are located in the following folders in the `package_root/`:

`mfpf-analytics/scripts/args`

`mfpf-server/scripts/args`

Example command execution usage: `prepareserver.sh`

`args/prepareserver.properties`

Procedure

In the following procedure, the first step describes how to retrieve a public IP address to bind to the container, which is a required argument when you run the `startanalytics.sh` script (as described in step 2).

1. Retrieve and take note of a public IP address to bind to the container.
To get IP information, use Cloud Foundry CLI plug-in for IBM Containers (**cf ic**) commands.
 - To retrieve the list of IP addresses that are potentially available to you (based on user ID), run **cf ic ip list**.
The IP addresses that are listed with no corresponding container ID are available for use.
An IP address with a corresponding container ID indicates that the IP address is already in use. If all IP addresses are already in use, you can request a new IP address.
 - To request a new IP address, run **cf ic ip request**.
2. Run the following scripts in order:

initenv.sh

This script logs in to the container service. You must run this script before you can run any subsequent scripts.

prepareanalytics.sh

This script builds the analytics image with your customizations and deploys it to IBM Containers.

startanalytics.sh

The script runs the analytics image as a standalone container.

startanalyticsgroup.sh

The script runs the analytics image as a container group.

Script overview and usage:

Use the scripts for configuring, building, and deploying a MobileFirst Operational Analytics container image.

The scripts are located in the *package_root/mfpf-analytics/scripts* folder.

initenv.sh script:

This script file creates the environment for building and running a MobileFirst Operational Analytics container and performs the tasks necessary for logging into Bluemix and the IBM Containers environment. You must run this script before running any other scripts for building and deploying MobileFirst Operational Analytics container images.

Table 12-40. Mandatory command-line arguments

Command-line argument	Description
[-u --user] <i>BLUEMIX_USER</i>	Bluemix user ID or email address
[-p --password] <i>BLUEMIX_PASSWORD</i>	Bluemix password
[-o --org] <i>BLUEMIX_ORG</i>	Bluemix organization name
[-s --space] <i>BLUEMIX_SPACE</i>	Bluemix space name

Usage example:

```
initenv.sh
  --user Bluemix_user_ID
  --password Bluemix_password
  --org Bluemix_organization_name
  --space Bluemix_space_name
```

Table 12-41. Optional command-line arguments

Command-line argument	Description
<code>[-a --api] BLUEMIX_API_URL</code>	Bluemix API endpoint (Defaults to <code>https://api.ng.bluemix.net</code>)

prepareanalytics.sh script:

This script creates the MobileFirst Operational Analytics image and pushes it to IBM Containers on Bluemix. Ensure that you have run the `initenv.sh` before running this script.

Table 12-42. Mandatory command-line arguments

Command-line argument	Description
<code>[-t --tag] ANALYTICS_IMAGE_TAG</code>	Name to be used for the customized analytics image. Format: <i>Bluemix registry URL/private namespace/image name</i>

Usage example:

```
prepareanalytics.sh --tag registry.ng.bluemix.net/your_private_repository_namespace/mfpfanalytics7
```

startanalytics.sh script:

This script runs the MobileFirst Operational Analytics image as a container on IBM Containers on Bluemix. Before running this script, ensure that you have run the `prepareanalytics.sh` script to upload the image to the IBM Containers registry.

Table 12-43. Mandatory command-line arguments

Command-line argument	Description
<code>[-t --tag] ANALYTICS_IMAGE_TAG</code>	Name of the analytics container image that has been loaded into the IBM Containers registry. Format: <i>BluemixRegistry/PrivateNamespace/TagName:Tag</i>
<code>[-n --name] ANALYTICS_CONTAINER_NAME</code>	Name of the analytics container
<code>[-i --ip] ANALYTICS_IP</code>	IP address that the container should be bound to. (You can provide an available public IP or request one using the <code>cf ic ip request</code> command.)

Usage example:

```
startanalytics.sh
--tag image_tag_name
--name container_name
--ip container_ip_address
```

Table 12-44. Optional command-line arguments

Command-line argument	Description
<code>[-h --http] EXPOSE_HTTP</code>	Expose HTTP port. Accepted values are Y (default) or N.

Table 12-44. Optional command-line arguments (continued)

Command-line argument	Description
<code>[-s --https] EXPOSE_HTTPS</code>	Expose HTTPS port. Accepted values are Y (default) or N.
<code>[-m --memory] SERVER_MEM</code>	Assign a memory size limit to the container in megabytes (MB). Accepted values are 1024 MB (default) and 2048 MB.
<code>[-se --ssh] SSH_ENABLE</code>	Enable SSH for the container. Accepted values are Y (default) or N.
<code>[-sk --sshkey] SSH_KEY</code>	The SSH Key to be injected into the container. (Provide the contents of your <code>id_rsa.pub</code> file.)
<code>[-tr --trace] TRACE_SPEC</code>	The trace specification to be applied. Default: <code>*=info</code>
<code>[-ml --maxlog] MAX_LOG_FILES</code>	The maximum number of log files to maintain before they are overwritten. The default is 5 files.
<code>[-ms --maxlogsize] MAX_LOG_FILE_SIZE</code>	The maximum size of a log file. The default size is 20 MB.
<code>[-v --volume] ENABLE_VOLUME</code>	Enable mounting volume for container logs. Accepted values are Y or N (default).
<code>[-ev --enabledatavolume] ENABLE_ANALYTICS_DATA_VOLUME</code>	Enable mounting volume for analytics data. Accepted values are Y or N (default).
<code>[-av --datavolumename] ANALYTICS_DATA_VOLUME_NAME</code>	Specify the name of the volume to be created and mounted for the analytic data. The default name is <code>mfpf_analytics_container_name</code> .
<code>[-ad --analyticsdatadirectory] ANALYTICS_DATA_DIRECTORY</code>	Specify the location to store the data. The default folder name is <code>/analyticsData</code> .
<code>[-e --env] MFPF_PROPERTIES</code>	Provide MobileFirst Operational Analytics properties as comma-separated key:value pairs. Note: If you specify properties using this script, ensure that

startanalyticsgroup.sh script:

This script runs a MobileFirst Operational Analytics image as a container group on IBM Containers on Bluemix. Before running `startanalyticsgroup.sh`, ensure that you have run the `prepareanalytics.sh` script to upload the container image to the IBM Containers registry.

Table 12-45. Mandatory command-line arguments

Command-line argument	Description
<code>[-t --tag] ANALYTICS_IMAGE_TAG</code>	The name of the analytics container image in the Bluemix registry.
<code>[-gn --name] ANALYTICS_CONTAINER_GROUP_NAME</code>	The name of the analytics container group.
<code>[-gh --host] ANALYTICS_CONTAINER_GROUP_HOST</code>	The host name of the route.

Table 12-45. Mandatory command-line arguments (continued)

Command-line argument	Description
[-gs --domain] ANALYTICS_CONTAINER_GROUP_DOMAIN	The domain name of the route.

Usage example:

```
startanalyticsgroup.sh
--tag image_name
--name container_group_name
--host container_group_host_name
--domain container_group_domain_name
```

Table 12-46. Optional command-line arguments

Command-line argument	Description
[-gm --min] ANALYTICS_CONTAINER_GROUP_MIN	The minimum number of container instances. The default value is 1.
[-gx --max] ANALYTICS_CONTAINER_GROUP_MAX	The maximum number of container instances. The default value is 10.
[-gd --desired] ANALYTICS_CONTAINER_GROUP_DESIRED	The desired number of container instances. The default value is 2.
[-a --auto] ENABLE_AUTORECOVERY	Enable the automatic recovery option for the container instances. Accepted values are Y or N (default).
[-tr --trace] TRACE_SPEC	The trace specification to be applied. Default: <i>*=info</i>
[-ml --maxlog] MAX_LOG_FILES	The maximum number of log files to maintain before they are overwritten. The default is 5 files.
[-ms --maxlogsize] MAX_LOG_FILE_SIZE	The maximum size of a log file. The default size is 20 MB.
[-e --env] MFPF_PROPERTIES	Specify MobileFirst properties as comma-separated key:value pairs. Example: <i>wl.analytics.url:http://127.0.0.1/analytics-service/o2</i>
[-m --memory] SERVER_MEM	Assign a memory size limit to the container in megabytes (MB). Accepted values are 1024 MB (default) and 2048 MB.
[-v --volume] ENABLE_VOLUME	Enable mounting volume for container logs. Accepted values are Y or N (default).
[-ev --enabledatavolume] ENABLE_ANALYTICS_DATA_VOLUME	Enable mounting volume for analytics data. Accepted values are Y or N (default)
[-av --datavolumename] ANALYTICS_DATA_VOLUME_NAME	Specify name of the volume to be created and mounted for analytics data. Default value is <i>analytics_<ANALYTICS_CONTAINER_GROUP_NAME></i>
[-ad --analyticsdatadirectory] ANALYTICS_DATA_DIRECTORY	Specify the directory to be used for storing analytics data. Default value is <i>/analyticsData</i>

Learn more about creating scalable container groups.

Securing containers

Security configuration for IBM MobileFirst Platform Foundation on IBM Containers:

Your IBM MobileFirst Platform Foundation on IBM Containers security configuration should include encrypting passwords, enabling application authenticity checking, and securing access to the consoles.

Encrypting passwords

Store the passwords for MobileFirst Server users in an encrypted format. You can use the **securityUtility** command available in the Liberty profile to encode passwords with either XOR or AES encryption. Encrypted passwords can then be copied into the `/usr/env/server.env` file. See “Encrypting passwords for user roles configured in MobileFirst Server” for instructions.

Application authenticity checking

To keep unauthorized mobile applications from accessing the MobileFirst Server, enable application authenticity. Learn more...

Configure SSL for Operations Console and Analytics Console

You can secure access to the MobileFirst Operations Console and the MobileFirst Analytics Console by enabling HTTP over SSL (HTTPS) on the MobileFirst Server.

To enable HTTPS on the MobileFirst Server, create the keystore containing the certificate and place it in the `usr/security` folder. Then, update the `usr/config/keystore.xml` file to use the keystore configured.

Securing a connection to the back end

If you need a secure connection between your container and an on-premise back-end system, you can use the Bluemix Secure Gateway service. Configuration details are provided in this article: [Connecting Securely to On-Premise Backends from MobileFirst on IBM Bluemix containers](#).

Encrypting passwords for user roles configured in MobileFirst Server:

The passwords for user roles that are configured for the MobileFirst Server can be encrypted.

Procedure

Passwords are configured in the `server.env` files in the `package_root/mfpf-server/usr/env` and `package_root/mfpf-analytics/usr/env` folders. Passwords should be stored in an encrypted format.

1. You can use the `securityUtility` command in the Liberty profile to encode the password. Choose either XOR or AES encryption to encode the password.
2. Copy the encrypted password to the `server.env` file. Example:
`MFPF_ADMIN_PASSWORD={xor}PjsyNjE=`
3. If you are using AES encryption and used your own encryption key instead of the default key, you must create a configuration file that contains your encryption key and add it to the `usr/config` directory. The Liberty server

accesses the file to decrypt the password during runtime. The configuration file must have the .xml file extension and resemble the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<server>
  <variable name="wlp.password.encryption.key" value="yourKey" />
</server>
```

Securing container communication using a private IP address:

To have secure communication between the MobileFirst Server container and the MobileFirst Operational Analytics container, you must include the private IP address of the MobileFirst Operational Analytics container in the `mfpfProperties.xml` file.

Before you begin

To complete this task, you need the private IP of the MobileFirst Operational Analytics container, which you can obtain using the following command: `cf ic inspect analytics_container_id`. Look for the IP Address field in the command output.

Remember: If you are going to use MobileFirst Operational Analytics, you must configure, build, and run the MobileFirst Operational Analytics image before configuring, deploying, and running the MobileFirst Server image.

Procedure

Complete the following steps by editing the `mfpf-server/usr/config/mfpfproperties.xml` file:

1. Set the `wl.analytics.url` property to the private IP address of the MobileFirst Operational Analytics container. Example:

```
<jndiEntry jndiName="wl.analytics.url" value="http://AnalyticsContainerPrivateIP:9080/analytic
```

Tip: When a private IP address changes, provide the new IP address in the `mfpfproperties.xml` file and rebuild and deploy the container by running the `prepareserver.sh` and `starterserver.sh` scripts respectively.

2. To ensure that the MobileFirst Operational Analytics console can be accessed on the network, set the `wl.analytics.console.url` property to the public IP address of the MobileFirst Operational Analytics container. Example:

```
<jndiEntry jndiName="wl.analytics.console.url" value="http://AnalyticsContainerPublicIP:9080/a
```

Restricting access to the consoles running on containers:

You can restrict access to the MobileFirst Operations Console and the MobileFirst Analytics Console in production environments by creating and deploying a Trust Association Interceptor (TAI) to intercept requests to the consoles running on IBM Containers.

About this task

The TAI can implement user-specific filtering logic that decides if a request is forwarded to the console or if an approval is required. This method of filtering provides the flexibility for you to add your own authentication mechanism if needed.

See also: [Developing a custom TAI for the Liberty profile](#)

Procedure

1. Create a custom TAI that implements your security mechanism to control access to the MobileFirst Operations Console. The following example of a custom TAI uses the IP Address of the incoming request to validate whether to provide access to the MobileFirst Operations Console or not.

```
package com.ibm.mfpconsole.interceptor;
import java.util.Properties;

import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

import com.ibm.websphere.security.WebTrustAssociationException;
import com.ibm.websphere.security.WebTrustAssociationFailedException;
import com.ibm.wsspi.security.tai.TAIResult;
import com.ibm.wsspi.security.tai.TrustAssociationInterceptor;

public class MFPCConsoleTAI implements TrustAssociationInterceptor {

    String allowedIP =null;

    public MFPCConsoleTAI() {
        super();
    }

    /*
     * @see com.ibm.wsspi.security.tai.TrustAssociationInterceptor#isTargetInterceptor
     * (javax.servlet.http.HttpServletRequest)
     */
    public boolean isTargetInterceptor(HttpServletRequest req)
        throws WebTrustAssociationException {
        //Add logic to determine whether to intercept this request

        boolean interceptMFPCConsoleRequest = false;
        String requestURI = req.getRequestURI();

        if(requestURI.contains("worklightConsole")) {
            interceptMFPCConsoleRequest = true;
        }

        return interceptMFPCConsoleRequest;
    }

    /*
     * @see com.ibm.wsspi.security.tai.TrustAssociationInterceptor#negotiateValidateandEstablishTrust
     * (javax.servlet.http.HttpServletRequest,javax.servlet.http.HttpServletResponse)
     */
    public TAIResult negotiateValidateandEstablishTrust(HttpServletRequest request,
        HttpServletResponse resp) throws WebTrustAssociationFailedException {
        // Add logic to authenticate a request and return a TAI result.
        String tai_user = "MFPCConsoleCheck";

        if(allowedIP != null) {

            String ipAddress = request.getHeader("X-FORWARDED-FOR");
            if (ipAddress == null) {
                ipAddress = request.getRemoteAddr();
            }

            if(checkIPMatch(ipAddress, allowedIP)) {
                TAIResult.create(HttpServletResponse.SC_OK, tai_user);
            }
            else {
                TAIResult.create(HttpServletResponse.SC_FORBIDDEN, tai_user);
            }
        }
    }
}
```

```

        return TAIResult.create(HttpServletResponse.SC_OK, tai_user);
    }

    private static boolean checkIPMatch(String ipAddress, String pattern) {
        if (pattern.equals("*. *.*.*") || pattern.equals("*"))
            return true;

        String[] mask = pattern.split("\\.");
        String[] ip_address = ipAddress.split("\\.");

        for (int i = 0; i < mask.length; i++)
        {
            if (mask[i].equals("*") || mask[i].equals(ip_address[i]))
                continue;
            else
                return false;
        }
        return true;
    }
}

/*
 * @see com.ibm.wsspi.security.tai.TrustAssociationInterceptor#initialize(java.util.Properties)
 */
public int initialize(Properties properties)
    throws WebTrustAssociationFailedException {

    if(properties != null) {
        if(properties.containsKey("allowedIPs")) {
            allowedIP = properties.getProperty("allowedIPs");
        }
    }
    return 0;
}

/*
 * @see com.ibm.wsspi.security.tai.TrustAssociationInterceptor#getVersion()
 */
public String getVersion() {
    return "1.0";
}

/*
 * @see com.ibm.wsspi.security.tai.TrustAssociationInterceptor#getType()
 */
public String getType() {
    return this.getClass().getName();
}

/*
 * @see com.ibm.wsspi.security.tai.TrustAssociationInterceptor#cleanup()
 */
public void cleanup()
{
}
}

```

2. Export the custom TAI Implementation into a .jar file and place it in the applicable env folder (mfpf-server/usr/env or mfpf-analytics/usr/env).
3. Create an XML configuration file that contains the details of the TAI interceptor (see the TAI configuration example code provided in step 1) and then add your .xml file to the applicable folder (mfpf-server/usr/config or mfpf-analytics/usr/config). Your .xml file should resemble the following example.

Tip: Be sure to update the class name and properties to reflect your implementation.

```
<?xml version="1.0" encoding="UTF-8"?>
<server description="new server">
  <featureManager>
    <feature>appSecurity-2.0</feature>
  </featureManager>

  <trustAssociation id="MFPConsoleTAI" invokeForUnprotectedURI="true"
    failOverToAppAuthType="false">
    <interceptors id="MFPConsoleTAI" enabled="true"
      className="com.ibm.mfpconsole.interceptor.MFPConsoleTAI"
      invokeBeforeSSO="true" invokeAfterSSO="false" libraryRef="MFPConsoleTAI">
      <properties allowedIPs="9.182.149.*"/>
    </interceptors>
  </trustAssociation>

  <library id="MFPConsoleTAI">
    <fileset dir="${server.config.dir}" includes="MFPConsoleTAI.jar"/>
  </library>

</server>
```

4. Build the image and run the container as described in “Building and running the MobileFirst Server container” on page 12-122 or “Building and running the MobileFirst Operational Analytics container” on page 12-135. The MobileFirst Operations Console and the Analytics Console are now accessible only when the configured TAI security mechanism is satisfied.

Configuring App Transport Security (ATS):

This topic outlines how to configure App Transport Security (ATS) for MobileFirst Server and MobileFirst Operational Analytics containers.

Before you begin

Before you begin, review Requirements for Connecting Using ATS.

About this task

ATS configuration does not impact applications connecting from other, non-iOS, mobile operating systems. Other mobile operating systems do not mandate that servers communicate on the ATS level of security but can still communicate with ATS-configured servers.

Before configuring your container image, have the generated certificates ready. The following steps assume that the keystore file `ssl_cert.p12` has the personal certificate and `ca.crt` is the signing certificate.

Procedure

1. Copy the `ssl_cert.p12` file to the `mfpf-server/usr/security/` folder.
2. Modify the `mfpf-server/usr/config/keystore.xml` file similar to the following example configuration:

```
<server>
  <featureManager>
    <feature>ssl-1.0</feature>
  </featureManager>
  <ssl id="defaultSSLConfig" sslProtocol="TLSv1.2" keyStoreRef="defaultKeyStore" enabledCiphers=
    <keyStore id="defaultKeyStore" location="ssl_cert.p12" password="*****" type="PKCS12"/>
</server>
```

- `ssl-1.0` is added as a feature in the feature manager to enable the server to work with SSL communication.
- `sslProtocol="TLSv1.2"` is added in the `ssl` tag to mandate that the server communicates only on Transport Layer Security (TLS) version 1.2 protocol. More than one protocol can be added. For example, adding `sslProtocol="TLSv1+TLSv1.1+TLSv1.2"` would ensure that the server could communicate on TLS V1, V1.1, and V1.2. (TLS V1.2 is required for iOS 9 apps.)
- `enabledCiphers="TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384"` is added in the `ssl` tag so that the server enforces communication using only that cipher.

More ciphers can be added to the list. The server will communicate with the accepted iOS 9 ciphers that have been added to this list.

- The `keyStore` tag tells the server to use the new certificates that are created as per the above requirements.

What to do next

The following specific ciphers require Java Cryptography Extension (JCE) policy settings and an additional JVM option:

```
TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384
TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384
```

If you use these ciphers and use an IBM Java SDK, you can download the policy files. There are two files: `US_export_policy.jar` and `local_policy.jar`. Add both the files to the `mfpf-server/usr/security` folder and then add the following JVM option to the `mfpf-server/usr/env/jvm.options` file:

```
Dcom.ibm.security.jurisdictionPolicyDir=/opt/ibm/wlp/usr/servers/worklight/resources/security/.
```

For development-stage purposes only, you can disable ATS by adding following property to the `info.plist` file:

```
<key>NSAppTransportSecurity</key>
<dict>
  <key>NSAllowsArbitraryLoads</key>
  <true/>
</dict>
```

See also `ATS` and `Bitcode` in iOS 9.

LDAP configuration for containers:

You can configure an IBM MobileFirst Platform Foundation container to securely connect out to an external LDAP repository.

The external LDAP registry can be used in a container for the following purposes:

- To configure the MobileFirst administration security with an external LDAP registry.
- To configure the MobileFirst mobile applications to work with an external LDAP registry.

Configuring administration security with LDAP:

Configure the MobileFirst administration security with an external LDAP registry

About this task

The configuration process includes the following steps:

- Set up and configuration of an LDAP repository
- Changes to the registry file (registry.xml)
- Configuration of a secure gateway to connect to a local LDAP repository and the container. (You need an existing app on Bluemix for this step.)

Procedure

LDAP repository

1. Create users and groups in the LDAP repository. For groups, authorization is enforced based on user membership.

Registry file

2. Open registry.xml and find the basicRegistry element. Replace the basicRegistry element with code that is similar to the following snippet:

```
<ldapRegistry id="ldap"
host="1.234.567.8910" port="1234" ignoreCase="true"
baseDN="dc=worklight,dc=com"
ldapType="Custom"
sslEnabled="false"
bindDN="uid=admin,ou=system"
bindPassword="secret">
<customFilters userFilter="(&(uid=%v)(objectclass=inetOrgPerson))"
groupFilter="(&(member=uid=%v)(objectclass=groupOfNames))"
userIdMap="*:uid"
groupIdMap="*:cn"
groupMemberIdMap="groupOfNames:member"/>
</ldapRegistry>
```

Table 12-47. Descriptions of the ldapRegistry entries

Entry	Description
host and port	Host name (IP address) and port number of your local LDAP server.
baseDN	The domain name (DN) in LDAP that captures all details about a specific organization.
bindDN="uid=admin,ou=system"	Binding details of the LDAP server. For example, the default values for an Apache Directory Service would be uid=admin,ou=system.
bindPassword="secret"	Binding password for the LDAP server. For example, the default value for an Apache Directory Service is secret.

Table 12-47. Descriptions of the ldapRegistry entries (continued)

Entry	Description
<pre><customFilters userFilter="(&uid=%v)(objectclass=inetOrgPerson)" groupFilter="(&member=uid=%v)(objectclass=groupOfNames)" userIdMap="*:uid" groupIdMap="*:cn" groupMemberIdMap="groupOfNames:member"/></pre>	<p>The custom filters that are used for querying the directory service (such as Apache) during authentication and authorization.</p>

3. Ensure that the following features are enabled for appSecurity-2.0 and ldapRegistry-3.0:

```
<featureManager>
  <feature>appSecurity-2.0</feature>
  <feature>ldapRegistry-3.0</feature>
</featureManager>
```

For details about configuring various LDAP server repositories, see the WebSphere Application Server Liberty Knowledge Center.

After you complete the registry.xml changes, configure a secure gateway to connect to the local LDAP server.

Secure gateway

To configure a secure gateway connection to your LDAP server, you must create an instance of the Secure Gateway service on Bluemix and then obtain the IP information for the LDAP registry. You need your local LDAP host name and port number for this task.

4. Log on to Bluemix and navigate to **Catalog, Category > Integration**, and then click **Secure Gateway**.
5. Under Add Service, select an app and then click **CREATE**. Now the service is bound to your app.
6. Go to the Bluemix dashboard for the app, click on the **Secure Gateway** service instance, and then click **ADD GATEWAY**.
7. Name the gateway and click **ADD DESTINATIONS** and enter the name, IP address, and port for your local LDAP server.
8. Follow the prompts to complete the connection. To see the destination initialized, navigate to the Destination screen of the LDAP gateway service.
9. To obtain the host and port information that you need, click the Information icon on the LDAP gateway service instance (located on the Secure Gateway dashboard). The details displayed are an alias to your local LDAP server.
10. Capture the **Destination ID** and **Cloud Host : Port** values. Go to the registry.xml file and add these values, replacing any existing values. See the following example of an updated code snippet in the registry.xml file:

```
<ldapRegistry id="ldap"
  host="cap-sg-prd-5.integration.ibmcloud.com" port="15163" ignoreCase="true"
  baseDN="dc=worklight,dc=com"
  ldapType="Custom"
  sslEnabled="false"
  bindDN="uid=admin,ou=system"
  bindPassword="secret">
  <customFilters userFilter="(&uid=%v)(objectclass=inetOrgPerson)"
    groupFilter="(&member=uid=%v)(objectclass=groupOfNames)"/>
```

```
userIdMap="*:uid"  
groupIdMap="*:cn"  
groupMemberIdMap="groupOfNames:member"/>  
</ldapRegistry>
```

Configuring apps to work with LDAP:

Configure MobileFirst mobile apps to work with an external LDAP registry

About this task

The configuration process includes the following steps:

- Configuring the LDAP login module in the MobileFirst project.
- Configuring a secure gateway to connect to a local LDAP repository and the container. (You need an existing app on Bluemix for this step.)

Procedure

1. Configure the LDAP login module in your MobileFirst project to authenticate the mobile app users against the LDAP server.
To configure a secure gateway connection to your LDAP server, you must create an instance of the Secure Gateway service on Bluemix and then obtain the IP information for the LDAP registry. You need your local LDAP host name and port number for this step.
2. Log on to Bluemix and navigate to **Catalog, Category > Integration**, and then click **Secure Gateway**.
3. Under Add Service, select an app and then click **CREATE**. Now the service is bound to your app.
4. Go to the Bluemix dashboard for the app, click on the **Secure Gateway** service instance, and then click **ADD GATEWAY**.
5. Name the gateway and click **ADD DESTINATIONS** and enter the name, IP address, and port for your local LDAP server.
6. Follow the prompts to complete the connection. To see the destination initialized, navigate to the Destination screen of the LDAP gateway service.
7. To obtain the host and port information that you need, click the Information icon on the LDAP gateway service instance (located on the Secure Gateway dashboard). The details displayed are an alias to your local LDAP server.
8. Capture the **Destination ID** and **Cloud Host : Port** values. Provide these values for the LDAP login module.

Results

The communication between the MobileFirst app in the container on Bluemix with your local LDAP server is established. The authentication and authorization from the Bluemix app is validated against your local LDAP server.

Removing a container from Bluemix

When you remove a container from Bluemix, you must also remove the image name from the registry.

Procedure

1. Run the following Cloud Foundry CLI plug-in for IBM Containers (**cf ic**) commands to remove a container from Bluemix:
 - a. `cf ic ps` (Lists the containers currently running)

- b. `cf ic stop container_id` (Stops the container)
 - c. `cf ic rm container_id` (Removes the container)
2. Run the following **cf ic** commands to remove an image name from the Bluemix registry:
 - a. `cf ic images` (Lists the images in the registry)
 - b. `cf ic rmi image_id` (Removes the image from the registry)

Removing the database service configuration app from Bluemix

If you ran the `prepareserverdbs.sh` script during the configuration of your MobileFirst Platform Foundation on IBM Containers image, a Bluemix app with a bound database service was created that ultimately created the database schema for the container.

About this task

To remove the database service configuration app from Bluemix, you can either use your Bluemix dashboard or run the following Cloud Foundry commands:

```
cf delete app_name
cf delete-service service_name
```

Log and trace collection

Syslog and Liberty log files are generated for MobileFirst Server and MobileFirst Operational Analytics containers.

To persist the log files, you must enable volume. Syslogs are persisted in the `/var/log/rsyslog` folder and Liberty logs are persisted in the `/opt/ibm/wlp/usr/servers/worklight/logs` folder.

Liberty logs get created at the trace specification level *info* by default (collecting general information that outlines task progress), however, you can change the logging level by manually adding a code override or by injecting code using a script file.

Enabling SSH to access container logs, enabling volume to persist log files, changing the trace level, and other logging-related options must be done during container creation when running one of the following start-up scripts:

- “startserver.sh script” on page 12-129
- “startservergroup.sh script” on page 12-130
- “startanalytics.sh script” on page 12-137
- “startanalyticsgroup.sh script” on page 12-138

Volume

When you enable the volume configuration option for a container, volumes persist the container logs regardless of whether the container is active or deleted. Volume for MobileFirst Server and MobileFirst Operational Analytics containers is not enabled by default.

You can enable volume when running one of the start-up scripts mentioned above.

Examples of how to enable volume using a start-up script for regular, silent, and interactive command modes:

- Command-line mode - If you are running scripts from the command line, pass-in the value `Y` for the `[-v|--volume]` command-line argument.

- Silent mode - If you are running scripts in silent mode, set the `ENABLE_VOLUME` property to `Y` in the related properties file for the script (such as `args/startserver.properties` or `args/startservergroup.properties`).
- Interactive mode - If you are running scripts in interactive mode, specify `Y` at the Enable mounting volume for the MobileFirst container logs prompt.

You can still view logs in the Bluemix dashboard using the Logmet service regardless of whether volume and SSH were enabled during container creation.

Monitoring

IBM Containers for Bluemix provides some built-in logging and monitoring capabilities around container CPU, memory, and the interfacing networks. Both container logs and server or runtime logs can be viewed from a Bluemix logmet console by means of the Kibana visualization tool. Active monitoring can be done from a Bluemix logmet console with Grafana, an open source metrics dashboard and graph editor.

See also:

- Monitoring and logging for IBM Containers
- IBM Containers troubleshooting

Accessing log files:

Logs are created for each container instance. You can access log files using the IBM Containers plug-in (`cf ic`) commands, the Bluemix™ logmet console, and the IBM Containers REST API. Alternatively, you can obtain container log files through Secure Shell (SSH).

Using SSH with containers:

When your IBM MobileFirst Platform Foundation container is created with a Secure Shell (SSH) key and bound to a public IP address, a private key can be used to securely view and download the logs for each container instance.

Before you begin

Prerequisites for accessing your MobileFirst Server and MobileFirst Operational Analytics containers to get syslog and Liberty logs:

- SSH must be enabled for the container.
- Volume has been enabled so that the log files are persisted.

For container groups, a public IP address must be bound to each container instance to view the logs using SSH.

Procedure

1. To enable SSH, copy the SSH public key to the `package_root/[mfpf-server or mfpf-analytics]/usr/ssh` folder before you run the `prepareserver.sh` or the `prepareanalytics.sh` scripts. This builds the image with SSH enabled. Any container created from that particular image will have the SSH enabled.

If SSH is not enabled as part of the image customization, you can enable it for the container using the `SSH_ENABLE` and `SSH_KEY` arguments when executing the start-up scripts. You can optionally customize the related script `.properties` files to include the key content.

2. Make an SSH request to the container. Example: *mylocal-workstation# ssh -i
~/ssh_key_directory/id_rsa
root@public_ip*
3. Archive the log file location. Example:
*container_instance@root# cd
/opt/ibm/wlp/usr/servers/worklight
container_instance@root# tar czf
logs_archived.tar.gz logs/*
4. Download the log archive to your local workstation. Example:
*mylocal-workstation# scp -i
~/ssh_key_directory/id_rsa
root@public_ip:/opt/ibm/wlp/usr/servers/worklight/logs_archived.tar.gz
/local_workstation_dir/target_location/*

Accessing containers from the command line:

You can access running MobileFirst Server and MobileFirst Operational Analytics container instances from the command line to obtain logs and traces.

Before you begin

- The container instance must be in a running state.

Procedure

1. Create an interactive terminal within the container instance by running the following command: *cf ic exec -it
container_instance_id "bash".*
2. To locate the log files or traces, use the following command example:
*container_instance@root# cd /opt/ibm/wlp/usr/servers/worklight
container_instance@root# vi messages.log*
3. To copy the logs to your local workstation, use the following command example:
*my_local_workstation# cf ic exec -it container_instance_id
"cat" "/opt/ibm/wlp/usr/servers/worklight/messages.log" > /tmp/local_messages.log*

Using IBM Containers REST API:

The container logs endpoint gets stdout logs with the given ID of the container instance.

Before you begin

Example: *GET /containers/container_id/logs*

Each API request requires an HTTP header X-Auth-Token set with a token obtained with the request authorization token API.

X-Auth-Token = *Bluemix JWT token*
X-Auth-Project-Id = *Space GUID*

See also:

Getting Container logs using IBM Container Cloud Service REST API

Logging overrides:

You can change the log levels by either adding a code override manually or by injecting code using a given script file.

Adding a code override manually to change the log level must be done when you are first preparing the image. You must add the new logging configuration to the `package_root/mfpf-[analytics|server]/usr/config` folder as a separate configuration snippet, which gets copied to the `configDropins/overrides` folder on the Liberty server.

Injecting code using a given script file to change the log level can be accomplished by using certain command-line arguments when running any of the `start*.sh` script files provided in the MobileFirst Platform Foundation on IBM Containers package (`startserver.sh`, `startanalytics.sh`, `startservergroup.sh`, `startanalyticsgroup.sh`). The following optional command-line arguments are applicable:

```
[-tr|--trace] trace_specification  
[-ml|--maxlog] maximum_number_of_log_files  
[-ms|--maxlogsize] maximum_size_of_log_files
```

Troubleshooting tips

Here are tips for resolving common problems that might occur.

Application not configured correctly:

The following error occurs while running the `prepareserverdbs.sh` script: Error : Application not configured correctly.

Explanation

When you run the `prepareserverdbs.sh` script, a series of configuration steps take place:

- A Bluemix app is created and started
- A database service is created and bound to the app
- A REST service is invoked in the app and the database schema is created

If there is a delay with the Bluemix app starting, the client is not able to invoke the reset interface, which could cause the error. Or, there could be an error related to the binding.

How to resolve

Run the same script again. If the same error occurs, verify that the Bluemix app is bound to the database service. If not bound, manually bind the database service to the app and then run the script again.

Docker-related error while running script:

If you encounter Docker-related errors after executing the `initenv.sh` or `prepareserver.sh` scripts, try restarting the Docker service.

Example message:

```
* Pulling repository docker.io/library/ubuntu  
* Error while pulling image: Get https://index.docker.io/v1/repositories/library/ubuntu/images: dial
```

Explanation

The error could occur when the internet connection has changed (such as connecting to or disconnecting from a VPN or network configuration changes) and the Docker runtime environment has not yet restarted. In this scenario, errors would occur when any Docker command is issued.

How to resolve

Restart the Docker service. If the error persists, reboot the computer and then restart the Docker service.

Bluemix registry error:

If you encounter a registry-related error after executing the `prepareserver.sh` or `prepareanalytics.sh` scripts, try running the `initenv.sh` script first.

Explanation

In general, any network problems that occur while the `prepareserver.sh` or `prepareanalytics.sh` scripts are running could cause processing to hang and then fail.

How to resolve

First, run the `initenv.sh` script again to log in to the container registry on Bluemix. Then, rerun the script that previously failed.

Unable to create the runtime .xml file:

An error occurs at the end of running the `prepareserverdbs.sh` script: Error : unable to create `runtime_name.xml`

How to resolve

If the `.war` artifacts for the runtime are in place within the `projects` folder, then the problem might be an intermittent database connectivity issue. Try to run the script again.

Taking a long time to push image:

When running the `prepareserver.sh` script, it takes more than 20 minutes to push an image to the IBM Containers Extension (ICE) registry.

Explanation

The `prepareserver.sh` script pushes the entire IBM MobileFirst Platform Foundation stack, which can take from 20 to 60 minutes.

How to resolve

If the script has not completed after a 60-minute time period has elapsed, the process might be hung because of a connectivity issue. After a stable connection is reestablished, restart the script.

Binding is incomplete error:

When running a script to start a container (such as `startserver.sh` or `startanalytics.sh`) you are prompted to manually bind an IP address because of an error that the binding is incomplete.

Explanation

The script is designed to exit after a certain time duration has passed.

How to resolve

Manually bind the IP address by running the related `cf ic` command. For example, `cf ic ip bind`.

If binding the IP address manually is not successful, ensure that the status of the container is running and then try binding again.

Note: Containers must be in a running state to be bound successfully.

Script fails and returns message about tokens:

Running a script is not successful and returns a message similar to Refreshing cf tokens or Failed to refresh token.

Explanation

The Bluemix session might have timed-out. The user must be logged in to Bluemix before running the container scripts.

How to resolve

Run the `initenv.sh` script again to log in to Bluemix and then run the failed script again.

No runtimes listed in console:

There are no runtimes listed in the IBM MobileFirst Platform Operations Console even though the `prepareserver.sh` script completed successfully.

Explanation

It is possible that either a connection to the database service did not get established or that a formatting problem occurred in the `server.env` file when additional values were appended during deployment.

If additional values were added to the `server.env` file without new line characters, the properties would not resolve. You can validate this potential problem by checking the log files for errors caused by unresolved properties that look similar to this error:

```
FWLSE0320E: Failed to check whether the admin services are ready. Caused by: [project Sample] java.n
```

How to resolve

Manually restart the containers. If the problem still exists, check to see if the number of connections to the database service exceeds the number of connections provisioned by your database plan. If so, make any needed adjustments before proceeding.

If the problem was caused by unresolved properties, ensure that your editor adds the linefeed (LF) character to demarcate the end of a line when editing any of the provided files. For example, the TextEdit app on OS X might use the CR character to mark the end of line instead of LF, which would cause the issue.

prepreserver.sh script fails:

The `prepreserver.sh` script fails and returns the error 405 Method Not Allowed.

Explanation

The following error occurs when running the `prepreserver.sh` script to push the image to the IBM Containers registry.

```
Pushing the MobileFirst Server image to the IBM Containers registry..
Error response from daemon: <!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 3.2 Final//EN">
<title>405 Method Not Allowed</title>
<h1>Method Not Allowed</h1>
<p>The method is not allowed for the requested URL.</p>
```

This error typically occurs if the Docker variables have been modified on the host environment. After executing the `initenv.sh` script, the tooling provides an option to override the local docker environment to connect to IBM Containers using native docker commands.

How to resolve

Do not modify the Docker variables (such as `DOCKER_HOST` and `DOCKER_CERT_PATH`) to point to the IBM Containers registry environment. For the `prepreserver.sh` script to work correctly, the Docker variables must point to the local Docker environment.

Applying IBM MobileFirst Platform Foundation interim fixes in an IBM Containers environment

Most interim fixes for IBM MobileFirst Platform Foundation V7.1 on IBM Containers can be obtained from IBM Fix Central (<http://www.ibm.com/support/fixcentral>).

Before you begin

Before you apply an interim fix, back up your existing configuration files. The configuration files are located in the `package_root/mfpf-analytics/usr` and `package_root/mfpf-server/usr` folders.

Procedure

1. After you back up the existing configuration files, download the interim fix archive and extract the contents to your existing installation folder, overwriting the existing files.
2. Restore your backed-up configuration files into the `/mfpf-analytics/usr` and `/mfpf-server/usr` folders, overwriting the newly installed configuration files.

Results

The interim fix has been applied successfully. You can now build and deploy new production-level containers.

Related links:

- IBM MobileFirst Platform Foundation V7.1 products
- IBM Passport Advantage
- IBM Fix Central

Resolving problems

When you are unable to resolve a problem encountered while working with IBM MobileFirst Platform Foundation on IBM Containers, be sure to gather this key information before contacting IBM Support.

To help expedite the troubleshooting process, gather the following information:

- The version of IBM MobileFirst Platform Foundation that you are using (must be V7.1 or later) and any interim fixes that were applied.
- The container size selected. For example, *Medium 2GB*.
- The Bluemix database plan type. For example, *sqldb_premium*.
- The container ID
- The public IP address (if assigned)
- The information returned from running the following Cloud Foundry CLI plug-in for IBM Containers (**cf ic**) commands from the organization and space where your IBM MobileFirst Platform Foundation container is deployed:

cf ic info

cf ic ps -a (If more than one container instance is listed, make sure to indicate the one with the problem.)

- If Secure Shell (SSH) and volumes were enabled during container creation (while running the `startServer.sh` script), collect all files in the following folders:

`/opt/ibm/wlp/usr/servers/worklight/logs`

`/var/log/rsyslog/syslog`

- If only volume was enabled and SSH was not, collect the available log information using the Bluemix dashboard. After you click on the container instance in the Bluemix dashboard, click the **Monitoring and Logs** link in the sidebar. Go to the Logging tab and then click **ADVANCED VIEW**. The Kibana dashboard opens separately. Using the search toolbar, search for the exception stack trace and then collect the complete details of the exception, `@time-stamp`, `_id`.

Deploying MobileFirst Server on IBM PureApplication System

IBM MobileFirst Platform Foundation provides the capability to deploy and manage IBM MobileFirst Platform Server and MobileFirst applications on IBM PureApplication System and IBM PureApplication Service on SoftLayer.

Using IBM MobileFirst Platform Foundation in combination with IBM PureApplication System and IBM PureApplication Service on SoftLayer provides a simple and intuitive environment for developers and administrators to develop mobile applications, test them, and deploy them to the cloud. This version of IBM MobileFirst Platform Foundation System Patterns provides MobileFirst runtime and artifacts support for the PureApplication Virtual System Pattern technologies

that are included in the latest versions of IBM PureApplication System and IBM PureApplication Service on SoftLayer, as opposed to the Classic Virtual System Pattern supported in earlier versions of IBM PureApplication System.

Key benefits

IBM MobileFirst Platform Foundation System Patterns provides the following benefits:

- Predefined templates enable you to build patterns in a simple way for the most typical MobileFirst Server deployment topologies such as IBM WebSphere Application Server Liberty Profile single and multiple nodes, IBM WebSphere Application Server full profile single and multiple nodes, and clusters of WebSphere Application Server Network Deployment servers.
- Script packages act as building blocks to compose extended deployment topologies such as automating the inclusion of an analytics server in a pattern, supporting multiple runtimes, and flexible DB VM deployment options. WebSphere Application Server and DB2 script packages are available through the inclusion of WebSphere Application Server and DB2 pattern types.
- Optional JNDI properties in the runtime deployment script package allow fine-grained tuning for the deployment topology. In addition, deployment topologies that are built with IBM WebSphere Application Server full profile now support accessing the WebSphere Application Server Administration Console, which gives you full control over the configuration of the application server.

Important restrictions

Depending on the pattern template you use, there are some component attributes that you should not change. If you change any of these component attributes, the deployment of patterns that are based on these templates fails:

MobileFirst Platform (WAS single node) template

In the **Standalone server** component of the **MobileFirst Platform Server** node, do not unlock or change the values for any of the following attributes:

- **Cell name**
- **Node name**
- **Profile name**

If you change any of these attributes, your pattern deployment will fail.

MobileFirst Platform (WAS server farm) template

In the **Standalone server** component of the **MobileFirst Platform Server** node, do not unlock or change the values for any of the following attributes:

- **Cell name**
- **Node name**
- **Profile name**

If you change any of these attributes, your pattern deployment will fail.

MobileFirst Platform (WAS ND) template

In the **Deployment manager** component of the **DmgrNode** node or the **Custom nodes** component of the **CustomNode** node, do not unlock or change the values for any of the following attributes:

- **Cell name**

- **Node name**
- **Profile name**

If you change any of these attributes, your pattern deployment will fail.

Limitations

The following limitations apply:

- Dynamic scaling for WebSphere Application Server Liberty profile server farms and IBM WebSphere Application Server full profile server farms is not supported. The number of server farm nodes can be specified in the pattern by setting the scaling policy but cannot be changed during run time.
- The IBM MobileFirst Platform Foundation System Patterns Extension for MobileFirst Studio and Ant command line interface supported in versions earlier than V7.0 are not available in this version of IBM MobileFirst Platform Foundation System Patterns.
- IBM MobileFirst Platform Foundation System Patterns depends on WebSphere Application Server Patterns, which has its own restrictions. For more information, see Restrictions for WebSphere Application Server Patterns.
- Due to restrictions in the uninstallation of Virtual System Patterns, you must delete the script packages manually after you delete the pattern type. In IBM PureApplication System, go to **Catalog > Script Packages** to delete the script packages that are listed in the “Components” section.
- The **MobileFirst Platform (WAS ND)** pattern template does not support token licensing. If you want to use this pattern, you must use perpetual licensing. All other patterns support token licensing.

Composition

IBM MobileFirst Platform Foundation System Patterns is composed of the following patterns:

- IBM WebSphere Application Server Network Deployment Patterns 1.0.0.2.
- [PureApplication Service] WebSphere8554ForMobile IM Repository to allow the WebSphere Application Server Network Deployment Patterns to work. (Contact the administrator for IBM PureApplication System to confirm that the WebSphere8554 IM Repository is installed.)
- IBM DB2 with BLU Acceleration® Pattern 1.2.2.
- IBM MobileFirst Platform Foundation System Patterns.

Components

In addition to all components provided by IBM WebSphere Application Server Pattern and IBM DB2 with BLU Acceleration Pattern, IBM MobileFirst Platform Foundation System Patterns provides the following Script Packages:

- MFP Administration DB
- MFP Runtime DB
- MFP Reports DB
- MFP Server Prerequisite
- MFP Server Administration
- MFP Server Runtime Deployment
- MFP Server Application Adapter Deployment
- MFP IHS Configuration

- MFP Analytics
- “MFP Open Firewalls for WAS” on page 12-237

Compatibility between pattern types and artifacts created with different product versions

If you use MobileFirst Studio V6.3.0 or earlier to develop your applications, you can upload the associated runtime, application, and adapter artifacts into patterns associated with IBM MobileFirst Platform Foundation V7.0.0 and later.

Pattern types that are associated with IBM MobileFirst Platform Foundation V6.3.0 or earlier are not compatible with runtime, application, and adapter artifacts created by using MobileFirst Studio V7.0.0 and later.

For versions V6.0.0 and earlier, only the same versions of server, .war file, application (.wlap file) and adapters are compatible.

For more information about version compatibility, see “Version compatibility” on page 7-1.

Installing IBM MobileFirst Platform Foundation System Patterns

You use the PureApplication System Workload Console to install IBM MobileFirst Platform Foundation System Patterns.

Before you begin

You can find the `vsys.mobilefirst-7.1.0.0.tgz` file in the `mobilefirst_patterns_7.1.0.zip` file. Make sure you extract it before you start this procedure.

Procedure

1. Log in to IBM PureApplication System with an account that has permission to create new pattern types.
2. Go to **Catalog > Pattern Types**.
3. Upload the IBM MobileFirst Platform Foundation System Patterns .tgz file:
 - a. On the toolbar, click **+**. The “Install a pattern type” window opens.
 - b. On the Local tab, click **Browse**, select the IBM MobileFirst Platform Foundation System Patterns .tgz file, and then wait for the upload process to complete. The pattern type is displayed in the list and is marked as not enabled.
4. In the list of pattern types, click the uploaded pattern type. Details of the pattern type are displayed.
5. In the License Agreement row, click **License**. The License window is displayed stating the terms of the license agreement.
6. To accept the license, click **Accept**. Details of the pattern type now show that the license is accepted.
7. In the Status row, click **Enable**. The pattern type is now listed as being enabled.
8. Mandatory for PureApplication Service: After the pattern type is enabled successfully, go to **Catalog > Script Packages** and select script packages with

names similar to "MFP ***". On the details page to the right, accept the license in the **License agreement** field. Repeat for all nine script packages listed in the "Components" on page 12-158 section.

Token licensing requirements for IBM MobileFirst Platform Foundation System Patterns

If you use token licensing to license IBM MobileFirst Platform Foundation, you must have IBM Rational License Key Server installed and configured with your licenses before you deploy the MobileFirst Platform Patterns.

Important: The **MobileFirst Platform (WAS ND)** pattern template does not support token licensing. You must be using perpetual licensing when you deploy patterns based on the MobileFirst Platform (WAS ND) pattern template. All other pattern templates support token licensing.

Your IBM Rational License Key Server must be external to your PureApplication System. MobileFirst Platform Patterns do not support the PureApplication System shared service for IBM Rational License Key Server.

In addition, you must know the following information about your Rational License Key Server in order to add the license key server information to your pattern attributes:

- Fully qualified host name or IP address of your Rational License Key Server
- License manager daemon (**lmgrd**) port
- Vendor daemon (**ibmrat1**) port

If you have a firewall between your Rational License Key Server and your PureApplication System, ensure that both daemon ports are open in your firewall.

The deployment of MobileFirst Platform Patterns fails if the license key server cannot be contacted or if insufficient license tokens are available.

For details about licensing in MobileFirst Server, see "Licensing in MobileFirst Server" on page 2-16.

For details about installing and configuring Rational License Key Server, see IBM Support - Rational licensing start page.

Deploying MobileFirst Server on a single-node WebSphere Application Server Liberty profile server

You use a predefined template to deploy MobileFirst Server on a single-node WebSphere Application Server Liberty profile server.

Before you begin

This procedure involves uploading certain artifacts to IBM PureApplication System such as the MobileFirst Server runtime. Before you begin, ensure that the artifacts are available for upload.

Token licensing requirements: If you use token licensing to license IBM MobileFirst Platform Foundation, review the requirements outlined in "Token licensing requirements for IBM MobileFirst Platform Foundation System Patterns" before you continue. The deployment of this pattern fails if the license key server cannot be contacted or if insufficient license tokens are available.

About this task

Note:

Some parameters of script packages in the template have been configured with the recommended values and are not mentioned in this section. For fine-tuning purposes, see more information about all the parameters of script packages in “Script packages for MobileFirst Server” on page 12-223.

For more information about the composition and configuration options of the predefined template that is used in this procedure, see “MobileFirst Platform (Liberty single node) template” on page 12-212.

Procedure

1. Create a pattern from the predefined template:
 - a. In the IBM PureApplication System dashboard, click **Patterns > Virtual System Patterns**. The Virtual System Patterns page opens.
 - b. On the Virtual System Patterns page, click **Create New**, and then in the pop-up window, select **MobileFirst Platform (Liberty single node)** from the list of predefined templates. If the name is only partially visible due to its length, you can confirm that the correct template is selected by viewing its description on the **More information** tab.
 - c. In the **Name** field, provide a name for the pattern.
 - d. In the **Version** field, specify the version number of the pattern.
 - e. Click **Start Building**.
2. Mandatory for AIX: In IBM PureApplication System running on Power®, the MobileFirst Platform DB node needs to use the AIX-specific add-on component “Default AIX add disk” to replace the “Default add disk” component in the template to support the jfs2 file system:
 - a. In the Pattern Builder, select the **MobileFirst Platform DB** node.
 - b. Click the **Add a Component Add-on** button (the button is visible above the component box when you hover the cursor over the **MobileFirst Platform DB** node).
 - c. From the **Add Add-ons** list, select **Default AIX add disk**. The component is added as the lowest component of the MobileFirst Platform DB node.
 - d. Select the **Default AIX add disk** component and specify the following attributes:
 - DISK_SIZE_GB**
Storage size (measured in GB) to be extended to the DB server.
Example value: 10.
 - FILESYSTEM_TYPE**
Supported file system in AIX. Default value: jfs2.
 - MOUNT_POINT**
Align with the attribute **Mount point for instance owner** in the Database Server component in the MobileFirst Platform DB node.
Example value: /dbinst.
 - VOLUME_GROUP**
Example value: group1. Contact your IBM PureApplication System administrator for the correct value.
 - e. In the MobileFirst Platform DB node, select the **Default add disk** component, and then click the **X** button to delete it.

- f. Save the pattern.
3. Optional: Configure MobileFirst Server administration. You can skip this step if you want to specify the user credential with MobileFirst Server administration privilege later during the pattern deployment configuration phase in step 9. To specify it now, complete these steps:

Note: If you want to configure administration security with an LDAP server, you need to supply additional LDAP information. For more information, see “Configuring MobileFirst administration security with an external LDAP repository” on page 12-192.

- a. In the MobileFirst Platform Server node, click the **MFP Server Administration** component. The properties of the selected component are displayed next to the canvas.
- b. Next to the **admin_user** and **admin_password** fields, click the **Delete** button to clear their pattern level parameter settings.
- c. In the **admin_user** and **admin_password** fields, specify the administration user name and password.
- d. If you use token licensing to license IBM MobileFirst Platform Foundation, complete the following fields. If you do not use token licensing, leave these fields blank.

ACTIVATE_TOKEN_LICENSE

Select this field to license your pattern with token licensing.

LICENSE_SERVER_HOSTNAME

Enter the fully qualified host name or IP address of your Rational License Key Server.

LMGRD_PORT

Enter the port number that the license manager daemon (**lmrgd**) listens for connections on. The default license manager daemon port is 27000.

IBMRATL_PORT

Enter the port number that the vendor daemon (**ibmratl**) listens for connections on. The default vendor daemon port is typically 27001.

A default administration account for MobileFirst Server is created during pattern deployment.

4. Upload the runtime WAR file:
 - a. In the MobileFirst Platform Server node, click the **MFP Server Runtime** component. The properties of the selected component are displayed next to the canvas.
 - b. Next to the **Additional file** field, click the **Delete** button to delete the sample runtime WAR file, and then click the **Browse** button to locate your runtime WAR file for uploading.
 - c. In the **Target path** field, specify the full path for your runtime WAR file including the file name; for example, `/opt/tmp/HelloWorld.war`.
5. Optional: Configure MobileFirst Server runtime deployment. You can skip this step if you want to specify the context root name for the runtime later during the pattern deployment configuration phase in step 9. To specify the context root name now, complete these steps:
 - a. In the MobileFirst Platform Server node, click the **MFP Server Runtime Deployment** component. The properties of the selected component are displayed next to the canvas.

- b. Next to the **runtime_contextRoot** field, click the **Delete** button to clear the pattern level parameter setting.
 - c. In the **runtime_contextRoot** field, specify the runtime context root name. Note that the context root name must start with a forward slash, /; for example, /HelloWorld.
6. Upload application and adapter artifacts:

Important: When specifying the Target path for applications and adapters, make sure all the applications and adapters are placed in the same directory. For example, if one target path is /opt/tmp/deploy/HelloWorld-common.wlapp, all the other target paths should be /opt/tmp/deploy/*.

- a. In the MobileFirst Platform Server node, click the **MFP Server Application** or **MFP Server Adapter** component. The properties of the selected component are displayed next to the canvas.
 - b. In the **Additional file** field, click the **Browse** button to locate and upload the application or adapter artifact.
 - c. In the **Target path** field, specify the full path for storing the artifact including its file name; for example, /opt/tmp/deploy/HelloWorld-common.wlapp.
 - d. If no application or adapter is to be deployed in the pattern, remove the relevant component by clicking the **X** button inside it. To get an empty MobileFirst Operations Console deployed without any app or adapter installed, remove the MFP Server Application Adapter Deployment component by clicking the **X** button inside it.
7. Optional: Add more application or adapter artifacts for deployment:
- a. From the **Assets** toolbar, expand **Software Components**, and then drag and drop an **Additional file** component onto the MobileFirst Platform Server node in the canvas. Rename it MobileFirst App_X or MobileFirst Adapter_X (where X stands for a unique number for differentiation).
 - b. Hover the cursor over the newly added App or Adapter component, and then click the **Move Up** and **Move Down** buttons to adjust its sequence in the node. Make sure it is placed after the MFP Runtime Deployment component but before the MFP Server Application Adapter Deployment component.
 - c. Click the newly added application or adapter component. The properties of the selected component are displayed next to the canvas. Upload the application or adapter artifact and specify its target path by referring to steps 6b-c
 - d. Repeat steps 7a-c to add more applications and adapters for deployment.
8. Optional: Configure application and adapter deployment to MobileFirst Server. You can skip this step if you want to specify the user credential with deployment privilege later during the pattern deployment configuration phase in step 9. If you have specified the default admin user credential in step 3, you can now specify the deployer user, which must align with the admin user credential:
- a. In the MobileFirst Platform Server node, select the **MFP Server Application Adapter Deployment** component. The properties of the selected component are displayed next to the canvas.
 - b. Find the parameters named **deployer_user** and **deployer_password**, and then click the adjacent **Delete** buttons to clear the pattern level parameter settings.

- c. In the **deployer_user** and **deployer_password** fields, specify the user name and password.
9. Configure and launch the pattern deployment:
 - a. In the IBM PureApplication System dashboard, click **Patterns > Virtual System Patterns**.
 - b. On the Virtual System Patterns page, use the **Search** field to find the pattern you created, and then select the pattern.
 - c. In the toolbar above the panel displaying detailed information about the pattern, click the **Deploy** button.
 - d. In the Deploy Pattern window, in the Configure panel, select the correct environment profile from the **Environment Profile** list, and provide other IBM PureApplication System environment parameters. To obtain the correct information, consult your IBM PureApplication System administrator.
 - e. In the middle column, click **Pattern attributes** to display attributes such as user names and passwords.

Supply the following information in the fields provided:

Note: Make appropriate changes to the default values of the pattern-level parameters even if an external LDAP server is configured. If you configure administration security by using an LDAP server, you need to supply additional LDAP information. For more information, see “Configuring MobileFirst administration security with an external LDAP repository” on page 12-192.

admin_user

Not visible if configured in step 3. Create a default MobileFirst Server administrator account. Default value: demo.

admin_password

Not visible if configured in step 3. Default admin account password. Default value: demo.

ACTIVATE_TOKEN_LICENSE

Not visible if configured in step 3. Select this field to license your pattern with token licensing. Leave this field clear if you use perpetual licenses.

LICENSE_SERVER_HOSTNAME

Not visible if configured in step 3. If you use token licensing to license IBM MobileFirst Platform Foundation, enter the fully-qualified hostname or IP address of your Rational License Key Server IP address. Otherwise, leave this field blank.

LMGRD_PORT

Not visible if configured in step 3. If you use token licensing to license IBM MobileFirst Platform Foundation, enter the port number that the license manager daemon (**lmrgd**) listens for connections on. Otherwise, leave this field blank.

The default license manager daemon port is 27000.

IBMRATL_PORT

Not visible if configured in step 3. If you use token licensing to license IBM MobileFirst Platform Foundation, enter the port number that the vendor daemon (**ibmratl**) listens for connections on. Otherwise, leave this field blank.

The default vendor daemon port is typically 27001.

runtime_contextRoot

Not visible if configured in step 5. Context root name for the MobileFirst Server runtime. The name must start with “/”.

deployer_user

Not visible if configured in step 8. User name for the account with deployment privilege. If an external LDAP server is not configured, you must enter the same value as was specified when creating the default admin user for the administration service, because in this case, the only authorized user for app and adapter deployment is the default admin user.

deployer_password

Not visible if configured in step 8. User password for the user with deployment privilege.

MFP Vms Password(root)

Root password for the MobileFirst Platform Server and MobileFirst Platform DB nodes. Default value: passw0rd.

MFP DB Password(Instance owner)

Instance owner password for the MobileFirst Platform DB node. Default value: passw0rd.

- f. Click **Quick Deploy** to launch your pattern deployment. After a few seconds, a message is displayed to indicate that the pattern has started to launch. You can click the URL provided in the message to track your pattern deployment status or go to **Patterns > Virtual System Instances** to open the Virtual System Instances page and search for your pattern there.

If you use token licensing to license IBM MobileFirst Platform Foundation, your pattern will fail to deploy if insufficient license tokens are available or if the license key server IP address and port were entered incorrectly.

10. Access the MobileFirst Operations Console:
 - a. Click **Patterns > Virtual System Instances** to open the Virtual System Instances page and search for your pattern there. Make sure it is in Running state.
 - b. Select the pattern name and expand the **Virtual machine perspective** option in the panel displaying details of the selected instance.
 - c. Find the MobileFirst Server VM that has a name similar to `MobileFirst_Platform_Server.*` and make a note of its Public IP address: you need this information in the following step.
 - d. In the browser, open the MobileFirst Operations Console by composing its URL with one of the following formats:
 - `http://{MFP Server VM Public IP}:9080/worklightconsole`
 - `https://{MFP Server VM Public IP}:9443/worklightconsole`
 - e. Log in to the Console with admin user and password specified in step 3 or step 9.

Deploying MobileFirst Server on a multiple-node WebSphere Application Server Liberty profile server

You use a predefined template to deploy MobileFirst Server on a multiple-node WebSphere Application Server Liberty profile server.

Before you begin

This procedure involves uploading certain artifacts to IBM PureApplication System such as the MobileFirst Server runtime. Before you begin, ensure that the artifacts are available for upload.

Token licensing requirements: If you use token licensing to license IBM MobileFirst Platform Foundation, review the requirements outlined in “Token licensing requirements for IBM MobileFirst Platform Foundation System Patterns” on page 12-160 before you continue. The deployment of this pattern fails if the license key server cannot be contacted or if insufficient license tokens are available.

About this task

Note:

Some parameters of script packages in the template have been configured with the recommended values and are not mentioned in this section. For fine-tuning purposes, see more information about all the parameters of script packages in “Script packages for MobileFirst Server” on page 12-223.

For more information about the composition and configuration options of the predefined template that is used in this procedure, see “MobileFirst Platform (Liberty server farm) template” on page 12-214.

Procedure

1. Create a pattern from the predefined template:
 - a. In the IBM PureApplication System dashboard, click **Patterns > Virtual System Patterns**. The Virtual System Patterns page opens.
 - b. On the Virtual System Patterns page, click **Create New**, and then in the pop-up window, select **MobileFirst Platform (Liberty server farm)** from the list of predefined templates. If the name is only partially visible due to its length, you can confirm that the correct template is selected by viewing its description on the **More information** tab.
 - c. In the **Name** field, provide a name for the pattern.
 - d. In the **Version** field, specify the version number of the pattern.
 - e. Click **Start Building**.
2. Mandatory for AIX: In IBM PureApplication System running on Power, the MobileFirst Platform DB node needs to use the AIX-specific add-on component “Default AIX add disk” to replace the “Default add disk” component in the template to support the jfs2 file system:
 - a. In the Pattern Builder, select the **MobileFirst Platform DB** node.
 - b. Click the **Add a Component Add-on** button (the button is visible above the component box when you hover the cursor over the **MobileFirst Platform DB** node).
 - c. From the **Add Add-ons** list, select **Default AIX add disk**. The component is added as the lowest component of the MobileFirst Platform DB node.

- d. Select the **Default AIX add disk** component and specify the following attributes:

DISK_SIZE_GB

Storage size (measured in GB) to be extended to the DB server.
Example value: 10.

FILESYSTEM_TYPE

Supported file system in AIX. Default value: jfs2.

MOUNT_POINT

Align with the attribute **Mount point for instance owner** in the Database Server component in the MobileFirst Platform DB node.
Example value: /dbinst.

VOLUME_GROUP

Example value: group1. Contact your IBM PureApplication System administrator for the correct value.

- e. In the MobileFirst Platform DB node, select the **Default add disk** component, and then click the **X** button to delete it.
 - f. Save the pattern.
3. Optional: Configure MobileFirst Server administration. You can skip this step if you want to specify the user credential with MobileFirst Server administration privilege later during the pattern deployment configuration phase in step 9. To specify it now, complete these steps:

Note: If you want to configure administration security with an LDAP server, you need to supply additional LDAP information. For more information, see “Configuring MobileFirst administration security with an external LDAP repository” on page 12-192.

- a. In the MobileFirst Platform Server node, click the **MFP Server Administration** component. The properties of the selected component are displayed next to the canvas.
- b. Next to the **admin_user** and **admin_password** fields, click the **Delete** button to clear their pattern level parameter settings.
- c. In the **admin_user** and **admin_password** fields, specify the administration user name and password.
- d. If you use token licensing to license IBM MobileFirst Platform Foundation, complete the following fields. If you do not use token licensing, leave these fields blank.

ACTIVATE_TOKEN_LICENSE

Select this field to license your pattern with token licensing.

LICENSE_SERVER_HOSTNAME

Enter the fully qualified host name or IP address of your Rational License Key Server.

LMGRD_PORT

Enter the port number that the license manager daemon (**lmrgd**) listens for connections on. The default license manager daemon port is 27000.

IBMRATL_PORT

Enter the port number that the vendor daemon (**ibmratl**) listens for connections on. The default vendor daemon port is typically 27001.

A default administration account for MobileFirst Server is created during pattern deployment.

4. Upload the runtime WAR file:
 - a. In the MobileFirst Platform Server node, click the **MFP Server Runtime** component. The properties of the selected component are displayed next to the canvas.
 - b. Next to the **Additional file** field, click the **Delete** button to delete the sample runtime WAR file, and then click the **Browse** button to locate your runtime WAR file for uploading.
 - c. In the **Target path** field, specify the full path for your runtime WAR file including the file name; for example, `/opt/tmp/HelloWorld.war`.
5. Optional: Configure MobileFirst Server runtime deployment. You can skip this step if you want to specify the context root name for the runtime later during the pattern deployment configuration phase in step 10. To specify the context root name now, complete these steps:
 - a. In the MobileFirst Platform Server node, click the **MFP Server Runtime Deployment** component. The properties of the selected component are displayed next to the canvas.
 - b. Next to the **runtime_contextRoot** field, click the **Delete** button to clear the pattern level parameter setting.
 - c. In the **runtime_contextRoot** field, specify the runtime context root name. Note that the context root name must start with a forward slash, `/`; for example, `/HelloWorld`.
6. Upload application and adapter artifacts:

Important: When specifying the Target path for applications and adapters, make sure all the applications and adapters are placed in the same directory. For example, if one target path is `/opt/tmp/deplo/HelloWorld-common.wlapp`, all the other target paths should be `/opt/tmp/deplo/*`.

- a. In the MobileFirst Platform Server node, click the **MFP Server Application** or **MFP Server Adapter** component. The properties of the selected component are displayed next to the canvas.
 - b. In the **Additional file** field, click the **Browse** button to locate and upload the application or adapter artifact.
 - c. In the **Target path** field, specify the full path for storing the artifact including its file name; for example, `/opt/tmp/deplo/HelloWorld-common.wlapp`.
 - d. If no application or adapter is to be deployed in the pattern, remove the relevant component by clicking the **X** button inside it. To get an empty MobileFirst Operations Console deployed without any app or adapter installed, remove the MFP Server Application Adapter Deployment component by clicking the **X** button inside it.
7. Optional: Add more application or adapter artifacts for deployment:
 - a. From the Assets toolbar, expand **Software Components**, and then drag and drop an **Additional file** component onto the MobileFirst Platform Server node in the canvas. Rename it `MobileFirst App_X` or `MobileFirst Adapter_X` (where `X` is any unique number for differentiation).
 - b. Hover the cursor over the newly added App or Adapter component, and then click the **Move Up** and **Move Down** buttons to adjust its sequence in the node. Make sure it is placed after the MFP Runtime Deployment component but before the MFP Server Application Adapter Deployment component.

- c. Click the newly added App or Adapter component. The properties of the selected component are displayed next to the canvas. Upload the application or adapter artifact and specify its target path by referring to steps 6b-c
 - d. Repeat steps 7a-c to add more applications and adapters for deployment.
8. Optional: Configure application and adapter deployment to MobileFirst Server. You can skip this step if you want to specify the user credential with deployment privilege later during the pattern deployment configuration phase in step 10. If you have specified the default admin user credential in step 3, you can now specify the deployer user, which must align with the admin user credential:
 - a. In the MobileFirst Platform Server node, click the **MFP Server Application Adapter Deployment** component. The properties of the selected component are displayed next to the canvas.
 - b. Find the parameters named **deployer_user** and **deployer_password**, and then click the adjacent **Delete** buttons to clear the pattern level parameter settings.
 - c. In the **deployer_user** and **deployer_password** fields, specify the user name and password.
 9. Configure base scaling policy:
 - a. In the **MobileFirst Platform Server** node, select the **Base Scaling Policy** component. The properties of the selected component are displayed next to the canvas.
 - b. In the **Number of Instances** field, specify the number of server nodes to be instantiated during pattern deployment. The default value is 2 in the predefined template. Because dynamic scaling is not supported in this release, do not specify values in the remaining attribute fields.
 10. Configure and launch the pattern deployment. Before pattern deployment, save your pattern after each modification by clicking the **Save** button in the Pattern Builder page:
 - a. In the IBM PureApplication System dashboard, click **Patterns > Virtual System Patterns**.
 - b. On the Virtual System Patterns page, use the **Search** field to find the pattern you created, and then select the pattern.
 - c. In the toolbar above the panel displaying detailed information about the pattern, click the **Deploy** button.
 - d. In the Deploy Pattern window, in the Configure panel, select the correct environment profile from the **Environment Profile** list, and provide other IBM PureApplication System environment parameters. To obtain the correct information, consult your IBM PureApplication System administrator.
 - e. In the middle column, click **Pattern attributes** to display attributes such as user names and passwords.
Supply the following information in the fields provided:

Note: Make appropriate changes to the default values of the pattern-level parameters even if an external LDAP server is configured. If you configure administration security by using an LDAP server, you need to supply additional LDAP information. For more information, see “Configuring MobileFirst administration security with an external LDAP repository” on page 12-192.

runtime_contextRoot_list

Context root names of the MobileFirst Server runtimes in case multiple runtimes exist. Use a semicolon (;) to separate each runtime context roots; for example, HelloMobileFirst;HelloWorld

Important: runtime_contextRoot_list must align with the context root specified in the MFP Server Runtime Deployment node; otherwise, IHS will not be able to correctly route requests that contain the runtime context root.

admin_user

Not visible if configured in step 3. Create a default administrator user account. Default value: demo.

admin_password

Not visible if configured in step 3. Default administrator account password. Default value: demo.

ACTIVATE_TOKEN_LICENSE

Not visible if configured in step 3. Select this field to license your pattern with token licensing. Leave this field clear if you use perpetual licenses.

LICENSE_SERVER_HOSTNAME

Not visible if configured in step 3. If you use token licensing to license IBM MobileFirst Platform Foundation, enter the fully-qualified hostname or IP address of your Rational License Key Server IP address. Otherwise, leave this field blank.

LMGRD_PORT

Not visible if configured in step 3. If you use token licensing to license IBM MobileFirst Platform Foundation, enter the port number that the license manager daemon (**lmrgd**) listens for connections on. Otherwise, leave this field blank.

The default license manager daemon port is 27000.

IBMRATL_PORT

Not visible if configured in step 3. If you use token licensing to license IBM MobileFirst Platform Foundation, enter the port number that the vendor daemon (**ibmratl**) listens for connections on. Otherwise, leave this field blank.

The default vendor daemon port is typically 27001.

runtime_contextRoot

Not visible if configured in step 5. Context root name for the runtime. The name must start with /.

deployer_user

Not visible if configured in step 8. User name for the account with deployment privilege. If an external LDAP server is not configured, you must enter the same value as was specified when creating the default admin user for the administration service, because in this case, the only authorized user for app and adapter deployment is the default admin user.

deployer_password

Not visible if configured in step 8. User password for the user with deployment privilege.

MFP Vms Password(root)

Root password for the MobileFirst Platform Server and MobileFirst Platform DB nodes. Default value: passw0rd.

MFP DB Password(Instance owner)

Instance owner password for the MobileFirst Platform DB node. Default value: passw0rd.

- f. Click **Quick Deploy** to launch your pattern deployment. After few seconds, a message is displayed to indicate that the pattern has started to launch. You can click the URL provided in the message to track your pattern deployment status or go to **Patterns > Virtual System Instances** to open the Virtual System Instances page and search for your pattern there.

If you use token licensing to license IBM MobileFirst Platform Foundation, your pattern will fail to deploy if insufficient license tokens are available or if the license key server IP address and port were entered incorrectly.

11. Access the MobileFirst Operations Console:

- a. Click **Patterns > Virtual System Instances** to open the Virtual System Instances page and search for your pattern there. Make sure it is in Running state.
- b. Select the pattern name and expand the **Virtual machine perspective** option in the panel displaying details of the selected instance.
- c. Find the IHS Server VM that has a name similar to `IHS_Server.*` and make a note of its Public IP address: you need this information in the following step.
- d. In the browser, open the MobileFirst Operations Console by composing its URL with one of the following formats:
 - `http://{IHS Server VM Public IP}/worklightconsole`
 - `https://{IHS Server VM Public IP}/worklightconsole`
- e. Log in to the Console with the admin user ID and password specified in step 3 or step 10.

Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server

You use a predefined template to deploy a single-node MobileFirst Server to a WebSphere Application Server full profile server.

Before you begin

This procedure involves uploading certain artifacts to IBM PureApplication System such as the MobileFirst Server runtime. Before you begin, ensure that the artifacts are available for upload.

Token licensing requirements: If you use token licensing to license IBM MobileFirst Platform Foundation, review the requirements outlined in “Token licensing requirements for IBM MobileFirst Platform Foundation System Patterns” on page 12-160 before you continue. The deployment of this pattern fails if the license key server cannot be contacted or if insufficient license tokens are available.

About this task

Note:

Some parameters of script packages in the template have been configured with the recommended values and are not mentioned in this section. For fine-tuning purposes, see more information about all the parameters of script packages in “Script packages for MobileFirst Server” on page 12-223.

For more information about the composition and configuration options of the predefined template that is used in this procedure, see “MobileFirst Platform (WAS single node) template” on page 12-216.

Procedure

1. Create a pattern from the predefined template:
 - a. In the IBM PureApplication System dashboard, click **Patterns > Virtual System Patterns**. The Virtual System Patterns page opens.
 - b. On the Virtual System Patterns page, click **Create New**, and then in the pop-up window, select **MobileFirst Platform (WAS single node)** from the list of predefined templates. If the name is only partially visible due to its length, you can confirm that the correct template is selected by viewing its description on the **More information** tab.
 - c. In the **Name** field, provide a name for the pattern.
 - d. In the **Version** field, specify the version number of the pattern.
 - e. Click **Start Building**.
2. Mandatory for AIX: In IBM PureApplication System running on Power, the MobileFirst Platform DB node needs to use the AIX-specific add-on component “Default AIX add disk” to replace the “Default add disk” component in the template to support the jfs2 file system:
 - a. In the Pattern Builder, select the **MobileFirst Platform DB** node.
 - b. Click the **Add a Component Add-on** button (the button is visible above the component box when you hover the cursor over the **MobileFirst Platform DB** node).
 - c. From the **Add Add-ons** list, select **Default AIX add disk**. The component is added as the lowest component of the MobileFirst Platform DB node.
 - d. Select the **Default AIX add disk** component and specify the following attributes:
 - DISK_SIZE_GB**
Storage size (measured in GB) to be extended to the DB server.
Example value: 10.
 - FILESYSTEM_TYPE**
Supported file system in AIX. Default value: jfs2.
 - MOUNT_POINT**
Align with the attribute **Mount point for instance owner** in the Database Server component in the MobileFirst Platform DB node.
Example value: /dbinst.
 - VOLUME_GROUP**
Example value: group1. Contact your IBM PureApplication System administrator for the correct value.
 - e. In the MobileFirst Platform DB node, select the **Default add disk** component, and then click the **X** button to delete it.
 - f. Save the pattern.
3. Optional: Configure MobileFirst Server administration. You can skip this step if you want to specify the user credential with MobileFirst Server

administration privilege later during the pattern deployment configuration phase in step 9. To specify it now, complete these steps:

Note: If you want to configure administration security with an LDAP server, you need to supply additional LDAP information. For more information, see “Configuring MobileFirst administration security with an external LDAP repository” on page 12-192.

- a. In the MobileFirst Platform Server node, click the **MFP Server Administration** component. The properties of the selected component are displayed next to the canvas.
- b. Next to the **admin_user** and **admin_password** fields, click the **Delete** button to clear their pattern level parameter settings.
- c. In the **admin_user** and **admin_password** fields, specify the administration user name and password.
- d. If you use token licensing to license IBM MobileFirst Platform Foundation, complete the following fields. If you do not use token licensing, leave these fields blank.

ACTIVATE_TOKEN_LICENSE

Select this field to license your pattern with token licensing.

LICENSE_SERVER_HOSTNAME

Enter the fully qualified host name or IP address of your Rational License Key Server.

LMGRD_PORT

Enter the port number that the license manager daemon (**lmrgd**) listens for connections on. The default license manager daemon port is 27000.

IBMRATL_PORT

Enter the port number that the vendor daemon (**ibmrat1**) listens for connections on. The default vendor daemon port is typically 27001.

A default administration account for MobileFirst Server is created during pattern deployment.

4. Upload the runtime WAR file:
 - a. In the MobileFirst Platform Server node, click the **MFP Server Runtime** component. The properties of the selected component are displayed next to the canvas.
 - b. Next to the **Additional file** field, click the **Delete** button to delete the sample runtime WAR file, and then click the **Browse** button to locate your runtime WAR file for uploading.
 - c. In the **Target path** field, specify the full path for your runtime WAR file including the file name; for example, `/opt/tmp/HelloWorld.war`.
5. Optional: Configure MobileFirst Server runtime deployment. You can skip this step if you want to specify the context root name for the runtime later during the pattern deployment configuration phase in step 9. To specify the context root name now, complete these steps:
 - a. In the MobileFirst Platform Server node, click the **MFP Server Runtime Deployment** component. The properties of the selected component are displayed next to the canvas.
 - b. Next to the **runtime_contextRoot** field, click the **Delete** button to clear the pattern level parameter setting.

- c. In the **runtime_contextRoot** field, specify the runtime context root name. Note that the context root name must start with a forward slash, /; for example, /HelloWorld.
6. Upload application and adapter artifacts:

Important: When specifying the Target path for applications and adapters, make sure all the applications and adapters are placed in the same directory. For example, if one target path is /opt/tmp/deploy/HelloWorld-common.wlapp, all the other target paths should be /opt/tmp/deploy/*.

 - a. In the MobileFirst Platform Server node, click the **MFP Server Application** or **MFP Server Adapter** component. The properties of the selected component are displayed next to the canvas.
 - b. In the **Additional file** field, click the **Browse** button to locate and upload the application or adapter artifact.
 - c. In the **Target path** field, specify the full path for storing the artifact including its file name; for example, /opt/tmp/deploy/HelloWorld-common.wlapp.
 - d. If no application or adapter is to be deployed in the pattern, remove the relevant component by clicking the **X** button inside it. To get an empty MobileFirst Operations Console deployed without any app or adapter installed, remove the MFP Server Application Adapter Deployment component by clicking the **X** button inside it.
7. Optional: Add more application or adapter artifacts for deployment:
 - a. From the **Assets** toolbar, expand **Software Components**, and then drag and drop an **Additional file** component onto the MobileFirst Platform Server node in the canvas. Rename it MobileFirst App_X or MobileFirst Adapter_X (where X stands for a unique number for differentiation).
 - b. Hover the cursor over the newly added App or Adapter component, and then click the **Move Up** and **Move Down** buttons to adjust its sequence in the node. Make sure it is placed after the MFP Runtime Deployment component but before the MFP Server Application Adapter Deployment component.
 - c. Click the newly added application or adapter component. The properties of the selected component are displayed next to the canvas. Upload the application or adapter artifact and specify its target path by referring to steps 6b-c
 - d. Repeat steps 7a-c to add more applications and adapters for deployment.
8. Optional: Configure MobileFirst Server application and adapter deployment. You can skip this step if you want to specify the user credential with deployment privilege later during the pattern deployment configuration phase in step 9. If you have specified the default admin user credential in step 3, you can now specify the deployer user, which should align with the admin user credential:
 - a. In the MobileFirst Platform Server node, select **MFP Server Application Adapter Deployment**. The properties of the selected component are displayed next to the canvas.
 - b. Find the parameters named **deployer_user** and **deployer_password**, and then click the adjacent **Delete** buttons to delete their Pattern Level Parameter settings.
 - c. In the **deployer_user** and **deployer_password** fields, specify the user name and password.
9. Configure and launch the pattern deployment:

- a. In the IBM PureApplication System dashboard, click **Patterns > Virtual System Patterns**.
- b. On the Virtual System Patterns page, use the **Search** field to find the pattern you created, and then select the pattern.
- c. In the toolbar above the panel displaying detailed information about the pattern, click the **Deploy** button.
- d. In the Deploy Pattern window, in the Configure panel, select the correct Environment Profile and other IBM PureApplication System environment parameters by consulting your IBM PureApplication System administrator.
- e. In the middle column, click **Pattern attributes** to set attributes such as user name and passwords.

Supply the following information in the fields provided:

Note: Make appropriate changes to the default values of the pattern-level parameters even if an external LDAP server is configured. If you configure administration security by using an LDAP server, you need to supply additional LDAP information. For more information, see “Configuring MobileFirst administration security with an external LDAP repository” on page 12-192.

WebSphere administrative user name

Admin user ID for WebSphere administration console login. Default value: virtuser.

WebSphere administrative password

Admin user password for WebSphere administration console login. Default value: passw0rd.

admin_user

Not visible if configured in step 3. Create a default user as MobileFirst Server administrator. Default value: demo.

admin_password

Not visible if configured in step 3. Default admin user password. Default value: demo.

ACTIVATE_TOKEN_LICENSE

Not visible if configured in step 3. Select this field to license your pattern with token licensing. Leave this field clear if you use perpetual licenses.

LICENSE_SERVER_HOSTNAME

Not visible if configured in step 3. If you use token licensing to license IBM MobileFirst Platform Foundation, enter the fully-qualified hostname or IP address of your Rational License Key Server IP address. Otherwise, leave this field blank.

LMGRD_PORT

Not visible if configured in step 3. If you use token licensing to license IBM MobileFirst Platform Foundation, enter the port number that the license manager daemon (**lmrgd**) listens for connections on. Otherwise, leave this field blank.

The default license manager daemon port is 27000.

IBMRATL_PORT

Not visible if configured in step 3. If you use token licensing to license

IBM MobileFirst Platform Foundation, enter the port number that the vendor daemon (**ibmrat1**) listens for connections on. Otherwise, leave this field blank.

The default vendor daemon port is typically 27001.

runtime_contextRoot

Not visible if configured in step 5. Context root name for the MobileFirst Server runtime. The name must start with /.

deployer_user

Not visible if configured in step 8. User name for the account with deployment privilege. If an external LDAP server is not configured, you must enter the same value as was specified when creating the default admin user for the administration service, because in this case, the only authorized user for app and adapter deployment is the default admin user.

deployer_password

Not visible if configured in step 8. User password for the user with deployment privilege.

MFP Vms Password(root)

Root password for the MobileFirst Platform Server and MobileFirst Platform DB virtual machines. Default value: passw0rd.

MFP DB Password(Instance owner)

Instance owner password for MobileFirst Platform DB. Default value: passw0rd.

Important restriction: When you set these attributes, do not change the following attributes in the **MobileFirst Platform Server** section:

- Cell name
- Node name
- Profile name

If you change any of these attributes, your pattern deployment will fail.

- f. Click **Quick Deploy** to launch your pattern deployment. After a few seconds, a message is displayed to indicate that the pattern has started to launch. You can click the URL provided in the message to track your pattern deployment status or go to **Patterns > Virtual System Instances** to open the Virtual System Instances page and search for your pattern there.

If you use token licensing to license IBM MobileFirst Platform Foundation, your pattern will fail to deploy if insufficient license tokens are available or if the license key server IP address and port were entered incorrectly.

10. Access the MobileFirst Operations Console:
 - a. Click **Patterns > Virtual System Instances** to open the Virtual System Instances page and search for your pattern there. Make sure it is in Running state.
 - b. Select the pattern name and expand the **Virtual machine perspective** option in the panel displaying details of the selected instance.
 - c. Find the MobileFirst Server VM that has a name similar to `MobileFirst_Platform_Server.*` and make a note of its Public IP address: you need this information in the following step.
 - d. In the browser, open the MobileFirst Operations Console by composing its URL with one of the following formats:

- `http://{MFP Server VM Public IP}:9080/worklightconsole`
 - `https://{MFP Server VM Public IP}:9443/worklightconsole`
- e. Log in to the Console with admin user and password specified in step 3 or step 9.

Deploying MobileFirst Server on a multiple-node WebSphere Application Server full profile server

You use a predefined template to deploy MobileFirst Server on a multiple-node WebSphere Application Server full profile server.

Before you begin

This procedure involves uploading certain artifacts to IBM PureApplication System such as the MobileFirst Server runtime. Before you begin, ensure that the artifacts are available for upload.

Token licensing requirements: If you use token licensing to license IBM MobileFirst Platform Foundation, review the requirements outlined in “Token licensing requirements for IBM MobileFirst Platform Foundation System Patterns” on page 12-160 before you continue. The deployment of this pattern fails if the license key server cannot be contacted or if insufficient license tokens are available.

About this task

Note:

Some parameters of script packages in the template have been configured with the recommended values and are not mentioned in this section. For fine-tuning purposes, see more information about all the parameters of script packages in “Script packages for MobileFirst Server” on page 12-223.

For more information about the composition and configuration options of the predefined template that is used in this procedure, see “MobileFirst Platform (WAS server farm) template” on page 12-219.

Procedure

1. Create a pattern from the predefined template:
 - a. In the IBM PureApplication System dashboard, click **Patterns > Virtual System Patterns**. The Virtual System Patterns page opens.
 - b. On the Virtual System Patterns page, click **Create New**, and then in the pop-up window, select **MobileFirst Platform (WAS server farm)** from the list of predefined templates. If the name is only partially visible due to its length, you can confirm that the correct template is selected by viewing its description on the **More information** tab.
 - c. In the **Name** field, provide a name for the pattern.
 - d. In the **Version** field, specify the version number of the pattern.
 - e. Click **Start Building**.
2. Mandatory for AIX: In IBM PureApplication System running on Power, the MobileFirst Platform DB node needs to use the AIX-specific add-on component “Default AIX add disk” to replace the “Default add disk” component in the template to support the jfs2 file system:

- a. In the Pattern Builder, select the **MobileFirst Platform DB** node.
- b. Click the **Add a Component Add-on** button (the button is visible above the component box when you hover the cursor over the **MobileFirst Platform DB** node).
- c. From the **Add Add-ons** list, select **Default AIX add disk**. The component is added as the lowest component of the MobileFirst Platform DB node.
- d. Select the **Default AIX add disk** component and specify the following attributes:

DISK_SIZE_GB

Storage size (measured in GB) to be extended to the DB server.
Example value: 10.

FILESYSTEM_TYPE

Supported file system in AIX. Default value: jfs2.

MOUNT_POINT

Align with the attribute **Mount point for instance owner** in the Database Server component in the MobileFirst Platform DB node.
Example value: /dbinst.

VOLUME_GROUP

Example value: group1. Contact your IBM PureApplication System administrator for the correct value.

- e. In the MobileFirst Platform DB node, select the **Default add disk** component, and then click the **X** button to delete it.
 - f. Save the pattern.
3. Optional: Configure MobileFirst Server administration. You can skip this step if you want to specify the user credential with MobileFirst Server administration privilege later during the pattern deployment configuration phase in step 9. To specify it now, complete these steps:

Note: If you want to configure administration security with an LDAP server, you need to supply additional LDAP information. For more information, see “Configuring MobileFirst administration security with an external LDAP repository” on page 12-192.

- a. In the MobileFirst Platform Server node, click the **MFP Server Administration** component. The properties of the selected component are displayed next to the canvas.
- b. Next to the **admin_user** and **admin_password** fields, click the **Delete** button to clear their pattern level parameter settings.
- c. In the **admin_user** and **admin_password** fields, specify the administration user name and password.
- d. If you use token licensing to license IBM MobileFirst Platform Foundation, complete the following fields. If you do not use token licensing, leave these fields blank.

ACTIVATE_TOKEN_LICENSE

Select this field to license your pattern with token licensing.

LICENSE_SERVER_HOSTNAME

Enter the fully qualified host name or IP address of your Rational License Key Server.

LMGRD_PORT

Enter the port number that the license manager daemon (**lmrgd**) listens for connections on. The default license manager daemon port is 27000.

IBMRATL_PORT

Enter the port number that the vendor daemon (**ibmrat1**) listens for connections on. The default vendor daemon port is typically 27001.

A default administration account for MobileFirst Server is created during pattern deployment.

4. Upload the runtime WAR file:
 - a. In the MobileFirst Platform Server node, click the **MFP Server Runtime** component. The properties of the selected component are displayed next to the canvas.
 - b. Next to the **Additional file** field, click the **Delete** button to delete the sample runtime WAR file, and then click the **Browse** button to locate your runtime WAR file for uploading.
 - c. In the **Target path** field, specify the full path for your runtime WAR file including the file name; for example, `/opt/tmp/HelloWorld.war`.
5. Optional: Configure MobileFirst Server runtime deployment. You can skip this step if you want to specify the context root name for the runtime later during the pattern deployment configuration phase in step 10. To specify the context root name now, complete these steps:
 - a. In the MobileFirst Platform Server node, click the **MFP Server Runtime Deployment** component. The properties of the selected component are displayed next to the canvas.
 - b. Next to the **runtime_contextRoot** field, click the **Delete** button to clear the pattern level parameter setting.
 - c. In the **runtime_contextRoot** field, specify the runtime context root name. Note that the context root name must start with a forward slash, `/`; for example, `/HelloWorld`.
6. Upload application and adapter artifacts:

Important: When specifying the Target path for applications and adapters, make sure all the applications and adapters are placed in the same directory. For example, if one target path is `/opt/tmp/deploy/HelloWorld-common.wlapp`, all the other target paths should be `/opt/tmp/deploy/*`.

 - a. In the MobileFirst Platform Server node, click the **MFP Server Application** or **MFP Server Adapter** component. The properties of the selected component are displayed next to the canvas.
 - b. In the **Additional file** field, click the **Browse** button to locate and upload the application or adapter artifact.
 - c. In the **Target path** field, specify the full path for storing the artifact including its file name; for example, `/opt/tmp/deploy/HelloWorld-common.wlapp`.
 - d. If no application or adapter is to be deployed in the pattern, remove the relevant component by clicking the **X** button inside it. To get an empty MobileFirst Operations Console deployed without any app or adapter installed, remove the MFP Server Application Adapter Deployment component by clicking the **X** button inside it.
7. Optional: Add more application or adapter artifacts for deployment:
 - a. From the **Assets** toolbar, expand **Software Components**, and then drag and drop an **Additional file** component onto the MobileFirst Platform Server node in the canvas. Rename it `MobileFirst App_X` or `MobileFirst Adapter_X` (where *X* stands for a unique number for differentiation).

- b. Hover the cursor over the newly added App or Adapter component, and then click the **Move Up** and **Move Down** buttons to adjust its sequence in the node. Make sure it is placed after the MFP Runtime Deployment component but before the MFP Server Application Adapter Deployment component.
 - c. Click the newly added App or Adapter component. The properties of the selected component are displayed next to the canvas. Upload the application or adapter artifact and specify its target path by referring to steps 6b-c.
 - d. Repeat steps 7a-c to add more applications and adapters for deployment.
8. Optional: Configure MobileFirst Server application and adapter deployment. You can skip this step if you want to specify the user credential with deployment privilege later during the pattern deployment configuration phase in step 10. If you have specified the default admin user credential in step 3, you can now specify the deployer user, which should align with the admin user credential:
- a. In the MobileFirst Platform Server node, select the **MFP Server Application Adapter Deployment** component. The properties of the selected component are displayed next to the canvas.
 - b. Find the parameters named **deployer_user** and **deployer_password**, and then click the **Delete** buttons to clear the Pattern Level Parameter settings.
 - c. In the **deployer_user** and **deployer_password** fields, specify the user name and password.
9. Configure base scaling policy:
- a. In the **MobileFirst Platform Server** node, select the **Base Scaling Policy** component. The properties of the selected component are displayed next to the canvas.
 - b. In the **Number of Instances** field, specify the number of server nodes to be instantiated during pattern deployment. The default value is 2 in the predefined template. Because dynamic scaling is not supported in this release, do not specify values in the remaining attribute fields.
10. Configure and launch the pattern deployment:
- a. In the IBM PureApplication System dashboard, click **Patterns > Virtual System Patterns**.
 - b. On the Virtual System Patterns page, use the **Search** field to find the pattern you created, and then select the pattern.
 - c. In the toolbar above the panel displaying detailed information about the pattern, click the **Deploy** button.
 - d. In the Deploy Pattern window, in the Configure panel, select the correct environment profile from the **Environment Profile** list, and provide other IBM PureApplication System environment parameters. To obtain the correct information, consult your IBM PureApplication System administrator.
 - e. In the middle column, click **Pattern attributes** to display attributes such as user names and passwords.

Supply the following information in the fields provided:

Note: Make appropriate changes to the default values of the pattern-level parameters even if an external LDAP server is configured. If you configure administration security by using an LDAP server, you need to supply

additional LDAP information. For more information, see “Configuring MobileFirst administration security with an external LDAP repository” on page 12-192.

runtime_contextRoot_list

Context root names of the MobileFirst Server runtimes in case multiple runtimes exist. Use a semicolon, “;” to separate each runtime context root; for example, HelloMobileFirst;HelloWorld

Important: **runtime_contextRoot_list** must align with the context root specified in the MFP Server Runtime Deployment node; otherwise, IHS will not be able to correctly route requests that contain the runtime context root.

WebSphere administrative user name

Admin user ID for WebSphere administration console login. Default value: virtuser.

WebSphere administrative password

Admin user password for WebSphere administration console login. Default value: passw0rd.

admin_user

Not visible if configured in step 3. Create a default user as MobileFirst Server administrator. Default value: demo.

admin_password

Not visible if configured in step 3. Default admin user password. Default value: demo.

ACTIVATE_TOKEN_LICENSE

Not visible if configured in step 3. Select this field to license your pattern with token licensing. Leave this field clear if you use perpetual licenses.

LICENSE_SERVER_HOSTNAME

Not visible if configured in step 3. If you use token licensing to license IBM MobileFirst Platform Foundation, enter the fully-qualified hostname or IP address of your Rational License Key Server IP address. Otherwise, leave this field blank.

LMGRD_PORT

Not visible if configured in step 3. If you use token licensing to license IBM MobileFirst Platform Foundation, enter the port number that the license manager daemon (**lmrgd**) listens for connections on. Otherwise, leave this field blank.

The default license manager daemon port is 27000.

IBMRATL_PORT

Not visible if configured in step 3. If you use token licensing to license IBM MobileFirst Platform Foundation, enter the port number that the vendor daemon (**ibmratl**) listens for connections on. Otherwise, leave this field blank.

The default vendor daemon port is typically 27001.

runtime_contextRoot

Not visible if configured in step 5. Context root name for the MobileFirst Server runtime. The name must start with a forward slash, /.

deployer_user

Not visible if configured in step 8. User name for the account with deployment privilege. If an external LDAP server is not configured, you must enter the same value as was specified when creating the default admin user for the administration service, because in this case, the only authorized user for app and adapter deployment is the default admin user.

deployer_password

Not visible if configured in step 8. User password for the user with deployment privilege.

MFP Vms Password(root)

Root password for the MobileFirst Platform Server and MobileFirst Platform DB nodes. Default value: passw0rd.

MFP DB Password(Instance owner)

Instance owner password for the MobileFirst Platform DB node. Default value: passw0rd.

Important restriction: When you set these attributes, do not change the following attributes in the **MobileFirst Platform Server** section:

- Cell name
- Node name
- Profile name

If you change any of these attributes, your pattern deployment will fail.

- f. Click **Quick Deploy** to launch your pattern deployment. After a few seconds, a message is displayed to indicate that the pattern has started to launch. You can click the URL provided in the message to track your pattern deployment status or go to **Patterns > Virtual System Instances** to open the Virtual System Instances page and search for your pattern there.

If you use token licensing to license IBM MobileFirst Platform Foundation, your pattern will fail to deploy if insufficient license tokens are available or if the license key server IP address and port were entered incorrectly.

11. Access the MobileFirst Operations Console:
 - a. Click **Patterns > Virtual System Instances** to open the Virtual System Instances page and search for your pattern there. Make sure it is in Running state.
 - b. Select the pattern name and expand the **Virtual machine perspective** option in the panel displaying details of the selected instance.
 - c. Find the IHS Server VM that has a name similar to `IHS_Server.*` and make a note of its Public IP address: you need this information in the following step.
 - d. In the browser, open the MobileFirst Operations Console by composing its URL with one of the following formats:
 - `http://{IHS Server VM Public IP}/worklightconsole`
 - `https://{IHS Server VM Public IP}/worklightconsole`
 - e. Log in to the Console with admin user and password specified in step 3 or step 10.

Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers

You can use a predefined template to deploy MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers. This application pattern template does not support token licensing.

Before you begin

This procedure involves uploading certain artifacts to IBM PureApplication System such as the MobileFirst Server runtime. Before you begin, ensure that the artifacts are available for upload.

If you are running the System Monitoring for WebSphere Application Server shared service, the MobileFirst runtime environment might fail to start correctly when you deploy the pattern. If possible, stop the shared service before you continue with this procedure. If you cannot stop the shared service, you might need to restart the IBM MobileFirst Platform runtime from the WebSphere Application Server administrative console to fix the problem. For more information, see “MobileFirst runtime synchronization limitation with WebSphere Application Server Network Deployment” on page 12-189.

Important token licensing restriction: This pattern template does not support token licensing. You must be using perpetual licensing when you deploy patterns based on the **MobileFirst Platform (WAS ND)** pattern template.

About this task

Note:

Some parameters of script packages in the template are configured with recommended values and are not covered in this topic. For fine-tuning purposes, see more information about all the parameters of script packages in “Script packages for MobileFirst Server” on page 12-223.

For more information about the composition and configuration options of the predefined template that is used in this procedure, see “MobileFirst Platform (WAS ND) template” on page 12-221.

Procedure

1. Create a pattern from the predefined template:
 - a. In the IBM PureApplication System dashboard, click **Patterns > Virtual System Patterns**. The Virtual System Patterns page opens.
 - b. On the Virtual System Patterns page, click **Create New**, and then in the pop-up window, select **MobileFirst Platform (WAS ND)** from the list of predefined templates. If the name is only partially visible due to its length, you can confirm that the correct template is selected by viewing its description on the **More information** tab.
 - c. In the **Name** field, provide a name for the pattern.
 - d. In the **Version** field, specify the version number of the pattern.
 - e. Click **Start Building**.
2. Mandatory for AIX: In IBM PureApplication System running on Power, the MobileFirst Platform DB node needs to use the AIX-specific add-on

component “Default AIX add disk” to replace the “Default add disk” component in the template to support the jfs2 file system:

- a. In the Pattern Builder, select the **MobileFirst Platform DB** node.
- b. Click the **Add a Component Add-on** button (the button is visible above the component box when you hover the cursor over the **MobileFirst Platform DB** node).
- c. From the **Add Add-ons** list, select **Default AIX add disk**. The component is added as the lowest component of the MobileFirst Platform DB node.
- d. Select the **Default AIX add disk** component and specify the following attributes:

DISK_SIZE_GB

Storage size (measured in GB) to be extended to the DB server.

Example value: 10.

FILESYSTEM_TYPE

Supported file system in AIX. Default value: jfs2.

MOUNT_POINT

Align with the attribute **Mount point for instance owner** in the Database Server component in the MobileFirst Platform DB node.

Example value: /dbinst.

VOLUME_GROUP

Example value: group1. Contact your IBM PureApplication System administrator for the correct value.

- e. In the MobileFirst Platform DB node, select the **Default add disk** component, and then click the **X** button to delete it.
 - f. Save the pattern.
3. Optional: Configure MobileFirst Server administration. You can skip this step if you want to specify the user credential with MobileFirst Server administration privilege later during the pattern deployment configuration phase in step 10 on page 12-186. To specify it now, complete these steps:

Note: If you want to configure administration security with an LDAP server, you need to supply extra LDAP information. For more information, see “Configuring MobileFirst administration security with an external LDAP repository” on page 12-192.

- a. In the DmgrNode node, click the **MFP Server Administration** component. The properties of the selected component are displayed next to the canvas.
- b. Next to the **admin_user** and **admin_password** fields, click the **Delete** button to clear their pattern level parameter settings.
- c. In the **admin_user** and **admin_password** fields, specify the administration user name and password.

A default administration account for MobileFirst Server is created during pattern deployment.

4. Upload the runtime WAR file:
 - a. In the DmgrNode node, click the **MFP Server Runtime** component. The properties of the selected component are displayed next to the canvas.
 - b. Next to the **Additional file** field, click the **Delete** button to delete the sample runtime WAR file, and then click the **Browse** button to locate your runtime WAR file for uploading.
 - c. In the **Target path** field, specify the full path for your runtime WAR file, including the file name. For example, /opt/tmp/HelloWorld.war.

5. Optional: Configure MobileFirst Server runtime deployment. You can skip this step if you want to specify the context root name for the runtime later during the pattern deployment configuration phase in step 10 on page 12-186. To specify the context root name now, complete these steps:
 - a. In the DmgrNode node, click the **MFP Server Runtime Deployment** component. The properties of the selected component are displayed next to the canvas.
 - b. Next to the **runtime_contextRoot** field, click the **Delete** button to clear the pattern level parameter setting.
 - c. In the **runtime_contextRoot** field, specify the runtime context root name. The context root name must start with a forward slash (/). For example, /HelloWorld.
6. Optional: Adjust the number of application server nodes in your WebSphere Application Server Network Deployment clusters for the MobileFirst Administration component and the MobileFirst runtime environment. By default, the Administration component and runtime environment each have two application server nodes in their respective clusters.
 - a. In the DmgrNode node, click the **MFP Server Administration** component. The properties of the component are displayed next to the canvas.
 - b. In the **NUMBER_OF_CLUSTERMEMBERS** field, specify the number of application server nodes that you want in your WebSphere Application Server Network Deployment cluster for the MobileFirst Administration component.
 - c. In the DmgrNode node, click the **MFP Server Runtime Deployment** component. The properties of the component are displayed next to the canvas.
 - d. In the **NUMBER_OF_CLUSTERMEMBERS** field, specify the number of application server nodes that you want in your WebSphere Application Server Network Deployment cluster for the MobileFirst runtime environment.
 - e. In the **CustomNode** node, click the **Base Scaling Policy** component.
 - f. Adjust the **Number of Instances** value to account for the total number of application server nodes that you entered in the **NUMBER_OF_CLUSTERMEMBERS** field for each component.

The minimum value for **Number of Instances** is the total number of server nodes for the MobileFirst Administration component and the MobileFirst runtime environments.

For example, the default value for **Number of Instances** is 4 for the default topology with two nodes for the administration component and two nodes for the runtime environment. If you change **NUMBER_OF_CLUSTERMEMBERS** values for the administration component to 3 and for the runtime environment to 5, the minimum value for **Number of Instances** is 8.
7. Upload application and adapter:

Important: When you specify the target path for applications and adapters, make sure all the applications and adapters are placed in the same directory. For example, if one target path is /opt/tmp/deploy/HelloWorld-common.wlapp, all the other target paths should be /opt/tmp/deploy/*.

- a. In the DmgrNode node, click the **MFP Application** or **MFP Adapter** component. The properties of the selected component are displayed next to the canvas.

- b. In the **Additional file** field, click the **Browse** button to locate and upload the application or adapter artifact.
 - c. In the **Target path** field, specify the full path for storing the artifact, including its file name. For example, /opt/tmp/deploy/HelloWorld-common.wlapp.
 - d. If no application or adapter is to be deployed in the pattern, remove the relevant component by clicking the **X** button inside it. To get an empty MobileFirst Operations Console deployed without any app or adapter installed, remove the MFP Server Application Adapter Deployment component by clicking the **X** button inside it.
8. Optional: Add more application or adapter artifacts for deployment:
- a. From the **COMPONENTS** toolbar, expand **Software Components**, and then drag and drop an **Additional file** component onto the DmgrNode node in the canvas. Rename it MobileFirst App_X or MobileFirst Adatper_X (where X stands for a unique number for differentiation).
 - b. Hover the cursor over the newly added App or Adapter component, and then click the **Move Up** and **Move Down** buttons to adjust its sequence in the node. Make sure that it is placed after the MFP Runtime Deployment component but before the MFP Server Application Adapter Deployment component.
 - c. Click the newly added application or adapter component. The properties of the selected component are displayed next to the canvas.
 - d. In the **Additional file** field, click the **Browse** button to locate and upload the application or adapter artifact.
 - e. In the **Target path** field, specify the full path for storing the artifact, including its file name. For example, /opt/tmp/deploy/HelloWorld-common.wlapp.

Repeat this step if you want to add more applications and adapters for deployment.

9. Optional: Configure application and adapter deployment to MobileFirst Server. You can skip this step if you want to specify the user credential with deployment privilege later during the pattern deployment configuration phase in step 10. If you specified the default administrative user credential in step 3 on page 12-184, you can now specify the deployer user, which must align with the administration user credential:
- a. In the DmgrNode node, select the **MFP Server Application Adapter Deployment** component. The properties of the selected component are displayed next to the canvas.
 - b. Find the parameters that are named **deployer_user** and **deployer_password**, and then click the adjacent **Delete** buttons to clear the pattern level parameter settings.
 - c. In the **deployer_user** and **deployer_password** fields, specify the user name and password.
10. Configure and launch the pattern deployment:
- a. In the IBM PureApplication System dashboard, click **Patterns > Virtual System Patterns**.
 - b. On the Virtual System Patterns page, use the **Search** field to find the pattern you created, and then select the pattern.
 - c. In the toolbar above the panel that displays detailed information about the pattern, click the **Deploy** button.

- d. In the Deploy Pattern window, in the Configure panel, select the correct environment profile from the **Environment Profile** list, and provide other IBM PureApplication System environment parameters. To obtain the correct information, consult your IBM PureApplication system administrator.
- e. In the middle column, click **Pattern attributes** to display attributes such as user names and passwords.

Supply the following information in the fields provided:

Note: Make appropriate changes to the default values of the pattern-level parameters even if an external LDAP server is configured. If you configure administration security by using an LDAP server, you need to supply extra LDAP information. For more information, see “Configuring MobileFirst administration security with an external LDAP repository” on page 12-192.

WebSphere administrative user name

Administrative user ID for the WebSphere administrative console login. Default value: virtuser.

WebSphere administrative password

Administrative user password for the WebSphere administrative console login. Default value: passw0rd.

runtime_contextRoot_list

Context root names of the MobileFirst Server runtimes in case multiple runtimes exist. Use a semicolon (;) to separate each runtime context root; for example, HelloMobileFirst;HelloWorld

Important: This value must align with the context root specified in the MobileFirst Platform Server Runtime Deployment node that you set in the **runtime_contextRoot** field (either earlier in step 5 on page 12-185 or later in this step); otherwise, IBM HTTP Server cannot correctly route requests that contain the runtime context root.

admin_user

Not visible if configured in step 3 on page 12-184. Create a default MobileFirst Server administrator account. Default value: demo.

admin_password

Not visible if configured in step 3 on page 12-184. Default admin account password. Default value: demo.

runtime_contextRoot

Not visible if configured in step 5 on page 12-185. Context root name for the MobileFirst Server runtime. The name must start with “/”.

deployer_user

Not visible if configured in step 9 on page 12-186. User name for the account with deployment privilege. If an external LDAP server is not configured, you must enter the same value as was specified when you create the default administrative user for the administration service, because in this case, the only authorized user for app and adapter deployment is the default administrative user.

deployer_password

Not visible if configured in step 9 on page 12-186. User password for the user with deployment privilege.

MFP VMs Password(root)

Root password for the DmgrNode, CustomNode, IHSNode, and MobileFirst Platform DB nodes. Default value: passw0rd.

MFP VMs Password(virtuser)

Password for the virtuser user of the DmgrNode, CustomNode, IHSNode and MobileFirst Platform DB nodes. Default value: passw0rd.

Open firewall ports for WAS

The WebSphere Application Server nodes that are deployed in the CustomNode VM nodes require open firewall ports to connect to the database server and the LDAP server (if configured for LDAP). If you need to specify multiple port numbers, separate the port numbers with a semicolon (;). For example, 50000;636The default value is 50000 (the default port for DB2 server).

Important restriction: When you set these attributes, do not change the following attributes in the **DmgrNode** or **CustomNode** sections:

- Cell name
- Node name
- Profile name

If you change any of these attributes, your pattern deployment will fail.

- f. Click **Quick Deploy** to launch your pattern deployment. After a few seconds, a message is displayed to indicate that the pattern started to launch. You can click the URL provided in the message to track your pattern deployment status or go to **Patterns > Virtual System Instances** open the Virtual System Instances page and search for your pattern there.
11. Access the MobileFirst Operations Console:
 - a. Click **Patterns > Virtual System Instances** to open the Virtual System Instances page and search for your pattern there. Make sure that it is in "Running" state.
 - b. Select the pattern name and expand the **Virtual machine perspective** option in the panel that displays details of the selected instance.
 - c. Find the IHS Server VM that has a name similar to IHS_Server.* and make a note of its Public IP address: you need this information in the following step.
 - d. In the browser, open the MobileFirst Operations Console with one of the following URLs:
 - `http://{IHS Server VM Public IP}:80/worklightconsole`
 - `https://{IHS Server VM Public IP}:443/worklightconsole`
 - e. Log in to the Console with admin user and password that you specified in step 3 on page 12-184 or step 10 on page 12-186.

If the console does not display the MobileFirst runtimes, restart the IBM MobileFirst Platform runtime node from the WebSphere Application Server administrative console. For instructions about restarting the runtime node from the administrative console, see "Restarting the IBM MobileFirst Platform runtime from the WebSphere Application Server administrative console" on page 12-190.

“MobileFirst runtime synchronization limitation with WebSphere Application Server Network Deployment”

If you deploy a PureApplication pattern based on the **MobileFirst Platform (WAS ND)** template and are running the System Monitoring for WebSphere Application Server shared service, the MobileFirst runtime environment might fail to start correctly when you deploy the pattern.

Related tasks:

“Restarting the IBM MobileFirst Platform runtime from the WebSphere Application Server administrative console” on page 12-190

If your MobileFirst Operations Console is empty after you deploy a PureApplication System pattern based on the **MobileFirst Platform (WAS ND)** template, you might need to restart the IBM MobileFirst Platform runtime from the WebSphere Application Server administrative console.

MobileFirst runtime synchronization limitation with WebSphere Application Server Network Deployment

If you deploy a PureApplication pattern based on the **MobileFirst Platform (WAS ND)** template and are running the System Monitoring for WebSphere Application Server shared service, the MobileFirst runtime environment might fail to start correctly when you deploy the pattern.

A PureApplication virtual system pattern based on the **MobileFirst Platform (WAS ND)** template deploys the MobileFirst administration service and the IBM MobileFirst Platform runtime into different WebSphere Application Server Network Deployment clusters. For the IBM MobileFirst Platform runtime to work correctly, it must be started after the MobileFirst administration service. If the IBM MobileFirst Platform runtime starts first, the runtime service fails to detect the MobileFirst administration service, which causes errors in the runtime service.

When the deployment of a PureApplication pattern is almost complete, the System Monitoring for WebSphere Application Server shared service restarts all of the WebSphere Application Server nodes that are deployed from the pattern. The nodes restart in a random order, so the nodes that contain the IBM MobileFirst Platform runtime might be restarted before the nodes that contain the MobileFirst administration service.

You can avoid this problem by stopping the System Monitoring for WebSphere Application Server shared service before deploying the pattern. If you cannot stop the shared service, you might need to restart the IBM MobileFirst Platform runtime from the WebSphere Application Server administrative console to fix the problem.

Related tasks:

“Restarting the IBM MobileFirst Platform runtime from the WebSphere Application Server administrative console” on page 12-190

“Deploying several MobileFirst runtimes in a pattern in MobileFirst Server” on page 12-203

You can deploy and configure the MobileFirst Server to install multiple runtimes

on all the supported pattern topologies.

Restarting the IBM MobileFirst Platform runtime from the WebSphere Application Server administrative console

If your MobileFirst Operations Console is empty after you deploy a PureApplication System pattern based on the **MobileFirst Platform (WAS ND)** template, you might need to restart the IBM MobileFirst Platform runtime from the WebSphere Application Server administrative console.

Before you begin

This procedure applies only when you are deploying PureApplication virtual system patterns based on the **MobileFirst Platform (WAS ND)** template when you are running the System Monitoring for WebSphere Application Server shared service. If you do not use this shared service or are deploying a pattern based on a different template, this procedure does not apply to you.

You must deploy your pattern before you do this procedure.

About this task

To work correctly, the MobileFirst administration service nodes must be started before the IBM MobileFirst Platform runtime nodes. If the System Monitoring for WebSphere Application Server shared service is running when you deploy a pattern, the shared service restarts all of the WebSphere Application Server nodes that are deployed from the pattern. The nodes restart in a random order, which means that the IBM MobileFirst Platform runtime nodes might be started before the MobileFirst administration service nodes.

Procedure

1. Confirm that the System Monitoring for WebSphere Application Server shared service is deployed and running:

- a. In the PureApplication System dashboard, click **Patterns** and then under **Pattern Instances**, click **Shared Services**.

Important: **Shared Services** appears twice in the **Patterns** menu, ensure that you click **Shared Services** under **Pattern Instances** and not under **Patterns**.

- b. On the Shared Service Instances page, look for a name that starts with **System Monitoring for WebSphere Application Server**. Click that name to expand its entry

If you do not see an entry for **System Monitoring for WebSphere Application Server**, the System Monitoring for WebSphere Application Server shared service is not deployed and you do not need to continue with this procedure.

- c. Check the **Status** column for the service.

If **Status** says **Stopped**, the System Monitoring for WebSphere Application Server shared service is stopped and you do not need to continue with this procedure. If **Status** says **Started**, the System Monitoring for WebSphere Application Server shared service is running. Continue with the rest of this procedure.

2. Confirm that your pattern is running, and access the MobileFirst Operations Console from the PureApplication System dashboard.

For instructions about how access the MobileFirst Operations Console from the PureApplication System dashboard, see step 11 on page 12-188 in “Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers” on page 12-183.

3. If the console appears empty or is otherwise not displaying MobileFirst runtimes, restart the IBM MobileFirst Platform runtime node from the WebSphere Application Server administrative console:
 - a. In the PureApplication System dashboard, click **Patterns > Virtual System Instances**.
 - b. On the Virtual System Instances page, find your pattern instance and confirm that it is running. If it is not running, start the pattern instance.
 - c. Click the name of your pattern instance and in the details panel, find the **Virtual machine perspective** section.
 - d. In the Virtual machine perspective section, find the virtual machine whose name starts with DmgrNode and note its public IP address.
 - e. Open the WebSphere Application Server administrative console at the following URL:
`https://{DmgrNode VM public IP address}:9043/ibm/console`
Use the user ID and password that you specified for the WebSphere Application Server administrative console when you deployed the pattern.
 - f. In the WebSphere Application Server administrative console, expand **Applications** and click **All applications**.
 - g. Restart the IBM MobileFirst Platform runtime:
 - 1) In the list of applications, select the application with name that begins with `IBM_Worklight_project_runtime_MFP`.
 - 2) In the **Action** column, select **Stop**.
 - 3) Click **Submit Action**.
 - 4) Wait until the application status in the **Status** column shows the stopped icon.
 - 5) In the **Action** column, select **Start**.
 - 6) Click **Submit Action**.Repeat this step for each IBM MobileFirst Platform runtime application in the list.
4. Access the MobileFirst Operations Console again and confirm that your IBM MobileFirst Platform runtimes are now visible.

Configuring MobileFirst administration security with an external LDAP repository

You can configure MobileFirst administration security to enable connecting out to an external LDAP repository. The configuration is common for both WebSphere Application Server Liberty profile and full profile.

Before you begin

This procedure involves configuring the LDAP parameters for connecting to the external user registry server. Before you begin, ensure the LDAP server is working and consult your LDAP administrator to obtain the required configuration information.

About this task

Important:

When the LDAP repository configuration is enabled, a default user for MobileFirst administration is not automatically created. Instead, you must specify the administration user name and password that are stored in the LDAP repository. This information is required by WebSphere Application Server Liberty profile and a server farm of WebSphere Application Server full profile.

If the runtime to be deployed in the pattern is configured to use LDAP for application authentication, make sure that the LDAP server configured in the runtime is the same as the LDAP server that is configured for the MobileFirst Administration; different LDAP servers are not supported. Also, the protocol and port for LDAP connection must be identical. For example, if connections from the runtime to the LDAP server are configured to use the SSL protocol and port is 636, connections from the MobileFirst Administration to the LDAP server must use the SSL protocol and port 636 as well.

Procedure

1. Build a pattern with any topology you need. For more information, see the following topics:
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server Liberty profile server” on page 12-160
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server Liberty profile server” on page 12-166
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server” on page 12-171
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server full profile server” on page 12-177
 - “Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers” on page 12-183
2. Mandatory for AIX: In IBM PureApplication System running on Power, the MobileFirst Platform DB node needs to use the AIX-specific add-on component

“Default AIX add disk” to replace the “Default add disk” component in the template to support the jfs2 file system:

- a. In the Pattern Builder, select the **MobileFirst Platform DB** node.
- b. Click the **Add a Component Add-on** button (the button is visible above the component box when you hover the cursor over the **MobileFirst Platform DB** node).
- c. From the **Add Add-ons** list, select **Default AIX add disk**. The component is added as the lowest component of the MobileFirst Platform DB node.
- d. Select the **Default AIX add disk** component and specify the following attributes:

DISK_SIZE_GB

Storage size (measured in GB) to be extended to the DB server. Example value: 10.

FILESYSTEM_TYPE

Supported file system in AIX. Default value: jfs2.

MOUNT_POINT

Align with the attribute **Mount point for instance owner** in the Database Server component in the MobileFirst Platform DB node. Example value: /dbinst.

VOLUME_GROUP

Example value: group1. Contact your IBM PureApplication System administrator for the correct value.

- e. In the MobileFirst Platform DB node, select the **Default add disk** component, and then click the **X** button to delete it.
 - f. Save the pattern.
3. Configure MobileFirst Server administration:
- a. In IBM PureApplication System, in the dashboard, click **Patterns > Virtual System Patterns**. The Virtual System Patterns page opens.
 - b. On the Virtual System Patterns page, use the **Search** field to find and select the pattern you created, and then click **Open** to open the Pattern Builder page.
 - c. In the MobileFirst Platform Server node (or the DmgrNode node when using the MobileFirst Platform (WAS ND) template), select the **MFP Server Administration** component. The properties of the selected component are displayed next to the canvas.
 - d. Supply the following LDAP information in the fields provided:

admin_user

User ID of the account that has MobileFirst Server administration privilege. This value is stored in the LDAP repository. Not required if the MobileFirst Server is to be deployed on a single node of WebSphere Application Server full profile.

admin_password

Admin user password. This value is stored in the LDAP repository. Not required if the MobileFirst Server is to be deployed on a single node of WebSphere Application Server full profile.

LDAP_TYPE

LDAP server type of your user registry. One of the following values:

None LDAP connection is disabled. When this is set, all the other LDAP parameters are treated as placeholders only.

TivoliDirectoryServer

Select this if the LDAP repository is an IBM Tivoli® Directory Server.

ActiveDirectory

Select this if the LDAP repository is a Microsoft Active Directory.

Default value: None.

LDAP_IP

LDAP server IP address.

LDAP_SSL_PORT

LDAP port for secure connection.

LDAP_PORT

LDAP port for non-secure connection.

BASE_DN

Base DN.

BIND_DN

Bind DN.

BIND_PASSWORD

Bind DN password.

REQUIRE_SSL

Select true for secure connection to the LDAP server. Default value: false.

USER_FILTER

LDAP user filter that applies when searching the existing user registry for users.

GROUP_FILTER

LDAP group filter that applies when searching the existing user registry for groups.

LDAP_REPOSITORY_NAME

LDAP server name.

CERT_FILE_PATH

Target path of the uploaded LDAP server certification.

worklightadmin

Admin role for MobileFirst Server. One of the following values:

None No user.

AllAuthenticatedUsers

Authenticated users

Everyone

All users.

Default value: None. For more information about security roles, see “Configuring user authentication for MobileFirst Server administration” on page 6-106.

worklightdeployer

Deployer role for MobileFirst Server. One of the following values:

None No user.

AllAuthenticatedUsers

Authenticated users

Everyone

All users.

Default value: None. For more information about security roles, see “Configuring user authentication for MobileFirst Server administration” on page 6-106.

worklightmonitor

Monitor role for MobileFirst Server. One of the following values:

None No user.

AllAuthenticatedUsers

Authenticated users

Everyone

All users.

Default value: None. For more information about security roles, see “Configuring user authentication for MobileFirst Server administration” on page 6-106.

worklightoperator

Operator role for MobileFirst Server. One of the following values:

None No user.

AllAuthenticatedUsers

Authenticated users

Everyone

All users.

Default value: None. For more information about security roles, see “Configuring user authentication for MobileFirst Server administration” on page 6-106.

4. Optional: Configure the LDAP SSL connection. This step is required only if you set **REQUIRE_SSL** to true in the previous step to use secure connections to the LDAP server:
 - a. From the Assets toolbar, expand **Software Components**, and then drag and drop an **Additional file** component onto the MobileFirst Platform Server node in the canvas. Rename the component “MobileFirst LDAP Cert”, for example.
 - b. Hover the cursor over the newly added component, and then click the **Move up** and **Move down** buttons to adjust the position of the component in the node. Make sure that it is placed between the MFP Server Prerequisite component and the MFP Server Administration component.
 - c. Click the **MobileFirst LDAP Cert** component. The properties of the selected component are displayed next to the canvas. Upload the LDAP certification artifact in the **Additional file** field by clicking the **Browse** button to locate it
 - d. In the **Target path** field, specify the full path for storing the artifact including its file name; for example, /opt/tmp/tdscert.der.
 - e. In the MobileFirst Platform Server node (or the DmgrNode node when using the MobileFirst Platform (WAS ND) template), select the **MFP Server Administration** component, and then click the **Add reference** button next to the **CERT_FILE_PATH** field. In the pop-up window, click the

- component-level parameter** tab. From the **Component** list, select **MobileFirst LDAP Cert**. In the **Output attribute** list, select **target_path**. Click the **ADD** button to refresh the **Output value** field, and then click **OK**.
5. Configure and launch the pattern deployment. On the Deploy Pattern page, in the Nodes list, you can adjust your LDAP configurations by clicking **MobileFirst Platform Server** (or **DmgrNode** when using the MobileFirst Platform (WAS ND) template) and then expanding **MFP Server Administration**. For more information about pattern deployment, see the “Configure and launch the pattern deployment” step in one of the following topics depending on the topology you selected when creating the pattern;
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server Liberty profile server” on page 12-160, step 9 on page 12-164
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server Liberty profile server” on page 12-166, step 10 on page 12-169
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server” on page 12-171, step 9 on page 12-174
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server” on page 12-171, step 10 on page 12-180
 - “Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers” on page 12-183, step 10 on page 12-186 onwards.
 6. Access the MobileFirst Operations Console. Use the administrator user name and password to log in to the MobileFirst Operations Console through your LDAP configuration. For more information, see the “Access the MobileFirst Operations Console:” step in one of the following topics depending on the topology you selected when creating the pattern;
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server Liberty profile server” on page 12-160, step 10 on page 12-165
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server Liberty profile server” on page 12-166, step 11 on page 12-171
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server” on page 12-171, step 10 on page 12-176
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server full profile server” on page 12-177, step 11 on page 12-182
 - “Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers” on page 12-183, step 11 on page 12-188 onwards.

Deploying and configuring MobileFirst Operational Analytics

You can deploy and configure the MobileFirst Operational Analytics on both WebSphere Application Server Liberty profile and full profile to enable the Analytics features in the pattern.

Before you begin

If you intend to use an LDAP repository to protect the Analytics Console, ensure that the LDAP server is working and consult your LDAP administrator to obtain the required configuration information.

About this task

Important:

When the LDAP repository configuration is enabled in the Analytics component, a default administration user is not created for MobileFirst Operational Analytics. Instead, you must specify the administration user name and password values that are stored in the LDAP repository. These values are required to protect the Analytics Console.

Procedure

1. Build a pattern with the topology you need. For more information, see the following topics:
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server Liberty profile server” on page 12-160
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server Liberty profile server” on page 12-166
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server” on page 12-171
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server full profile server” on page 12-177
 - “Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers” on page 12-183
2. Add and configure MobileFirst Operational Analytics:
 - a. In the IBM PureApplication System dashboard, click **Patterns > Virtual System Patterns**. The Virtual System Patterns page opens.
 - b. On the Virtual System Patterns page, use the **Search** field to find and select the pattern you created, and then click **Open** to open the Pattern Builder page.
 - c. From the Assets list, expand **Software Components**, and then drag and drop one of the following components onto the canvas:

Liberty profile server

Select this component if you want to deploy MobileFirst Operational Analytics on WebSphere Application Server Liberty profile.

Standalone server

Select this component if you want to deploy MobileFirst Operational Analytics on WebSphere Application Server full profile.

A new node is created with the name “OS Node”. Rename it “MobileFirst Platform Analytics”.

- d. Make the following configuration changes depending on the type of application server you want to deploy Analytics to:
 - If you are deploying MobileFirst Operational Analytics to WebSphere Application Server Liberty profile, click **Liberty profile server** in the MobileFirst Platform Analytics node. The properties of the selected component are displayed next to the canvas. In the **Configuration data location** field, enter the path `/opt/IBM/WebSphere/Liberty` and specify the administrative user name and password. Use the default values for the other parameters.
 - If you are deploying MobileFirst Operational Analytics to WebSphere Application Server full profile, click **Standalone server** in the MobileFirst Platform Analytics node. The properties of the selected component are displayed next to the canvas. In the **Configuration data location** field, enter the path `/opt/IBM/WebSphere/AppServer/Profiles`, change **Profile name** to `AppSrv01`, and specify the administrative user name and password. Use the default values for the other parameters.

Important: The WebSphere Application Server administrative user will be created in the WebSphere Application Server user repository. If LDAP will be configured for the Analytics server, avoid user name conflicts with the WebSphere Application Server administrative user. For example, if “user1” will be introduced by the LDAP server through its configuration, do not set “user1” as the WebSphere Application Server administrative user name.

- e. From the Assets list, expand **Scripts**, and then drag and drop an **MFP Analytics** component onto the MobileFirst Platform Analytics node on the canvas. Make sure the MFP Analytics component is positioned after the Liberty profile server component (or the Standalone server component).
- f. Supply the following MobileFirst Operational Analytics information in the fields provided:

The LDAP parameters are exactly the same as the MFP Server Administration parameters. For more information, see the “Configure MFP Server Administration” step in 3 on page 12-193:

Important: For LDAP SSL connection configuration in MobileFirst Operational Analytics, make sure that in step 4b in “Configuring MobileFirst administration security with an external LDAP repository” on page 12-192, the dragged-in MobileFirst LDAP Cert component in the MobileFirst Platform Analytics node must be moved to between the Liberty profile server (or Standalone server) and the MFP Analytics script package.

WAS_ROOT

- If MobileFirst Operational Analytics is being installed on WebSphere Application Server Liberty profile, specify the installation directory of the Liberty profile for Analytics:
 - 1) Click the **Add reference** button next to the **WAS_ROOT** field and in the pop-up window, click the **component-level parameter** tab.
 - 2) In the **Component** field, select **Liberty profile server**.(it might be called **Liberty profile server_1** if the MobileFirst Server is also deployed on WebSphere Application Server Liberty profile).
 - 3) In the **Output attribute** field, select **install_directory**. Click the **ADD** button to refresh the **Output value** field, and then click **OK**.
- If MobileFirst Operational Analytics is being installed on WebSphere Application Server full profile, specify the installation directory of the WebSphere Application Server full profile for Analytics:
 - 1) Click the **Add reference** button next to the **WAS_ROOT** field and in the pop-up window, click the **component-level parameter** tab.
 - 2) In the **Component** field, select **Standalone server**.(it might be called **Standalone server_1** if the MobileFirst Server is also deployed on WebSphere Application Server full profile)
 - 3) In the **Output attribute** field, select **install_directory**. Click the **ADD** button to refresh the **Output value** field, and then click **OK**.

HEAP_MIN_SIZE

Applicable to WebSphere Application Server full profile only.

The amount of Analytics data that is generated is directly proportional to the amount of memory required to handle it. Set this value to allow a larger minimum heap size for WebSphere Application Server full profile. Make sure that the **Memory size** value specified in the Core OS

component of the MobileFirst Platform Analytics node is larger than **HEAP_MIN_SIZE**. Consider setting a value equal to **HEAP_MAX_SIZE**

Default value: 4096 MB.

HEAP_MAX_SIZE

Applicable to WebSphere Application Server full profile only.

The amount of Analytics data that is generated is directly proportional to the amount of memory required to handle it. Set this value to allow a larger maximum heap size for WebSphere Application Server full profile. Make sure that the **Memory size** value specified in the Core OS component of the MobileFirst Platform Analytics node is larger than **HEAP_MAX_SIZE**. Consider setting a value equal to **HEAP_MIN_SIZE**

Default value: 4096 MB.

WAS_admin_user

Applicable to WebSphere Application Server full profile only.

WebSphere Application Server full profile admin user ID for the Analytics server.

- 1) Click the **Add reference** button next to the **WAS_admin_user** field and in the pop-up window, click the **component-level parameter** tab.
- 2) In the **Component** field, select **Standalone server**.(it may be called **Standalone server_1** if the MobileFirst Server is also deployed on WebSphere Application Server full profile)
- 3) In the **Output attribute** field, select **was_admin**. Click the **ADD** button to refresh the **Output value** field, and then click **OK**.

For Liberty profile, the default value can be used.

WAS_admin_password

Applicable to WebSphere Application Server full profile only.

WebSphere Application Server full profile admin user ID for the Analytics server.

- 1) Click the **Add reference** button next to the **WAS_admin_password** field and in the pop-up window, click the **component-level parameter** tab.
- 2) In the **Component** field, select **Standalone server**.(it may be called **Standalone server_1** if the MobileFirst Server is also deployed on WebSphere Application Server full profile)
- 3) In the **Output attribute** field, select **was_admin_password**. Click the **ADD** button to refresh the **Output value** field, and then click **OK**.

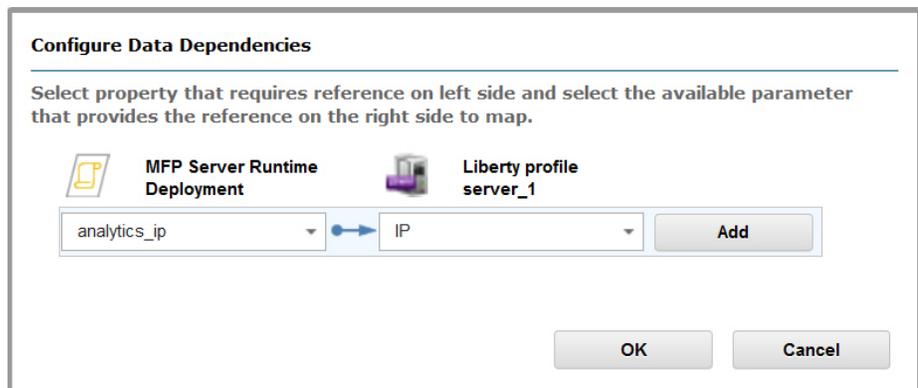

For Liberty profile, the default value can be used.

admin_user

- If an LDAP repository is not enabled, create a default administration user for MobileFirst Operational Analytics console protection.
- If an LDAP repository is enabled, specify the user name that has MobileFirst Operational Analytics administration privilege. The value is stored in the LDAP repository.

admin_password

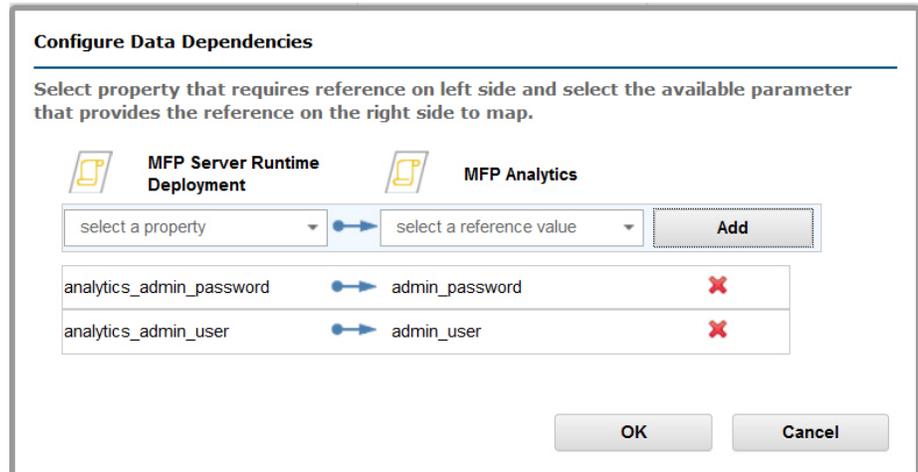

- If an LDAP repository is not enabled, specify the password for the default administration user for MobileFirst Operational Analytics console protection.
 - If an LDAP repository is enabled, specify the administration user password. The value is stored in the LDAP repository.
- g. Optional: Enable the LDAP repository for MobileFirst Operational Analytics console protection. The LDAP parameters in MobileFirst Operational Analytics are exactly the same as those for MobileFirst Server Administration. For more information, see “Configure MFP Server Administration” (step 3 on page 12-193) in “Configuring MobileFirst administration security with an external LDAP repository” on page 12-192.
3. Configure MobileFirst Server runtime deployment for MobileFirst Operational Analytics connection:
- a. In the MobileFirst Platform Server node (or the DmgrNode node when using the MobileFirst Platform (WAS ND) template), select the **MFP Server Runtime Deployment** component.
 - b. Drag a link from the MFP Server Runtime Deployment component to the Liberty profile server component or to the Standalone server component in the MobileFirst Platform Analytics node, depending on the type of application server being used. The Configure Data Dependencies pop-up window opens.
 - c. Configure the data dependencies:
 - 1) In the Configure Data Dependencies window, clear any existing recommended data dependency entries by clicking the **X** button next to each entry.
 - 2) Below MFP Server Runtime Deployment component, select **analytics_ip** and below Liberty profile server or Standalone server, select **IP**.
 - 3) Click the **Add** button to add the new data dependency.
 - 4) Click **OK** to save your changes.

The link from the MFP Server Runtime Deployment component to the Liberty profile server component (or the Standalone server component) is built.

- d. Drag another link from the MFP Server Runtime Deployment component to the MFP Analytics component in the MobileFirst Platform Analytics node. The Configure Data Dependencies pop-up window opens.
- e. Configure the data dependencies:
 - 1) In the Configure Data Dependencies window, clear all the recommended data dependencies entries by clicking the **X** button next to each entry.

- 2) Below MFP Server Runtime Deployment component, select **analytics_admin_user** and below MFP Analytics, select **admin_user**.
- 3) Click the **Add** button to add the new data dependency.
- 4) Repeat the process to configure a data dependency from **analytics_admin_password** to **admin_password**.
- 5) Click **OK** to save your changes.

The link from the MFP Server Runtime Deployment component to the MFP Analytics component is built.

The following figure shows an example of a MobileFirst Platform Analytics node added to a MobileFirst Platform Liberty profile single node pattern:

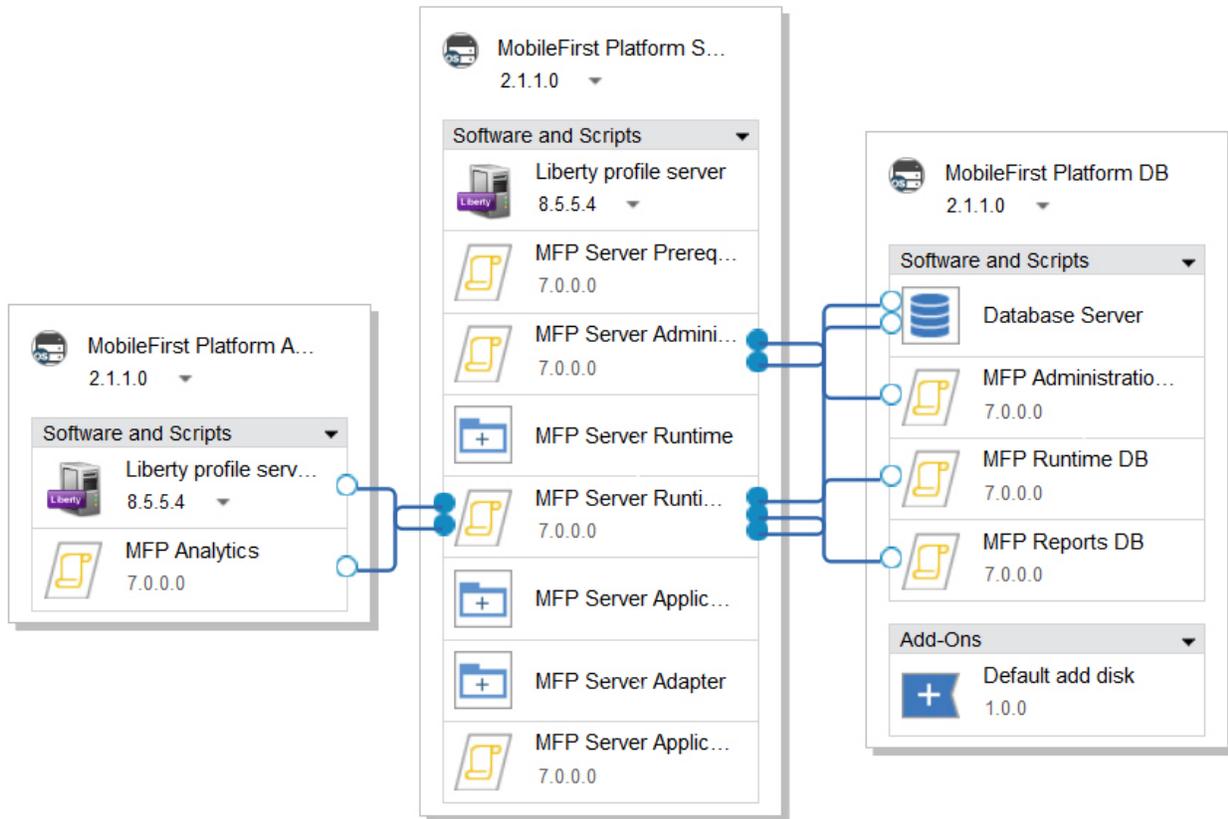

Figure 12-4. MobileFirst Platform Analytics node added to a MobileFirst Platform Liberty profile single node pattern

4. Configure and launch the pattern deployment.

On the Deploy Pattern page, you can adjust your MobileFirst Operational Analytics configuration settings by clicking the **MobileFirst Platform Analytics** component under the Nodes list in the middle column and then expanding **MFP Analytics**.

For more information about pattern deployment, see the “Configure and launch the pattern deployment” step in the following topics depending on the topology you selected when creating the pattern:

- “Deploying MobileFirst Server on a single-node WebSphere Application Server Liberty profile server” on page 12-160, step 9 on page 12-164
- “Deploying MobileFirst Server on a multiple-node WebSphere Application Server Liberty profile server” on page 12-166, step 10 on page 12-169
- “Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server” on page 12-171, step 9 on page 12-174
- “Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server” on page 12-171, step 10 on page 12-180
- “Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers” on page 12-183, step 10 on page 12-186

5. Access MobileFirst Operational Analytics through the MobileFirst Operations Console.

For more information, see the “Access the MobileFirst Operations Console” step in one of the following topics depending on the topology you selected when creating the pattern:

- “Deploying MobileFirst Server on a single-node WebSphere Application Server Liberty profile server” on page 12-160, step 10 on page 12-165
- “Deploying MobileFirst Server on a multiple-node WebSphere Application Server Liberty profile server” on page 12-166, step 11 on page 12-171
- “Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server” on page 12-171, step 10 on page 12-176
- “Deploying MobileFirst Server on a multiple-node WebSphere Application Server full profile server” on page 12-177, step 11 on page 12-182
- “Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers” on page 12-183, step 11 on page 12-188

Deploying several MobileFirst runtimes in a pattern in MobileFirst Server

You can deploy and configure the MobileFirst Server to install multiple runtimes on all the supported pattern topologies.

Before you begin

If you plan to deploy several MobileFirst runtimes on a cluster of WebSphere Application Server Network Deployment servers, review “MobileFirst runtime synchronization limitation with WebSphere Application Server Network Deployment” on page 12-189 before continuing with this procedure

Procedure

1. Build a pattern with the topology you need. For more information, see the following topics:
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server Liberty profile server” on page 12-160, steps 1 through 8 on page 12-163.
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server Liberty profile server” on page 12-166, steps 1 through 9 on page 12-169.
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server” on page 12-171, steps 1 through 8 on page 12-174.
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server full profile server” on page 12-177, steps 1 through 9 on page 12-180.
 - “Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers” on page 12-183, steps 1 through 9 on page 12-186.
2. Add an MFP Runtime DB component to support the additional runtime:
 - a. In the IBM PureApplication System dashboard, click **Patterns > Virtual System Patterns**.
 - b. On the Virtual System Patterns page, use the **Search** field to find the pattern you created, and then click **Open** to open the pattern.
 - c. From the **COMPONENTS** list, click **Scripts**, and then drag and drop an **MFP Runtime DB** script package onto the MobileFirst Platform DB node in the canvas. Rename it MFP Runtime DB_X (where X stands for a unique number for differentiation).
 - d. Click the **Add reference** button next to the **db_user** field and in the pop-up window, click the **component-level parameter** tab.
 - 1) From the **Component** list, select **Database Server**.

- 2) From the **Output attribute** list, select **instanceName**.
- 3) Click the **ADD** button to refresh the **Output value** field, and then click **OK**
- e. In the **db_name** field, rename the database to differentiate it from the existing database in the MFP Runtime DB component; for example, name it WLRTIME2.
- f. In the **db_password** field, make sure that the password aligns with the password in the **Password (Instance owner)** field of the Database Server component.
- g. In the **other_db_args** field, keep the default value.
3. Add a runtime component and upload an additional runtime WAR file:
 - a. From the **COMPONENTS** list, click **Software Components**, and then drag and drop an **Additional file** component onto the MobileFirst Platform Server node in the canvas or onto the DmgrNode when using the MobileFirst Platform (WAS ND) template.
 - b. Rename the component MFP RuntimeX (where X stands for a unique number for differentiation).
 - c. Hover the cursor over the newly added **MFP RuntimeX** component, and then click the **Move Up** and **Move Down** buttons to adjust its position in the node. Make sure it is placed after the MFP Server Application Adapter Deployment component of the existing MFP runtime component.
 - d. Upload the runtime WAR file:
 - 1) Click the **MFP RuntimeX** component. The properties of the selected component are displayed next to the canvas.
 - 2) Next to the **Additional file** field, click the **Browse** button to locate your runtime WAR file for uploading.
 - 3) In the **Target path** field, specify the full path for your runtime WAR file including the file name; for example, /opt/tmp/HelloWorld.war.
 - e. From the **COMPONENTS** list, click **Scripts**, and then drag and drop an MFP Server Runtime Deployment component onto the MobileFirst Platform Server node in the canvas or onto the DmgrNode when using the MobileFirst Platform (WAS ND) template. Rename it MFP Server Runtime Deployment_X (where X stands for a unique number for differentiation).
4. Configure the MobileFirst Server Runtime Deployment_X for MFP Runtime DB_X connection:
 - a. Click the **MFP Server Runtime Deployment_X** component.
 - b. Drag a link from the **MFP Server Runtime Deployment_X** component to the **MFP Runtime DB_X** component created in step 2 on page 12-203 in the MobileFirst Platform DB node. The Configure Data Dependencies pop-up window opens.
 - c. Configure the data dependencies:
 - 1) In the Configure Data Dependencies window, clear all the recommended data dependency entries by clicking the **X** button next to each entry.
 - 2) Below MFP Server Runtime Deployment_X component, select **rtdb_name** and below MFP Runtime DB_X, select **db_name**.
 - 3) Click the **Add** button to add the new data dependency.
 - 4) Repeat the process to configure a data dependency from **rtdb_user** to **db_user** and **rtdb_password** to **db_password**.
 - 5) Click **OK** to save your changes.

5. Configure the remaining parameters of the MobileFirst Server Runtime Deployment_X component:

Important: Most of the parameters of the MFP Server Runtime Deployment_X component for the additional MFP runtime can share the same values via **Add reference** with those of the MFP Server Runtime Deployment component.

- a. Click the **MFP Server Runtime Deployment_X** component. Supply the following information in the fields provided:

Take the **WAS_ROOT** field as an example to illustrate the steps involved in using the **Add reference** field:

- 1) Click the **Add reference** button next to the **WAS_ROOT** field and in the pop-up window, click the **component-level parameter** tab.
- 2) From the **Component** list, select **MFP Server Runtime Deployment**.
- 3) From the **Output attribute** list, select **WAS_ROOT**.
- 4) Click the **ADD** button to refresh the **Output value** field, and then click **OK**.

In addition to the **WAS_ROOT** parameter, the following parameters of MFP Server Runtime Deployment_X can also add reference to the corresponding parameter of MFP Server Runtime Deployment. (for detailed descriptions of the parameters, see “Script packages for MobileFirst Server” on page 12-223)

- **profile_name**
 - **db_ip**
 - **db_port**
 - **admin_user**
 - **admin_password**
 - **rptdb_name** (not required if the MFP Report DB is not installed)
 - **rptdb_user** (not required if the MFP Report DB is not installed)
 - **rptdb_password** (not required if the MFP Report DB is not installed)
 - **was_admin_user** (not required if the application server is WebSphere Application Server Liberty profile)
 - **was_admin_password** (not required if the application server is WebSphere Application Server Liberty profile)
 - **server_farm_mode**
 - **server_hostname**
 - **analytics_ip** (not required if the analytics server is not installed)
 - **analytics_admin_user** (not required if the analytics server is not installed)
 - **analytics_admin_password** (not required if the analytics server is not installed)
- b. Optional: This step only applies to patterns built from the MobileFirst Platform (WAS ND) template. For other templates, this step can be skipped. In the **NUMBER_OF_CLUSTERMEMBERS** field, specify the number of the server nodes you want to create for the cluster which will deploy the additional MobileFirst runtime.

Important: Increase the number of instances of the CustomNode node to contain the increase in the number of cluster members specified in the **NUMBER_OF_CLUSTERMEMBERS** field. In the CustomNode node, click the **Base Scaling Policy** component. The properties of the selected component are displayed next to the canvas. The default value for the **Number of Instances** field, 4, deploys four CustomNode VM nodes to meet

the requirement of the default topology that requires two server nodes for the MFP administration service and two server nodes for the sole MFP runtime. With the new number of cluster members input above, the **Number of Instances** field needs to at least equal the sum of the number of server nodes for the MobileFirst administration service and the number of server nodes for all the runtimes.

c. Configure the **runtime_path** field:

- 1) Next to the **runtime_path** field, click the **Add reference** button and then in the pop-up window, click the **component-level parameter** tab.
- 2) From the **Component** list, select **MFP RuntimeX** (where X stands for the number to differentiate the several MFP runtimes).
- 3) From the **Output attribute** list, select **target_path**.
- 4) Click the **ADD** button to refresh the **Output value** field, and then click **OK**.

d. In the **runtime_contextRoot** field, specify the runtime context root name for the additional runtime. Note that the context root name must start with a forward slash, /; for example, /HelloWorld.

6. Optional: Upload application or adapter artifacts for deployment:

Important: When specifying the target path for applications and adapters, make sure all the applications and adapters are placed in the same directory. For example, if one target path is /opt/tmp/deploy/HelloWorld-common.wlapp, all the other target paths should be /opt/tmp/deploy/*.

a. From the **COMPONENTS** list, select **Software Components**, and then drag and drop an **Additional file** component onto the MobileFirst Platform Server node in the canvas or onto the DmgrNode when using the MobileFirst Platform (WAS ND) template. Rename it MobileFirst App_X or MobileFirst Adapter_X (where X stands for a unique number for differentiation).

b. Hover the cursor over the newly added App or Adapter component, and then click the **Move Up** and **Move Down** buttons to adjust its sequence in the node. Make sure it is placed after the MFP Runtime Deployment_X component.

c. Click the newly added application or adapter component. The properties of the selected component are displayed next to the canvas. Upload the application or adapter artifact and specify its target path:

- 1) In the **Additional file** field, click the **Browse** button to locate and upload the application or adapter artifact.
- 2) In the **Target path** field, specify the full path for storing the artifact including its file name; for example, /opt/tmp/deploy/HelloWorld-common.wlapp.

d. Repeat steps 6a through 6c to add more applications and adapters for deployment.

7. Optional: Add and configure application and adapter deployment. You can skip this step if step 6 is not done.

a. From the **COMPONENTS** list, select **Scripts**, and then drag and drop an **MFP Server Application Adapter Deployment** component onto the MobileFirst Platform Server node in the canvas or onto the DmgrNode when using the MobileFirst Platform (WAS ND) template. Rename it MFP Server Application Adapter Deployment_X (where X stands for a unique number for differentiation).

- b. Hover the cursor over the newly added MFP Server Application Adapter Deployment_X component, and then click the **Move Up** and **Move Down** buttons to adjust its sequence in the node. Make sure it is placed after all the MobileFirst App_X or MobileFirst Adatper_X components created in step 6 on page 12-206.
- c. Click the **MFP Server Application Adapter Deployment_X** component. The properties of the selected component are displayed next to the canvas. Supply the following information in the fields provided:

artifact_dir

- 1) Click the **Add reference** button next to the **artifact_dir** field and in the pop-up window, click the **component-level parameter** tab.
- 2) In the **Component** field, select **MobileFirst App_X** or **MobileFirst Adatper_X** created in step 6 on page 12-206 (where X stands for the unique number for differentiation).
- 3) In the **Output attribute** field, select **target_path**.
- 4) Click the **ADD** button to refresh the **Output value** field, and then click **OK**.

runtime_context

- 1) Click the **Add reference** button next to the **runtime_context** field and in the pop-up window, click the **component-level parameter** tab.
- 2) In the **Component** field, select **MFP Server Runtime Deployment_X** created in step 2 on page 12-203 (where X stands for the unique number for differentiation).
- 3) In the **Output attribute** field, select **runtime_contextRoot**.
- 4) Click the **ADD** button to refresh the **Output value** field, and then click **OK**.

deployer_user

- 1) Click the **Add reference** button next to the **deployer_user** field and in the pop-up window, click the **component-level parameter** tab.
- 2) In the **Component** field, select **MFP Server Administration**.
- 3) In the **Output attribute** field, select **admin_user**.
- 4) Click the **ADD** button to refresh the **Output value** field, and then click **OK**.

deployer_password

- 1) Click the **Add reference** button next to the **deployer_password** field and in the pop-up window, click the **component-level parameter** tab.
- 2) In the **Component** field, select **MFP Server Administration**
- 3) In the **Output attribute** field, select **admin_password**.
- 4) Click the **ADD** button to refresh the **Output value** field, and then click **OK**.

webserver_ip

- 1) Click the **Add reference** button next to the **webserver_ip** field and in the pop-up window, click the **component-level parameter** tab.
- 2) In the **Component** field, select **MFP Server Administration**
- 3) In the **Output attribute** field, select **webserver_ip**.

- 4) Click the **ADD** button to refresh the **Output value** field, and then click **OK**.
8. Optional: To add more runtimes, repeat the process from steps 2 on page 12-203 through 7 on page 12-206 and use different numbers in the X placeholders for differentiation as described earlier in this procedure.
9. Complete the deployment process by following the instructions in one of the following topics, depending on your deployment scenario:
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server Liberty profile server” on page 12-160, step 9 on page 12-164 onwards.
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server Liberty profile server” on page 12-166, step 10 on page 12-169 onwards.
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server” on page 12-171, step 9 on page 12-174 onwards.
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server full profile server” on page 12-177, step 10 on page 12-180 onwards.
 - “Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers” on page 12-183, step 10 on page 12-186 onwards.

Deploying MobileFirst Server without the Reports database

The Reports database is optional in the pattern. You can customize the pattern built from the predefined template to remove the Reports database.

Procedure

1. Build a pattern with the required topology. For more information, see the following topics:
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server Liberty profile server” on page 12-160
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server Liberty profile server” on page 12-166
 - “Deploying MobileFirst Server on a single-node WebSphere Application Server full profile server” on page 12-171
 - “Deploying MobileFirst Server on a multiple-node WebSphere Application Server full profile server” on page 12-177
 - “Deploying MobileFirst Server on clusters of WebSphere Application Server Network Deployment servers” on page 12-183
2. Remove the Reports database:
 - a. In IBM PureApplication System, in the dashboard, click **Patterns > Virtual System Patterns**. The Virtual System Patterns page opens.
 - b. On the Virtual System Patterns page, use the **Search** field to find and select the pattern you created, and then click **Open** on the right side to open the Pattern Builder page.
 - c. In the MobileFirst Platform DB node in the canvas, select **MFP Reports DB**, and then click the **X** button to delete it.
 - d. In the MobileFirst Platform Server node (or the DmgrNode node when using the MobileFirst Platform (WAS ND) template), select **MFP Server Runtime Deployment** and make sure the **rptdb_name** attribute in it is blank.
 - e. Save the pattern.

Deployment of the Application Center to the cloud

You must configure and connect the operational components of the Application Center to deploy the enterprise application on PureApplication System or IBM PureApplication Service on SoftLayer.

The operational model of the Application Center is composed of:

- An application server that hosts the administration console and services.
- A user authentication system; here, an LDAP server that handles user and group authentication and user management, but the basic authentication mechanism of the application server can be used.
- The database, a repository for tracking users, applications, and feedback.

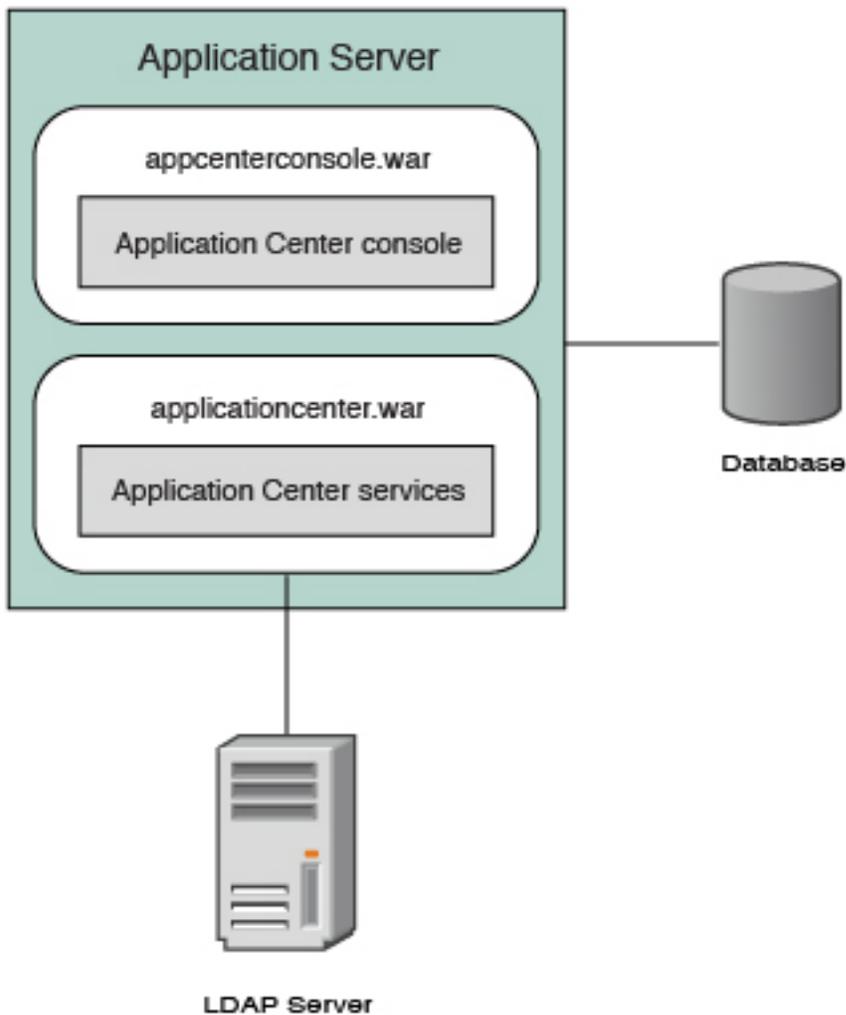

Figure 12-5. Typical operational model of the Application Center

Related concepts:

Application Center

Learn about the Application Center: what it is for, the different components and features, and how to use the console and the client.

Configuring the Application Center after installation

You configure user authentication and choose an authentication method. The configuration procedure depends on the web application server that you use.

Managing users with LDAP

Use the Lightweight Directory Access Protocol (LDAP) registry to manage users.

Deploying the Application Center on IBM PureApplication System

Configure the enterprise application, the database, the user registry, and map the security roles before you deploy the Application Center on PureApplication System.

Before you begin

This procedure involves working with the `ApplicationCenterEAR.ear` file and the `create-appcenter-db2.sql` file. You can find both files in the `mobilefirst_server_patterns_7.1.0.zip` file.

You must have an IBM PureApplication System environment and the privilege to create and deploy virtual application patterns.

This procedure requires the use of IBM DB2 with BLU Acceleration Pattern V1.1.0.10. Contact your system administrator to ensure that this virtual application pattern is installed in your IBM PureApplication System environment.

About this task

By following this procedure, you prepare the operational components of the Application Center for deployment of the enterprise application on PureApplication System. You connect the operational components to each other and then you can save the configuration and deploy the Application Center on PureApplication System as a web application.

Procedure

1. Get the enterprise archive (EAR) file, `ApplicationCenterEAR.ear`, for the Application Center. This file is in the `mobilefirst_server_patterns_7.1.0.zip` file. As of V5.0.6, the Application Center has two web archive (WAR) files, one for the console and one for the services. An EAR file containing them is supplied to simplify deployment on PureApplication System. The context roots of the WAR files within the EAR file are:

- `/appcenterconsole` for the console
- `/applicationcenter` for the services

If you choose to build the EAR file manually, you must remember the context roots of the WAR files.

2. Create the Virtual Application Pattern.
 - a. Log in to IBM PureApplication System
 - b. Select **Patterns > Virtual Application Patterns**.
 - c. Select **Web Application Pattern Type 2.0**.
 - d. Click **Create New**.
 - e. Select a template to start from and then click **Start Building**. You can select any template that conforms with the operational model used in this documentation. You must create one web application component, one

database component, and one user registry component. The example is based on selection of “Blank application”.

3. Add an Enterprise Application component.
 - a. From the **COMPONENTS** list, expand **Application Components**.
 - b. Drag the **Enterprise Application** component onto the canvas.
 - c. Click the **Enterprise Application** component, and in the **EAR file** field, specify the path of the Application Center EAR file.
4. Add routing policy.
 - a. Move the mouse over the Enterprise Application component and click the plus sign (+).
 - b. Click **Routing Policy**.
 - c. In the property pane, click **Routing Policy** and specify **Virtual Host name**. Take a note of the host name because you use it later.
5. Optional: Add JVM policy. If you use the supplied EAR file or have defined the context root of the services WAR file as `/applicationcenter`, this step is optional.
 - a. Select **JVM Policy** in the same way as you selected Routing Policy.
 - b. In the property pane, specify **Generic JVM arguments**:
`-Dibm.appcenter.services.endpoint=http://{virtual_host}/{services_context_root}` where:
 - *virtual_host* is the virtual host name that you specified in Routing Policy.
 - *services_context_root* is the context root of the services WAR file.
6. Add a database component.
 - a. In the left pane, expand **Database Components**.
 - b. Drag a database into the property pane on the right. The database used in the example is DB2.
 - c. In the property panel, click the Database component and specify the schema file. You can find `create-appcenter-db2.sql` in the `mobilefirst_server_patterns_7.1.0.zip` file.
7. Connect enterprise application and database.
 - a. On the Enterprise Application component, click and drag the connection point on the right edge to the Database component. This gesture creates the connection between the web application and the database.
 - b. Click the connector and specify the data source as `jdbc/AppCenterDS`.
8. Add a user registry component.
 - a. In the left pane, expand **User Registry Components**.
 - b. Drag the user registry component into the property pane.
 - c. In the property pane, select the User Registry component and specify the “Base DN” and the “LDIF file”.
9. Connect web application and user registry.
 - a. Drag two connectors between the Enterprise Application component and the User Registry component.
 - b. Specify the “Role name” `appcenteradmin`.
 - c. Set “Mapping special subjects” to `AllAuthenticatedUsers`.
 - d. Specify the next “Role name” `appcenteruser`.
 - e. Set “Mapping special subjects” to `AllAuthenticatedUsers`.

10. Save the configuration and deploy the Application Center on PureApplication System.
 - a. Save the virtual application; give it a name, for example, “MobileFirst Application Center”.
 - b. Return to **Virtual Application Patterns**. You should see the pattern that you created in this procedure.
 - c. Click **Deploy** to deploy the Application Center on PureApplication System.

Predefined templates for MobileFirst Platform Patterns

IBM MobileFirst Platform Foundation System Patterns includes predefined templates that you can use to build patterns for the most typical deployment topologies.

The following templates are available:

- “MobileFirst Platform (Liberty single node) template”
- “MobileFirst Platform (Liberty server farm) template” on page 12-214
- “MobileFirst Platform (WAS single node) template” on page 12-216
- “MobileFirst Platform (WAS server farm) template” on page 12-219
- “MobileFirst Platform (WAS ND) template” on page 12-221

MobileFirst Platform (Liberty single node) template

Figure 12-6 on page 12-213 shows the composition of the “MobileFirst Platform (Liberty single node)” template.

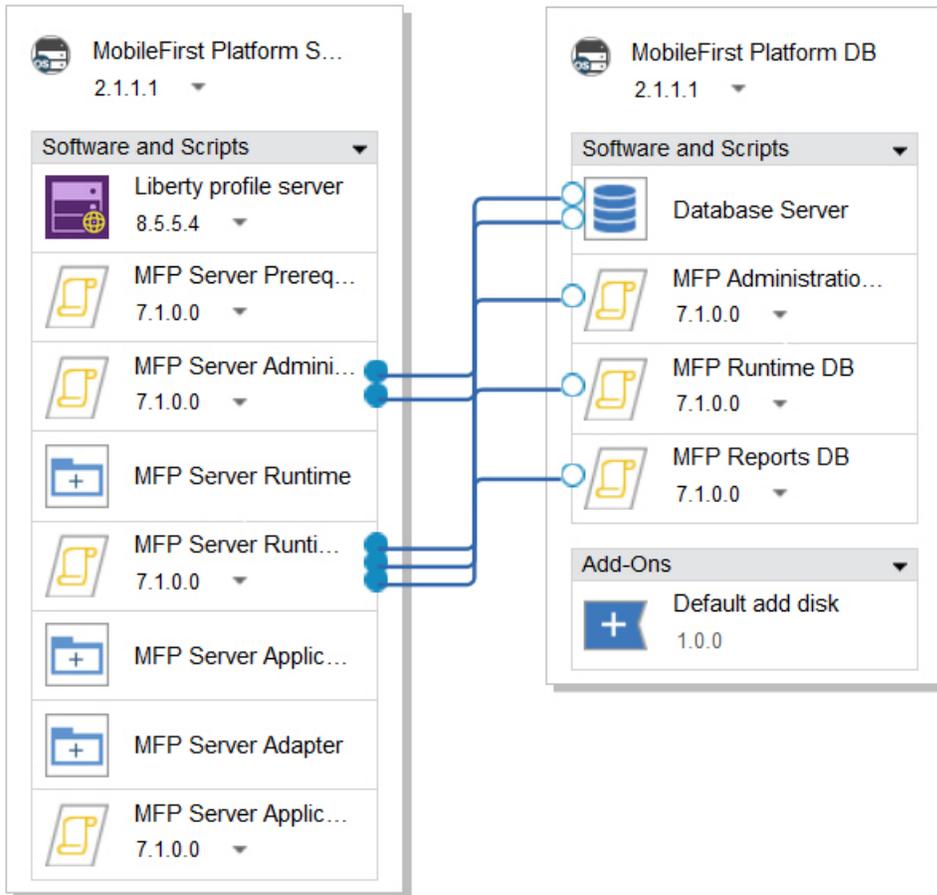

Figure 12-6. MobileFirst Platform (Liberty single node) template

The “MobileFirst Platform (Liberty single node)” template is composed of the following nodes and components:

Table 12-48. MobileFirst Platform (Liberty single node) template nodes and components.

Node	Components
MobileFirst Platform Server	<p>Liberty profile server WebSphere Application Server Liberty profile server installation.</p> <p>MFP Server Prerequisite Prerequisites for MobileFirst Server installation including SSL and Ant.</p> <p>MFP Server Administration MobileFirst Server Administration web application including MobileFirst Operations Console.</p> <p>MFP Server Runtime Runtime WAR file.</p> <p>MFP Server Runtime Deployment Runtime context root configuration.</p> <p>MFP Server Application MobileFirst application to be added to the deployment.</p> <p>MFP Server Adapter MobileFirst adapter to be added to the deployment.</p> <p>MFP Server Application Adapter Deployment Application and adapter deployment to the MobileFirst Server.</p>
MobileFirst Platform DB	<p>Database Server DB2 database server installation.</p> <p>MFP Administration DB MobileFirst administration database schema installation.</p> <p>MFP Runtime DB MobileFirst runtime database schema installation.</p> <p>MFP Reports DB MobileFirst reports database schema installation.</p> <p>Default add disk Disk size configuration.</p>

MobileFirst Platform (Liberty server farm) template

Figure 12-7 on page 12-215 shows the composition of the “MobileFirst Platform (Liberty server farm)” template.

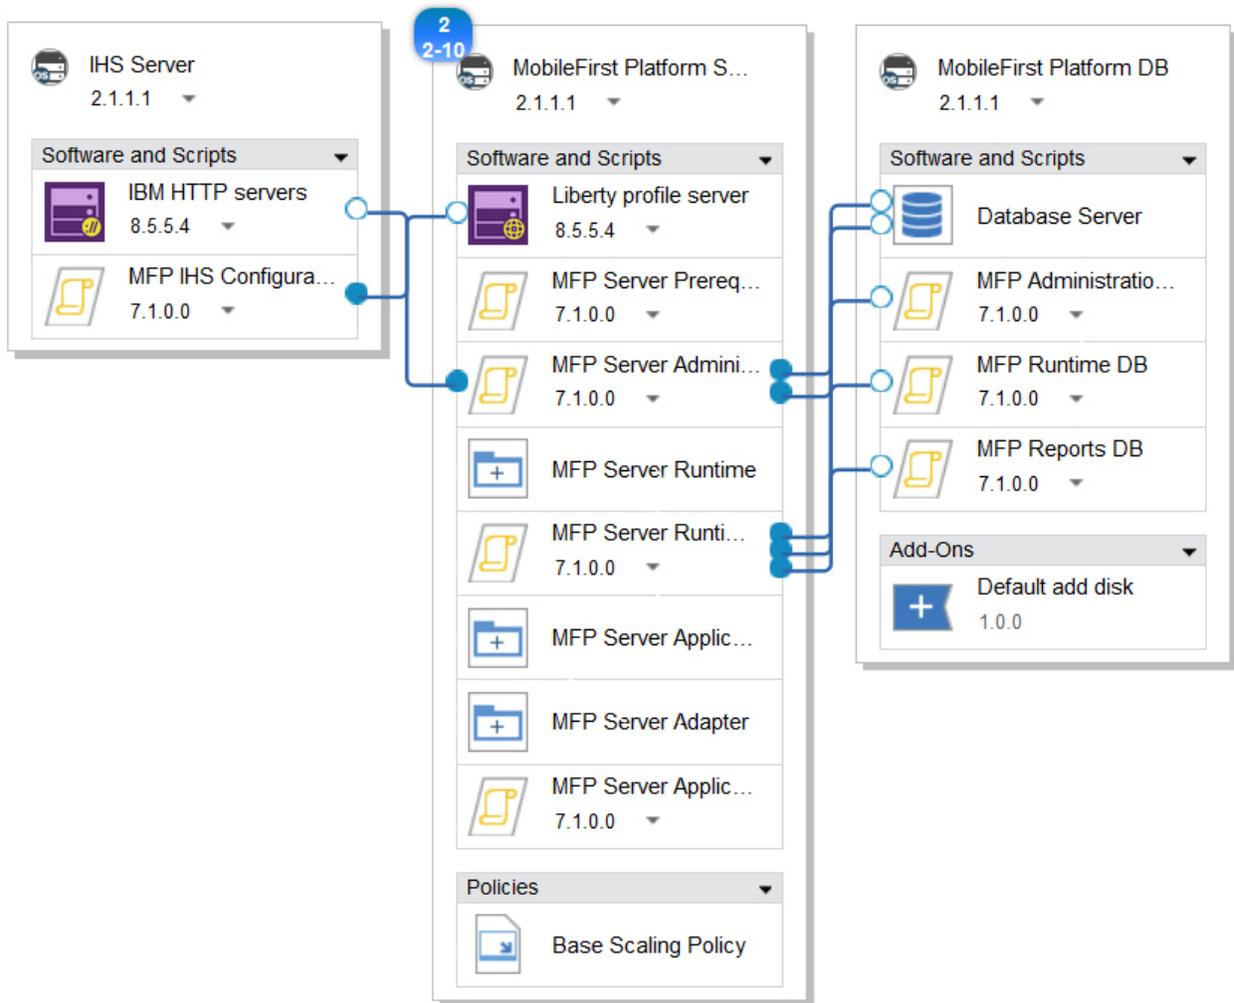

Figure 12-7. MobileFirst Platform (Liberty server farm) template

The “MobileFirst Platform (Liberty server farm)” template is composed of the following nodes and components:

Table 12-49. MobileFirst Platform (Liberty server farm) template nodes and components.

Node	Components
IHS Server	<p>IBM HTTP servers IBM HTTP Server installation.</p> <p>MFP IHS Configuration Automatic configuration of IBM HTTP Server.</p>

Table 12-49. MobileFirst Platform (Liberty server farm) template nodes and components (continued).

Node	Components
MobileFirst Platform Server	<p>Liberty profile server WebSphere Application Server Liberty profile server installation.</p> <p>MFP Server Prerequisite Prerequisites for MobileFirst Server installation including SSL and Ant.</p> <p>MFP Server Administration MobileFirst Server Administration web application including MobileFirst Operations Console.</p> <p>MFP Server Runtime Runtime WAR file.</p> <p>MFP Server Runtime Deployment Runtime context root configuration.</p> <p>MFP Server Application MobileFirst application to be added to the deployment.</p> <p>MFP Server Adapter MobileFirst adapter to be added to the deployment.</p> <p>MFP Server Application Adapter Deployment Application and adapter deployment to the MobileFirst Server.</p> <p>Base Scaling Policy VM scaling policy: number of VMs.</p>
MobileFirst Platform DB	<p>Database Server DB2 database server installation.</p> <p>MFP Administration DB MobileFirst administration database schema installation.</p> <p>MFP Runtime DB MobileFirst runtime database schema installation.</p> <p>MFP Reports DB MobileFirst reports database schema installation.</p> <p>Default add disk Disk size configuration.</p>

MobileFirst Platform (WAS single node) template

Figure 12-8 on page 12-217 shows the composition of the “MobileFirst Platform (WAS single node)” template.

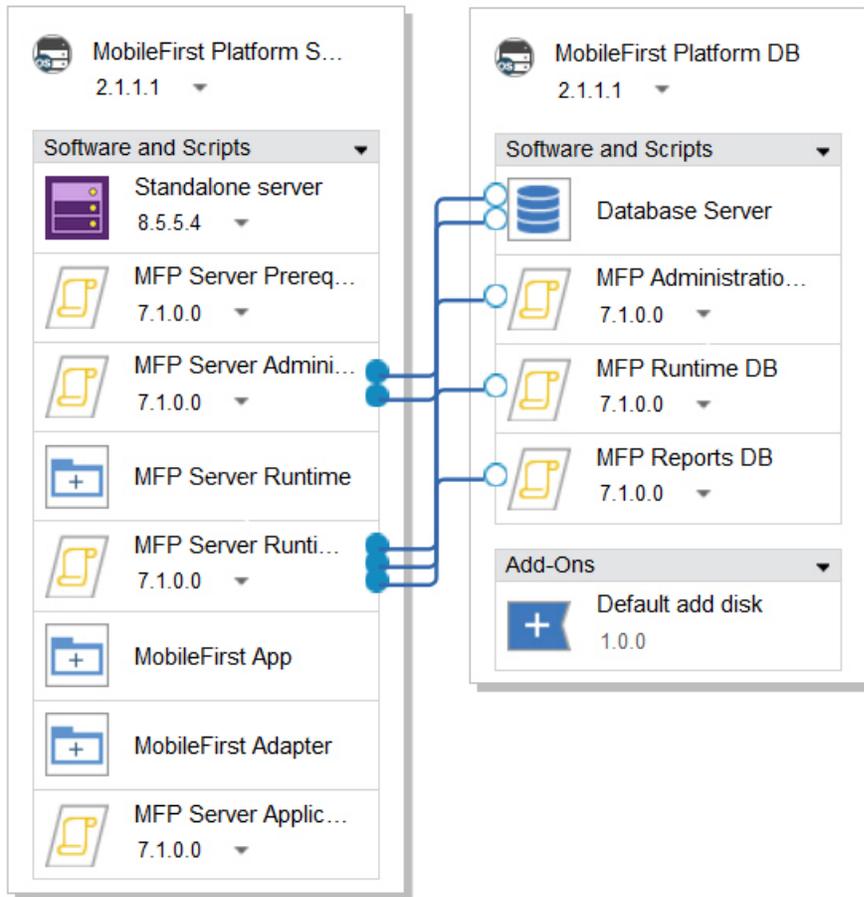

Figure 12-8. MobileFirst Platform (WAS single node) template

The “MobileFirst Platform (WAS single node)” template is composed of the following nodes and components:

Table 12-50. MobileFirst Platform (WAS single node) template nodes and components.

Node	Components
MobileFirst Platform Server	<p>Standalone server WebSphere Application Server full profile server installation. Restriction: Do not change the values for the following component attributes:</p> <ul style="list-style-type: none"> • Cell name • Node name • Profile name <p>If you change any of these attributes, the deployment of patterns that are based on this template fails.</p> <p>MFP Server Prerequisite Prerequisites for MobileFirst Server installation including SSL and Ant.</p> <p>MFP Server Administration MobileFirst Server Administration web application including MobileFirst Operations Console.</p> <p>MFP Server Runtime Runtime WAR file.</p> <p>MFP Server Runtime Deployment Runtime context root configuration.</p> <p>MFP Server Application MobileFirst application to be added to the deployment.</p> <p>MFP Server Adapter MobileFirst adapter to be added to the deployment.</p> <p>MFP Server Application Adapter Deployment Application and adapter deployment to the MobileFirst Server.</p>

Script packages for MobileFirst Server

IBM MobileFirst Platform Foundation System Patterns provides script packages that are the building blocks to compose various pattern topologies.

The following sections list and describe the parameters for each script package.

- “MFP Administration DB” on page 12-224
- “MFP Runtime DB” on page 12-224
- “MFP Reports DB” on page 12-225
- “MFP Server Prerequisite” on page 12-225
- “MFP Server Administration” on page 12-225
- “MFP Server Runtime Deployment” on page 12-229

- “MFP Server Application Adapter Deployment” on page 12-232
- “MFP IHS Configuration” on page 12-233
- “MFP Analytics” on page 12-234
- “MFP Open Firewalls for WAS” on page 12-237

MFP Administration DB

This script package sets up the administration database schema in a DB2 database. It must be used with the Database Server (DB2) software component.

Table 12-53. MFP Administration DB.

Parameter	Description
db_user	Mandatory. User name to create the Administration database. It can be mapped to the Instance name of the Database Server component. Default value: db2inst1.
db_name	Mandatory. Database name to create the Administration database. Default value: WLADM.
db_password	Mandatory. User password to create the Administration database. It can be mapped to the Instance owner password of the Database Server component. Default value: passw0rd (as pattern level parameter).
other_db_args	Mandatory. Four parameters to create the Administration database: SQL type , Codeset , Territory and Collate . Default value: DB2 UTF-8 US SYSTEM.

MFP Runtime DB

This script package sets up the runtime database schema in a DB2 database.

Table 12-54. MFP Runtime DB. This script package sets up the runtime database schema in a DB2 database. It must be used with the Database Server (DB2) software component.

Parameter	Description
db_user	Mandatory. User name to create the Runtime database. It can be mapped to the Instance name of the Database Server component. Default value: db2inst1.
db_name	Mandatory. Database name to create the Runtime database. Default value: WLRTIME.
db_password	Mandatory. User password to create the Runtime database. It can be mapped to the Instance owner password of the Database Server component. Default value: passw0rd (as pattern level parameter).
other_db_args	Mandatory. Four parameters to create the Runtime database: SQL type , Codeset , Territory and Collate . Default value: DB2 UTF-8 US SYSTEM.

MFP Reports DB

This script package sets up the reports database schema in a DB2 database. It must be used with the Database Server (DB2) software component. The reports database is optional, but if used, must be installed on the same node as the runtime database script package.

Table 12-55. MFP Reports DB.

Parameter	Description
db_user	Mandatory. User name to create the Reports database. It can be mapped to the Instance name of the Database Server component. Default value: db2inst1.
db_name	Mandatory. Database name to create the Reports database. Default value: WLREPORT.
db_password	Mandatory. User password to create the Reports database. It can be mapped to the Instance owner password of the Database Server component. Default value: password (as pattern level parameter).
other_db_args	Mandatory. Four parameters to create the Reports database: SQL type , Codeset , Territory and Collate . Default value: DB2 UTF-8 US SYSTEM.

MFP Server Prerequisite

This script package includes all prerequisites that are required to install the MobileFirst Server, including the DB2 JDBC driver and Apache Ant. The script package must be used with the WebSphere Application Server Liberty profile server software component or the WebSphere Application Server full profile software component (display name: Standalone server), and must be installed after the server software component but prior to any other MFP* script packages in the MobileFirst Platform Server node.

Table 12-56. MFP Server Prerequisite.

Parameter	Description
None	No parameters for this script package.

MFP Server Administration

This script package sets up the MobileFirst Administration component (including the MobileFirst Operations Console) in a WebSphere Application Server full profile or WebSphere Application Server Liberty profile server, and setting up the connection and mapping administration security roles to an external TDS or AD server.

The script package must be used with the WebSphere Application Server Liberty profile server software component or the WebSphere Application Server full profile software component (display name: Standalone server), and must be installed after the MFP Server Prerequisite but prior to any other MFP * Script Packages in the MobileFirst Platform Server VM node.

Table 12-57. MFP Server Administration.

Parameter	Description
WAS_ROOT	Mandatory. Installation directory of WebSphere Application Server Liberty profile or WebSphere Application Server full profile in the MobileFirst Platform Server node or the installation directory of the Deployment manager in the DmgrNode node. In the pattern templates, it is mapped to output attribute install_directory of Liberty profile server, Standalone server, or Deployment manager.
profile_name	Optional. The profile name that contains the files for the WebSphere Application Server runtime environment. In the pattern templates, it is mapped to output attribute dmgr_profile_name of Deployment manager or sa_profile_name of Standalone server.
NUMBER_OF_CLUSTERMEMBERS	Optional. Only applicable for the MobileFirst Platform (WAS ND) pattern template. It specifies the number of cluster members for the cluster to deploy the MFP administration service. Default value: 2.
db_user	Mandatory. User name that created the Administration database. It is mapped to the db_user output attribute of the MFP Administration DB script package in the pattern template.
db_name	Mandatory. Name of the Administration database. It is mapped to the db_name output attribute of the MFP Administration DB script package in the pattern template.
db_password	Mandatory. password for user who created the Administration database. It is mapped to the db_password output attribute of the MFP Administration DB script package in the pattern template.
db_ip	IP address of the DB server where the Administration database is installed. It is mapped to the IP output attribute of the Database Server software component in the pattern template.
db_port	Port number of the DB server where the Administration database is installed. It is mapped to the instancePort output attribute of the Database Server software component in the pattern template.

Table 12-57. MFP Server Administration (continued).

Parameter	Description
admin_user	<p>User name that has MobileFirst Server administration privilege.</p> <ul style="list-style-type: none"> • When LDAP_TYPE is None, create the default admin user. • When LDAP_TYPE is set to <code>TivoliDirectoryServer</code> or <code>ActiveDirectory</code> and other LDAP parameters are specified according to your LDAP server configuration, the admin_user value should be taken from the configured LDAP user repository. Not required when the MobileFirst Server is to be deployed on a single node of WebSphere Application Server full profile.
admin_password	<p>Password of the admin user.</p> <ul style="list-style-type: none"> • When LDAP_TYPE is None, create the default admin user password. • When an external LDAP server is configured, the user password is taken from the LDAP repository. Not required when the MobileFirst Server is to be deployed on a single node of WebSphere Application Server full profile.
install_console	<p>Whether the MobileFirst Operations Console is to be deployed in the MobileFirst Platform Server node.</p> <p>Default value: Selected. (Check box)</p>
WAS_admin_user	<p>Optional. When the MobileFirst Server is deployed on WebSphere Application Server full profile, it is mapped to the was_admin output attribute of Standalone server in the pattern template.</p> <p>When the MobileFirst Server is deployed on WebSphere Application Server Network Deployment, it is mapped to the was_admin output attribute of Deployment manager in the pattern template.</p>
WAS_admin_password	<p>Optional. When the MobileFirst Server is deployed on WebSphere Application Server full profile, it is mapped to the was_admin_password output attribute of Standalone server in the pattern template.</p> <p>When the MobileFirst Server is deployed on WebSphere Application Server Network Deployment, it is mapped to the was_admin_password output attribute of Deployment manager in the pattern template.</p>

Table 12-57. MFP Server Administration (continued).

Parameter	Description
server_hostname	Mandatory. Host name of the MobileFirst Server or Deployment manager. Mapped to the host output attribute of Liberty profile server, Standalone Server, or Deployment manager.
server_farm_mode	Mandatory. Whether the MobileFirst Server is to be deployed in server farm mode. Must be selected for a server farm topology and must be cleared for a standalone topology. Default value: set according to the topology defined in the pattern template.
webservice_ip	Optional. When IBM HTTP servers is deployed in the pattern template, this parameter is mapped to the IP output attribute of IBM HTTP servers.
LDAP_TYPE	(LDAP parameter) Mandatory. LDAP server type of your user registry. One of the following values: <ul style="list-style-type: none"> • None – LDAP connection is disabled. When this value is selected, all the other LDAP parameters are treated as placeholders only. • TivoliDirectoryServer: Select this value if the LDAP repository is IBM Tivoli Directory Server • ActiveDirectory: Select this value if the LDAP repository is Microsoft Active Directory Default value: None.
LDAP_IP	(LDAP parameter) LDAP server IP address.
LDAP_SSL_PORT	(LDAP parameter) LDAP port for secure connection.
LDAP_PORT	(LDAP parameter) LDAP port for non-secure connection.
BASE_DN	(LDAP parameter) Base DN.
BIND_DN	(LDAP parameter) Bind DN.
BIND_PASSWORD	(LDAP parameter) Bind DN password.
REQUIRE_SSL	(LDAP parameter) Set to true for secure connection to LDAP server. <ul style="list-style-type: none"> • When true, the LDAP_SSL_PORT is used and CERT_FILE_PATH is required to locate the certification file of the LDAP server. • When false, LDAP_PORT is used. Default value: false.
USER_FILTER	(LDAP parameter) User filter that searches the existing user registry for users.

Table 12-57. MFP Server Administration (continued).

Parameter	Description
GROUP_FILTER	(LDAP parameter) LDAP group filter that searches the existing user registry for groups.
LDAP_REPOSITORY_NAME	(LDAP parameter) LDAP server name.
CERT_FILE_PATH	(LDAP parameter) Target path of the uploaded LDAP server certification. It is mandatory when REQUIRE_SSL is set to true.
worklightadmin	Admin role for MobileFirst Server. One of the following values: None No user. AllAuthenticatedUsers Authenticated users Everyone All users. Default value: None.
worklightdeployer	Deployer role for MobileFirst Server. One of the following values: None No user. AllAuthenticatedUsers Authenticated users Everyone All users. Default value: None.
worklightmonitor	Monitor role for MobileFirst Server. One of the following values: None No user. AllAuthenticatedUsers Authenticated users Everyone All users. Default value: None.
worklightoperator	Operator role for MobileFirst Server. One of the following values: None No user. AllAuthenticatedUsers Authenticated users Everyone All users. Default value: None.

MFP Server Runtime Deployment

This script package installs the MobileFirst runtime in a WebSphere Application Server full profile or WebSphere Application Server Liberty profile server with the

MobileFirst Operations Console installed. The script package also sets up the connection to the MobileFirst Analytics server. It must be installed after the MFP Server Administration script package.

Table 12-58. MFP Server Runtime Deployment.

Parameter	Description
WAS_ROOT	Mandatory. Installation directory of WebSphere Application Server Liberty profile or WebSphere Application Server full profile in the MobileFirst Platform Server node, or installation directory of Deployment manager in the DmgrNode node. In the pattern templates, it is mapped to output attribute install_directory of Liberty profile server or Standalone server.
profile_name	Optional. The profile name that contains the files for the WebSphere Application Server runtime environment. In the pattern templates, it is mapped to output attribute dmgr_profile_name of Deployment manager or sa_profile_name of Standalone server.
NUMBER_OF_CLUSTERMEMBERS	Optional. Only applicable for the MobileFirst Platform (WAS ND) pattern template. It specifies the number of cluster members for the cluster to deploy MFP runtime. Default value: 2.
db_ip	IP address of the DB server where the Runtime (and optional Reports) database is installed. It is mapped to the IP output attribute of the Database Server software component in the pattern template.
db_port	Port number of the DB server where the Runtime (and optional Reports) database is installed. It is mapped to the instancePort output attribute of the Database Server software component in the pattern template.
admin_user	Mandatory. User name that has MobileFirst Server administration privilege. In the pattern template, it is associated with the parameter of the same name in the MFP Server Administration script package as a pattern level parameter to ensure they are set to the same value
admin_password	Mandatory. admin user password. In the pattern template, it is associated with the parameter of the same name in the MFP Server Administration script package as a pattern level parameter to ensure they are set to the same value

Table 12-58. MFP Server Runtime Deployment (continued).

Parameter	Description
runtime_path	Mandatory. Runtime WAR file installed path. For example: it can be mapped to the target_path output attribute of MFP Server Runtime in the pattern template.
runtime_contextRoot	Mandatory. Runtime context root. Must start with a forward slash, /; for example, "/HelloWorld". It is set as a pattern level parameter in the pattern template.
rtdb_name	Mandatory. Name of the Runtime database. It is mapped to the thedb_name output attribute of the MFP Runtime DB script package in the pattern template.
rtdb_user	Mandatory. User that created the Runtime database. It is mapped to the db_user output attribute of the MFP Runtime DB script package in the pattern template.
rtdb_password	Mandatory. Password of the user that created the Runtime database. It is mapped to the db_password output attribute of the MFP Runtime DB script package in the pattern template.
rptdb_name	Optional. Name of the Reports database. It is mapped to the thedb_name output attribute of the MFP Reports DB script package in the pattern template. Leave blank if you do not want to connect to a Reports database.
rptdb_user	Optional. User that created the Reports database. It is mapped to the thedb_user output attribute of the MFP Reports DB script package in the pattern template.
rptdb_password	Optional. Password of the user that created the Reports database. It is mapped to the db_password output attribute of MFP Reports DB script package in the pattern template.
was_admin_user	Optional. When the MobileFirst Server is deployed on WebSphere Application Server full profile, it is mapped to the was_admin output attribute of Standalone server in the pattern template. When the MobileFirst Server is deployed on WebSphere Application Server Network Deployment, it is mapped to the was_admin output attribute of Deployment manager in the pattern template.

Table 12-58. MFP Server Runtime Deployment (continued).

Parameter	Description
was_admin_password	Optional. When the MobileFirst Server is deployed on WebSphere Application Server full profile, it is mapped to the was_admin_password output attribute of Standalone server in the pattern template. When the MobileFirst Server is deployed on WebSphere Application Server Network Deployment, it is mapped to the was_admin_password output attribute of Deployment manager in the pattern template.
server_farm_mode	Mandatory. Map it to the same attribute of MFP Server Administration.
server_hostname	Mandatory. Host name of the MobileFirst Server. It is mapped to the host output attribute of Liberty profile server, Standalone Server, or Deployment manager.
analytics_ip	Optional. MobileFirst Operational Analytics Node IP address to enable the Analytics capability in the MFP Server Runtime.
analytics_admin_user	Optional. Administrator name of the MobileFirst Operational Analytics server.
analytics_admin_password	Optional. Password of administrator of the MobileFirst Operational Analytics server.

MFP Server Application Adapter Deployment

This script package deploys applications and adapters to the MobileFirst Server. It must be installed after the corresponding MFP Server Runtime Deployment script package that installed the runtime where the application and adapter are to be deployed.

Table 12-59. MFP Server Application Adapter Deployment.

Parameter	Description
artifact_dir	Mandatory. Installation path of application and adapter for deployment. It is mapped to the target_path output attribute of the MobileFirst App component in the pattern template.
admin_context	Mandatory. Must be worklightadmin.
runtime_context	Mandatory. Align with the runtime context root specified in the MFP Server Runtime Deployment component. It is mapped to runtime_contextRoot output attribute of the MFP Server Runtime Deployment component.

Table 12-59. MFP Server Application Adapter Deployment (continued).

Parameter	Description
deployer_user	Mandatory. User account with application and adapter deployment privilege. Set as pattern level parameter in the pattern template.
deployer_password	Mandatory. User password with application and adapter deployment privilege. Set as pattern level parameter in the pattern template.
webserver_ip	Optional. When IBM HTTP servers is deployed in the pattern template, it is mapped to the same output attribute of MFP Server Administration.

MFP IHS Configuration

This script package configures the IBM HTTP Server to work as a load balancer for multiple instances of MobileFirst Server. It must be used with the IBM HTTP servers software component . It must be installed after the IBM HTTP servers software component.

Table 12-60. MFP IHS Configuration.

Parameter	Description
WAS_ROOT	Mandatory. Installation directory of WebSphere Application Server Liberty profile or WebSphere Application Server full profile in the MobileFirst Platform Server node, or installation directory of Deployment manager in the DmgrNode node. In the pattern templates, it is mapped to output attribute install_directory of Liberty profile server, Standalone server, or Deployment manager.
profile_name	Optional. The profile name that contains the files for the WebSphere Application Server runtime environment. In the pattern templates, it is mapped to output attribute dmgr_profile_name of Deployment manager or sa_profile_name of Standalone server.
runtime_contextRoot_list	Mandatory. Runtime context root list that allows IHS to route requests that have matching context roots. Use semicolons (;) to separate the runtime context roots. For example, HelloMobileFirst;HelloWorld Important: It must align with the context root specified in the MFP Server Runtime Deployment. Otherwise, IHS cannot correctly route requests that contain the Runtime context root.

Table 12-60. MFP IHS Configuration (continued).

Parameter	Description
http_port	Mandatory. Open the firewall port in the IHS Server node to allow the HTTP transport from IHS Server to MobileFirst Server. Must be 9080.
https_port	Mandatory. Open the firewall port in the IHS Server node to allow the HTTPS transport from IHS Server to MobileFirst Server. Must be 9443.
server_hostname	Mandatory. Host name of IBM HTTP servers. It is mapped to the host output attribute of IBM HTTP servers in the pattern template.

MFP Analytics

This script package sets up the MobileFirst Analytics server in a WebSphere Application Server full profile or WebSphere Application Server Liberty profile server, and sets up the connection and mapping of Analytics administration security roles to an external TDS or AD server. It must be used with the WebSphere Application Server Liberty profile server or WebSphere Application Server full profile (display name: Standalone server) software component . It must be installed after the Liberty profile or Standalone server software component.

Table 12-61. MFP Analytics.

Parameter	Description
WAS_ROOT	<p>Mandatory.</p> <ul style="list-style-type: none"> • If Analytics is installed on WebSphere Application Server Liberty profile, specify the installation directory of the WebSphere Application Server Liberty profile for Analytics. • If Analytics is installed on WebSphere Application Server full profile, specify the installation directory of the WebSphere Application Server full profile for Analytics.
HEAP_MIN_SIZE	<p>WebSphere Application Server full profile only.</p> <p>Depending on the amount of Analytics data that is generated, more memory is required for more data handling. Set this to allow larger minimum heap size for WebSphere Application Server full profile. Make sure the memory size specified in the Core OS component of MobileFirst Operational Analytics is larger than this. It is recommended to set the same value as HEAP_MAX_SIZE.</p> <p>Default value: 4096 (MB).</p>

Table 12-61. MFP Analytics (continued).

Parameter	Description
HEAP_MAX_SIZE	<p>WebSphere Application Server full profile only.</p> <p>Depending on the amount of Analytics data that is generated, more memory is required for more data handling. Set this to allow larger maximum heap size for WebSphere Application Server full profile. Make sure the memory size specified in the Core OS component of MobileFirst Operational Analytics is larger than this. It is recommended to set the same value as HEAP_MIN_SIZE.</p> <p>Default value: 4096 (MB).</p>
WAS_admin_user	<p>WebSphere Application Server full profile only.</p> <p>WebSphere Application Server full profile admin user for the Analytics server. For WebSphere Application Server Liberty profile, leave the default value unchanged.</p>
WAS_admin_password	<p>WebSphere Application Server full profile only.</p> <p>WebSphere Application Server full profile admin user password for the Analytics server. For WebSphere Application Server Liberty profile, leave the default value unchanged.</p>
admin_user	<p>Mandatory.</p> <ul style="list-style-type: none"> • If LDAP repository not enabled, create a default administration user for MobileFirst Operational Analytics console protection. • If LDAP repository is enabled, specify the user name that has MobileFirst Operational Analytics administration privilege. The value is stored in the LDAP repository.
admin_password	<p>Mandatory.</p> <ul style="list-style-type: none"> • If an LDAP repository is not enabled, specify the password for the default administration user for MobileFirst Operational Analytics console protection. • If an LDAP repository is enabled, specify the admin user password. The value is stored in the LDAP repository.

Table 12-61. MFP Analytics (continued).

Parameter	Description
LDAP_TYPE	<p>(LDAP parameter) Mandatory. LDAP server type of your user registry:</p> <p>None LDAP connection is disabled. When this is set, all the other LDAP parameters are treated as placeholders only.</p> <p>TivoliDirectoryServer Select this if the LDAP repository is an IBM Tivoli Directory Server.</p> <p>ActiveDirectory Select this if the LDAP repository is a Microsoft Active Directory.</p> <p>Default value: None.</p>
LDAP_IP	(LDAP parameter). LDAP server IP address.
LDAP_SSL_PORT	(LDAP parameter) LDAP port for secure connection.
LDAP_PORT	(LDAP parameter) LDAP port for non-secure connection.
BASE_DN	(LDAP parameter) Base DN.
BIND_DN	(LDAP parameter) Bind DN.
BIND_PASSWORD	(LDAP parameter) Bind DN password.
REQUIRE_SSL	<p>(LDAP parameter) Set it to true for secure connection to LDAP server.</p> <ul style="list-style-type: none"> • When it is true, LDAP_SSL_PORT is used and CERT_FILE_PATH is required to locate the certification file of the LDAP server. • When it is false, LDAP_PORT is used. <p>Default value: false.</p>
USER_FILTER	(LDAP parameter) LDAP user filter that searches the existing user registry for users.
GROUP_FILTER	(LDAP parameter) LDAP group filter that searches the existing user registry for groups.
LDAP_REPOSITORY_NAME	(LDAP parameter) LDAP server name.
CERT_FILE_PATH	(LDAP parameter) Target path of the uploaded LDAP server certification. It is mandatory when REQUIRE_SSL is set to true.
worklightadmin	<p>(LDAP parameter) Admin role for MobileFirst Server:</p> <p>None No user.</p> <p>AllAuthenticatedUsers Authenticated users</p> <p>Everyone All users.</p> <p>Default value: None.</p>

Table 12-61. MFP Analytics (continued).

Parameter	Description
worklightdeployer	(LDAP parameter) Deployer role for MobileFirst Server: None No user. AllAuthenticatedUsers Authenticated users Everyone All users. Default value: None.
worklightmonitor	(LDAP parameter) Monitor role for MobileFirst Server: None No user. AllAuthenticatedUsers Authenticated users Everyone All users. Default value: None.
worklightoperator	(LDAP parameter) Operator role for MobileFirst Server: None No user. AllAuthenticatedUsers Authenticated users Everyone All users. Default value: None.

MFP Open Firewalls for WAS

This script package is only applicable for Custom nodes in the MobileFirst Platform (WAS ND) pattern template. Its purpose is to open the necessary firewall ports of the Custom nodes that host the MobileFirst Administration Services and runtime. As well as defining some WebSphere Application Server predefined ports, you need to specify the other ports for connecting to the DB2 server and the LDAP server.

Table 12-62. MFP Open Firewalls for WAS.

Parameter	Description
WAS_ROOT	Mandatory. Installation directory of WebSphere Application Server Network Deployment Custom nodes in the CustomNode node. In the pattern templates, it is mapped to output attribute install_directory of Custom nodes server.

Table 12-62. MFP Open Firewalls for WAS (continued).

Parameter	Description
profile_name	Mandatory. The profile name that contains the files for the WebSphere Application Server runtime environment. In the pattern templates, it is mapped to output attribute cn_profile_name of Custom nodes.
WAS_admin_user	Mandatory. It is mapped to the was_admin output attribute of Custom nodes in the pattern template.
Ports	Mandatory. Other ports that need to be opened for connecting to DB2 server and LDAP server (optional). Port values can be separated by semicolons; for example, '50000;636' Default value: 50000.

Upgrading IBM MobileFirst Platform Application Pattern

To upgrade IBM MobileFirst Platform Application Pattern, upload the .tgz file that contains the latest updates.

Procedure

1. Log into IBM PureApplication System with an account that is allowed to upload new system plugins.
2. Navigate to **Workload Console > Cloud > System Plug-ins**.
3. Upload the IBM MobileFirst Platform Application Pattern .tgz file that contains the updates.
4. Enable the plugins you have uploaded.
5. Redeploy the pattern.

Administering MobileFirst applications

Run and maintain MobileFirst applications in production.

IBM MobileFirst Platform Foundation provides several ways to administer MobileFirst applications in development or in production. MobileFirst Operations Console is the main tool with which you can monitor all deployed MobileFirst applications from a centralized web-based console.

The main operations that you can perform through MobileFirst Operations Console are:

- Deploy mobile applications and adapters to MobileFirst Server.
- Manage application versions to deploy new versions or remotely disable old versions.
- Manage mobile devices and users to manage access to a specific device or access for a specific user to an application.
- Display notification messages on application startup.
- Monitor push notification services.
- Collect client-side logs for specific applications installed on a specific device.

Not every kind of administration user can perform every administration operation. MobileFirst Operations Console, and all administration tools, have four different roles defined for administration of MobileFirst applications. The following MobileFirst administration roles are defined:

Monitor

In this role, a user can monitor deployed MobileFirst projects and deployed artifacts. This role is read-only.

Operator

An Operator can perform all mobile application management operations, but cannot add or remove application versions or adapters.

Deployer

In this role, a user can perform the same operations as the Operator, but can also deploy applications and adapters.

Administrator

In this role, a user can perform all application administration operations.

Note: In IBM MobileFirst Platform Foundation V7.1.0, the predefined MobileFirst Operations Console that is deployed to the embedded Liberty server has the following authentication configuration:

- Role "worklightadmin", user "admin", password "admin"
- Role "worklightdeployer", user "deployer", password: "demo"
- Role "worklightmonitor", user "monitor", password: "demo"
- Role "worklightoperator", user "operator", password: "demo"

You must map the different administrators to these roles when you configure MobileFirst Server during installation of MobileFirst Operations Console. See "Installing the MobileFirst Server administration" on page 6-58.

MobileFirst Operations Console can be used to administer several runtime environments, which are issued from several independent MobileFirst projects and are deployed to the same application server or cluster. For more information about deploying a MobileFirst project, see “Deploying an application from development to a test or production environment” on page 12-2.

MobileFirst Operations Console is not the only way to administer MobileFirst applications. IBM MobileFirst Platform Foundation also provides other tools to incorporate administration operations into your build and deployment process.

A set of REST services is available to perform administration operations. For API reference documentation of these services, see “REST API Administration Services” on page 11-9.

With this set of REST services, you can perform the same operations that you can do in MobileFirst Operations Console. You can manage applications, adapters, and, for example, upload a new version of an application or disable an old version.

MobileFirst applications can also be administered by using Ant tasks or with the `wladmin` command line tool. See “Administering MobileFirst applications through Ant” on page 13-12 or “Administering MobileFirst applications through the command line” on page 13-37.

Similar to the web-based console, the REST services, Ant tasks, and command line tools are secured and require you to provide your administrator credentials, which enable you to perform operations within your specified role.

Administering MobileFirst applications with MobileFirst Operations Console

You can administer MobileFirst applications through the MobileFirst Operations Console by deploying new versions of mobile and desktop apps, by locking apps or denying access, or by displaying notification messages.

In V6.1.0 and earlier versions of the product, MobileFirst Operations Console was deployed in the project WAR file. If two project WAR files were deployed, each one had its own administration console. Starting with V6.2.0, MobileFirst Operations Console is deployed separately and can administer all runtime environments in the same server.

You can start the console by entering one of the following URLs:

- Secure mode for production or test: `https://hostname:secure_port/worklightconsole`
- Development: `http://server_name:port/worklightconsole`

In either case, the list of all runtime environments is always present. Select the runtime environment that you want to administer to access the functions of the MobileFirst Operations Console.

Use the MobileFirst Operations Console to manage your applications.

- To see all the applications that are installed and all the device platforms that are supported.
- To disable specific application versions on specific platforms and force users to upgrade before they continue to use the application. When you implement direct

updates to mobile devices and desktop apps, software updates are pushed directly to application web resources or users' desktops

- To send out notifications to application users and to manage push notifications from defined event sources to applications.
- To install and manage adapters that are used by applications, and to inspect aggregated usage statistics from MobileFirst Server.
- To lock apps to prevent them from being mistakenly updated and to prevent the redeployment of web resources for a particular application.
- To display a notification message on app start to inform users without causing the application to exit.

Note: Deleting an application from MobileFirst Operations Console will remove all push subscriptions on that application as well.

For an easy way to upgrade an application, see "Upgrading a mobile application in MobileFirst Server and the Application Center" on page 13-98.

Locking an application

You can prevent developers or administrators from mistakenly updating an application, by locking it in MobileFirst Operations Console.

About this task

You can lock applications for Android, iPhone, iPad, and Windows Phone.

Procedure

Locking an application version for a specific mobile environment

1. From the first page of MobileFirst Operations Console, select the application name.
2. Select **Lock this version** for the application version in the relevant environment.

Remotely disabling application connectivity

You can use the Remote Disable procedure to deny a user's access to a certain application version due to phase-out policy or due to security issues encountered in the application.

Before you begin

If you need to use the Remote Disable feature with servers and clusters that experience heavy loads, consider enabling the Remote Disable cache. Enabling the cache can improve performance by reducing how frequently the database is checked to see if an app has been remotely disabled. By default, the cache is disabled. To enable and configure the cache, add the following lines to the MobileFirst project `worklight.properties` file:

- `wl.remoteDisable.cache.enabled=true`
- `wl.remoteDisable.cache.refreshIntervalInSeconds=1`

The refresh interval determines how long (measured in seconds) values are kept in the cache before they are refreshed from the database. If you increase the interval, performance is improved as a result of fewer connections being made to the database, but you increase the duration before the remote disable state comes into effect. For example, if your infrastructure contains a cluster of four MobileFirst

Server and you set `wl.remoteDisable.cache.refreshIntervalInSeconds=1`, the database is accessed 4 times per second to check the remote disable state.

Note: If code that uses the Remote Disable feature accesses a resource that is protected by OAuth authentication, and the client has a valid token, the MobileFirst Server is not called. As a result, the server does not check whether a specific application is disabled. The MobileFirst Server is called when the token expires or when the Remote Disable realm inside the token expires. When the realm expires, the Remote Disable authenticator is invoked and the server checks whether the specific application version is disabled. For more information about token expiration, see “OAuth-based tokens” on page 8-534.

About this task

Using the MobileFirst Operations Console, you can disable access to a specific version of a specific application for a specific mobile environment and provide a custom message to the user.

Procedure

1. To use this Remote Disable feature, from the first page of MobileFirst Operations Console, click the application name and change the access of the application version that must be disabled from **Active** to **Access Disabled**.
2. Add a custom message as shown in the following text:
This version is no longer supported. Please upgrade to the next version.
You can also specify a URL for the new version of the application (usually in the appropriate public or private app store). For some environments, the Application Center provides a URL to access the Details view of an application version directly. See “Application properties” on page 13-94.
3. Click **Save**.

When users run an application that is Remotely Disabled, they receive a text message about the access denial. They can either close the dialog and continue working offline, that is, without access to the MobileFirst Server, or they can upgrade to the latest version of the application. Closing the dialog keeps the application running, but any application interaction that requires server connectivity causes the dialog to be displayed again.

Modifying the behavior of the remote disable operation

As noted above, the *default* dialog that is displayed to a user when an application is remotely disabled contains two buttons, **Get new version**, and **Close**. Clicking **Close** closes the dialog, but allows the user to continue working offline, with no connection to the MobileFirst Server.

Note: The actual text on the two buttons is customizable, and can be overridden in the `message.properties` file.

In older versions of IBM MobileFirst Platform Foundation, when you disabled an application using the MobileFirst Operations Console, the default behavior was to completely disable or end it, such that the application would not function, even in offline mode.

There is a way to modify the default behavior of the Remote Disable feature to completely disable an application if there is a need to do so (such as a severe security flaw).

- Add a new Boolean attribute to your `initOptions.js` file, named **showCloseOnRemoteDisableDenial**.
- If this attribute is missing or is set to **true**, the Remote Disable notification displays the default behavior described earlier.
- If this attribute is set to **false** (that is, "Do not show the **Close** button on the dialog"), the behavior is as follows:
 - If you disable the application on the MobileFirst Operations Console and specify a link to the new version, the dialog displays only a single button, the **Get new version** button. The **Close** button is not shown. The user has no choice but to update the application, and this preserves the older behavior of forcing the user to exit the application.
 - If you disable the application and do not specify a link to the new version, the dialog again displays only a single button, but in this case it displays the **Close** button.

Related tasks:

"Defining administrator messages from MobileFirst Operations Console in multiple languages"

You can set the deny and notification messages from IBM MobileFirst Platform Operations Console in multiple languages.

Displaying a notification message on application startup

You can set a notification message that is displayed for the user when the application starts, but does not cause the application to exit.

About this task

You can use this type of message to notify application users of temporary situations, such as planned service downtime.

Procedure

1. From the first page of MobileFirst Operations Console, click the relevant application name and change the access of the application version from **Active** to **Active, Notifying**.
2. Add a custom message, such as the following text:
Server downtime is planned for Saturday 4am to 6am.
3. Click **Save**.

Results

The message is displayed the next time that the app is started or resumed. The message is displayed only once.

Related tasks:

"Defining administrator messages from MobileFirst Operations Console in multiple languages"

You can set the deny and notification messages from IBM MobileFirst Platform Operations Console in multiple languages.

Defining administrator messages from MobileFirst Operations Console in multiple languages

You can set the deny and notification messages from IBM MobileFirst Platform Operations Console in multiple languages.

About this task

The messages are sent based on the locale of the device, and must comply with the ISO 639-1 and ISO 3166-2 standards.

Procedure

To add the deny and notification messages for multiple languages, follow these steps.

1. From the first page of MobileFirst Operations Console, click the relevant application name and select the access **Active**, **Notifying** or **Access Disabled**.
2. In the application access section, click “Edit.. button”. The label “Supported locales” is followed by the number of available locales. For example, “Supported locales (7)” indicates that seven locales are available for the messages that you want to add.

In the Messages for multiple languages window, you can upload a CSV file. Such a CSV file must define a series of lines. Each line contains a locale code, such as “fr-FR” for French (France) or “en” for English, a comma, and the corresponding message text. The specified locale codes must comply with the ISO 639-1 and ISO 3166-2 standards. The first line with an empty locale defines the default message. If you did not define an alternative, or if the locale from the client matches none of the uploaded locales, this default message is displayed.

Note: To create a CSV file, you must use an editor that supports UTF-8 encoding, such as Notepad.

The following figure shows an example of a CSV file:

```
,your application is disabled (default)
en,Your application is disabled
en-US,Your application in disabled in US
en-GB,Your application is disabled in GB
ru,аппликация была выключена
fr,votre application est désactivée
he,האפליקציה חסומה
ja,あなたのアプリケーションが無効になっていた
```

Figure 13-1. Sample CSV file

3. Click **Upload CSV** to browse and select the CSV file that you want to upload. In “List of supported locales”, you can see the locales and translated messages that you uploaded.

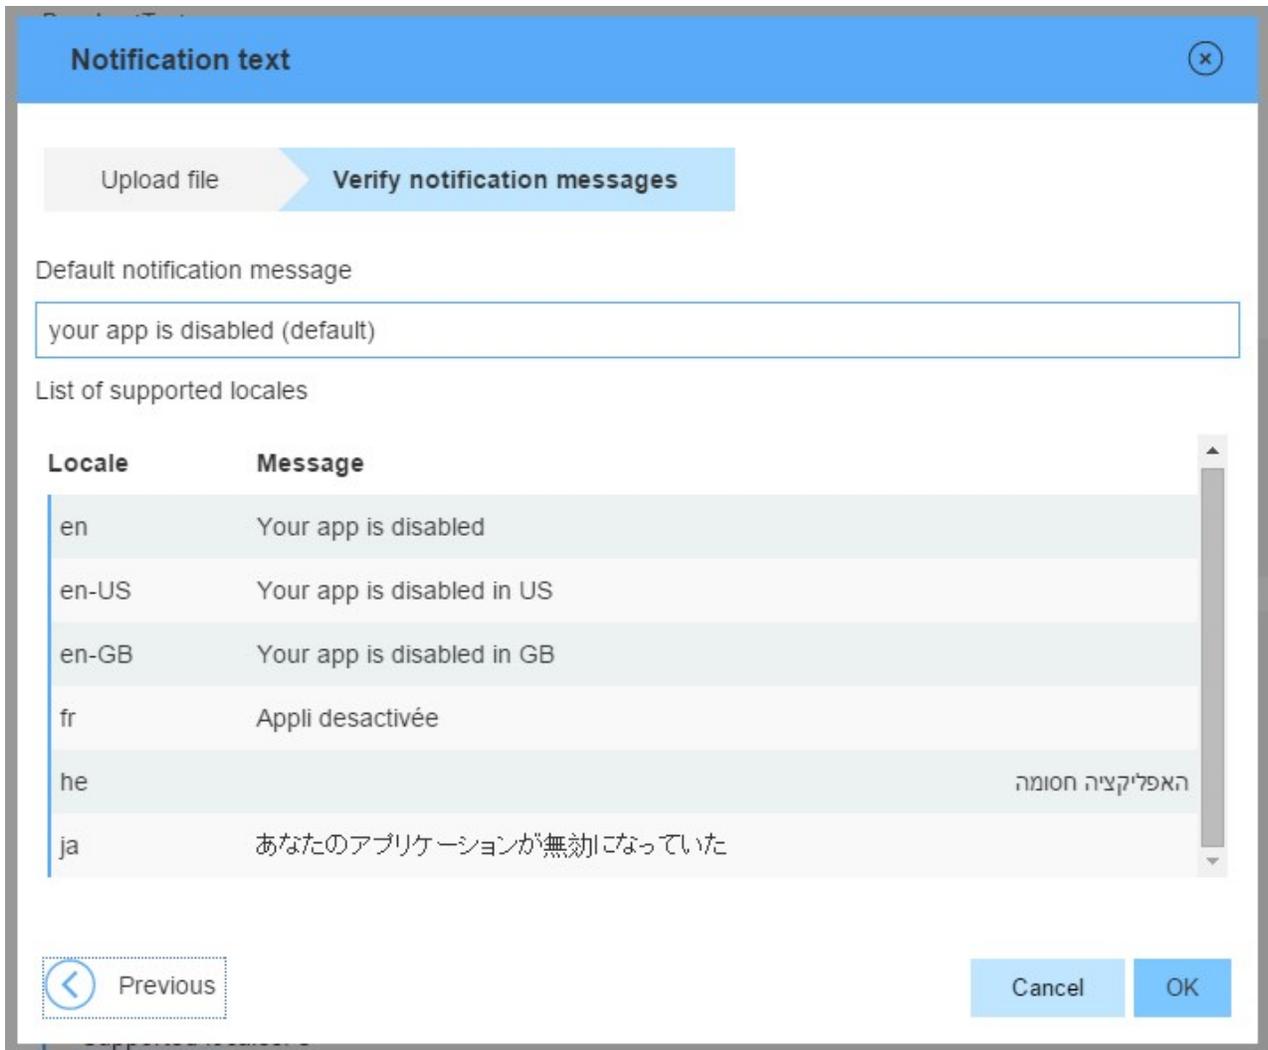

Figure 13-2. Verifying locales and notification messages in CSV file

4. Process the uploaded messages:
 - To validate the messages that you uploaded, click **OK**.
 - To discard the changes and return to the console, click **CANCEL**.

Note: If you modified the default message, then the new default message shows.

5. To clear “List of supported locales”, click **Clear**. This action does not clear the default message.
6. Click **Save** to save the default message and the multilingual messages.

The following figure displays the mobile device of the user, which shows the localized message. The title and the button caption are in English. If the locale does not supply any messages, the default message is returned.

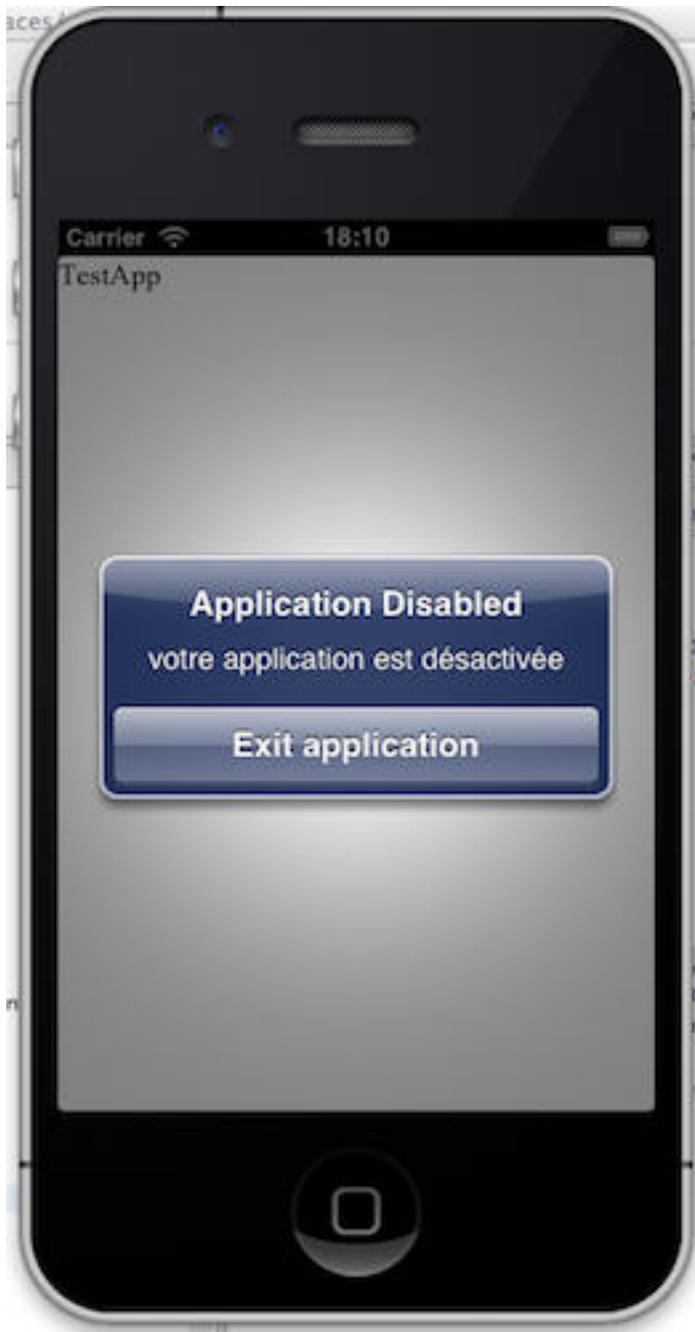

Figure 13-3. Application Disabled message

Application status and token licensing

You must manually restore the correct application status in MobileFirst Operations Console after Blocked status because of insufficient tokens.

If you use token licensing and you no longer have enough license tokens for an application, the application status of all versions of the application changes to Blocked. You are no longer able to change the status of any version of the application. The following message is displayed in MobileFirst Operations Console:

The application got blocked because its license expired

If later enough tokens to run the application become free or your organization purchases more tokens, the following message is displayed in MobileFirst Operations Console:

The application got blocked because its license expired but a license is available now

The display status is still Blocked. You must restore the correct current status manually from memory or your own records by editing the **Status** field. IBM MobileFirst Platform Foundation does not manage the display of Blocked status in MobileFirst Operations Console of an application that was blocked because of insufficient license tokens. You are responsible for restoring such a blocked application to a real status that can be displayed through MobileFirst Operations Console.

Error log of operations on runtime environments

Use the error log to access failed management operations initiated from MobileFirst Operations Console or the command line on the selected runtime environment, and to see the effect of the failure on the servers.

When a transaction fails, the status bar displays a notification of the error and shows a link to the error log. Use the error log to have more detail about the error, for example, the status of each server with a specific error message, or to have a history of errors. The error log shows the most recent operation first.

You access the error log by clicking **Error log** of a runtime environment in MobileFirst Operations Console.

Expand the row that refers to the failed operation to access more information about the current state of each server. To access the complete log, download the log by clicking **Download log**.

Audit log of administration operations

In the MobileFirst Operations Console, you can refer to an audit log of administration operations.

MobileFirst Operations Console provides access to an audit log for login, logout, and all administration operations, such as deploying apps or adapters or locking apps. The audit log can be disabled by setting the `ibm.worklight.admin.audit` Java Naming and Directory Interface (JNDI) property on the web application of the MobileFirst Administration service (`worklightadmin.war`) to false.

To access the audit log, click the user name in the header bar and select **About**. Click **Additional support information** and then **Download audit log**.

Each record in the audit log has the following fields, which are separated by a vertical bar (|); see Figure 13-5 on page 13-12.

Table 13-1. Fields in audit log records

Field name	Description
Timestamp	Date and time when the record was created.
Type	The type of operation. See list of operation types for the possible values.
User	The username of the user who is signed in.
Outcome	The outcome of the operation; possible values are SUCCESS, ERROR, PENDING.
ErrorCode	If the outcome is ERROR, ErrorCode indicates what the error is.

Table 13-1. Fields in audit log records (continued)

Field name	Description
Runtime	Name of the MobileFirst project that is associated with the operation.

The following list shows the possible values of **Type** of operation.

- Login
- Logout
- AdapterDeployment
- AdapterDeletion
- ApplicationDeployment
- ApplicationDeletion
- ApplicationLockChange
- ApplicationAuthenticityCheckRuleChange
- ApplicationAccessRuleChange
- ApplicationVersionDeletion
- add config profile

Figure 13-5. Sample audit log of MobileFirst administration operations

Administering MobileFirst applications through Ant

You can administer MobileFirst applications through the **wladm** Ant task.

Comparison with other facilities

You can execute administration operations with IBM MobileFirst Platform Foundation in the following ways:

- The MobileFirst Operations Console, which is interactive.
- The **wladm** Ant task.
- The **wladm** program.
- The MobileFirst administration REST services.

The **wladm** Ant task, **wladm** program, and REST services are useful for automated or unattended execution of operations, such as eliminating operator errors in repetitive operations or operating outside the operator's normal working hours.

The **wladm** Ant task and the **wladm** program are simpler to use and have better error reporting than the REST services. The advantage of the **wladm** Ant task over the **wladm** program is that it is platform independent and easier to integrate when integration with Ant is already available.

Prerequisites

Apache Ant is required to run the **wladm** task. For information about the minimum supported version of Ant, see “System requirements” on page 2-15.

For convenience, Apache Ant 1.8.4 is included in MobileFirst Server. In the *product_install_dir/shortcuts/* directory, the following scripts are provided.

- ant for UNIX / Linux
- ant.bat for Windows

These scripts are ready to run, which means that they do not require specific environment variables. If the environment variable `JAVA_HOME` is set, the scripts accept it.

You can use the **wladm** Ant task on a different computer than the one on which you installed MobileFirst Server.

- Copy the file *product_install_dir/WorklightServer/worklight-ant-deployer.jar* to the computer.
- Make sure that a supported version of Apache Ant and a Java runtime environment are installed on the computer.

To use the **wladm** Ant task, add this initialization command to the Ant script:

```
<taskdef resource="com/worklight/ant/deployers/antlib.xml">
  <classpath>
    <pathelement location="product_install_dir/WorklightServer/worklight-ant-deployer.jar"/>
  </classpath>
</taskdef>
```

Other initialization commands that refer to the same *worklight-ant-deployer.jar* file are redundant because the initialization by *defaults.properties* is also implicitly done by *antlib.xml*. Here is one example of a redundant initialization command:

```
<taskdef resource="com/worklight/ant/defaults.properties">
  <classpath>
    <pathelement location="product_install_dir/WorklightServer/worklight-ant-deployer.jar"/>
  </classpath>
</taskdef>
```

Calling the wladm Ant task

You can use the **wladm** Ant task and its associated commands to administer MobileFirst applications.

Syntax

Call the **wladm** Ant task as follows:

```
<wladm url=... user=... password=...|passwordfile=... [secure=...]>
  some commands
</wladm>
```

Attributes

The **wladm** Ant task has the following attributes:

Table 13-2. List of <wladm> attributes.

Attribute	Description	Required	Default
url	The base URL of the MobileFirst web application for administration services	Yes	
secure	Whether to avoid operations with security risks	No	true
user	The user name for accessing the MobileFirst administration services	Yes	
password	The password for the user	Either one is required	
passwordfile	The file that contains the password for the user		
timeout	Timeout for the entire REST service access, in seconds	No	
connectTimeout	Timeout for establishing a network connection, in seconds	No	
socketTimeout	Timeout for detecting the loss of a network connection, in seconds	No	
connectionRequestTimeout	Timeout for obtaining an entry from a connection request pool, in seconds	No	

url

The base URL preferably uses the HTTPS protocol. For example, if you use default ports and context roots, use the following URL.

- For WebSphere Application Server: `https://server:9443/worklightadmin`
- For Tomcat: `https://server:8443/worklightadmin`

secure The default value is true. Setting `secure="false"` might have the following effects:

- The user and password might be transmitted in an unsecured way, possibly even through unencrypted HTTP.
- The server's SSL certificates are accepted even if self-signed or if they were created for a different host name than the specified server's host name.

password

Specify the password either in the Ant script, through the **password** attribute, or in a separate file that you pass through the **passwordfile** attribute. The password is sensitive information and therefore needs to be protected. You must prevent other users on the same computer from knowing this password. To secure the password, before you enter the password into a file, remove the read permissions of the file for users other than yourself. For example, you can use one of the following commands:

- On UNIX: `chmod 600 adminpassword.txt`
- On Windows: `cacls adminpassword.txt /P Administrators:F %USERDOMAIN%\%USERNAME%:F`

Additionally, you might want to obfuscate the password to hide it from an occasional glimpse. To do so, use the **wladm config password** command to store the obfuscated password in a configuration file. Then, you can copy and paste the obfuscated password to the Ant script or to the password file.

The **wladm** call contains commands that are encoded in inner elements. These commands are executed in the order in which they are listed. If one of the commands fails, the remaining commands are not executed, and the **wladm** call fails.

Elements

You can use the following elements in **wladm** calls:

Table 13-3. Elements that can be used in <wladm>.

Element	Description	Count
show-info	Shows user and configuration information	0..∞
show-versions	Shows versions information	0..∞
list-runtimes	Lists the runtimes	0..∞
show-runtime	Shows information about a runtime	0..∞
delete-runtime	Deletes a runtime	0..∞
list-adapters	Lists the adapters	0..∞
deploy-adapter	Deploys an adapter	0..∞
show-adapter	Shows information about an adapter	0..∞
delete-adapter	Deletes an adapter	0..∞
adapter	Other operations on an adapter	0..∞
list-apps	Lists the apps	0..∞
deploy-app	Deploys an app	0..∞
show-app	Shows information about an app	0..∞
delete-app	Deletes an app	0..∞
delete-app-version	Delete a version of an app	0..∞
app-version	Other operations on an app	0..∞
list-beacons	Lists the beacons	0..∞
set-beacon	Specifies information about a beacon	0..∞
show-beacon	Shows information about a beacon	0..∞
remove-beacon	Removes information about a beacon	0..∞
list-beacon-triggers	Lists the beacon triggers	0..∞
set-beacon-trigger	Specifies a beacon trigger	0..∞
show-beacon-trigger	Shows a beacon trigger	0..∞
delete-beacon-trigger	Deletes a beacon trigger	0..∞
list-beacon-trigger-associations	Lists the associations between beacons and beacon triggers	0..∞

Table 13-3. Elements that can be used in <wladm> (continued).

Element	Description	Count
set-beacon-trigger-association	Specifies an association between a beacon and a beacon trigger	0..∞
show-beacon-trigger-association	Shows the association between a beacon and a beacon trigger	0..∞
delete-beacon-trigger-association	Deletes the association between a beacon and a beacon trigger	0..∞
list-devices	Lists the devices	0..∞
remove-device	Removes a device	0..∞
device	Other operations for a device	0..∞

XML Format

The output of most commands is in XML, and the input to specific commands, such as <set-accessrule>, is in XML too. You can find the XML schemas of these XML formats in the *product_install_dir/WorklightServer/wladm-schemas/* directory. The commands that receive an XML response from the server verify that this response conforms to the specific schema. You can disable this check by specifying the attribute `xmlvalidation="none"`.

Output character set

Normal output from the **wladm** Ant task is encoded in the encoding format of the current locale. On Windows, this encoding format is the so-called "ANSI code page". The effects are as follows:

- Characters outside of this character set are converted to question marks when they are output.
- When the output goes to a Windows command prompt window (`cmd.exe`), non-ASCII characters are incorrectly displayed because such windows assume characters to be encoded in the so-called "OEM code page".

To work around this limitation:

- On operating systems other than Windows, use a locale whose encoding is UTF-8. This locale is the default locale on Red Hat Linux and OS X. Many other operating systems have the `en_US.UTF-8` locale.
- Or use the attribute `output="some file name"` to redirect the output of a **wladm** command to a file.

Commands for adapters

When you call the **wladm** Ant task, you can include various commands for adapters.

The list-adapters command

The **list-adapters** command returns a list of the adapters deployed for a given runtime. It has the following attributes:

Table 13-4. list-adapters command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Example

```
<list-adapters runtime="worklight"/>
```

This command is based on the “Adapters (GET)” on page 11-21 REST service.

The deploy-adapter command

The **deploy-adapter** command deploys an adapter in a runtime. It has the following attributes:

Table 13-5. deploy-adapter command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
file	Binary adapter file (.adapter).	Yes	Not available

Example

```
<deploy-adapter runtime="worklight" file="MyAdapter.adapter"/>
```

This command is based on the “Adapter (POST)” on page 11-18 REST service.

The show-adapter command

The **show-adapter** command shows details about an adapter. It has the following attributes:

Table 13-6. show-adapter command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
name	Name of an adapter.	Yes	Not available
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Example

```
<show-adapter runtime="worklight" name="MyAdapter"/>
```

This command is based on the “Adapter (GET)” on page 11-13 REST service.

The delete-adapter command

The **delete-adapter** command removes (undeploys) an adapter from a runtime. It has the following attributes:

Table 13-7. **delete-adapter** command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
name	Name of an adapter.	Yes	Not available

Example

```
<delete-adapter runtime="worklight" name="MyAdapter"/>
```

This command is based on the “Adapter (DELETE)” on page 11-10 REST service.

The adapter command group

The **adapter** command group has the following attributes:

Table 13-8. **adapter** command group attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
name	Name of an adapter.	Yes	Not available

The command supports the following elements:

Table 13-9. **adapter** command group elements

Element	Description	Count
get-binary	Gets the binary data.	0..∞

The get-binary command

The **get-binary** command inside an <adapter> element returns the binary adapter file. It has the following attributes:

Table 13-10. **get-binary** command attributes

Attribute	Description	Required	Default
tofile	Name of the output file.	Yes	Not available

Example

```
<adapter runtime="worklight" name="MyAdapter">  
  <get-binary tofile="/tmp/MyAdapter.adapter"/>  
</adapter>
```

This command is based on the “Adapter Binary (GET, HEAD)” on page 11-9 REST service.

Commands for apps

When you call the `wladm` Ant task, you can include various commands for apps.

The `enable-extended-authenticity` command

The `enable-extended-authenticity` command creates a `.wlap` file that is based on an original `.wlap` file but has extended authenticity checking enabled. It has the following attributes:

Table 13-11. The `enable-extended-authenticity` command's attributes

Attribute	Description	Required	Default
<code>srcwlapfile</code>	Original binary app file (.wlap, not .apk or .ipa)	Yes	Not available
<code>devicefile</code>	Binary mobile app file (.apk, .appx, .ipa, or .xap)	Yes	Not available
<code>destwlapfile</code>	Output binary app file (.wlap, not .apk or .ipa)	Yes	Not available

Example

```
<enable-extended-authenticity srcwlapfile="myapp-iphone-1.0.wlap"  
  devicefile="MyApp.ipa"  
  destwlapfile="myapp-iphone-1.0.extauth.wlap"/>
```

Note: This command operates locally, without connecting to the server.

For more information about enabling extended app authenticity checking, see “Configuring extended app authenticity checking” on page 12-56.

The `list-apps` command

The `list-apps` command returns a list of the apps that are deployed in a runtime. It has the following attributes:

Table 13-12. The `list-apps` command's attributes

Attribute	Description	Required	Default
<code>runtime</code>	Name of the runtime web application / MobileFirst project.	Yes	Not available
<code>output</code>	Name of output file.	No	
<code>outputproperty</code>	Name of Ant property for the output.	No	

Example

```
<list-apps runtime="worklight"/>
```

This command is based on the “Applications (GET)” on page 11-56 REST service.

The `deploy-app` command

The `deploy-app` command deploys an app (possibly with multiple environments) in a run time. It has the following attributes:

Table 13-13. The `deploy-app` command's attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
file	Binary app file (.wlapp, not .apk, or .ipa).	Yes	Not available

Example

```
<deploy-app runtime="worklight" file="MyApp-all.wlapp"/>
```

This command is based on the “Application (POST)” on page 11-52 REST service.

The `show-app` command

The **show-app** command returns a list of the apps that are deployed in a runtime. It has the following attributes:

Table 13-14. The `show-app` command's attributes

Attribute	Description	Required	Default
runtime	Name of the run time web application / MobileFirst project.	Yes	Not available
name	Name of an app.	Yes	Not available
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Example

```
<show-app runtime="worklight" name="MyApp"/>
```

This command is based on the “Application (GET)” on page 11-48 REST service.

The `delete-app` command

The **delete-app** command removes (undeploys) an app, with all its app versions, for all environments for which it was deployed, from a runtime. It has the following attributes:

Table 13-15. The `delete-app` command's attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
name	Name of an app.	Yes	Not available

Example

```
<delete-app runtime="worklight" name="MyApp"/>
```

This command is based on the “Application (DELETE)” on page 11-45 REST service.

The delete-app-version command

The **delete-app-version** command removes (undeploys) an app version from a runtime. It has the following attributes:

Table 13-16. The delete-app-version command's attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
name	Name of an app.	Yes	Not available
environment	Mobile platform.	Yes	Not available
version	Version of the app.	Yes	Not available

Note: Deleting an application from MobileFirst Operations Console will remove all push subscriptions on that application as well.

Example

```
<delete-app-version runtime="worklight" name="MyApp" environment="iphone"
version="1.1"/>
```

This command is based on the “App Version (DELETE)” on page 11-38 REST service.

The app-version command group

The **app-version** command group has the following attributes:

Table 13-17. The app-version command's group attributes

Attribute	Description	Required	Default
runtime	Name of the run time web application / MobileFirst project.	Yes	Not available
name	Name of an app.	Yes	Not available
environment	Mobile platform.	Yes	Not available
version	Version of the app.	Yes	Not available

It supports the following elements:

Table 13-18. The app-version command's group elements

Element	Description	Count
get-binary	Gets the binary data.	0..∞
get-accessrule	Gets the access rule.	0..∞
set-accessrule	Changes the access rule.	0..∞
get-authenticitycheckrule	Gets the authenticity check rule.	0..∞

Table 13-18. The `app-version` command's group elements (continued)

Element	Description	Count
<code>set-authenticitycheckrule</code>	Changes the authenticity check rule.	0..∞
<code>get-lock</code>	Gets the lock state.	0..∞
<code>set-lock</code>	Changes the lock state.	0..∞

The `get-binary` command

The `get-binary` command, inside an `<app-version>` element, returns the binary file `wlapp` for a version of an app. It has the following attributes:

Table 13-19. The `get-binary` command's attributes

Attribute	Description	Required	Default
<code>tofile</code>	Name of the output file.	Yes	Not available

Example

```
<app-version runtime="worklight" name="MyApp" environment="iphone" version="1.1">
  <get-binary tofile="/tmp/MyApp.wlapp"/>
</app-version>
```

This command is based on the “Application Binary (GET, HEAD)” on page 11-43 REST service.

The `get-accessrule` command

The `get-accessrule` command returns the access rule for an app version. It has the following attributes:

Table 13-20. The `get-accessrule` command's attributes

Attribute	Description	Required	Default
<code>output</code>	Name of a file in which to store the output.	No	Not applicable
<code>outputproperty</code>	Name of an Ant property in which to store the output.	No	Not applicable

Example

```
<app-version runtime="worklight" name="MyApp" environment="iphone" version="1.1">
  <get-accessrule output="/tmp/MyApp-accessrule.xml"/>
</app-version>
```

This command is based on the “Application (GET)” on page 11-48 REST service.

The `set-accessrule` command

The `set-accessrule` command changes the access rule for an app version. It has the following attributes:

Table 13-21. The **set-accessrule** command's attributes

Attribute	Description	Required	Default
file	Name of the input file.	Yes	Not available

Example

```
<app-version runtime="worklight" name="MyApp" environment="iphone" version="1.1">
  <set-accessrule file="/tmp/new-accessrule.xml"/>
</app-version>
```

This command is based on the “App Version Access Rule (PUT)” on page 11-34 REST service.

The **get-authenticitycheckrule** command

The **get-authenticitycheckrule** command returns the authenticity check rule for an app version. This command is no longer supported with servers of IBM MobileFirst Platform Foundation V7.1.0 or later. This command is only available with V6.2.0 and V6.3.0. It has the following attributes:

Table 13-22. The **get-authenticitycheckrule** command's attributes

Attribute	Description	Required	Default
output	Name of a file in which to store the output.	No	
outputproperty	Name of an Ant property in which to store the output.	No	

Example

```
<app-version runtime="worklight" name="MyApp" environment="iphone" version="1.1">
  <get-authenticitycheckrule output="/tmp/MyApp-authenticitycheckrule.txt"/>
</app-version>
```

This command is based on the “Application (GET)” on page 11-48 REST service.

The **set-authenticitycheckrule** command

The **set-authenticitycheckrule** command changes the authenticity check rule for an app version. This command is no longer supported with servers of IBM MobileFirst Platform Foundation V7.1.0 or later. This command is only available with V6.2.0 and V6.3.0. It has the following attributes:

Table 13-23. The **set-authenticitycheckrule** command's attributes

Attribute	Description	Required	Default
action	Action to perform for authenticity checking.	Yes	Not available

The possible actions are:

- **DISABLED:** Authenticity is not checked.
- **IGNORED:** Authenticity is checked, but not enforced. If it fails, only a warning is given and the session is authorized.
- **ENABLED:** Authenticity is checked and enforced.

Example

```
<app-version runtime="worklight" name="MyApp" environment="iphone" version="1.1">  
  <set-authenticitycheckrule action="enabled"/>  
</app-version>
```

The get-lock command

The **get-lock** command returns information about whether an app version is locked or unlocked. It has the following attributes:

Table 13-24. The **get-lock** command's attributes

Attribute	Description	Required	Default
output	Name of a file in which to store the output.	No	
outputproperty	Name of an Ant property in which to store the output.	No	

Example

```
<app-version runtime="worklight" name="MyApp" environment="iphone" version="1.1">  
  <get-lock output="/tmp/MyApp-lock.txt"/>  
</app-version>
```

This command is based on the “Application (GET)” on page 11-48 REST service.

The set-lock command

The **set-lock** command sets an app version to locked or unlocked state. It has the following attributes:

Table 13-25. The **set-lock** command's attributes

Attribute	Description	Required	Default
lock	New lock state.	Yes	Not available

The possible lock values are true and false.

Example

```
<app-version runtime="worklight" name="MyApp" environment="iphone" version="1.1">  
  <set-lock lock="true"/>  
</app-version>
```

This command is based on the “App Version Lock (PUT)” on page 11-42 REST service.

Commands for beacons

When you call the **wladm** Ant task, you can include various commands for the beacons and beacon triggers. A beacon is a piece of information that is associated with an iBeacon. A beacon trigger is an action that a mobile device runs in relation to an iBeacon, when there is an association between the beacon and the beacon trigger.

The list-beacons command

The **list-beacons** command returns a list of the beacons that match a given UUID and optionally, a given major and minor number. It has the following attributes.

Table 13-26. `list-beacons` command attributes

Attribute	Description	Required	Default
uuid	UUID (32 hex digits) of the beacons to search for.	Only if major or minor are specified	wild
major	Major number of the beacons to search for.	No	wild
minor	Minor number of the beacons to search for.	No	wild
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Example:

```
<list-beacons uuid="496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6"/>
```

This command is based on the “Beacons (GET)” on page 11-90 REST service.

The `set-beacon` command

The `set-beacon` command specifies or updates information about a beacon. It has the following attributes:

Table 13-27. `set-beacon` command attributes

Attribute	Description	Required	Default
file	Name of the input file.	Yes	Not available

The input file can be in JSON or XML format. If it is in XML format, it must follow the schema that is given in the file `product_install_dir/WorklightServer/wladmin-schemas/input/beacon.xsd`.

Example:

```
<set-beacon file="entrance.xml"/>
```

This command is based on the “Beacons (PUT)” on page 11-93 REST service.

The `show-beacon` command

The `show-beacon` command shows details about a beacon. It has the following attributes:

Table 13-28. `show-beacon` command attributes

Attribute	Description	Required	Default
uuid	UUID (32 hex digits) of the beacon.	Yes	Not available
major	Major number of the beacon.	Yes	Not available
minor	Minor number of the beacon.	Yes	Not available

Table 13-28. **show-beacon** command attributes (continued)

Attribute	Description	Required	Default
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Example:

```
<show-beacon uuid="496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6" major="1"
minor="23"/>
```

This command is based on the “Beacons (GET)” on page 11-90 REST service.

The remove-beacon command

The **remove-beacon** command removes (clears) the information about a beacon. It has the following attributes:

Table 13-29. **remove-beacon** command attributes

Attribute	Description	Required	Default
uuid	UUID (32 hex digits) of the beacon.	Yes	Not available
major	Major number of the beacon.	Yes	Not available
minor	Minor number of the beacon.	Yes	Not available

Example:

```
<remove-beacon uuid="496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6" major="1"
minor="23"/>
```

This command is based on the “Beacons (DELETE)” on page 11-87 REST service.

The list-beacon-triggers command

The **list-beacon-triggers** command returns the list of beacon triggers, belonging to a given runtime. It has the following attributes:

Table 13-30. **list-beacon-triggers** command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Example:

```
<list-beacon-triggers runtime="worklight"/>
```

This command is based on the “Beacon Triggers (GET)” on page 11-76 REST service.

The set-beacon-trigger command

The **set-beacon-trigger** command specifies or updates information about a beacon trigger, belonging to a given runtime. It has the following attributes:

Table 13-31. set-beacon-trigger command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
file	Name of the input file.	Yes	Not available

The input file can be in JSON or XML format. If it is in XML format, it must follow the schema that is given in the file *product_install_dir/WorklightServer/wladmin-schemas/input/beacon-trigger.xsd*.

Example:

```
<set-beacon-trigger runtime="worklight" file="entrance-alert.xml"/>
```

This command is based on the “Beacon Triggers (PUT)” on page 11-83 REST service.

The show-beacon-trigger command

The **show-beacon-trigger** command shows details about a beacon trigger, belonging to a given runtime. It has the following attributes:

Table 13-32. show-beacon-trigger command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
name	Name of the beacon trigger.	Yes	Not available
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Example:

```
<show-beacon-trigger runtime="worklight" name="entrance-alert"/>
```

This command is based on the “Beacon Trigger (GET)” on page 11-74 REST service.

The delete-beacon-trigger command

The **delete-beacon-trigger** command deletes a beacon trigger from a given runtime. It has the following attributes:

Table 13-33. delete-beacon-trigger command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
name	Name of the beacon trigger.	Yes	Not available

Example:

```
<delete-beacon-trigger runtime="worklight" name="entrance-alert"/>
```

This command is based on the “Beacon Trigger (DELETE)” on page 11-71 REST service.

The list-beacon-trigger-associations command

The **list-beacon-trigger-associations** command returns the list of associations between beacons and beacon triggers that match given criteria, belonging to an app in a given runtime. It has the following attributes:

Table 13-34. list-beacon-trigger-associations command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
app	Name of an app.	Yes	Not available
uuid	UUID (32 hex digits) of the beacon.	Only if major or minor are specified	
major	Major number of the beacon.	No	
minor	Minor number of the beacon.	No	
triggerName	Name of the beacon trigger.	No	
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Examples:

```
<list-beacon-trigger-associations runtime="worklight" app="productguide"/>
```

```
<list-beacon-trigger-associations runtime="worklight" app="productguide"
uuid="496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6" major="1" minor="23"/>
```

```
<list-beacon-trigger-associations runtime="worklight" app="productguide"
triggerName="entrance-alert"/>
```

This command is based on the “Associate beacons and triggers (GET)” on page 11-64 REST service.

The set-beacon-trigger-association command

The **set-beacon-trigger-association** command specifies an association between a beacon and a beacon trigger, belonging to an app in a given runtime. It has the following attributes:

Table 13-35. **set-beacon-trigger-association** command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
app	Name of an app.	Yes	Not available
uuid	UUID (32 hex digits) of the beacon.	Yes	Not available
major	Major number of the beacon.	Yes	Not available
minor	Minor number of the beacon.	Yes	Not available
triggerName	Name of the beacon trigger.	Yes	Not available

Example:

```
<set-beacon-trigger-association runtime="worklight" app="productguide"
uuid="496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6" major="1" minor="23"
triggerName="entrance-alert"/>
```

This command is based on the “Associate beacons and triggers (PUT)” on page 11-66 REST service.

The show-beacon-trigger-association command

The **show-beacon-trigger-association** command shows an association between a beacon and a beacon trigger, belonging to an app in a given runtime. It has the following attributes:

Table 13-36. **show-beacon-trigger-association** command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
app	Name of an app.	Yes	Not available
uuid	UUID (32 hex digits) of the beacon.	Yes	Not available
major	Major number of the beacon.	Yes	Not available

Table 13-36. `show-beacon-trigger-association` command attributes (continued)

Attribute	Description	Required	Default
minor	Minor number of the beacon.	Yes	Not available
triggerName	Name of the beacon trigger.	Yes	Not available
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Example:

```
<show-beacon-trigger-association runtime="worklight" app="productguide"
uuid="496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6" major="1" minor="23"
triggerName="entrance-alert"/>
```

This command is based on the “Associate beacons and triggers (GET)” on page 11-64 REST service.

The delete-beacon-trigger-association command

The `delete-beacon-trigger-association` command deletes an association between a beacon and a beacon trigger from an app in a given runtime. It has the following attributes:

Table 13-37. `delete-beacon-trigger-association` command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
app	Name of an app.	Yes	Not available
uuid	UUID (32 hex digits) of the beacon.	Yes	Not available
major	Major number of the beacon.	Yes	Not available
minor	Minor number of the beacon.	Yes	Not available
triggerName	Name of the beacon trigger.	Yes	Not available

Example:

```
<delete-beacon-trigger-association runtime="worklight" app="productguide"
uuid="496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6" major="1" minor="23"
triggerName="entrance-alert"/>
```

This command is based on the “Associate beacons and triggers (DELETE)” on page 11-60 REST service.

Commands for devices

When you call the `wladm` Ant task, you can include various commands for devices.

The `list-devices` command

The `list-devices` command returns the list of devices that have contacted the apps of a runtime. It has the following attributes:

Table 13-38. list-devices command attributes

Attribute	Description	Required	Default
<code>runtime</code>	Name of the runtime web application / MobileFirst project.	Yes	Not available
<code>query</code>	A friendly name or user identifier to search for.	No	
<code>output</code>	Name of output file.	No	
<code>outputproperty</code>	Name of Ant property for the output.	No	

The `query` parameter specifies a string to search for. All devices that have a friendly name or user identifier that contains this string (with case-insensitive matching) are returned.

Examples:

```
<list-devices runtime="worklight"/>
```

```
<list-devices runtime="worklight" query="john"/>
```

This command is based on the “Devices (GET)” on page 11-107 REST service.

The `remove-device` command

The `remove-device` command clears the record about a device that has contacted the apps of a runtime. It has the following attributes:

Table 13-39. remove-device command attributes

Attribute	Description	Required	Default
<code>runtime</code>	Name of the runtime web application / MobileFirst project.	Yes	Not available
<code>id</code>	Unique device identifier.	Yes	Not available

Example:

```
<remove-device runtime="worklight" id="496E974CCEDE86791CF9A8EF2E5145B6"/>
```

This command is based on the “Device (DELETE)” on page 11-101 REST service.

The device command group

The **device** command group has the following attributes:

Table 13-40. **device** command group attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application / MobileFirst project.	Yes	Not available
id	Unique device identifier.	Yes	Not available

It supports the following elements:

Table 13-41. **device** command group elements

Element	Description	Count
set-status	Changes the status.	0..∞
set-appstatus	Changes the status for an app.	0..∞

The set-status command

The **set-status** command changes the status of a device, in the scope of a runtime. It has the following attributes:

Table 13-42. **set-status** command attributes

Attribute	Description	Required	Default
status	New status.	Yes	Not available

The status can be one of:

- ACTIVE
- LOST
- STOLEN
- EXPIRED
- DISABLED

Example:

```
<device runtime="worklight" id="496E974CCEDE86791CF9A8EF2E5145B6">  
  <set-status status="EXPIRED"/>  
</device>
```

This command is based on the “Device Status (PUT)” on page 11-104 REST service.

The set-appstatus command

The **set-appstatus** command changes the status of a device, regarding an app in a runtime. It has the following attributes:

Table 13-43. **set-appstatus** command attributes

Attribute	Description	Required	Default
app	Name of an app.	Yes	Not available

Table 13-43. `set-appstatus` command attributes (continued)

Attribute	Description	Required	Default
<code>status</code>	New status.	Yes	Not available

The status can be one of:

- ENABLED
- DISABLED

Example:

```
<device runtime="worklight" id="496E974CCEDE86791CF9A8EF2E5145B6">
  <set-appstatus app="MyApp" status="DISABLED"/>
</device>
```

This command is based on the “Device Application Status (PUT)” on page 11-97 REST service.

Commands for troubleshooting

The following commands can help investigate problems with the MobileFirst Server web applications.

The `show-info` command

The `show-info` command shows basic information about the MobileFirst administration services that can be returned without accessing any runtime nor database. This command can be used to test whether the MobileFirst administration services are running at all. It has the following attributes:

Table 13-44. `show-info` command attributes

Attribute	Description	Required	Default
<code>output</code>	Name of output file.	No	
<code>outputproperty</code>	Name of Ant property for the output.	No	

Example:

```
<show-info/>
```

The `show-versions` command

The `show-versions` command displays the MobileFirst versions of various components:

- **wladmVersion:** the exact MobileFirst Server version number from which `worklight-ant-deployer.jar` is taken.
- **productVersion:** the exact MobileFirst Server version number from which `worklightadmin.war` is taken.

And for every project WAR file:

- **serverVersion:** the exact MobileFirst Server version number from which `worklight-jee-library.jar` is taken.
- **platformVersion:** the exact version number of the MobileFirst development tools (Studio) that built the project WAR file.

It has the following attributes:

Table 13-45. **show-versions** command attributes

Attribute	Description	Required	Default
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Example:

```
<show-versions/>
```

The **list-runtimes** command

The **list-runtimes** command returns a list of the deployed runtimes (MobileFirst projects). It has the following attributes:

Table 13-46. **list-runtimes** command attributes

Attribute	Description	Required	Default
inDatabase	Whether to look in the database instead of via MBeans.	No	false
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Examples:

```
<list-runtimes/>
```

```
<list-runtimes inDatabase="true"/>
```

This command is based on the “Runtimes (GET)” on page 11-166 REST service.

The **show-runtime** command

The **show-runtime** command shows information about a given deployed runtime (MobileFirst project). It has the following attributes:

Table 13-47. **show-runtime** command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application or MobileFirst project.	Yes	Not available
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Example:

```
<show-runtime runtime="worklight"/>
```

This command is based on the “Runtime (GET)” on page 11-154 REST service.

The delete-runtime command

The **delete-runtime** command deletes the runtime, including its apps and adapters, from the database. It is only possible to delete a runtime when its web application is stopped. It has the following attributes:

Table 13-48. delete-runtime command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application or MobileFirst project.	Yes	Not available
condition	Condition when to delete it: empty or always (dangerous!)	No	

Example:

```
<delete-runtime runtime="worklight" condition="empty"/>
```

This command is based on the “Runtime (DELETE)” on page 11-153 REST service.

The list-farm-members command

The **list-farm-members** command returns a list of the farm member servers on which a given runtime is deployed. It has the following attributes:

Table 13-49. list-farm-members command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application or MobileFirst project.	Yes	Not available
output	Name of output file.	No	
outputproperty	Name of Ant property for the output.	No	

Example:

```
<list-farm-members runtime="worklight"/>
```

This command is based on the “Farm topology members (GET)” on page 11-114 REST service.

The remove-farm-member command

The **remove-farm-member** command removes a server from the list of farm members on which a given runtime is deployed. This command should be used when the server has become unavailable or disconnected. It has the following attributes:

Table 13-50. `remove-farm-member` command attributes

Attribute	Description	Required	Default
runtime	Name of the runtime web application or MobileFirst project.	Yes	Not available
serverId	Identifier of the server.	Yes	Not available
force	Force removal of a farm member, even if it is available and connected.	No	false

Example:

```
<remove-farm-member runtime="worklight" serverId="srvlx15"/>
```

This command is based on the “Farm topology members (DELETE)” on page 11-117 REST service.

A complex example of a `wladm` Ant task

Here is an example of how to use several `wladm` invocations and XML processing to solve more complex tasks.

This example lists all access rules of all apps in all runtimes. The third-party XMLTask Ant task, from oopsconsultancy is used, which provides, in particular:

- Iteration over a list of XML elements that are specified through an XPath expression.
- Access to several attributes of an XML element, in each iteration.

Here is an example of the code:

```
<?xml version="1.0" encoding="UTF-8"?>
<project default="main">
  <!-- Prerequisite for using the <wladm> Ant task. -->
  <taskdef resource="com/worklight/ant/deployers/antlib.xml">
    <classpath>
      <pathelement location="/opt/IBM/Worklight/WorklightServer/worklight-ant-deployer.jar"/>
    </classpath>
  </taskdef>
  <!-- Prerequisite for using the <xmltask> Ant task. -->
  <taskdef name="xmltask" classname="com.oopsconsultancy.xmltask.ant.XmlTask">
    <classpath>
      <pathelement location="/opt/xmltask/xmltask.jar"/>
    </classpath>
  </taskdef>

  <!-- Parameters for every <wladm> invocation. -->
  <property name="url" value="https://localhost:8443/worklightadmin"/>
  <property name="user" value="demo"/>
  <property name="password" value="demo"/>
  <property name="secure" value="false"/>

  <target name="main">
    <wladm url="${url}" user="${user}" password="${password}" secure="${secure}">
      <list-runtimes output="/tmp/ListRuntimes.xml" inDatabase="true"/>
    </wladm>
    <xmltask source="/tmp/ListRuntimes.xml">
      <call path="/projectconfiguration/projects/project">
        <param name="runtime" path="@name"/>
      </call>
    </xmltask>
  </target>
</project>
```

```

<echo message="runtime=@{runtime}"/>
<sequential>
  <wladm url="{url}" user="{user}" password="{password}" secure="{secure}">
    <list-apps runtime="@{runtime}" output="/tmp/ListApps.xml"/>
  </wladm>
  <xmltask source="/tmp/ListApps.xml">
    <call path="/applications/items/item/appVersions/appVersion">
      <param name="name" path="@application"/>
      <param name="environment" path="@environment"/>
      <param name="version" path="@version"/>
      <actions>
        <sequential>
          <echo message="Access rules for app name=@{name}, environment=@{environment}, version=@{version}:"/>
          <wladm url="{url}" user="{user}" password="{password}" secure="{secure}">
            <app-version runtime="@{runtime}" name="@{name}" environment="@{environment}" version="@{version}">
              <get-accessrule/>
            </app-version>
          </wladm>
        </sequential>
      </actions>
    </call>
  </xmltask>
</sequential>
</actions>
</call>
</xmltask>
</target>
</project>

```

Administering MobileFirst applications through the command line

You can administer MobileFirst applications through the `wladm` program.

Comparison with other facilities

You can execute administration operations with IBM MobileFirst Platform Foundation in the following ways:

- The MobileFirst Operations Console, which is interactive.
- The `wladm` Ant task.
- The `wladm` program.
- The MobileFirst administration REST services.

The `wladm` Ant task, `wladm` program, and REST services are useful for automated or unattended execution of operations, such as eliminating operator errors in repetitive operations or operating outside the operator's normal working hours.

The `wladm` program and the `wladm` Ant task are simpler to use and have better error reporting than the REST services. The advantage of the `wladm` program over the `wladm` Ant task is that it is easier to integrate when integration with operating system commands is already available. Moreover, it is more suitable to interactive use.

Prerequisites

The `wladm` command is provided in the `product_install_dir/shortcuts/` directory as a set of scripts:

- `wladm` for UNIX / Linux
- `wladm.bat` for Windows

These scripts are ready to run, which means that they do not require specific environment variables. If the environment variable `JAVA_HOME` is set, the scripts accept it.

To use the `wladm` program, either put the `product_install_dir/shortcuts/` directory into your `PATH` environment variable, or reference its absolute file name in each call.

Calling the wladm program

You can use the `wladm` program to administer MobileFirst applications.

Syntax

Call the `wladm` program as follows:

```
wladm --url= --user= ... [--passwordfile=...] [--secure=false] some command
```

The `wladm` program has the following options:

Table 13-51. wladm program options

Option	Type	Description	Required	Default
<code>--url</code>	URL	Base URL of the MobileFirst web application for administration services	Yes	
<code>--secure</code>	Boolean	Whether to avoid operations with security risks	No	true
<code>--user</code>	name	User name for accessing the MobileFirst admin services	Yes	
<code>--passwordfile</code>	file	File containing the password for the user	No	
<code>--timeout</code>	Number	Timeout for the entire REST service access, in seconds	No	
<code>--connect-timeout</code>	Number	Timeout for establishing a network connection, in seconds	No	
<code>--socket-timeout</code>	Number	Timeout for detecting the loss of a network connection, in seconds	No	
<code>--connection-request-timeout</code>	Number	Timeout for obtaining an entry from a connection request pool, in seconds	No	
<code>--verbose</code>		Detailed output	No	

url

The URL preferably uses the HTTPS protocol. For example, if you use default ports and context roots, use this URL:

- For WebSphere Application Server: `https://server:9443/wladmin`
- For Tomcat: `https://server:8443/wladmin`

secure

The `--secure` option is set to true by default. Setting it to `--secure=false` might have the following effects:

- The user and password might be transmitted in an unsecured way (possibly even through unencrypted HTTP).

- The server's SSL certificates are accepted even if self-signed or if they were created for a different host name from the server's host name.

password

Specify the password in a separate file that you pass in the **--passwordfile** option. In interactive mode (see “Interactive mode” on page 13-40), you can alternatively specify the password interactively. The password is sensitive information and therefore needs to be protected. You must prevent other users on the same computer from knowing these passwords. To secure the password, before you enter the password into a file, you must remove the read permissions of the file for users other than yourself. For example, you can use one of the following commands:

- On UNIX: `chmod 600 adminpassword.txt`
- On Windows: `cacls adminpassword.txt /P Administrators:F %USERDOMAIN%\%USERNAME%:F`

For this reason, do not pass the password to a process through a command-line argument. On many operating systems, other users can inspect the command-line arguments of your processes.

The `wladm` calls contains a command. The following commands are supported.

Table 13-52. *wladm* invocation supported commands

Command	Description
<code>show info</code>	Shows user and configuration information
<code>show versions</code>	Shows version information
<code>list runtimes [--in-database]</code>	Lists the runtimes
<code>show runtime [runtime-name]</code>	Shows information about a runtime
<code>delete runtime [runtime-name] condition</code>	Deletes a runtime
<code>list adapters [runtime-name]</code>	Lists the adapters
<code>deploy adapter [runtime-name] file</code>	Deploys an adapter
<code>show adapter [runtime-name] adapter-name</code>	Shows information about an adapter
<code>delete adapter [runtime-name] adapter-name</code>	Deletes an adapter
<code>adapter [runtime-name] adapter-name get binary [> tofile]</code>	Get the binary data of an adapter
<code>list apps [runtime-name]</code>	Lists the apps
<code>deploy app [runtime-name] file</code>	Deploys an app
<code>show app [runtime-name] app-name</code>	Shows information about an app
<code>delete app [runtime-name] app-name</code>	Deletes an app
<code>delete app version [runtime-name] app-name environment version</code>	Deletes a version of an app
<code>app version [runtime-name] app-name environment version get binary [> tofile]</code>	Gets the binary data of an app version
<code>app version [runtime-name] app-name environment version get accessrule</code>	Gets the access rule of an app version
<code>app version [runtime-name] app-name environment version set accessrule file</code>	Changes the access rule of an app version

Table 13-52. *wladm* invocation supported commands (continued)

Command	Description
<code>app version [runtime-name] app-name environment version get authenticitycheckrule</code>	Gets the authenticity check rule of an app version
<code>app version [runtime-name] app-name environment version set authenticitycheckrule action</code>	Changes the authenticity check rule of an app version
<code>app version [runtime-name] app-name environment version get lock</code>	Gets the lock state of an app version
<code>app version [runtime-name] app-name environment version set lock lock</code>	Changes the lock state of an app version
<code>list beacons [uuid [major minor]]</code>	Lists the beacons
<code>set beacon file</code>	Specifies information about a beacon
<code>show beacon uuid major minor</code>	Shows information about a beacon
<code>remove beacon uuid major minor</code>	Removes information about a beacon
<code>list beacon-triggers [runtime-name]</code>	Lists the beacon triggers
<code>set beacon-trigger [runtime-name] file</code>	Specifies a beacon trigger
<code>show beacon-trigger [runtime-name] trigger-name</code>	Shows a beacon trigger
<code>delete beacon-trigger [runtime-name] trigger-name</code>	Deletes a beacon trigger
<code>list beacon-trigger-associations [runtime-name] app-name [uuid major minor] [trigger-name]</code>	Lists the associations between beacons and beacon triggers
<code>set beacon-trigger-association [runtime-name] app-name uuid major minor trigger-name</code>	Specifies an association between a beacon and a beacon trigger
<code>show beacon-trigger-association [runtime-name] app-name uuid major minor trigger-name</code>	Shows the association between a beacon and a beacon trigger
<code>delete beacon-trigger-association [runtime-name] app-name uuid major minor trigger-name</code>	Deletes the association between a beacon and a beacon trigger
<code>list devices [runtime-name] [--query query]</code>	Lists the devices
<code>remove device [runtime-name] id</code>	Removes a device
<code>device [runtime-name] id set status new-status</code>	Changes the status of a device
<code>device [runtime-name] id set appstatus app-name new-status</code>	Changes the status of a device for an app

Interactive mode

Alternatively, you can also call `wladm` without any command in the command line. You can then enter commands interactively, one per line.

The **exit** command, or end-of-file on standard input (**Ctrl-D** on UNIX terminals) terminates `wladm`.

Help commands are also available in this mode. For example:

- **help**
- **help show versions**
- **help device**
- **help device set status**

Command history in interactive mode

On some operating systems, the interactive `wladm` command remembers the command history. With the command history, you can select a previous command, using the arrow-up and arrow-down keys, edit it, and execute it.

- On Linux, the command history is enabled in terminal emulator windows if the `rlwrap` package is installed and found in `PATH`. To install the `rlwrap` package:
 - On Red Hat Linux: **sudo yum install rlwrap**
 - On SUSE Linux: **sudo zypper install rlwrap**
 - On Ubuntu: **sudo apt-get install rlwrap**
- On OS X, the command history is enabled in the Terminal program if the `rlwrap` package is installed and found in `PATH`. To install the `rlwrap` package:
 1. Install MacPorts by using the installer from www.macports.org.
 2. Run the command:
sudo /opt/local/bin/port install rlwrap
Then, to make the `rlwrap` program available in `PATH`, use this command in a Bourne-compatible shell:
PATH=/opt/local/bin:\$PATH
- On Windows, the command history is enabled in `cmd.exe` console windows.

In environments where `rlwrap` does not work or is not required, you can disable its use through the option `--no-readline`.

The configuration file

You can also store the options in a configuration file, instead of passing them on the command line at every call. When a configuration file is present and the option `--configfile=file` is specified, you can omit the following options:

- `--url=URL`
- `--secure=boolean`
- `--user=name`
- `--passwordfile=file`
- `--timeout=seconds`
- `--connect-timeout=seconds`
- `--socket-timeout=seconds`
- `--connection-request-timeout=seconds`
- `runtime-name`

Use these commands to store these values in the configuration file.

Table 13-53. Commands to store values in the configuration file

Command	Comment
<code>wladm [--configfile=file] config url URL</code>	

Table 13-53. Commands to store values in the configuration file (continued)

Command	Comment
wladm [--configfile= <i>file</i>] config secure <i>boolean</i>	
wladm [--configfile= <i>file</i>] config user <i>name</i>	
wladm [--configfile= <i>file</i>] config password	Prompts for the password.
wladm [--configfile= <i>file</i>] config timeout <i>seconds</i>	
wladm [--configfile= <i>file</i>] config connect-timeout <i>seconds</i>	
wladm [--configfile= <i>file</i>] config socket-timeout <i>seconds</i>	
wladm [--configfile= <i>file</i>] config connection-request-timeout <i>seconds</i>	
wladm [--configfile= <i>file</i>] config runtime <i>runtime-name</i>	

Use this command to list the values that are stored in the configuration file: `wladm [--configfile=file] config`

The configuration file is a text file, in the encoding of the current locale, in Java .properties syntax. The default configuration file is on

- UNIX: \$HOME/.wladm.config
- Windows: My Documents\IBM MobileFirst Platform Server Data\wladm.config, or My Documents\IBM Worklight Server Data\wladm.config

Note: When you do not specify a **--configfile** option, the default configuration file is used only in interactive mode and in **config** commands. For noninteractive use of the other commands, you must explicitly designate the configuration file if you want to use one.

Important: The password is stored in an obfuscated format that hides the password from an occasional glimpse. However, this obfuscation provides no security.

Generic options

There are also the usual generic options:

Table 13-54. Generic options

Option	Description
--help	Shows some usage help
--version	Shows the version

XML format

The commands that receive an XML response from the server verify that this response complies with the specific schema. You can disable this check by specifying `--xmlvalidation=none`.

Output character set

Normal output that is produced by the `wladm` program is encoded in the encoding format of the current locale. On Windows, this encoding format is "ANSI code page". The effects are as follows:

- Characters outside of this character set are converted to question marks when they are output.
- When the output goes to a Windows command prompt window (`cmd.exe`), non-ASCII characters are incorrectly displayed because such windows assume characters to be encoded in "OEM code page".

To work around this limitation:

- On operating systems other than Windows, use a locale whose encoding is UTF-8. This format is the default locale on Red Hat Linux and OS X. Many other operating systems have a `en_US.UTF-8` locale.
- Or use the `wladm` Ant task, with attribute `output="some file name"` to redirect the output of a command to a file.

Commands for adapters

When you invoke the `wladm` program, you can include various commands for adapters.

The `list adapters` command

The `list adapters` command returns a list of the adapters that are deployed for a runtime.

Syntax:

```
list adapters [runtime-name]
```

It takes the following arguments:

Table 13-55. list adapters command arguments

Argument	Description
<code>runtime-name</code>	Name of the runtime web application / MobileFirst project.

It takes the following options after the object:

Table 13-56. list adapters options

Option	Description
<code>--xml</code>	Produce XML output instead of tabular output.

Example:

```
list adapters worklight
```

This command is based on the "Adapters (GET)" on page 11-21 REST service.

The deploy adapter command

The deploy adapter command deploys an adapter in a runtime.

Syntax:

```
deploy adapter [runtime-name] file
```

It takes the following arguments:

Table 13-57. deploy adapter command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
file	Binary adapter file (.adapter)

Example:

```
deploy adapter worklight MyAdapter.adapter
```

This command is based on the “Adapter (POST)” on page 11-18 REST service.

The show adapter command

The show adapter command shows details about an adapter.

Syntax:

```
show adapter [runtime-name] adapter-name
```

It takes the following arguments:

Table 13-58. show adapter command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
adapter-name	Name of an adapter

It takes the following options after the object:

Table 13-59. show adapter options

Option	Description
--xml	Produce XML output instead of tabular output.

Example:

```
show adapter worklight MyAdapter
```

This command is based on the “Adapter (GET)” on page 11-13 REST service.

The delete adapter command

The delete adapter command removes (undeploys) an adapter from a runtime.

Syntax:

```
delete adapter [runtime-name] adapter-name
```

It takes the following arguments:

Table 13-60. delete adapter command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
adapter-name	Name of an adapter

Example:

```
delete adapter worklight MyAdapter
```

This command is based on the “Adapter (DELETE)” on page 11-10 REST service.

The adapter command prefix

The adapter command prefix takes the following arguments before the verb:

Table 13-61. adapter command prefix arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
adapter-name	Name of an adapter

The adapter get binary command

The adapter get binary command returns the binary adapter file.

Syntax:

```
adapter [runtime-name] adapter-name get binary [> tofile]
```

It takes the following options after the verb:

Table 13-62. adapter get binary options

Option	Description	Required	Default
> <i>tofile</i>	Name of the output file.	No	Standard output

Example:

```
adapter worklight MyAdapter get binary > /tmp/MyAdapter.adapter
```

This command is based on the “Adapter Binary (GET, HEAD)” on page 11-9 REST service.

Commands for apps

When you invoke the `wl adm` program, you can include various commands for apps.

The enable extended-authenticity command

The **enable extended-authenticity** command creates a `.wlap` file that is based on an original `.wlap` file. But, this new file's extended authenticity property is enabled.

Syntax:

```
enable extended-authenticity src-wlap-file device-file > dest-wlap-file
```

It takes the following arguments:

Table 13-63. The enable extended-authenticity command's arguments

Argument	Description
<code>src-wlap-file</code>	Original binary app file (<code>.wlap</code> , not <code>.apk</code> , or <code>.ipa</code>)
<code>device-file</code>	Binary mobile app file (<code>.apk</code> , <code>.appx</code> , <code>.ipa</code> , or <code>.xap</code>)
<code>dest-wlap-file</code>	Output binary app file (<code>.wlap</code> , not <code>.apk</code> , or <code>.ipa</code>)

Example:

```
enable extended-authenticity myapp-iphone-1.0.wlap MyApp.ipa > myapp-iphone-1.0.extauth.wlap
```

If you are invoking this command from the operating system command line, you need to escape the ">" character so that the command interpreter (shell or `cmd.exe`) does not intercept it. For example:

```
wladm enable extended-authenticity myapp-iphone-1.0.wlap MyApp.ipa ">" myapp-iphone-1.0.extauth.wlap
```

This command operates locally, without connecting to the server. For more information about enabling extended app authenticity checking, see "Configuring extended app authenticity checking" on page 12-56.

The list apps command

The **list apps** command returns a list of the apps that are deployed in a run time.

Syntax:

```
list apps [runtime-name]
```

It takes the following arguments:

Table 13-64. The list apps command's arguments

Argument	Description
<code>runtime-name</code>	Name of the runtime web application / MobileFirst project.

It takes the following options after the object:

Table 13-65. The list apps command's options

Option	Description
<code>--xml</code>	Produce XML output instead of tabular output.

Example:

```
list apps worklight
```

This command is based on the “Applications (GET)” on page 11-56 REST service.

The deploy app command

The **deploy app** command deploys an app (possibly with multiple environments) in a run time.

Syntax:

```
deploy app [runtime-name] file
```

It takes the following arguments:

Table 13-66. The **deploy app** command's arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
file	Binary app file (.wlapp, not .apk, or .ipa)

Example:

```
deploy app worklight MyApp-all.wlapp
```

This command is based on the “Application (POST)” on page 11-52 REST service.

The show app command

The **show app** command shows details about an app in a run time, in particular its environments and versions.

Syntax:

```
show app [runtime-name] app-name
```

It takes the following arguments:

Table 13-67. The **show app** command's arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
app-name	Name of an app

It takes the following options after the object:

Table 13-68. The **show app** command's options

Option	Description
--xml	Produce XML output instead of tabular output.

Example:

```
show app worklight MyApp
```

This command is based on the “Application (GET)” on page 11-48 REST service.

The delete app command

The **delete app** command removes (undeploys) an app (from all environments, and all versions) from a run time. Deleting an application from MobileFirst Operations Console will remove all push subscriptions on that application as well.

Syntax:

```
delete app [runtime-name] app-name
```

It takes the following arguments:

Table 13-69. The delete app command's arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project
app-name	Name of an app

Example:

```
delete app worklight MyApp
```

This command is based on the “Application (DELETE)” on page 11-45 REST service.

The delete app version command

The **delete app version** command removes (undeploys) an app version from a run time.

Syntax:

```
delete app version [runtime-name] app-name environment version
```

It takes the following arguments:

Table 13-70. The delete app version command's arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
app-name	Name of an app
environment	Mobile platform
version	Version of the app

Example:

```
delete app version worklight MyApp iPhone 1.1
```

This command is based on the “App Version (DELETE)” on page 11-38 REST service.

The app version command prefix

The **app version** command prefix takes the following arguments before the verb:

Table 13-71. The app version command's prefix arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
app-name	Name of an app
environment	Mobile platform
version	Version of the app

The app version get binary command

The **app version get binary** command returns the binary wlap file for a version of an app.

Syntax:

```
app version [runtime-name] app-name environment version get binary [> tofile]
```

It takes the following arguments after the verb:

Table 13-72. The app version get binary command's arguments

Argument	Description	Required	Default
> tofile	Name of the output file.	No	Standard output

Example:

```
app version worklight MyApp iPhone 1.1 get binary > /tmp/MyApp.wlap
```

This command is based on the “Application Binary (GET, HEAD)” on page 11-43 REST service.

The app version get accessrule command

The **app version get accessrule** command returns the access rule for an app version.

Syntax:

```
app version [runtime-name] app-name environment version get accessrule
```

Example:

```
app version worklight MyApp iPhone 1.1 get accessrule
```

This command is based on the “Application (GET)” on page 11-48 REST service.

The app version set accessrule command

The **app version set accessrule** command changes the access rule for an app version.

Syntax:

app version [*runtime-name*] *app-name environment version* set accessrule *file*

It takes the following arguments after the verb:

Table 13-73. The **app version set accessrule** command's arguments

Argument	Description
file	Name of the input file.

Example:

```
app version worklight MyApp iPhone 1.1 set accessrule /tmp/new-accessrule.xml
```

This command is based on the “App Version Access Rule (PUT)” on page 11-34 REST service.

The app version get authenticitycheckrule command

The **app version get authenticitycheckrule** command returns the authenticity check rule for an app version. This command is no longer supported with servers of IBM MobileFirst Platform Foundation V7.1.0 or later. This command is only available with V6.2.0 and V6.3.0.

Syntax:

```
app version [runtime-name] app-name environment version get authenticitycheckrule
```

Example:

```
app version worklight MyApp iPhone 1.1 get authenticitycheckrule
```

This command is based on the “Application (GET)” on page 11-48 REST service.

The app version set authenticitycheckrule command

The **app version set authenticitycheckrule** command changes the authenticity check rule for an app version. This command is no longer supported with servers of IBM MobileFirst Platform Foundation V7.1.0 or later. This command is only available with V6.2.0 and V6.3.0.

Syntax:

```
app version [runtime-name] app-name environment version set authenticitycheckrule action
```

It takes the following arguments after the verb:

Table 13-74. The **app version set authenticitycheckrule** command's arguments

Argument	Description
action	Action to perform for authenticity checking

The following actions are possible:

- **DISABLED:** Authenticity is not checked
- **IGNORED:** Authenticity is checked, but not enforced. If it fails, only a warning is given and the session is authorized
- **ENABLED:** Authenticity is checked and enforced

Example:

```
app version worklight MyApp iPhone 1.1 set authenticitycheckrule enabled
```

The app version get lock command

The **app version get lock** command returns information about whether an app version is locked or unlocked.

Syntax:

```
app version [runtime-name] app-name environment version get lock
```

Example:

```
app version worklight MyApp iPhone 1.1 get lock
```

This command is based on the “Application (GET)” on page 11-48 REST service.

The app version set lock command

The **app version set lock** command sets an app version to locked or unlocked state.

Syntax:

```
app version [runtime-name] app-name environment version set lock lock
```

It takes the following arguments after the verb:

Table 13-75. The app version set lock command's arguments

Argument	Description
lock	New lock state.

The possible lock values are true and false.

Example:

```
app version worklight MyApp iPhone 1.1 set lock true
```

This command is based on the “App Version Lock (PUT)” on page 11-42 REST service.

Commands for beacons

When you call the `wladm` program, you can include various commands for the beacons and beacon triggers. A beacon is a piece of information that is associated with an iBeacon. A beacon trigger is an action that a mobile device executes in relation to an iBeacon, when there is an association between the beacon and the beacon trigger.

The list beacons command

The **list beacons** command returns the list of beacons that match a given UUID and optionally, a given major and minor number.

Syntax:

```
list beacons [uuid [major minor]]
```

It takes the following arguments:

Table 13-76. list beacons command arguments

Argument	Description
uuid	UUID (32 hex digits) of the beacons to search for.
major	Major number of the beacons to search for. Use '_' as a wildcard.
minor	Minor number of the beacons to search for. Use '_' as a wildcard.

It takes the following options after the object:

Table 13-77. list beacons options

Option	Description
--xml	Produce XML output instead of tabular output.

Example:

```
list beacons 496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6
```

This command is based on the “Beacons (GET)” on page 11-90 REST service.

The set beacon command

The set beacon command specifies or updates information about a beacon.

Syntax:

```
set beacon file
```

It takes the following arguments:

Table 13-78. set beacon command arguments

Argument	Description
file	Name of the input file.

The input file can be in JSON or XML format. If it is in XML format, it must follow the schema that is given in the file `product_install_dir/WorklightServer/wladmin-schemas/input/beacon.xsd`.

Example:

```
set beacon entrance.xml
```

This command is based on the “Beacons (PUT)” on page 11-93 REST service.

The show beacon command

The show beacon command shows details about a beacon.

Syntax:

```
show beacon uuid major minor
```

It takes the following arguments:

Table 13-79. show beacon command arguments

Argument	Description
uuid	UUID (32 hex digits) of the beacon.
major	Major number of the beacon.
minor	Minor number of the beacon.

It takes the following options after the object:

Table 13-80. show beacon options

Option	Description
--xml	Produce XML output instead of tabular output.

Example:

```
show beacon 496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6 1 23
```

This command is based on the “Beacons (GET)” on page 11-90 REST service.

The remove beacon command

The remove beacon command removes (clears) the information about a beacon.

Syntax:

```
remove beacon uuid major minor
```

It takes the following arguments:

Table 13-81. remove beacon command arguments

Argument	Description
uuid	UUID (32 hex digits) of the beacon.
major	Major number of the beacon.
minor	Minor number of the beacon.

Example:

```
remove beacon 496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6 1 23
```

This command is based on the “Beacons (DELETE)” on page 11-87 REST service.

The list beacon-triggers command

The list beacon-triggers command returns the list of beacon triggers, belonging to a given runtime.

Syntax:

```
list beacon-triggers [runtime-name]
```

It takes the following arguments:

Table 13-82. list beacon-triggers command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.

It takes the following options after the object:

Table 13-83. list beacon-triggers options

Option	Description
--xml	Produce XML output instead of tabular output.

Example:

```
list beacon-triggers worklight
```

This command is based on the “Beacon Triggers (GET)” on page 11-76 REST service.

The set beacon-trigger command

The set beacon-trigger command specifies or updates information about a beacon trigger, belonging to a given runtime.

Syntax:

```
set beacon-trigger [runtime-name] file
```

It takes the following arguments:

Table 13-84. set beacon-trigger command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
file	Name of the input file.

The input file can be in JSON or XML format. If it is in XML format, it must follow the schema that is given in the file *product_install_dir/WorklightServer/wladmin-schemas/input/beacon-trigger.xsd*.

Example:

```
set beacon-trigger worklight entrance-alert.xml
```

This command is based on the “Beacon Triggers (PUT)” on page 11-83 REST service.

The show beacon-trigger command

The show beacon-trigger command shows details about a beacon trigger, belonging to a given runtime.

Syntax:

```
show beacon-trigger [runtime-name] trigger-name
```

It takes the following arguments:

Table 13-85. show beacon-trigger command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
trigger-name	Name of the beacon trigger.

It takes the following options after the object:

Table 13-86. show beacon-trigger options

Option	Description
--xml	Produce XML output instead of tabular output.

Example:

```
show beacon-trigger worklight entrance-alert
```

This command is based on the “Beacon Trigger (GET)” on page 11-74 REST service.

The delete beacon-trigger command

The delete beacon-trigger command deletes a beacon trigger from a given runtime.

Syntax:

```
delete beacon-trigger [runtime-name] trigger-name
```

It takes the following arguments:

Table 13-87. delete beacon-trigger command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
trigger-name	Name of the beacon trigger.

Example:

```
delete beacon-trigger worklight entrance-alert
```

This command is based on the “Beacon Trigger (DELETE)” on page 11-71 REST service.

The list beacon-trigger-associations command

The list beacon-trigger-associations command returns the list of associations between beacons and beacon triggers that match given criteria, belonging to an app in a given runtime.

Syntax:

```
list beacon-trigger-associations [runtime-name] app-name [uuid major minor] [trigger-name]
```

It takes the following arguments:

Table 13-88. list beacon-trigger-associations command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
app-name	Name of an app.
uuid	UUID (32 hex digits) of the beacon.
major	Major number of the beacon. Use '_' as a wildcard.
minor	Minor number of the beacon. Use '_' as a wildcard.
trigger-name	Name of the beacon trigger.

It takes the following options after the object:

Table 13-89. list beacon-trigger-associations options

Option	Description
--xml	Produce XML output instead of tabular output.

Examples:

```
list beacon-trigger-associations worklight productguide
```

```
list beacon-trigger-associations worklight productguide 496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6 1 23
```

```
list beacon-trigger-associations worklight productguide entrance-alert
```

This command is based on the “Associate beacons and triggers (GET)” on page 11-64 REST service.

The set beacon-trigger-association command

The set beacon-trigger-association command specifies an association between a beacon and a beacon trigger, belonging to an app in a given runtime.

Syntax:

```
set beacon-trigger-association [runtime-name] app-name uuid major minor trigger-name
```

It takes the following arguments:

Table 13-90. set beacon-trigger-association command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
app-name	Name of an app.
uuid	UUID (32 hex digits) of the beacon.
major	Major number of the beacon.

Table 13-90. *set beacon-trigger-association* command arguments (continued)

Argument	Description
minor	Minor number of the beacon.
trigger-name	Name of the beacon trigger.

Example:

```
set beacon-trigger-association worklight productguide 496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6 1 23 entrance-alert
```

This command is based on the “Associate beacons and triggers (PUT)” on page 11-66 REST service.

The show beacon-trigger-association command

The show beacon-trigger-association command shows an association between a beacon and a beacon trigger, belonging to an app in a given runtime.

Syntax:

```
show beacon-trigger-association [runtime-name] app-name uuid major minor trigger-name
```

It takes the following arguments:

Table 13-91. *show beacon-trigger-association* command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
app-name	Name of an app.
uuid	UUID (32 hex digits) of the beacon.
major	Major number of the beacon.
minor	Minor number of the beacon.
trigger-name	Name of the beacon trigger.

It takes the following options after the object:

Table 13-92. *show beacon-trigger-association* options

Option	Description
--xml	Produce XML output instead of tabular output.

Example:

```
show beacon-trigger-association worklight productguide 496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6 1 23 entrance-alert
```

This command is based on the “Associate beacons and triggers (GET)” on page 11-64 REST service.

The delete beacon-trigger-association command

The delete beacon-trigger-association command deletes an association between a beacon and a beacon trigger from an app in a given runtime.

Syntax:

```
delete beacon-trigger-association [runtime-name] app-name uuid major minor trigger-name
```

It takes the following arguments:

Table 13-93. delete beacon-trigger-association command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
app-name	Name of an app.
uuid	UUID (32 hex digits) of the beacon.
major	Major number of the beacon.
minor	Minor number of the beacon.
trigger-name	Name of the beacon trigger.

Example:

```
delete beacon-trigger-association worklight productguide  
496E-974C-CEDE-8679-1CF9-A8EF-2E51-45B6 1 23 entrance-alert
```

This command is based on the “Associate beacons and triggers (DELETE)” on page 11-60 REST service.

Commands for devices

When you invoke the wladm program, you can include various commands for devices.

The list devices command

The list devices command returns the list of devices that have contacted the apps of a runtime.

Syntax:

```
list devices [runtime-name] [--query query]
```

It takes the following arguments:

Table 13-94. list devices command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
query	A friendly name or user identifier, to search for.

The query parameter specifies a string to search for. All devices that have a friendly name or user identifier that contains this string (with case-insensitive matching) are returned.

It takes the following options after the object:

Table 13-95. list devices options

Option	Description
--xml	Produce XML output instead of tabular output.

Examples:

```
list-devices worklight
list-devices worklight --query=john
```

This command is based on the “Devices (GET)” on page 11-107 REST service.

The remove device command

The remove device command clears the record about a device that has contacted the apps of a runtime.

Syntax:

```
remove device [runtime-name] id
```

It takes the following arguments:

Table 13-96. remove device command arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
id	Unique device identifier.

Example:

```
remove device worklight 496E974CCEDE86791CF9A8EF2E5145B6
```

This command is based on the “Device (DELETE)” on page 11-101 REST service.

The device command prefix

The device command prefix takes the following arguments before the verb:

Table 13-97. device command prefix arguments

Argument	Description
runtime-name	Name of the runtime web application / MobileFirst project.
id	Unique device identifier.

The device set status command

The device set status command changes the status of a device, in the scope of a runtime.

Syntax:

```
device [runtime-name] id set status new-status
```

It takes the following arguments:

Table 13-98. device set status command arguments

Argument	Description
new-status	New status.

The status can be:

- ACTIVE
- LOST
- STOLEN
- EXPIRED
- DISABLED

Example:

```
device worklight 496E974CCEDE86791CF9A8EF2E5145B6 set status EXPIRED
```

This command is based on the “Device Status (PUT)” on page 11-104 REST service.

The device set appstatus command

The device set appstatus command changes the status of a device, regarding an app in a runtime.

Syntax:

```
device [runtime-name] id set appstatus app-name new-status
```

It takes the following arguments:

Table 13-99. device set appstatus command arguments

Argument	Description
app-name	Name of an app.
new-status	New status.

The status can be:

- ENABLED
- DISABLED

Example:

```
device worklight 496E974CCEDE86791CF9A8EF2E5145B6 set appstatus MyApp DISABLED
```

This command is based on the “Device Application Status (PUT)” on page 11-97 REST service.

Commands for troubleshooting

When you invoke the `wl adm` program, you can include various commands for troubleshooting.

The show info command

The `show info` command shows basic information about the MobileFirst administration services that can be returned without accessing any runtime nor database. This command can be used to test whether the MobileFirst administration services are running at all.

Syntax:

```
show info
```

It takes the following options after the object:

Table 13-100. show info options

Option	Description
--xml	Produce XML output instead of tabular output.

Example:

```
show info
```

The show versions command

The show versions command displays the MobileFirst versions of various components:

- `wladmVersion`: the exact MobileFirst Server version number from which `worklight-ant-deployer.jar` is taken.
- `productVersion`: the exact MobileFirst Server version number from which `worklightadmin.war` is taken

and for every project WAR file:

- `serverVersion`: the exact MobileFirst Server version number from which `worklight-jee-library.jar` is taken
- `platformVersion`: the exact version number of the MobileFirst development tools that built the project WAR file

Syntax:

```
show versions
```

It takes the following options after the object:

Table 13-101. show versions options

Option	Description
--xml	Produce XML output instead of tabular output.

Example:

```
show versions
```

The list runtimes command

The list runtimes command returns a list of the deployed runtimes (MobileFirst projects).

Syntax:

```
list runtimes [--in-database]
```

It takes the following options:

Table 13-102. list runtimes options

Option	Description
--in-database	Whether to look in the database instead of via MBeans
--xml	Produce XML output instead of tabular output.

Examples:

```
list runtimes
list runtimes --in-database
```

This command is based on the “Runtimes (GET)” on page 11-166 REST service.

The show runtime command

The show runtime command shows information about a given deployed runtime (MobileFirst project).

Syntax:

```
show runtime [runtime-name]
```

It takes the following arguments:

Table 13-103. show runtime arguments

Argument	Description
runtime-name	Name of the runtime web application or MobileFirst project.

It takes the following options after the object:

Table 13-104. show runtime options

Option	Description
--xml	Produce XML output instead of tabular output.

Example:

```
show runtime worklight
```

This command is based on the “Runtime (GET)” on page 11-154 REST service.

The delete runtime command

The delete runtime command deletes a runtime, including its apps and adapters, from the database. It is only possible to delete a runtime when its web application is stopped.

Syntax:

```
delete runtime [runtime-name] condition
```

It takes the following arguments:

Table 13-105. delete runtime arguments

Argument	Description
runtime-name	Name of the runtime web application or MobileFirst project.
condition	Condition when to delete it: 'empty' or 'always' (dangerous!)

Example:

```
delete runtime worklight empty
```

This command is based on the “Runtime (DELETE)” on page 11-153 REST service.

The list farm-members command

The list farm-members command returns a list of the farm member servers on which a given runtime is deployed.

Syntax:

```
list farm-members [runtime-name]
```

It takes the following arguments:

Table 13-106. list farm-members arguments

Argument	Description
runtime-name	Name of the runtime web application or MobileFirst project.

It takes the following options after the object:

Table 13-107. list farm-members options

Option	Description
--xml	Produce XML output instead of tabular output.

Example:

```
list farm-members worklight
```

This command is based on the “Farm topology members (GET)” on page 11-114 REST service.

The remove farm-member command

The remove farm-member command removes a server from the list of farm members on which a given runtime is deployed. This command should be used when the server has become unavailable or disconnected.

Syntax:

```
remove farm-member [runtime-name] server-id
```

It takes the following arguments:

Table 13-108. remove farm-member arguments

Argument	Description
runtime-name	Name of the runtime web application or MobileFirst project.
server-id	Identifier of the server.

It takes the following options after the object:

Table 13-109. remove farm-member option

Option	Description
--force	Force removal of a farm member, even if it is available and connected.

Example:

```
remove farm-member worklight srvlx15
```

This command is based on the “Farm topology members (DELETE)” on page 11-117 REST service.

Administering push notifications with the MobileFirst Operations Console

The Push Notifications page in the MobileFirst Operations Console provides you with a quick view of the various entities in the push notification chain.

The **Event Sources** tab displays the list of data sources that are configured in your MobileFirst Server, including the number of users that are subscribed to notifications from each source.

WorklightStarter > Push notifications

Unsubscribe devices...

Push Notifications

Event sources

Name	Adapter	Users	Messages
PushEventSource	PushAdapter	0	0

Figure 13-6. Data sources of push notifications in the MobileFirst Operations Console

Clicking **Applications** displays the deployed applications that can receive push notifications. For each application, the push notification services available for this application are also displayed. The console displays the number of notifications that are retrieved by an event source and sent to each application since system startup. It also displays errors that are related to connectivity to the push notification services.

Applications					
Name	Users	Devices	Environments	Messages	Tags
TagsTest	0	0		0	Tag1
Environments					
Name	Users	Devices	Messages		
 Apple	0	0	0		
BroadcastTest	0	0		0	

Figure 13-7. Deployed applications that receive push notifications in the MobileFirst Operations Console

As Administrator, you can forcibly unsubscribe existing SMS subscriptions by clicking **Unsubscribe Devices**. As Administrator, you can enter the mobile phone numbers to be unsubscribed.

Note: You can have two subscriptions for the same phone number and user name; one created by using the device and one created by using the subscribe SMS servlet. If two subscriptions exist for the same phone number and user name, unsubscribing by using the MobileFirst Operations Console unsubscribes both subscriptions.

Application Center

Learn about the Application Center: what it is for, the different components and features, and how to use the console and the client.

The sale of mobile devices now exceeds that of personal computers. Consequently, mobile applications become critical for businesses.

The Application Center is a tool to make sharing mobile applications within an organization easier.

You can use the Application Center as an enterprise application store. With the Application Center, you can target some mobile applications to particular groups of users within the company.

A development team can also use the Application Center during the development phase of an application to share applications with testers, designers, or executives in the company. In such a scenario, it makes collaboration easier between all the people who are involved in the development process.

Concept of Application Center

Application Center can be used as an Enterprise application store and is a means of sharing information among different team members within a company.

The concept of Application Center is similar to the concept of the Apple public App Store or the Android Market, except that it targets only private usage within a company.

By using Application Center, users from the same company or organization download applications to mobile phones or tablets from a single place that serves as a repository of mobile applications.

Application Center targets mobile applications that are installed on the device itself. Those applications can be native applications that are built by using the device SDK or hybrid applications that mix native and web content. Application Center does not target mobile web applications; such applications are delivered to the mobile device web browser through a URL like a website.

In the current version, Application Center supports applications that are built for the Google Android platform, the Apple iOS platform, the Windows Phone 8 platform, Windows 8 platform, and the BlackBerry platform for OS versions 6 and 7.

For Windows Phone, only the Windows Phone application package (.xap) file format is currently supported, **not** the app package (.appx) file format (universal app format). For Windows Store (Desktop applications), the app package (.appx) file format is supported.

Windows Phone 7, Windows RT, and BlackBerry OS 10 are not supported by the current version of the Application Center. Support for BlackBerry platform OS versions 6 and 7 is deprecated and might be removed in future versions; it continues to work in this version of Application Center.

Application Center manages mobile applications; it supports any kind of Android, iOS, Windows Phone 8, Windows 8, or BlackBerry OS 6 or OS 7 application, including applications that are built on top of the MobileFirst platform.

You can use the Application Center as part of the development process of an application. A typical scenario of Application Center is a team building a mobile application; the development team creates a new version of an Android, iOS, Windows Phone, Windows 8, or BlackBerry application. The development team wants this new version to be reviewed and tested by the extended team. A developer goes to Application Center console and uploads the new version of the application to Application Center. As part of this process, the developer can enter a description of the application version. For example, the description could mention the elements that the development team added or fixed from the previous version. The new version of the application is then available to the other members of the team.

Another person, for example, a beta tester, can launch Application Center installer application, the mobile client, to locate this new version of a mobile application in the list of available applications and install it on his mobile device. After testing the new version, the beta tester can rate the application and submit feedback. The feedback is visible to the developer from the Application Center console.

Application Center is a convenient way to share mobile applications within a company or a group; it is a means of sharing information among team members.

Specific platform requirements

Different operating systems impose specific requirements for deploying, installing, or using applications on the appropriate mobile devices.

Android

The mobile device must be configured for installation from unknown

sources. The corresponding toggle can be found in the Android Settings. See User Opt-in for apps from unknown sources for details.

In Application Center, applications have an internal and a commercial version number. The internal version number is used to distinguish which version is newer while the commercial version is only used as an informative display string. For Android applications, the internal version is the `android:versionCode` from the application manifest, and it must be an integer.

iOS All applications that are managed through Application Center must be packaged for “Ad Hoc Distribution”. With an iOS developer account, you can share your application with up to 100 iOS devices. With an iOS enterprise account, you can share your in-house application with an unlimited number of iOS devices. See iOS Developer Program and iOS Enterprise Program for details.

In Application Center, applications have an internal and a commercial version number. The internal version number is used to distinguish which version is newer while the commercial version is used only as an informative display string. For iOS applications, the internal version is the `CFBundleVersion` from the application manifest `Info.plist`. The version number must have the following format: `a`, or `a.b`, or `a.b.c`, where `a`, `b`, `c` are non-negative integers, and `a` is not 0.

BlackBerry

Applications must be signed with a signing key for “BlackBerry OS 7 and earlier”, which can be obtained by BlackBerry. Unsigned applications cannot access the full BlackBerry API of the device. Therefore, only very simple applications do not require this signing process. See BlackBerry Keys Order Form for details.

In Application Center, applications have only one version number. The version number is used to distinguish which version is newer. For BlackBerry apps, the version is the Midlet-version in the `.jad` file and must have the following format: `a`, or `a.b`, or `a.b.c`, where `a`, `b`, `c` is a sequence of digits.

Windows Phone 8

Applications are not installed from the Windows Store, but from Application Center, which acts as what Microsoft documentation calls a *Company Hub*. See Company app distribution for Windows Phone for details.

To use a company hub, you must register a company account with Microsoft and sign all applications, including the Application Center client, with the company certificate. Only signed applications can be managed through Application Center.

You must enroll all mobile devices through an application enrollment token that is associated with your company account. Application Center helps you to enroll devices through facilities to distribute the application enrollment token. See “Application enrollment tokens in Windows Phone 8” on page 13-111 for details.

Application Center supports the distribution of applications as Windows Phone application package (`.xap`) files for Microsoft Windows Phone 8.0 and Microsoft Windows Phone 8.1. With Microsoft Windows Phone 8.1, Microsoft introduced a new universal format as app package (`.appx`) files for Windows Phone. Currently, Application Center does not support the

distribution of app package (.appx) files for Microsoft Windows Phone 8.1, but is limited to Windows Phone application package (.xap) files only.

In Application Center, applications have only one version number. The version number is used to distinguish which version is newer. For Windows Phone 8 applications, the version number is in the Version field in the WMApManifest.xml file. This version number must have the following format: a.b.c.d where a, b, c, d are non-negative integers.

Windows 8

The Application Center mobile client is provided as a normal desktop executable file (.exe). Use this file to install Windows Store applications, which are packaged as .appx files, on the device.

Installing an .appx file on your device without using Windows Store is called *sideloading* an app. To sideload an app, you must comply with the prerequisites in Prepare to Sideload Apps. The Windows 8.1 update simplifies the prerequisites for sideloading. For more information, see Sideload Store Apps to Windows 8.1 Devices.

Files of type .exe cannot be executed on ARM-based tablets, so Application Center does not support Windows RT; only Windows 8 and Windows 8.1 are supported.

The device user needs administrator rights on the device to execute the Application Center client.

Application Center does not provide any predefined way of distributing the mobile client.

In Application Center, applications have only one version number. The version number is used to distinguish which version is newer. For Windows 8 applications, the version number is in the Version field in the AppManifest.xml file. This version number must have the following format: a.b.c.d, where a, b, c, d are non-negative integers.

General architecture

The Application Center is composed of these main elements: a server-side component, a repository, an administration console, and a mobile client application.

Server-side component

The server-side component is a Java Enterprise application that must be deployed in a web application server such as IBM WebSphere or Apache Tomcat.

The server-side component consists of an administration console and a mobile application. This mobile application installs the mobile applications available to the client-side component.

The web console and the installer application communicate through REST services with the server component.

Several services compose the Application Center server-side component; for example, a service that lists available applications, a service that delivers the application binary files to the mobile device, or a service that registers feedback and ratings.

Repository

A database that stores information such as which application is installed on which devices, the feedback about applications, and the mobile application binary files. The Application Center application is associated with the database when you configure the Application Center for a particular web application server and a supported database.

Administration console

A web console through which administrators can manage applications, user access rights to install applications, user feedback about mobile applications, and details about applications installed on devices. See “The Application Center console” on page 13-86.

Mobile client application

You use the mobile client to install applications on a mobile device and to send feedback about an application to the server. See “The mobile client” on page 13-121.

The following figure shows an overview of the architecture.

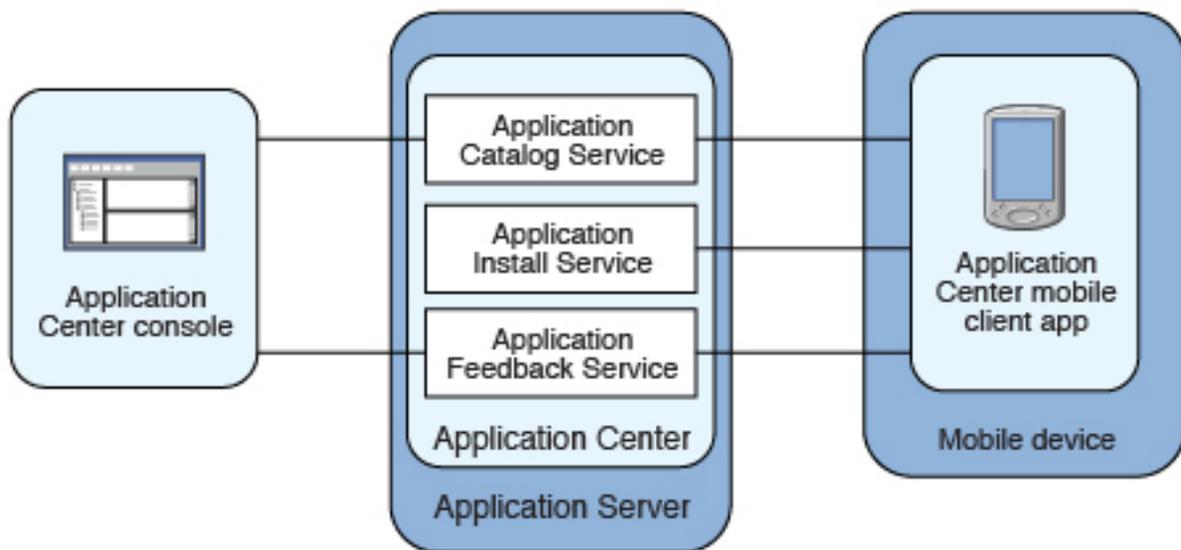

Figure 13-8. Architecture of the Application Center

From the Application Center console you can:

- Upload different versions of mobile applications.
- Remove unwanted applications.
- Control access to applications.

Access to the applications stored in the Application Center can be controlled from the Application Center console. Each application is associated with the list of people who can install the application.

- View feedback that mobile users have sent about an application.

- Obtain information about applications installed on a device.
- Make an application inactive so that it is not visible in the available applications for download.

From the mobile client you can:

- List available mobile applications.
- Install a new application on a device.
- Send feedback about an application.

The Application Center supports applications for Android, iOS, Windows Phone 8, Windows 8, and BlackBerry devices. Therefore, the mobile client comes in several versions: an Android, an iOS, a Windows Phone 8, a Windows 8, and a BlackBerry version.

The Android, iOS and Windows Phone 8 mobile clients are built on the MobileFirst platform. You will find instructions in this document about how to configure the Application Center server-side component on various Java application servers after the product is installed, as well as how to build MobileFirst applications for the Application Center client.

Preliminary information

To use the Application Center, you must configure security settings, start the web application server where IBM MobileFirst Platform Foundation is installed, start the Application Center console, and log in.

When you install IBM MobileFirst Platform Foundation, the Application Center is automatically installed in the specified application server.

If you install the Application Center in WebSphere Application Server Liberty profile, the server is created and located in *installation-directory/server*.

After the installation is complete, you must configure the security settings for the applications. See “Configuring user authentication for Application Center” on page 6-270 or, if you are using LDAP authentication, “Managing users with LDAP” on page 6-274.

The following example shows how to start the server and then the Application Center console on Liberty profile.

You can start the Liberty server by using the server command located in the directory *installation-directory/server/wlp/bin*.

To start the server, use the command:

```
server start worklightServer
```

When the server is running, you can start the Application Center console by entering this address in your browser:

```
http://localhost:9080/appcenterconsole/
```

You are requested to log in. By default, the Application Center installed on Apache Tomcat or WebSphere Liberty Profile has two users defined for this installation:

- **demo** with password demo
- **appcenteradmin** with password admin

To start using the Application Center console, refer to “The Application Center console” on page 13-86.

To install and run the mobile client on:

- Android operating system: see “Installing the client on an Android mobile device” on page 13-121.
- iOS operating system: see “Installing the client on an iOS mobile device” on page 13-124.
- BlackBerry OS 6 and OS 7: see “Installing the client on a BlackBerry mobile device” on page 13-128.
- Windows Phone 8: see “Installing the client on Windows Phone 8” on page 13-129.

Windows 8: The mobile client for Windows 8 is not intended to be deployed in Application Center for later distribution. See “Microsoft Windows 8: Building the project” on page 13-76.

Preparations for using the mobile client

To use the mobile client to install apps on mobile devices, you must either generate the app by using the provided Eclipse and Visual Studio projects or use the version of the client provided for Android, iOS, Windows Phone, Windows 8, or BlackBerry directly.

Prerequisites for building the Application Center installer

The Application Center comes with an Android, an iOS, a Windows Phone, a Windows 8, and a BlackBerry version of the client application that runs on the mobile device. This mobile application that supports installation of applications on your mobile device is called the mobile client. The mobile client is a MobileFirst mobile application.

The MobileFirst project **IBMAppCenter** contains the Android, the iOS, and the Windows Phone versions of the client.

The Windows 8 project is provided as a Visual Studio project located at `IBMApplicationCenterWindowsStore\AppCenterClientWindowsStore.csproj`.

The BlackBerry project **IBMAppCenterBlackBerry6** contains the version of the client for BlackBerry OS 6 and OS 7 devices. BlackBerry OS 10 is not supported by the current version of the Application Center.

Prerequisites specific to the Android operating system

The Android version of the mobile client is included in the software delivery in the form of an Android application package (.apk) file. The `IBMApplicationCenter.apk` file is in the directory `ApplicationCenter/installer`. Push notifications are disabled. If you want to enable push notifications, you must rebuild the .apk file. See “Push notifications of application updates” on page 13-80 for more information about push notifications in the Application Center.

To build the Android version, you must have the latest version of the Android development tools.

Prerequisites specific to Apple iOS operating system

The iOS version for iPad and iPhone is not delivered as a compiled application. The application must be created from the MobileFirst project named **IBMAppCenter**. This project is also delivered as part of the distribution in the `ApplicationCenter/installer` directory.

To build the iOS version, you must have the appropriate MobileFirst and Apple software. The version of MobileFirst Studio must be the same as the version of IBM MobileFirst Platform Server on which this documentation is based. The Apple Xcode version is V6.1.

Prerequisites specific to Microsoft Windows Phone operating system

The Windows Phone version of the mobile client is included as an unsigned Windows Phone application package (.xap) file in the software delivery. The `IBMApplicationCenterUnsigned.xap` file is in the `ApplicationCenter/installer` directory.

The unsigned .xap file cannot be used directly. You must sign it with your company certificate obtained from Symantec/Microsoft **before** you can install it on a device.

Optional: If necessary, you can also build the Windows Phone version from sources.

To build the Windows Phone version, you must have the latest version of the Microsoft Visual Studio development tools.

Prerequisites specific to Microsoft Windows 8 operating system

The Windows 8 version of the mobile client is included as an archive (.zip file). The `IBMApplicationCenterWindowsStore.zip` file contains an executable file (.exe) and its dependent Dynamic-Link Library (.dll) files. To use the content of this archive, you download the archive to a location on your local drive and run the executable file.

Optional: If necessary, you can also build the Windows 8 version from sources. For this purpose, you must have the latest version of Microsoft Visual Studio.

Prerequisites specific to the BlackBerry operating system

The BlackBerry version is included as an archive (.zip) file. The `IBMApplicationCenterBB6.zip` file is in the `ApplicationCenter/installer` directory.

Optional: If necessary, you can also build the BlackBerry version from sources by using the BlackBerry project named **IBMAppCenterBlackBerry6**. This project is delivered as part of the distribution in the `ApplicationCenter/installer` directory.

To build the BlackBerry version, you must have the BlackBerry Eclipse IDE (or Eclipse with the BlackBerry Java plug-in) with the BlackBerry SDK 6.0. The application also runs on BlackBerry OS 7 when compiled with BlackBerry SDK 6.0.

Download the software from: <https://developer.blackberry.com/java/download/eclipse/>.

1. Start the BlackBerry Eclipse IDE.
2. Select **Help > Install New Software > Work with: BlackBerry Update Site**.
3. Expand the BlackBerry Java Plug-in Category and select “BlackBerry Java SDK 6.0.x.y.”

Importing and building the project (Android, iOS, Windows Phone)

You must import the **IBMAppCenter** project into MobileFirst Studio and then build the project.

About this task

Follow the normal procedure to import a project into MobileFirst Studio.

Procedure

1. Select **File > Import**.
2. Select **General > Existing Project into Workspace**.
3. On the next page, select **Select root directory** and locate the root of the **IBMAppCenter** project.
4. Select “**IBMAppCenter project**”.
5. Select “**Copy projects into workspace**”. This selection creates a copy of the project in your workspace. On UNIX systems, the **IBMAppCenter** project is read only at the original location. so copying projects into workspace avoids problems with file permissions.
6. Click **Finish** to import the **IBMAppCenter** project into MobileFirst Studio.

What to do next

Build the **IBMAppCenter** project. The MobileFirst project contains a single application named AppCenter. Right-click the application and select **Run as > Build All Environments**.

Android

MobileFirst Studio generates a native Android project in `IBMAppCenter/apps/AppCenter/android/native`. A native Android development tools (ADT) project is in the `android/native` folder. You can compile and sign this project by using the ADT tools. This project requires Android SDK level 16 to be installed, so that the resulting APK is compatible with all Android versions 2.3 and later. If you choose a higher level of the Android SDK when you build the project, the resulting APK will not be compatible with Android version 2.3.

See the Android site for developers for more specific Android information that affects the mobile client application.

If you want to enable push notifications for application updates, you must first configure the Application Center client properties. See “Configuring push notifications for application updates” on page 13-81 for more information.

iOS MobileFirst Studio generates a native iOS project in `IBMAppCenter/apps/AppCenter/iphone/native`. The `IBMAppCenterAppCenterIphone.xcodeproj` file is in the `iphone/native` folder. This file is the Xcode project that you must compile and sign by using Xcode.

See The Apple developer site to learn more about how to sign the iOS mobile client application. To sign an iOS application, you must change the

Bundle Identifier of the application to a bundle identifier that can be used with the provisioning profile that you use. The value is defined in the Xcode project settings as `com.your_internet_domain_name.appcenter`, where `your_internet_domain_name` is the name of your internet domain.

If you want to enable push notifications for application updates, you must first configure the Application Center client properties. See “Configuring push notifications for application updates” on page 13-81 for more information.

Windows Phone 8

MobileFirst Studio generates a native Windows Phone 8 project in `IBMApCenter/apps/AppCenter/windowsphone8/native`. The `AppCenter.csproj` file is in the `windowsphone8/native` folder. This file is the Visual Studio project that you must compile by using Visual Studio and the Windows Phone 8.0 SDK.

The application is built with the Windows Phone 8.0 SDK so that it can run on Windows Phone 8.0 and 8.1 devices. It is not built with the Windows Phone 8.1 SDK, because the result would not run on earlier Windows Phone 8.0 devices.

The installation of Visual Studio 2013 enables you to select the installation of the Windows Phone 8.0 SDK in addition to the 8.1 SDK. The Windows Phone 8.0 SDK is also available from Windows Phone SDK Archives.

See Windows Phone Dev Center to learn more about how to build and sign the Windows Phone mobile client application.

See “Developing MobileFirst applications” on page 8-1 for more information about how you can create hybrid mobile applications with MobileFirst Studio.

Customizing features (for experts): Android, iOS, Windows Phone

You can customize features by editing a central property file and manipulating some other resources.

Purpose

To customize features: several features are controlled by a central property file called `config.json` in the directory `IBMApCenter/apps/AppCenter/common/js/appcenter/`. If you want to change the default application behavior, you can adapt this property file before you build the project.

Properties

This file contains the properties shown in the following table.

Table 13-110. Properties in the `config.js` file

Property	Description
<code>url</code>	The hardcoded address of the Application Center server. If this property is set, the address fields of the Login view are not displayed.
<code>defaultPort</code>	If the <code>url</code> property is null, this property prefills the <code>port</code> field of the Login view on a phone. This is a default value; the field can be edited by the user.

Table 13-110. Properties in the config.js file (continued)

Property	Description
defaultContext	If the url property is null, this property prefills the context field of the Login view on a phone. This is a default value; the field can be edited by the user.
ssl	The default value of the SSL switch of the Login view.
allowDowngrade	This property indicates whether installation of older versions is authorized or not; an older version can be installed only if the operating system and version permit downgrade,
showPreviousVersions	This property indicates whether the device user can show the details of all the versions of applications or only details of the latest version.
showInternalVersion	This property indicates whether the internal version is shown or not. If the value is false, the internal version is shown only if no commercial version is set.
listItemRenderer	This property can have one of these values: <ul style="list-style-type: none"> • full, the default value; the application lists show application name, rating, and latest version. • simple: the application lists show the application name only.
listAverageRating	This property can have one of these values: <ul style="list-style-type: none"> • latestVersion: the application lists show the average rating of the latest version of the application. • allVersions: the application lists show the average rating of all versions of the application.
requestTimeout	This property indicates the timeout in milliseconds for requests to the Application Center server.
gcmProjectId	The Google API project ID (project name = com.ibm.appcenter), which is required for Android push notifications; for example, 123456789012.
allowAppLinkReview	This property indicates whether local reviews of applications from external application stores can be registered and browsed in the Application Center. These local reviews are not visible in the external application store. These reviews are stored in the Application Center server.

Other resources

Other resources that are available are application icons, application name, splash screen images, icons, and translatable resources of the application.

Application icons

Android: The file named `icon.png` in the `IBMAppCenter/apps/AppCenter/android/native/res/drawable` directories; one directory exists for each density.

iOS: Files named `iconsize.png` in the `IBMAppCenter/apps/AppCenter/iphone/native/Resources` directory.

Windows Phone: Files named `ApplicationIcon.png`, `IconicTileSmallIcon.png`, and `IconicTileMediumIcon.png` in the `IBMAppCenter/apps/AppCenter/windowsphone8/native` directory.

Application name

Android: Edit the **app_name** property in the `IBMAppCenter/apps/AppCenter/android/native/res/values/strings.xml` file.

iOS: Edit the **CFBundleDisplayName** key in the `IBMAppCenter/apps/AppCenter/iphone/native/IBMAppCenterAppCenterIphone-Info.plist` file.

Windows Phone: Edit the **Title** attribute of the **App** entry in the `IBMAppCenter/apps/AppCenter/windowsphone8/native/Properties/WMAAppManifest.xml` file.

Splash screen images

Android: Edit the file named `splashimage.9.png` in the `IBMAppCenter/apps/AppCenter/android/native/res/drawable/density` directories; one directory exists for each density. This file is a patch 9 image.

iOS: Files named `Default-size.png` in the `IBMAppCenter/apps/AppCenter/iphone/native/Resources` directory.

Hybrid splash screen during auto login: `/IBMAppCenter/apps/AppCenter/common/js/idx/mobile/themes/common/idx/Launch.css`

Windows Phone: Edit the file named `SplashScreenImage.png` in the `IBMAppCenter/apps/AppCenter/windowsphone8/native` directory.

Icons (buttons, stars, and similar objects) of the application

`IBMAppCenter/apps/AppCenter/common/css/images`.

Translatable resources of the application

`IBMAppCenter/apps/AppCenter/common/js/appcenter/nls/common.js`.

Microsoft Windows 8: Building the project

Build the Application Center client project for Windows 8 in Microsoft Visual Studio 2013.

About this task

You must build the client project in Microsoft Visual Studio 2013 before you can distribute it.

Building the project is a prerequisite to distributing it to your users, but the Windows 8 mobile client is not intended to be deployed on Application Center for later distribution.

Procedure

To build the Windows 8 project:

1. Open the Visual Studio project file called `IBMApplicationCenterWindowsStore\AppCenterClientWindowsStore.csproj` in Microsoft Visual Studio 2013.
2. Perform a full build of the application.

What to do next

To distribute the mobile client to your Application Center users, you can later generate an installer that will install the generated executable (.exe) file and its dependent Dynamic-Link Library (.dll) files. Alternatively, you can provide these files without including them in an installer.

Importing and building the project (BlackBerry)

You must import the BlackBerry project into the BlackBerry Eclipse IDE and then build the project.

About this task

Follow the normal procedure to import a project into the BlackBerry Eclipse IDE. Support for BlackBerry platform OS versions 6 and 7 is deprecated and might be removed in future versions; it continues to work in this version of Application Center.

Procedure

1. Select **File > Import**.
2. Select **General > Existing Project into Workspace**.
3. On the next page, select **Select root directory** and locate the root of the **IBMApCenterBlackBerry6** project.
4. Select "IBMApCenterBlackBerry6 project".
5. Click **Finish** to import the **IBMApCenterBlackBerry6** project into the BlackBerry Eclipse IDE.

What to do next

The **IBMApCenterBlackBerry6** project is a native BlackBerry application that requires protected BlackBerry API. Therefore, you must first obtain a signature to sign the project. In your web browser, open <https://www.blackberry.com/SignedKeys/codesigning.html>. Follow the instructions to obtain the signature, which consists of several keys. All signature keys must be imported into Eclipse by using **Window > Preferences > BlackBerry Java Plugin > Signature Tool**.

To build the **IBMApCenterBlackBerry6** project:

1. Right-click the project and select **BlackBerry > Package Project(s)**.
This action packages the project.
2. Right-click the project and select **BlackBerry > Sign with Signature Tool**.
This action signs the project.

The result is located in a generated directory called `deliverables`. This directory contains two subdirectories:

Standard

This directory contains the packaged application for uploading with USB cable to the device. This method is incompatible with the packaging required for the Application Center server.

Web

This directory contains the packaged application for uploading over the air. This method is compatible with the Application Center. Therefore, use this directory and **not** the Standard directory. Place this directory into an archive (.zip) file.

Important: Make sure that the archive file does not contain the Standard directory.

Refer to the BlackBerry site for developers for more specific information that affects the mobile client application for BlackBerry projects.

Customizing features (for experts): BlackBerry

You can customize features by adapting a central property file and manipulating some other resources .

Note: Support for BlackBerry platform OS versions 6 and 7 is deprecated and might be removed in future versions; it continues to work in this version of Application Center.

Purpose

To customize features: look and feel and various features are controlled by a central property file called `appcenter.properties` in the directory `IBMAppCenterBlackBerry6/src/main/resources`. If you want to disable or customize various features, you can adapt this property file before you build the project. For example, you can disable the feature for reverting the installation of an application to a previous version.

Properties

This file contains the properties shown in the following table.

Table 13-111. Properties in the `appcenter.properties` file

Property	Description
<code>defaultServer</code>	The default value of the <code>server</code> field of the Login view. The field can be edited by the user.
<code>defaultPort</code>	The default value of the <code>port</code> field of the Login view. The field can be edited by the user.
<code>defaultContext</code>	The default value of the <code>context</code> field of the Login view. The field can be edited by the user.
<code>defaultUseSSL</code>	The default value of the SSL switch of the Login view.
<code>serverSettingVisibleInLoginScreen</code>	This property indicates whether the server, port, and context fields and the SSL check box are visible in the login screen. If this property is disabled, the <code>defaultServer</code> , <code>defaultPort</code> , <code>defaultContext</code> , and <code>defaultUseSSL</code> properties must be set, because the user cannot edit their values when they are not visible.
<code>KeepLoginCredentialsTime</code>	The number of minutes the password remains valid after exiting the application. If set to 0, the user must log in again whenever the application starts. If set to -1, the login credentials are kept forever until the user explicitly logs out. If any other value is given and the user restarts the application within this time, it is not necessary to log in again.

Table 13-111. Properties in the appcenter.properties file (continued)

Property	Description
listAverageRating	This property can have one of these values: <ul style="list-style-type: none"> latestVersion: the application lists show the average rating of the latest version of the application. allVersions: the application lists show the average rating of all versions of the application.
AdaptAppCatalogInfoLineToSorting	This property indicates whether the rendering of the application list shows popularity or updates when sorting according to popularity and updates. Normally, the rendering shows version numbers. When this feature is enabled and you choose sorting according to the timestamps of popularity or updates, the rendering shows popularity or update timestamps instead of versions.

Other resources

Other resources that are available are application icon, application name, icons, and translatable resources of the application.

Application icon

IBMAppCenterBlackBerry6/src/main/resources/img/launchicon-144x144.png.

Application name

Edit the IBMAppCenterBlackBerry6/BlackBerry_App_Descriptor.xml file. The key **title** is the application name.

Icons (buttons, stars, and similar objects) of the application

IBMAppCenterBlackBerry6/src/main/resources/img/.

Depending on the color theme, either dark or light icons are chosen. For example, if the background is dark, light icons are chosen. Therefore, all icon file names have the suffix “light” or “dark”. Several buttons can be disabled. To show the corresponding icon on a disabled button, some icons have the file name suffix “t50”. The visual indicator of disabled buttons is implemented by adding 50% transparency to the icon.

Translatable resources of the application

IBMAppCenterBlackBerry6/src/main/resources/com/ibm/appcenter/i18n/I18N.rrc.

Deploying the mobile client in Application Center

Deploy the different versions of the client application to Application Center.

The Windows 8 mobile client is not intended to be deployed in Application Center for later distribution. You can choose to distribute the Windows 8 mobile client the way you want, either by providing users with the client executable file (.exe) and dynamic link library (.dll) files directly packaged in an archive, or by creating an executable installer for the Windows 8 mobile client.

The Android, iOS, Windows Phone, and BlackBerry versions of the mobile client must be deployed to the Application Center. To do so, you must upload the Android application package (.apk) files, iOS application (.ipa) files, Windows Phone application (.xap) files, and BlackBerry Web directory archive (.zip) files to the Application Center.

Follow the steps described in “Adding a mobile application” on page 13-89 to add the mobile client application for Android, iOS, Windows Phone, and BlackBerry. Make sure that you select the **Installer** application property to indicate that the application is an installer. Selecting this property enables mobile device users to install the mobile client application easily over the air. To install the mobile client, see the related task that corresponds to the version of the mobile client app determined by the operating system.

Related tasks:

“Installing the client on an Android mobile device” on page 13-121

You can install the mobile client, or any signed application marked with the installer flag, on your Android mobile device by entering the access URL in your browser, entering your credentials, and completing the required steps.

“Installing the client on an iOS mobile device” on page 13-124

You can install the mobile client, or any signed application marked with the installer flag, on your iOS mobile device by entering the access URL in your browser, entering your credentials, and completing the required steps.

“Installing the client on Windows Phone 8” on page 13-129

You can install the mobile client, or any signed application marked with the installer flag, on Windows Phone 8 by entering the access URL in your browser, entering your credentials, and completing the required steps. The company account must be preinstalled on your mobile device.

“Installing the client on a BlackBerry mobile device” on page 13-128

You can install the mobile client, or any signed application marked with the installer flag, on your BlackBerry mobile device by entering the access URL in your browser, entering your credentials, and completing the required steps.

Push notifications of application updates

You can configure the Application Center client so that push notifications are sent to users when an update is available for an application in the store.

The Application Center administrator uses push notifications to send notification automatically, to any iOS or Android device. Notifications are sent for updates to favorite applications and of new applications that are deployed on the Application Center server and that are marked as recommended.

Restriction: Push notifications are not available for the BlackBerry Application Center client.

Push notification process

Push notifications are sent to a device if the following conditions are met:

- The device has Application Center installed and started it at least one time.
- The user has not disabled push notification for this device for the Application Center in the **Settings > Notifications** interface.
- The user is allowed to install the application. Such permissions are controlled through the Application Center access rights.

- The application is marked as recommended, or is marked as preferred for the user who is using Application Center on this device. Those flags are set automatically when the user installs an application through Application Center. You can see which applications are marked as preferred by looking at the Application Center **Favorites** tab on the device.
- The application is not installed on the device or a more recent version is available than the version that is installed on the device.

The first time that the Application Center client starts on a device, the user might be asked whether to accept incoming push notifications. This is the case for iOS mobile devices. The push notification feature does not work when the service is disabled on the mobile device.

iOS and modern Android operating system versions offer a way to switch this service on or off on a per application basis.

Refer to your device vendor to learn how to configure your mobile device for push notifications.

Related concepts:

“Marking or unmarking a favorite app” on page 13-160

Mark your favorite apps or unmark an app to have it removed from the favorites list.

Related reference:

“Application properties” on page 13-94

Applications have their own sets of properties that depend on the operating system on the mobile device and that cannot be edited. Applications also have a common property and editable properties.

Configuring push notifications for application updates

Configure the Application Center services to communicate with Google or Apple push notification servers.

Purpose

You must configure the credentials or certificates of the Application Center services to be able to communicate with third-party push notification servers.

Configuring the server scheduler of the Application Center

The server scheduler is a background service that automatically starts and stops with the server. This scheduler is used to empty at regular intervals a stack that is automatically filled by administrator actions with push update messages to be sent. The default interval between sending two batches of push update messages is twelve hours. If this default value does not suit you, you can modify it by using the server environment variables *ibm.appcenter.push.schedule.period.amount* and *ibm.appcenter.push.schedule.period.unit*.

The value of *ibm.appcenter.push.schedule.period.amount* is an integer. The value of *ibm.appcenter.push.schedule.period.unit* can be seconds, minutes, or hours. If the unit is not specified, the amount is an interval that is expressed in hours. These variables are used to define the elapsed time between two batches of push messages.

Use JNDI properties to define these variables.

Important: In production, you should avoid setting the unit to seconds. The shorter the elapsed time, the higher the load on the server; the unit expressed in

seconds is only implemented for testing and evaluation purposes. For example, when the elapsed time is set to 10 seconds, push messages are sent almost immediately.

See “List of JNDI properties for the Application Center” on page 6-307 for a complete list of properties that you can set.

Example for Apache Tomcat server

Define these variables with JNDI properties in the `server.xml` file:

```
<Environment name="ibm.appcenter.push.schedule.period.unit" override="false" type="java.lang.String"
<Environment name="ibm.appcenter.push.schedule.period.amount" override="false" type="java.lang.String"/>
```

For information about how to configure JNDI variables for WebSphere Application Server v8.5, see Using resource environment providers in WebSphere Application Server.

For information about how to configure JNDI variables for WebSphere Application Server Liberty profile, see Using JNDI binding for constants from the server configuration files.

The remaining actions for setting up the push notification service depend on the vendor of the device where the target application is installed. See the following topics.

Configuring the Application Center server for connection to Google Cloud Messaging

Enable Google Cloud Messaging (GCM) for your application.

About this task

To enable Google Cloud Messaging (GCM) for an application, you must attach the GCM services to a developer Google account with the Google API enabled. See Getting Started with GCM for details.

Important: The Application Center client without Google Cloud Messaging: The Application Center relies on the availability of the Google Cloud Messaging (GCM) API. This API might not be available on devices in some territories such as China. To support those territories, you can build a version of the Application Center client that does not depend on the GCM API. The push notification feature does not work on that version of the Application Center client. See “Building a version of the mobile client that does not depend on the GCM API” on page 13-85 for details.

Procedure

1. If you do not have the appropriate Google account, go to Create a Google account and create one for the Application Center client.
2. Register this account by using the Google API in the Google API console. Registration creates a new default project that you can rename. The name you give to this GCM project is not related to your Android application package name. When the project is created, a GCM project ID is appended to the end of the project URL. You should record this trailing number as your project ID for future reference.

3. Enable the GCM service for your project; in the Google API console, click the **Services** tab on the left and enable the “Google Cloud Messaging for Android” service in the list of services.
4. Make sure that a Simple API Access Server key is available for your application communications.
 - a. Click the **API Access** vertical tab on the left of the console.
 - b. Create a Simple API Access Server key or, if a default key is already created, note the details of the default key. Two other kinds of key exist that are not of interest at this time.
 - c. Save the Simple API Access Server key for future use in your application communications through GCM. The key is about 40 characters long and is referred to as the Google API key that you will need later on the server side.
5. Enter the GCM project ID as a string resource property in the JavaScript project of the Application Center Android client; in the `IBMAppCenter/apps/AppCenter/common/js/appcenter/config.json` template file, modify this line with your own value:

```
gcmProjectId:""// Google API project (project name = com.ibm.appcenter) ID needed for Android push.
// example : 123456789012
```

6. Register the Google API key as a JNDI property for the Application Center server. The key name is : **ibm.appcenter.gcm.signature.googleapikey**. For example, you can configure this key for an Apache Tomcat server as a JNDI property in the `server.xml` file:

```
<Context docBase="AppCenterServices" path="/applicationcenter" reloadable="true" source="org.eclipse.jst.jee.server:AppCenterServices">
<Environment name="ibm.appcenter.gcm.signature.googleapikey" override="false" type="java.lang.String"
value="AIxaScCHg0VSGdgf0ZKtzDJ44-oi0muUasMZvAs"/>
</Context>
```

The JNDI property must be defined in accordance with your application server requirements.

See “List of JNDI properties for the Application Center” on page 6-307 for a complete list of properties that you can set.

Important:

- If you use GCM with earlier versions of Android, you might need to pair your device with an existing Google account for GCM to work effectively. See GCM service: “It uses an existing connection for Google services. For pre-3.0 devices, this requires users to set up their Google account on their mobile devices. A Google account is not a requirement on devices running Android 4.0.4 or higher.”
- You must also ensure that your firewall accepts outgoing connections to `android.googleapis.com` on port 443 for push notifications to work.

Configuring the Application Center server for connection to Apple Push Notification Services

Configure your iOS project for Apple Push Notification Services (APNs).

Before you begin

Ensure that the following servers are accessible from Application Center server.

Sandbox servers

- `gateway.sandbox.push.apple.com:2195`
- `feedback.sandbox.push.apple.com:2196`

Production servers

- gateway.push.apple.com:2195
- feedback.push.apple.com:2196

About this task

You must be a registered Apple developer to successfully configure your iOS project with Apple Push Notification Services (APNs). In the company, the administrative role responsible for Apple development requests APNs enablement. The response to this request should provide you with an APNs-enabled provisioning profile for your iOS application bundle; that is, a string value that is defined in the configuration page of your Xcode project. This provisioning profile is used to generate a signature certificate file.

Two kinds of provisioning profile exist: development and production profiles, which address development and production environments respectively. Development profiles address Apple development APNs servers exclusively. Production profiles address Apple production APNs servers exclusively. These kinds of servers do not offer the same quality of service.

Note: Devices that are connected to a company wifi behind a firewall are only able to receive push notifications if connection to the following type of address is not blocked by the firewall.

`x-courier.sandbox.push.apple.com:5223`

Where x is an integer number.

Procedure

1. Obtain the APNs-enabled provisioning profile for the Application Center Xcode project. The result of your administrator's APNs enablement request is shown as a list accessible from `https://developer.apple.com/ios/my/bundles/index.action`. Each item in the list shows whether or not the profile has APNs capabilities. When you have the profile, you can download and install it in the Application Center client Xcode project directory by double-clicking the profile. The profile is then automatically installed in your keystore and Xcode project.
2. If you want to test or debug the Application Center on a device by launching it directly from Xcode, in the Xcode Organizer window, go to the Provisioning Profiles section and install the profile on your mobile device.
3. Create a signature certificate used by the Application Center services to secure communication with the APNs server. This server will use the certificate for purposes of signing each and every push request to the APNs server. This signature certificate is produced from your provisioning profile.
 - a. Open the Keychain Access utility and click the **My Certificates** category in the left pane.
 - b. Find the certificate you want to install and disclose its contents. You see both a certificate and a private key; for the Application Center, the certificate line contains the Application Center application bundle `com.ibm.imf.AppCenter`.
 - c. Select **File > Export Items** to select both the certificate and the key and export them as a Personal Information Exchange (.p12) file. This .p12 file contains the private key required when the secure handshaking protocol is involved to communicate with the APNs server.
 - d. Copy the .p12 certificate to the computer responsible for running the Application Center services and install it in the appropriate place. Both the

certificate file and its password are needed to create the secure tunneling with the APNs server. You also require some information that indicates whether a development certificate or a production certificate is in play. A development provisioning profile produces a development certificate and a production profile gives a production certificate. The Application Center services web application uses JNDI properties to reference this secure data.

The examples in the table show how the JNDI properties are defined in the server.xml file of the Apache Tomcat server.

Table 13-112. JNDI properties

JNDI Property	Type and description	Example for Apache Tomcat server
<code>ibm.appcenter.apns.p12.certificate.location</code>	defines the full path to the .p12 certificate.	Environment name=" <code>ibm.appcenter.apns.p12.certificate.location</code> " override="false" type="java.lang.String" value=" <code>"/Users/someUser/someDirectory/apache-tomcat/conf/AppCenter.p12</code> ">
<code>ibm.appcenter.apns.p12.certificate.password</code>	defines the password needed to access the certificate.	Environment name=" <code>ibm.appcenter.apns.p12.certificate.password</code> " type="java.lang.String" value=" <code>"this_is_a_secure_password"</code> ">
<code>ibm.appcenter.apns.p12.certificate.isDevelopmentCertificate</code>	(identified as true or false) that defines whether or not the provisioning profile used to generate the authentication certificate was a development certificate.	Environment name=" <code>ibm.appcenter.apns.p12.certificate.isDevelopmentCertificate</code> " override="false" type="java.lang.String" value=" <code>"true"</code> ">

See “List of JNDI properties for the Application Center” on page 6-307 for a complete list of JNDI properties that you can set.

Building a version of the mobile client that does not depend on the GCM API

You can remove the dependency on Google Cloud Messaging (GCM) API from the Android version of the client to comply with constraints in some territories. Push notifications do not work on this version of the client.

About this task

The Application Center relies on the availability of the Google Cloud Messaging (GCM) API. This API might not be available on devices in some territories such as China. To support those territories, you can build a version of the Application Center client that does not depend on the GCM API. The push notification feature does not work on that version of the Application Center client.

Procedure

1. Check that push notifications are disabled by checking that the `IBMAppCenter/apps/AppCenter/common/js/appcenter/config.json` file contains this line: `"gcmProjectId": ""` ,.

2. Remove from two places in the `IBMAppCenter/apps/AppCenter/android/native/AndroidManifest.xml` file all the lines that are located between these comments: `<!-- AppCenter Push configuration -->` and `<!-- end of AppCenter Push configuration -->`.
3. Delete the `IBMAppCenter/apps/AppCenter/android/native/src/com/ibm/appcenter/GCMIntenteService.java` class.
4. In Eclipse, run "Build Android Environment" in the `IBMAppCenter/apps/AppCenter/android` folder.
5. Delete the `IBMAppCenter/apps/AppCenter/android/native/libs/gcm.jar` file that was created by the MobileFirst plug-in when you ran the previous "Build Android Environment" command.
6. Refresh the newly created `IBMAppCenterAppCenterAndroid` project, so that the removal of the GCM library is taken into account.
7. Build the `.apk` file of the Application Center.

What to do next

The `gcm.jar` library is automatically added by the MobileFirst Eclipse plug-in each time that the Android environment is built. Therefore, this java archive file must be deleted from the `IBMAppCenter/apps/AppCenter/android/native/libs/` directory each time that the MobileFirst Android build process is run. Otherwise, the `gcm.jar` library is present in the resulting `appcenter.apk` file.

The Application Center console

With the Application Center console, you can manage the repository of the Application Center and your applications.

The Application Center console is a web application to manage the repository of the Application Center. The Application Center repository is the central location where you store the mobile applications that can be installed on mobile devices.

Use the Application Center console to:

- Upload applications written for these operating systems: Android, iOS, BlackBerry OS 6 and OS 7, Windows 8 (Windows Store packages only), or Windows Phone 8.
- Manage several different versions of mobile applications.
- Review the feedback of testers of mobile applications.
- Define the users who have the rights to list and install an application on the mobile devices.
- Track which applications are installed on which devices.

Note:

Only users with the administrator role can log in to the Application Center console.

Multicultural support: the user interface of the Application Center console has not been translated.

Starting the Application Center console

You can start the Application Center with your web browser and log in if you have the administrator role.

Procedure

1. Start a web browser session on your desktop.
2. Contact your system administrator to obtain the address and port of the server where the Application Center is installed.
3. Enter the following URL: `http://server/appcenterconsole`
Where *server* is the address and port of the server where the Application Center is installed.
`http://localhost:9080/appcenterconsole`
4. Log in to the Application Center console
Contact your system administrator to get your credentials so that you can log in to the Application Center console.

Figure 13-9. Login of the Application Center console

Note:

Only users with the administrator role can log in to the Application Center console.

Troubleshooting a corrupt login page (Apache Tomcat)

You can recover from a corrupt login page of the Application Center console when the Application Center is running in Apache Tomcat.

Symptom

When the Application Center is running in Apache Tomcat, the use of a wrong user name or password might corrupt the login page of the Application Center console.

When you try to log in to the console with an incorrect user name or an incorrect password, you receive an error message. When you correct the user name or password, instead of a successful login, you have one of the following errors; the message depends on your web browser.

- The same error message as before
- The message "The connection was reset"
- The message "The time allowed for login exceeded"

Cause

The behavior is linked to the management by Apache Tomcat of the `j_security_check` servlet. This behavior is specific to Apache Tomcat and does not occur in any of the WebSphere Application Server profiles.

Solution

The workaround is to click the refresh button of the browser to refresh the web page after a login failure. Then, enter the correct credentials.

Troubleshooting a corrupted login page in Safari browsers

You can recover from a corrupted login page of the Application Center console when you use the Safari browser.

Symptom

When the Application Center console is open in a Safari browser, you might navigate away from the console. When you come back to the console, you might see the login page. Even though you enter the correct login details, you see the following message instead of a successful login:

```
HTTP Status 404 - appcenterconsole/j_security_check.
```

Cause

The behavior is linked to a caching problem in the Safari browser.

Solution

The workaround is to trigger a forced reload when you see the login page without entered or autocompleted credentials. Here is how to trigger a forced reload:

- On a Mac computer, press Shift + the **Refresh** button.
- On an iPad or iPhone device: Double-click the refresh button or clean the cache by closing Safari: you double-click the home button and then swipe Safari away.

Application Management

You can use Application Management to add new applications and versions and to manage those applications.

The Application Center enables you to add new applications and versions and to manage those applications.

Click **Applications** to access Application Management.

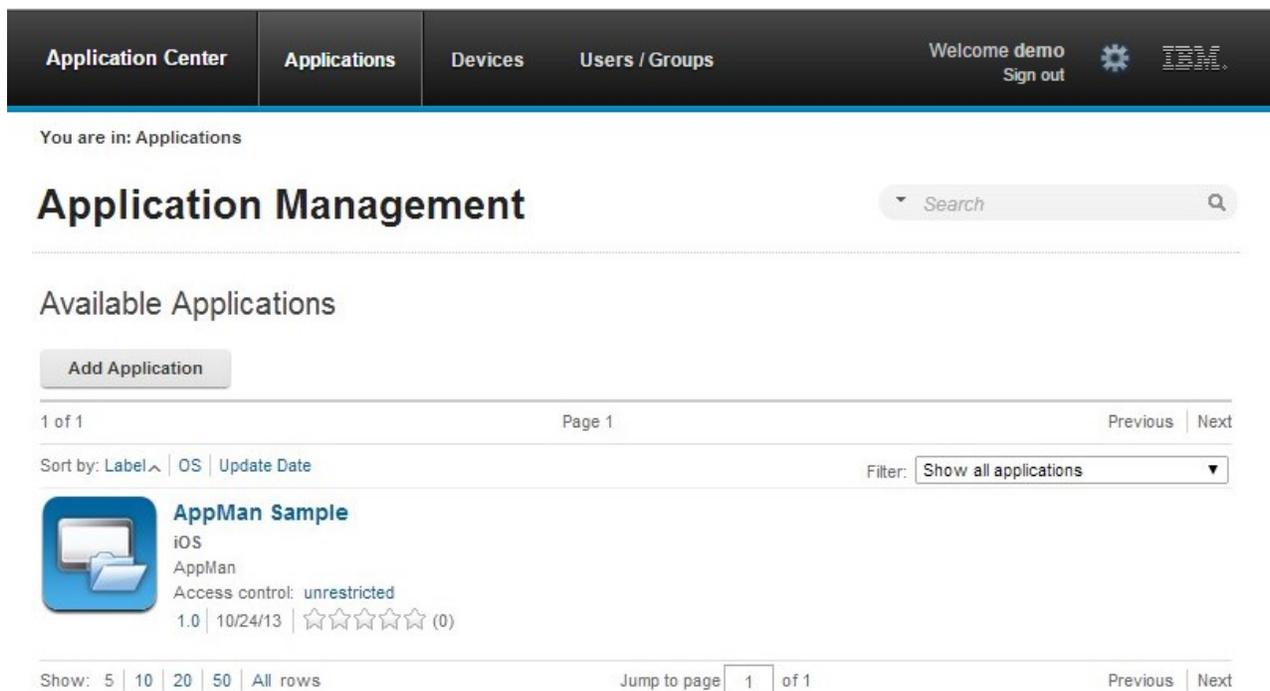

Application Center installed on WebSphere Application Server Liberty profile or on Apache Tomcat

Installations of the Application Center on these application servers, during installation of IBM MobileFirst Platform Foundation with the IBM Installation Manager package, have two different users defined that you can use to get started.

- User with login demo and password demo
- User with login appcenteradmin and password admin

WebSphere Application Server full profile

If you installed the Application Center on WebSphere Application Server full profile, one user named appcenteradmin is created by default with the password indicated by the installer.

The screenshot shows the Application Center console interface. At the top, there is a navigation bar with tabs for 'Application Center', 'Applications', 'Devices', and 'Users / Groups'. The 'Applications' tab is selected. On the right side of the navigation bar, it says 'Welcome demo' and 'Sign out' with a gear icon and the IBM logo. Below the navigation bar, it says 'You are in: Applications'. The main heading is 'Application Management' with a search bar on the right. Below the heading, there is a section for 'Available Applications' with an 'Add Application' button. Below that, there is a table showing one application: 'AppMan Sample'. The application details include 'iOS', 'AppMan', 'Access control: unrestricted', and '1.0 | 10/24/13 | ☆☆☆☆☆ (0)'. At the bottom, there is a pagination bar showing '1 of 1', 'Page 1', 'Previous', 'Next', 'Sort by: Label', 'OS', 'Update Date', 'Filter: Show all applications', 'Show: 5 | 10 | 20 | 50 | All rows', 'Jump to page 1 of 1', and 'Previous | Next'.

Figure 13-10. Available applications

Adding a mobile application

Add applications to the repository on the server by using the Application Center console. These applications can then be installed on mobile devices by using the mobile client.

About this task

In the Applications view, you can add applications to Application Center. Initially the list of applications is empty and you must upload an application file. Application files are described in this procedure.

Procedure

To add an application to make it available to be installed on mobile devices:

1. Click **Add Application**.
2. Click **Upload**.
3. Select the application file to upload to the Application Center repository.

Android

The application file extension is apk.

iOS

The application file extension is ipa for normal iOS applications.

The application file extension is zip for instrumented iOS applications for use in IBM MobileFirst Platform Test Workbench.

BlackBerry OS 6 and OS 7

The application file extension is zip. This archive file must contain a file with extension jad and all related files with extension cod. If you are using the BlackBerry Eclipse IDE for a native application, the files are in the deliverables/Web folder. You can place the entire folder in an archive (.zip) file.

If you are using the Ripple Environment in combination with IBM MobileFirst Platform Studio for a hybrid application, the files are in the OTAInstall folder. You can place the entire folder in an archive (.zip) file.

Windows Phone 8

The application file extension is xap. The application must be signed with a company account. The application enrollment token for this company account must be made available to Windows Phone 8 devices before the application can be installed on the devices. See “Application enrollment tokens in Windows Phone 8” on page 13-111 for details.

Windows 8

The application is provided as a Windows Store package; the file extension is appx.

Windows Store appx packages can be dependent on one or more Windows component library app packages, also known as “framework” packages. MobileFirst hybrid applications for Windows 8 depend on the Microsoft.WinJS framework package. When you use Microsoft Visual Studio to generate the application package, the dependencies packages are also generated and packaged as separate .appx files. To successfully install such applications by using the mobile client, you must upload onto the Application Center server the application appx package as well as any other dependency package. When you upload a dependency package, it appears as inactive in the Application Center console. This behavior is expected, so that the framework package does not appear as an installable application in the client. Later, when a user installs an application, the mobile client checks whether the dependency is already installed on the device. If the dependency package is not installed, the client will automatically retrieve the dependency package from the Application Center server and install it on the device. For more information about dependencies, see this topic

in the Windows developer documentation about packages and deployment of applications, Dependencies.

4. Click **Next** to access the properties to complete the definition of the application.
5. Complete the properties to define the application. See Application properties for information about how to complete property values.
6. Click **Finish**.

The screenshot shows the 'Add an application' form in the Application Management section. The form is titled 'Application Details' and includes a warning: 'Package, Version and Label must be set in the uploaded application package and cannot be modified afterwards.' The form fields are as follows:

Package:	AppMan <small>Identifies the application</small>
Internal Version:	1.0 <small>Internal version number used to compare versions</small>
Commercial Version:	No value set <small>Version displayed on the mobile device</small>
* Label:	AppMan Sample <small>Label of the application as defined by the developer</small>
External URL:	ibmappctr://show-app?id=AppMan <small>URL to open the Application Center mobile client on this application.</small>
Author:	demo <small>User who has uploaded this application</small>
Description:	<input type="text"/> <small>(2048 characters maximum)</small>
Minimal OS Version:	3.1 <small>The application runs on devices with OS at least this version</small>
Device Family:	iphone <small>The application runs on devices from this device family</small>
Recommended:	<input type="checkbox"/> <small>This application will be listed as a recommended application on the mobile device</small>
Installer:	<input type="checkbox"/> <small>Indicates whether this application is an installer</small>
Active:	<input checked="" type="checkbox"/> <small>An active application can be installed on a device</small>
Ready for production:	<input type="checkbox"/> <small>Indicates whether this application is ready for production</small>
Instrumented	No <small>Indicates whether this application is instrumented for IBM MobileFirst Platform Test Workbench</small>

At the bottom of the form are three buttons: 'Previous', 'Done', and 'Cancel'.

Figure 13-11. Application properties, adding an application

Adding an application from a public app store

Application Center supports adding to the catalog applications that are stored in third-party application stores, such as Google play or Apple iTunes.

About this task

Applications from third-party app stores appear in the Application Center catalog like any other application, but users are directed to the corresponding public app store to install the application. You add an application from a public app store in the console, in the same place as you add an application created within your own enterprise. See “Adding a mobile application” on page 13-89.

Note: Currently, the Application Center supports only Google play and Apple iTunes. Windows Phone Store, Windows Store, and BlackBerry App World are not yet supported.

Instead of providing the application executable, you must provide a URL to the third party application store where the application is stored. To make it easy to find the correct application link, the console provides direct links in the “Add an application” page to the supported third-party application store web sites.

The Google play store address is <https://play.google.com/store/apps>.

The Apple iTunes store address is <https://linkmaker.itunes.apple.com/>; use the linkmaker site rather than the iTunes site, because you can search this site for all kinds of iTunes items, including songs, podcasts, and other items supported by Apple. Only selecting iOS applications provides you with compatible links to create application links.

Procedure

1. Click the URL of the public app store that you want to browse.
2. Copy the URL of the application in the third-party app store to the Application URL text field in the “Add an application” page of the Application Center console.

- **Google play:**

- a. Select an application in the store.
- b. Click the detail page of the application.
- c. Copy the address bar URL.

- **Apple iTunes:**

- a. When the list of items is returned in the search result, select the item that you want.
- b. At the bottom of the selected application, click “Direct Link” to open the application details page.

Note: Do not copy the “Direct Link” to the Application Center. “Direct Link” is a URL with redirection, you will need to get the URL it redirects to.

- c. Copy the address bar URL.

3. When the application link is in the Application URL text field of the console, click **Next** to validate the creation of the application link. If the validation is successful, this action will display the application properties.

If the validation is unsuccessful, an error message will be displayed in the “Add an application” page. You can either try another link or cancel the attempt to create the current link.

If the validation of the application link is successful, you can modify the application description in the application properties before performing the next

step.

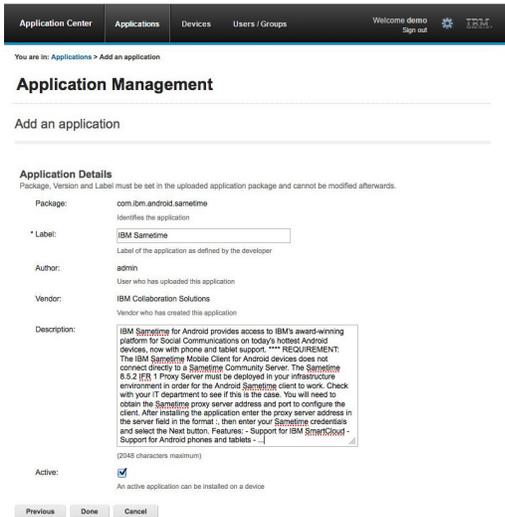

Figure 13-12. Modified application description in application properties

4. Click **Done** to create the application link. This action makes the application available to the corresponding version of the Application Center mobile client. A small link icon appears on the application icon to show that this application is stored in a public app store and is different from a binary app.

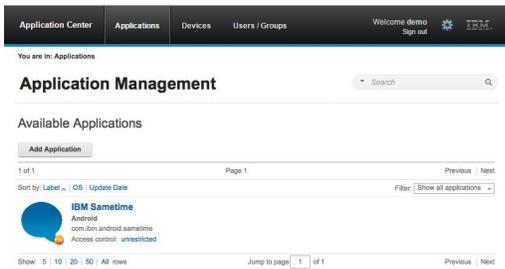

Figure 13-13. Link to an application stored in Google play

Related concepts:

Configuring WebSphere Application Server to support applications in public app stores

Configure WebSphere Application Server full profile and Liberty profile before access to public app stores through application links, because of the use of SSL connections.

Related tasks:

Configuring WebSphere Application Server to support applications in Google play
Configure WebSphere Application Server to enable links in the Application Center console to access applications in Google play.

Configuring WebSphere Application Server to support applications in Apple iTunes
Configure WebSphere Application Server to enable links in the Application Center console to access applications in Apple iTunes.

“Installing applications through public app stores” on page 13-151

You can link from the mobile client to applications that are stored in supported public app stores and install these applications on your compatible device by

following the normal procedure of the public app store.

Application properties

Applications have their own sets of properties that depend on the operating system on the mobile device and that cannot be edited. Applications also have a common property and editable properties.

The values of the following fields are taken from the application and you cannot edit them.

- **Package.**
- **Internal Version.**
- **Commercial Version.**
- **Label.**
- **External URL;** this property is supported for applications that run on Android, iOS, and Windows Phone 8.

Properties of Android applications

- **Package** is the package name of the application; **package** attribute of the **manifest** element in the manifest file of the application. See the Android SDK documentation.
- **Internal Version** is the internal version identification of the application; **android:versionCode** attribute of the **manifest** element in the manifest file of the application. See the Android SDK documentation.
- **Commercial Version** is the published version of the application.
- **Label** is the label of the application; **android:label** attribute of the **application** element in the manifest file of the application. See the Android SDK documentation.
- **External URL** Use this URL to have the mobile client of the Application Center started automatically in the Details view of the latest version of the current application.

Properties of iOS applications

- **Package** is the company identifier and the product name; **CFBundleIdentifier** key. See the iOS SDK documentation.
- **Internal Version** is the build number of the application; **CFBundleVersion** key of the application. See the iOS SDK documentation.
- **Commercial Version** is the published version of the application.
- **Label** is the label of the application; **CFBundleDisplayName** key of the application. See the iOS SDK documentation.
- **Instrumented** indicates whether the uploaded application is an instrumented application for use in IBM MobileFirst Platform Test Workbench for IBM MobileFirst Platform Foundation or a normal iOS application.
- **External URL** Use this URL to have the mobile client of the Application Center started automatically in the Details view of the latest version of the current application.

Properties of BlackBerry applications

- **Package** is the name of the application project; **MIDlet-Name** entry of the jad file. See JSR-118 specification.
- **Internal Version** is the version of the application; **MIDlet-Version** entry of the jad file. See JSR-118 specification.

- **Commercial Version**, like **Internal Version**, is the version of the application.
- **Label** is the label of the application; **MIDlet-1** entry of the jad file. See JSR-118 specification. This property is optional. The label can be set or updated during the import of the application to the Application Center.
- **Vendor** is the vendor who created this application; **MIDlet-Vendor** entry of the jad file. See JSR-118 specification.

Properties of Windows Phone 8 applications

- **Package** is the product identifier of the application; **ProductID** attribute of the **App** element in the manifest file of the application. See Windows Phone documentation.
- **Internal Version** is the version identification of the application; **Version** attribute of the **App** element in the manifest file of the application. See Windows Phone documentation.
- **Commercial Version**, like **Internal Version**, is the version of the application.
- **Label** is the title of the application; **Title** attribute of the **App** element in the manifest file of the application. See Windows Phone documentation.
- **Vendor** is the vendor who created the application; **Publisher** attribute of the **App** element in the manifest file of the application. See Windows Phone documentation.
- **External URL**: Use this URL to have the mobile client of the Application Center started automatically in the Details view of the latest version of the current application.
- **Commercial Version**, like **Internal Version**, is the version of the application.

Properties of Windows Store applications

- **Package** is the product identifier of the application; **Package name** attribute in the manifest file of the application. See Windows Store documentation about application development.
- **Internal Version** is the version identification of the application; **Version** attribute in the manifest file of the application. See Windows Store documentation about application development.
- **Commercial Version**, like **Internal Version**, is the version of the application.
- **Label** is the title of the application; **Package display name** attribute in the manifest file of the application. See Windows Store documentation about application development.
- **Vendor** is the vendor who created the application; **Publisher** attribute in the manifest file of the application. See Windows Store documentation about application development.

Common property

Author

The **Author** field is read only. It displays the user name of the user who uploads the application.

Editable properties

You can edit the following fields:

Description

Use this field to describe the application to the mobile user.

Recommended

Select **Recommended** to indicate that you recommend users to install this application. Recommended applications appear in a special list of recommended applications in the mobile client.

Installer

For the Administrator only: This property indicates that the application is used to install other applications on the mobile device and send feedback on an application from the mobile device to the Application Center. Usually only one application is qualified as **Installer** and is called the mobile client. This application is documented in "The mobile client" on page 13-121.

Active

Select **Active** to indicate that an application can be installed on a mobile device. If you do not select **Active**, the mobile user does not see the application in the list of available applications that are displayed on the device.

If you do not select **Active**, the application is inactive. In the list of available applications in Application Management, if **Show inactive** is selected, the application is disabled.

If **Show inactive** is not selected, the application does not appear in the list of available applications.

Ready for production

Select **Ready for production** to indicate that an application can be managed by the application store of Tivoli Endpoint Manager. Applications with this property selected are the only ones that are flagged to Tivoli Endpoint Manager. The property **Ready for production** indicates that an application is ready to be deployed in a production environment and is therefore suitable to be managed by Tivoli Endpoint Manager through its application store.

Editing application properties

You can edit the properties of an application in the list of uploaded applications.

Procedure

To edit the properties of an uploaded application:

1. Select **Applications** to see the list of uploaded applications: Available Applications.
2. Click the version of the application to edit the properties: Application Details.
3. Edit any of the editable properties that you want. See "Application properties" on page 13-94 for details about these properties. The name of the current application file is shown after the properties.

Important: If you want to update the file, it must belong to the same package and be the same version number. If either of these properties is not the same you must go back to the application list and add the new version first.

4. Click **OK** to save your changes and return to Available Applications or **Apply** to save and keep Application Details open.

Figure 13-14. Application properties for editing

Upgrading a mobile application in MobileFirst Server and the Application Center

You can easily upgrade deployed mobile applications by using a combination of MobileFirst Operations Console and the Application Center.

Before you begin

The mobile client of the Application Center must be installed on the mobile device. The HelloWorld application must be installed on the mobile device and must connect to MobileFirst Server when the application is running. See “Connecting to MobileFirst Server” on page 8-341.

About this task

You can use this procedure to update Android, iOS, and Windows Phone applications that have been deployed on MobileFirst Server and also in the Application Center. In this task, the application HelloWorld version 1.0 is already deployed on MobileFirst Server and in the Application Center.

Procedure

HelloWorld version 2.0 is released and you would like users of version 1.0 to upgrade to the later version. To deploy the new version of the application:

1. Deploy HelloWorld 2.0 in the Application Center. See “Adding a mobile application” on page 13-89.
2. From the Application Details page, copy the setting of the external URL.

Application Details

Package, Version and Label must be set in the uploaded application package and cannot be modified afterwards.

Package:	com.HelloWorld
	Identifies the application
Internal Version:	2
	Internal version number used to compare versions
Commercial Version:	2.0
	Version displayed on the mobile device
* Label:	<input type="text" value="HelloWorld"/>
	Label of the application as defined by the developer
External URL:	<input type="text" value="ibmappctr://show-app?id=com.HelloWorld"/>
	URL to open the Application Center mobile client on this application.

Figure 13-15. Copying the external URL from Application Details

3. When the external URL is copied to the clipboard, open the MobileFirst Operations Console.
4. Change the access rule of HelloWorld version 1.0 to “Access Disabled”.
5. Paste the external URL into the URL field.

Running the client: When a mobile device connects to MobileFirst Server to try to run HelloWorld version 1.0, the device user is requested to upgrade the version of

the application.

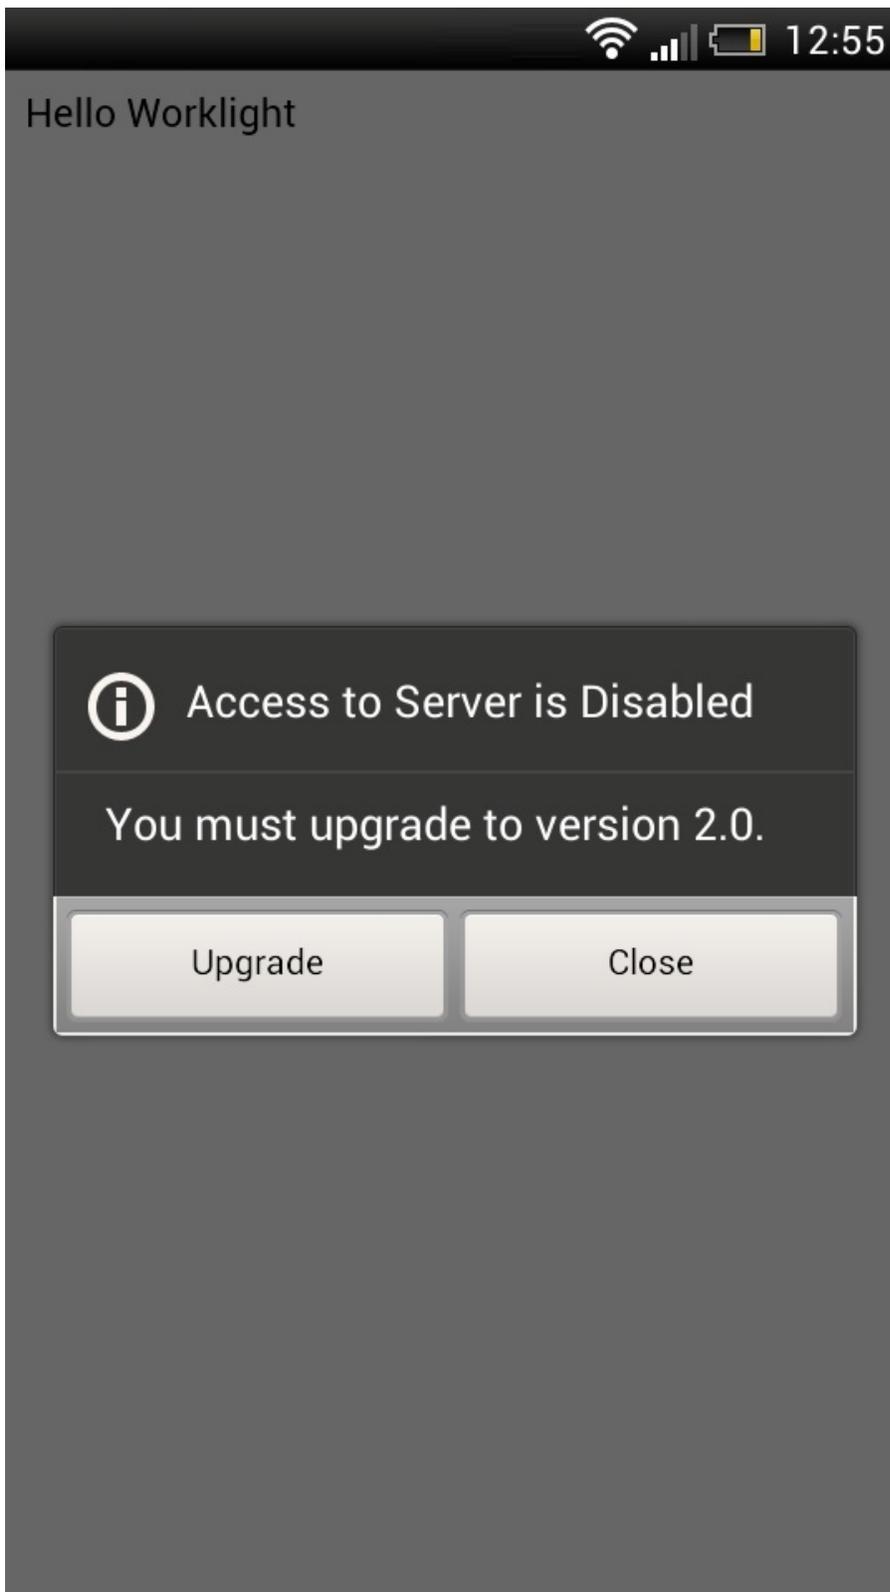

Figure 13-16. Remotely disabling an old version of an application

6. Click **Upgrade** to open the Application Center client. When the login details are correctly completed, you access the Details page of HelloWorld version 2.0 directly.

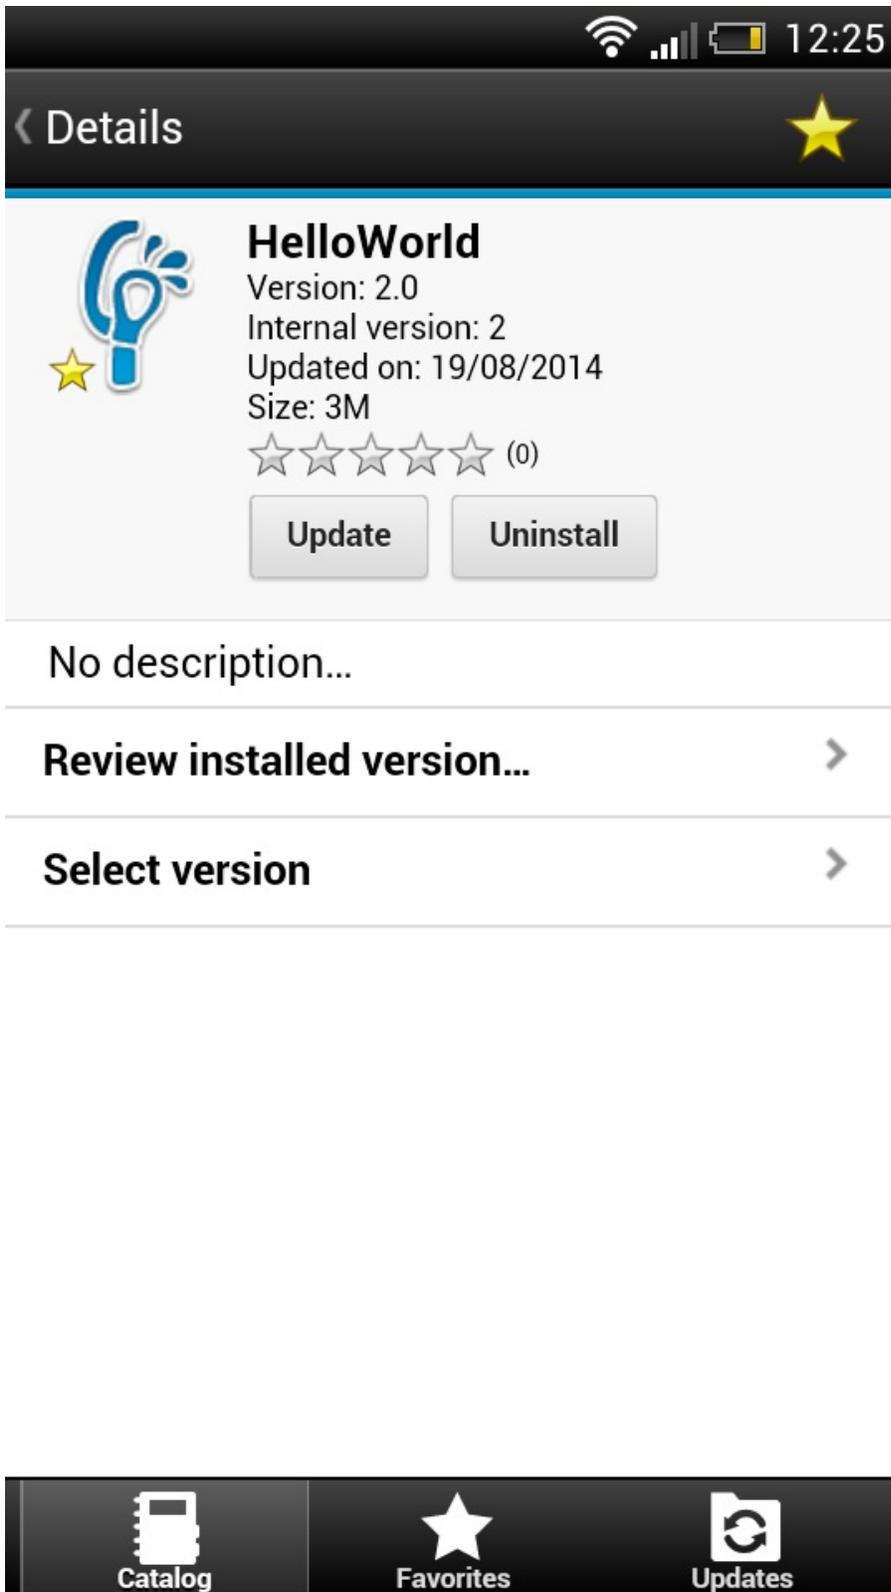

Figure 13-17. Details of HelloWorld 2.0 in the Application Center client

Downloading an application file

You can download the file of an application registered in the Application Center.

Procedure

1. Select **Applications** to see the list of uploaded applications: **Available Applications**.
2. Tap the version of the application under **Application Details**.
3. Tap the file name in the "Application File" section.

Viewing application reviews

In the Application Center console, you can see reviews about mobile application versions sent by users.

About this task

Users of mobile applications can write a review, which includes a rating and a comment, and submit the review through the Application Center client. Reviews are available in the Application Center console and the client. Individual reviews are always associated with a particular version of an application.

Procedure

To view reviews from mobile users or testers about an application version:

1. Select **Applications** to see the list of uploaded applications: Available Applications.
2. Select the version of the application.
3. In the menu, select **Reviews**.

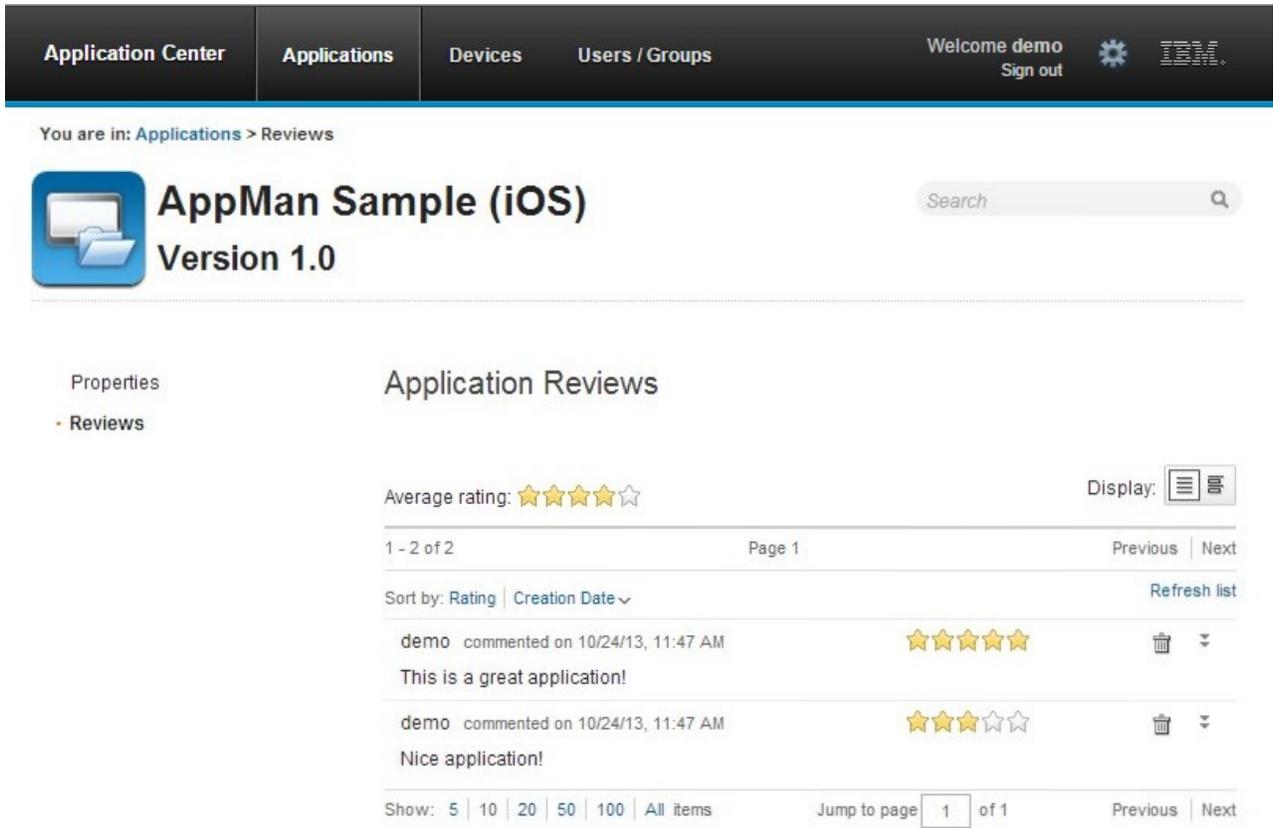

Figure 13-18. Reviews of application versions

The rating is an average of the ratings in all recorded reviews. It consists of one to five stars, where one star represents the lowest level of appreciation and five stars represent the highest level of appreciation. The client cannot send a zero star rating.

The average rating gives an indication of how the application satisfies the intended use of the application.

4. Click the two arrow heads  on the right to expand the comment that is part of the review and to view the details of the mobile device where the review is generated.

For example, the comment can give the reason for submitting the review, such as failure to install.

If you want to delete the review, click the trash can on the right.

User and group management

You can use users and groups to define who has access to some features of the Application Center, such as installing applications on mobile devices.

Purpose

Use users and groups in the definition of access control lists (ACL).

Managing registered users

To manage registered users, click the **Users/Groups** tab and select **Registered users**. You obtain a list of registered users of the Application Center that includes:

- Mobile client users
- Console users
- Local group members
- Members of an access control list

The screenshot shows the 'Users / Groups' management interface. At the top, there are navigation tabs: 'Application Center', 'Applications', 'Devices', and 'Users / Groups'. The 'Users / Groups' tab is active. On the right, there is a user profile 'Welcome demo' with a 'Sign out' link and an IBM logo. Below the navigation, it says 'You are in: Users/Groups > Users'. The main heading is 'User and Group Management' with a search bar. On the left, there are 'User Groups' and 'Registered Users' sections. The 'Registered Users' section has a 'Register user...' button and a list of users. The list shows one user named 'demo'. Below the list, there are pagination controls: '1 of 1', 'Page 1', 'Previous', 'Next', 'Sort by: Name', and 'Show: 10 | 20 | 50 | 100 | All items'. There is also a 'Jump to page' field with '1' of 1.

Figure 13-19. List of registered users of the Application Center

If the Application Center is connected to an LDAP repository, you cannot edit the user display names. If the repository is not LDAP, you can change a user display name by selecting it and editing it.

To register new users, click **Register User**, enter the login name and the display name, and click **OK**.

To unregister a user, click the trash icon next to the user name.

Unregistering a user from the Application Center has the effect of:

XX

- Removing feedback given by the user
- Removing the user from the access control lists
- Removing the user from local groups

Note:

When you unregister a user, the user is not removed from the application server or the LDAP repository.

Managing local groups

To manage local groups, click the **Users/Groups** tab and select **User group**.

To create a local group, click **Create group**. Enter the name of the new group and click **OK**.

If the Application Center is connected to an LDAP repository, the search includes local groups as well as the groups defined in the LDAP repository. If the repository is not LDAP, only local groups are available to the search.

The screenshot shows the Application Center interface. The top navigation bar includes 'Application Center', 'Applications', 'Devices', and 'Users / Groups'. The 'Users / Groups' section is active, showing 'Welcome demo' and 'Sign out' options. Below the navigation bar, the breadcrumb 'You are in: Users/Groups > Groups' is visible. The main heading is 'User and Group Management' with a search bar. On the left, a sidebar shows 'User Groups' and 'Registered Users'. The main content area is titled 'User Groups' and contains the text 'Groups defined in Application Center that are available when defining access control lists.' A 'Create group...' button is present. Below this, a table lists one group: 'New Group' with a trash icon and an 'Edit members' link. The table has pagination controls showing '1 of 1' items and 'Page 1'. The bottom of the table shows 'Show: 10 | 20 | 50 | 100 | All items' and 'Jump to page 1 of 1'.

Figure 13-20. Local user groups

To delete a group, click the trash icon next to the group name. The group is also removed from the access control lists.

To add or remove members of a group, click the **Edit members** link of the group.

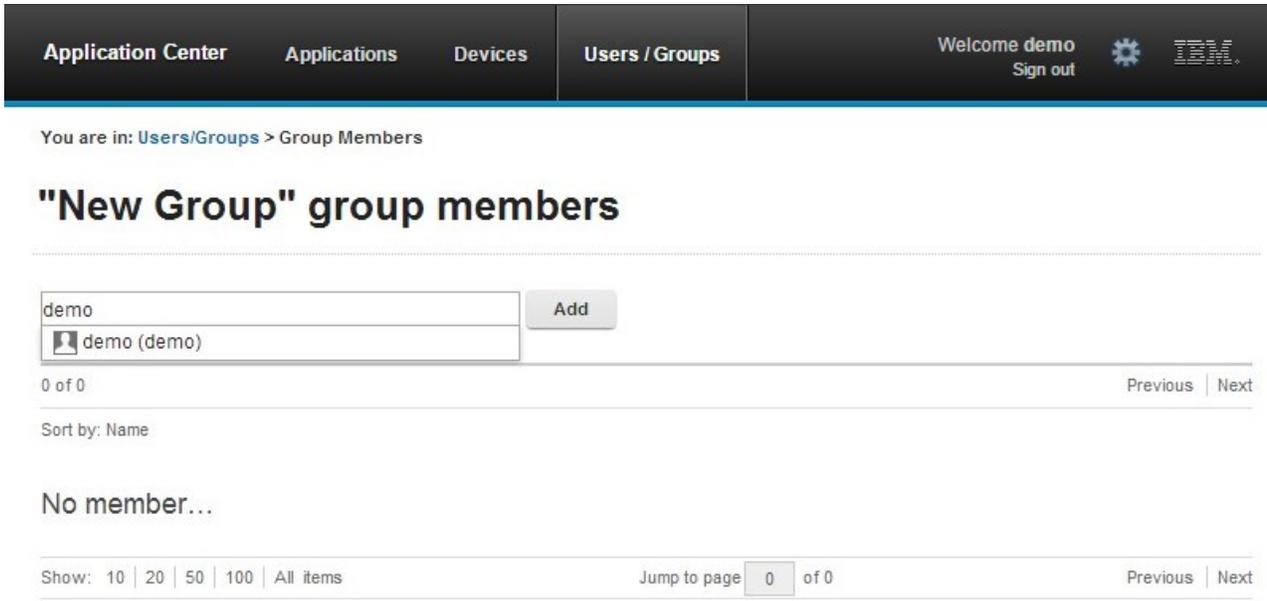

Figure 13-21. Managing group membership

To add a new member, search for the user by entering the user display name, select the user, and click **Add**.

If the Application Center is connected to an LDAP repository, the search for the user is performed in the LDAP repository. If the repository is not LDAP, the search is performed in the list of registered users.

To remove a member from a group, click the cross on the right of the user name.

Access control

You can decide whether installation of an application on mobile devices is open to any users or whether you want to restrict the ability to install an application.

Installation of applications on a mobile device can be limited to specific users or available to any users.

Access control is defined at the application level and not at the version level.

By default, after an application is uploaded, any user has the right to install the application on a mobile device.

The current access control for an application is displayed in Available Applications for each application. The unrestricted or restricted access status for installation is shown as a link to the page for editing access control.

Installation rights are only about the installation of the application on the mobile device. If access control is not enabled, everybody has access to the application.

Managing access control

You can add or remove access for users or groups to install an application on mobile devices.

Procedure

You can edit access control:

1. In Application Management under Available Applications, click the **unrestricted** or **restricted** state of Installation of an application.

2. Select **Access control enabled** to enable access control.
3. Add users or groups to the access list.

To add a single user or group, enter a name, select the entry in the matching entries found, and click **Add**.

If the Application Center is connected to an LDAP repository, you can search for users and groups in the repository as well as locally defined groups. If the repository is not LDAP, you can search only local groups and registered users. Local groups are exclusively defined in the **Users/Groups** tab. When you use the Liberty profile federated registry, you can only search for users by using the login name; the result is limited to a maximum of 15 users and 15 groups (instead of 50 users and 50 groups).

To register a user at the same time as you add the user to the access list, enter the name and click **Add**. Then you must specify the login name and the display name of the user.

To add all the users of an application, click **Add users from application** and select the appropriate application.

Unique Identifier:	myDeviceId

Figure 13-24. Device properties

Select **Properties** to view the device properties.

Name

The name of the device. You can edit this property.

Note: on iOS, the user can define this name in the settings of the device in **Settings > General > Information > Name**. The same name is displayed on iTunes.

User Name

The name of the first user who logged into the device.

Manufacturer

The manufacturer of the device.

Model

The model identifier.

Operating System

The operating system of the mobile device.

Unique identifier

The unique identifier of the mobile device.

If you edit the device name, click **OK** to save the name and return to Registered Devices or **Apply** to save and keep Edit Device Properties open.

Applications installed on device

Select **Applications installed on device** to list all the applications installed on the device.

The screenshot shows the IBM Worklight Application Center interface. At the top, there is a navigation bar with tabs for 'Applications', 'Devices', and 'Users / Groups'. The 'Devices' tab is active. Below the navigation bar, there is a breadcrumb trail: 'You are in: Devices > Installed applications'. The main content area is titled 'Demo's phone' and features a search bar. On the left, there is a sidebar with 'Properties' and 'Installed Applications' (selected). The main content area displays 'Applications installed on device' with a table listing one application: 'AppMan Sample' (AppMan 1.0). The table includes pagination controls (1 of 1, Page 1, Previous, Next) and sorting options (Sort by: Label, Update Date). At the bottom of the table, there are display options (Show: 5, 10, 20, 50, All items) and a 'Jump to page' control (1 of 1).

Figure 13-25. Applications installed on a device

Application enrollment tokens in Windows Phone 8

The Windows Phone 8 operating system requires users to enroll each device with the company before users can install company applications on their devices. One way to enroll devices is by using an application enrollment token.

Purpose

Application enrollment tokens enable you to install company applications on a Windows Phone 8 device. You must first install the enrollment token for a specified company on the device to enroll the device with the company. Then, you can install applications that are created and signed by the corresponding company.

The Application Center simplifies the delivery of the enrollment token. In your role of administrator of the Application Center catalog, you can manage the enrollment

tokens from the Application Center console. Once the enrollment tokens are declared in the Application Center console, they are available for Application Center users to enroll their devices.

The enrollment tokens interface available from the Application Center console in the Settings view enables you to manage application enrollment tokens for Windows Phone 8 by registering, updating, or deleting them.

Managing application enrollment tokens

In your role of administrator of the Application Center, you can access the list of registered tokens by clicking the gear icon  in the screen header to display Application Center Settings. Then, select **Enrollment Tokens** to display the list of registered tokens.

To enroll a device, the device user must upload and install the token file **before** installing the Application Center mobile client. The mobile client is also a company application. Therefore, the device must be enrolled before the mobile client can be installed.

The registered tokens are available through the bootstrap page at `http://hostname:portnumber/applicationcenter/installers.html`, where *hostname* is the host name of the server hosting the Application Center and *portnumber* is the corresponding port number.

To register a token in the Application Center console, click **Upload Token** and select a token file. The token file extension is `aetx`.

To update the certificate subject of a token, select the token name in the list, change the value, and click **OK**.

To delete a token, click the trash can icon on the right side of the token in the list.

Signing out of the Application Center console

For security purposes, you must sign out of the console when you have finished your administrative tasks.

Purpose

To log out of the secure sign-on to the Application Center console.

To sign out of the Application Center console, click **Sign out** next to the Welcome message that is displayed in the banner of every page.

Command-line tool for uploading or deleting an application

To deploy applications to the Application Center through a build process, use the command-line tool.

You can upload an application to the Application Center by using the web interface of the Application Center console. You can also upload a new application by using a command-line tool.

This is particularly useful when you want to incorporate the deployment of an application to the Application Center into a build process. This tool is located at:

```
installDir/ApplicationCenter/tools/applicationcenterdeploytool.jar
```

The tool can be used for application files with extension APK or IPA. It can be used stand alone or as an ant task.

The tools directory contains all the files required to support the use of the tool.

- `applicationcenterdeploytool.jar`: the upload tool.
- `json4j.jar`: the library for the JSON format required by the upload tool.
- `build.xml`: a sample ant script that you can use to upload a single file or a sequence of files to the Application Center.
- `acdeploytool.sh` and `acdeploytool.bat`: Simple scripts to call java with `applicationcenterdeploytool.jar`.

Using the stand-alone tool to upload an application

To upload an application, call the stand-alone tool from the command line.

Procedure

Use the stand-alone tool by following these steps.

1. Add `applicationcenterdeploytool.jar` and `json4j.jar` to the java classpath environment variable.
2. Call the upload tool from the command line:

```
java com.ibm.appcenter.Upload [options] [files]
```

You can pass any of the available options in the command line.

Option	Content indicated by	Description
-s	serverpath	The path to the Application Center server.
-c	context	The context of the Application Center web application.
-u	user	The user credentials to access the Application Center.
-p	password	The password of the user.
-d	description	The description of the application to be uploaded.
-l	label	The fallback label. Normally the label is taken from the application descriptor stored in the file to be uploaded. If the application descriptor does not contain a label, the fallback label is used.
-isActive	true or false	The application is stored in the Application Center as an active or inactive application.
-isInstaller	true or false	The application is stored in the Application Center with the "installer" flag set appropriately.
-isReadyForProduction	true or false	The application is stored in the Application Center with the "ready-for-production" flag set appropriately.

Option	Content indicated by	Description
-isRecommended	true or false	The application is stored in the Application Center with the "recommended" flag set appropriately.
-e		Shows the full exception stack trace on failure.
-f		Force uploading of applications, even if they exist already.
-y		Disable SSL security checking, which allows publishing on secured hosts without verification of the SSL certificate. Use of this flag is a security risk, but may be suitable for testing localhost with temporary self-signed SSL certificates.

The **files** parameter can specify files of type Android application package (.apk) files or iOS application (.ipa) files.

In this example user demo has the password demopassword. Use this command line.

```
java com.ibm.appcenter.Upload -s http://localhost:9080 -c applicationcenter -u demo -p demopassword -f appl.ipa app2.ipa
```

Using the stand-alone tool to delete an application

To delete an application from the Application Center, call the stand-alone tool from the command line.

Procedure

Use the stand-alone tool by following these steps.

1. Add applicationcenterdeploytool.jar and json4j.jar to the java *classpath* environment variable.
2. Call the upload tool from the command line:

```
java com.ibm.appcenter.Upload -delete [options] [files or applications]
```

You can pass any of the available options in the command line.

Option	Content indicated by	Description
-s	serverpath	The path to the Application Center server.
-c	context	The context of the Application Center web application.
-u	user	The user credentials to access the Application Center.
-p	password	The password of the user.

Option	Content indicated by	Description
-y		Disable SSL security checking, which allows publishing on secured hosts without verification of the SSL certificate. Use of this flag is a security risk, but may be suitable for testing localhost with temporary self-signed SSL certificates.

You can specify files or the application package, operating system, and version. If files are specified, the package, operating system and version are determined from the file and the corresponding application is deleted from the Application Center. If applications are specified, they must have one of the following formats:

package@os@version: This exact version is deleted from the Application Center. The version part must specify the “internal version”, not the “commercial version” of the application.

package@os: All versions of this application are deleted from the Application Center.

package: All versions of all operating systems of this application are deleted from the Application Center.

Example

In this example, user **demo** has the password **demopassword**. Use this command line to delete the iOS application demo.HelloWorld with internal version 3.0.

```
java com.ibm.appcenter.Upload -delete -s http://localhost:9080 -c applicationcenter -u demo -p demopassword demo.HelloWorld@iOS@3.0
```

Using the stand-alone tool to clear the LDAP cache

Use the stand-alone tool to clear the LDAP cache and make changes to LDAP users and groups visible immediately in the Application Center.

About this task

When the Application Center is configured with LDAP, changes to users and groups on the LDAP server become visible to the Application Center after a delay. The Application Center maintains a cache of LDAP data and the changes only become visible after the cache expires. By default, the delay is 24 hours. If you do not want to wait for this delay to expire after changes to users or groups, you can call the stand-alone tool from the command line to clear the cache of LDAP data. By using the stand-alone tool to clear the cache, the changes become visible immediately.

Procedure

Use the stand-alone tool by following these steps.

1. Add applicationcenterdeploytool.jar and json4j.jar to the java *classpath* environment variable.
2. Call the upload tool from the command line:

```
java com.ibm.appcenter.Upload -clearLdapCache [options]
```

You can pass any of the available options in the command line.

Option	Content indicated by	Description
-s	serverpath	The path to the Application Center server.
-c	context	The context of the Application Center web application.
-u	user	The user credentials to access the Application Center.
-p	password	The password of the user.
-y		Disable SSL security checking, which allows publishing on secured hosts without verification of the SSL certificate. Use of this flag is a security risk, but may be suitable for testing localhost with temporary self-signed SSL certificates.

Example

In this example, user **demo** has the password **demopassword**.

```
java com.ibm.appcenter.Upload -clearLdapCache -s http://localhost:9080 -c applicationcenter -u
demo -p demopassword
```

Ant task for uploading or deleting an application

You can use the upload and delete tools as an Ant task and use the Ant task in your own Ant script.

Apache Ant is required to run these tasks. The minimum supported version of Apache Ant is listed in “System requirements” on page 2-15.

For convenience, Apache Ant 1.8.4 is included in IBM MobileFirst Platform Server. In the *product_install_dir/shortcuts/* directory, the following scripts are provided:

- ant for UNIX / Linux
- ant.bat for Windows

These scripts are ready to run, which means that they do not require specific environment variables. If the environment variable `JAVA_HOME` is set, the scripts accept it.

When you use the upload tool as an Ant task, the **classname** value of the **upload** Ant task is `com.ibm.appcenter.ant.UploadApps`. The **classname** value of the **delete** Ant task is `com.ibm.appcenter.ant.DeleteApps`.

Parameters of Ant task	Description
serverPath	To connect to the Application Center. The default value is <code>http://localhost:9080</code> .
context	The context of the Application Center. The default value is <code>/applicationcenter</code> .
loginUser	The user name with permissions to upload an application.

Parameters of Ant task	Description
loginPass	The password of the user with permissions to upload an application.
forceOverwrite	If set to true, the Ant task attempts to overwrite applications in the Application Center when it uploads an application that is already present. This parameter is available only in the upload Ant task.
file	The .apk or .ipa file to be uploaded to the Application Center or to be deleted from the Application Center. This parameter has no default value.
fileset	To upload or delete multiple files.
application	The package name of the application; this parameter is available only in the delete Ant task.
os	The operating system of the application. (For example, Android, iOS, or BlackBerry.) This parameter is available only in the delete Ant task.
version	The internal version of the application; this parameter is available only in the delete Ant task. Do not use the commercial version here, because the commercial version is unsuitable to identify the version exactly.

Example

You can find an extended example in the `ApplicationCenter/tools/build.xml` directory.

The following example shows how to use the Ant task in your own Ant script.

```
<?xml version="1.0" encoding="UTF-8"?>
<project name="PureMeapAntDeployTask" basedir="." default="upload.AllApps">

  <property name="install.dir" value="../../" />
  <property name="workspace.root" value="../../" />

  <!-- Server Properties -->
  <property name="server.path" value="http://localhost:9080/" />
  <property name="context.path" value="applicationcenter" />
  <property name="upload.file" value="" />
  <property name="force" value="true" />

  <!-- Authentication Properties -->
  <property name="login.user" value="appcenteradmin" />
  <property name="login.pass" value="admin" />
  <path id="classpath.run">
    <fileset dir="${install.dir}/ApplicationCenter/tools/">
      <include name="applicationcenterdeploytool.jar" />
      <include name="json4j.jar" />
    </fileset>
  </path>
  <target name="upload.init">
    <taskdef name="uploadapps" classname="com.ibm.appcenter.ant.UploadApps">
      <classpath refid="classpath.run" />
    </taskdef>
  </target>
  <target name="upload.App" description="Uploads a single application" depends="upload.init">
    <uploadapps serverPath="${server.path}"
      context="${context.path}"
      loginUser="${login.user}"
      loginPass="${login.pass}"
      forceOverwrite="${force}"
      file="${upload.file}" />
  </target>
  <target name="upload.AllApps" description="Uploads all found APK and IPA files" depends="upload.init">
    <uploadapps serverPath="${server.path}"
      loginUser="${login.user}"
      loginPass="${login.pass}"
      forceOverwrite="${force}"
      context="${context.path}" >
    <fileset dir="${workspace.root}">
      <include name="**/*.ipa" />
    </fileset>
  </uploadapps>
  </target>
</project>
```

This sample Ant script is in the `tools` directory. You can use it to upload a single application to the Application Center.

```
ant upload.App -Dupload.file=sample.ipa
```

You can also use it to upload all applications that are found in a directory hierarchy.

```
ant upload.AllApps -Dworkspace.root=myDirectory
```

Properties of the sample Ant script

Property	Comment
<code>install.dir</code>	Defaults to <code>../..</code>
<code>server.path</code>	The default value is <code>http://localhost:9080</code> .
<code>context.path</code>	The default value is <code>applicationcenter</code> .
<code>upload.file</code>	This property has no default value. It must include the exact file path.
<code>workspace.root</code>	Defaults to <code>../..</code>
<code>login.user</code>	The default value is <code>appcenteradmin</code> .
<code>login.pass</code>	The default value is <code>admin</code> .
<code>force</code>	The default value is <code>true</code> .

To specify these parameters by command line when you call Ant, add `-D` before the property name. For example:

```
-Dserver.path=http://localhost:8888/
```

Publishing MobileFirst applications to the Application Center

You can use the application management plug-in to publish native applications to the Application Center.

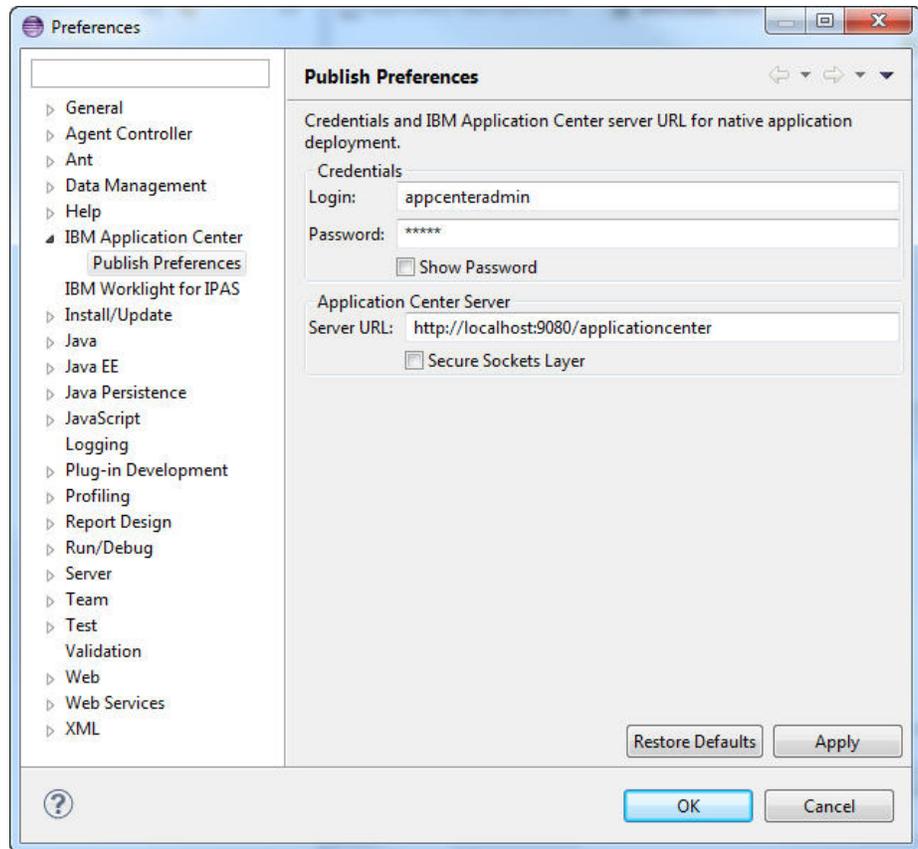

About this task

You can deploy applications for Android, iOS, Windows Phone, Windows 8 (Windows Store applications only), and BlackBerry operating systems to the Application Center directly from the MobileFirst Studio IDE. In MobileFirst Studio, you can deploy Android application package (`.apk`) files, iOS application (`.ipa`) files, Windows Phone application (`.xap`) files, Windows Store application package (`.appx`) files, and BlackBerry (`.zip`) files that you choose from your file system. You can right-click an application (`.apk`, `.ipa`, `.xap`, `.appx`, or `.zip`) file to deploy it to the Application Center.

Procedure

To publish an application to the Application Center, complete the following steps:

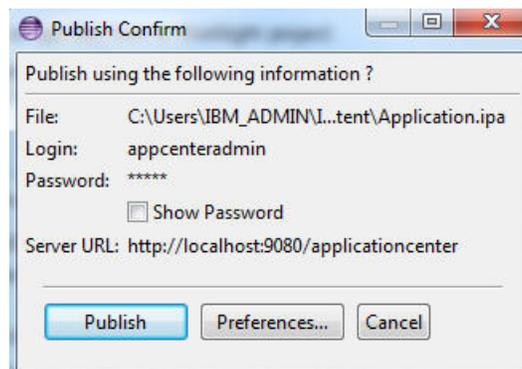

1. Specify the publish preferences for the Application Center:
 - a. In the main menu, click **Window > Preferences**.
 - b. Expand **IBM Application Center > Publish Preferences**.

c. Specify the default publish preference settings for the Application Center:

Preference	Description
Credentials	Specify the login and password required to access the application repository.
Application Center Server	Specify the URL of the application center server to use when publishing applications.

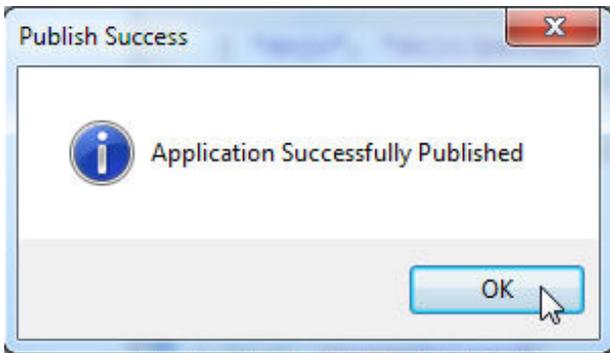

2. Publish an application (.apk, .ipa, .xap, .appx, or .zip file) from a MobileFirst project:
 - a. Right-click the application and click **IBM Application Center > Publish on IBM Application Center**. The Publish Confirm dialog opens.

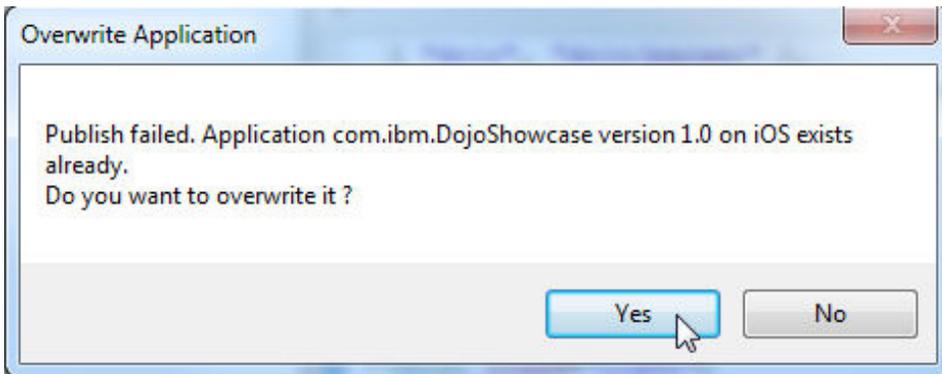

b. In the Publish Confirm dialog, choose one of the following options:

Option	Description
Publish the application by using the current preferences.	Click Publish .
Change any of the preferences before publishing the application.	Click Preferences to open the Publish Preferences page and edit the preference settings.

You receive confirmation when publication is successful.

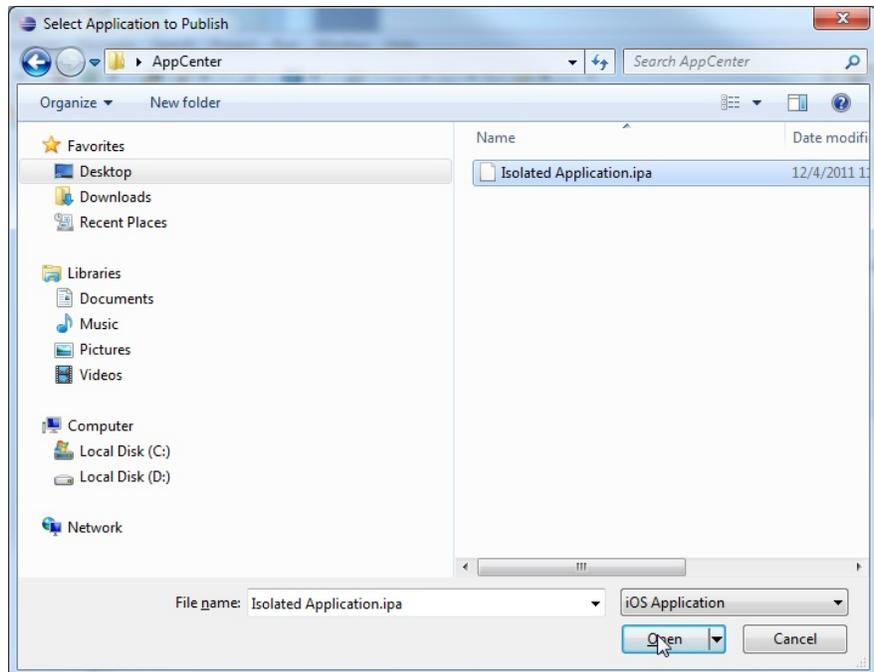

If the application already exists, publication will fail. You are given the option to overwrite the existing version of the application.

Tip: To publish an application that is not part of the MobileFirst project:

- 1) Right-click the MobileFirst project and click **IBM Application Center > Publish on IBM Application Center**. The Select Application to Publish window opens.

- 2) Navigate to the application (.apk, .ipa, .xap, .appx, or .zip) file that you want to publish and click **Open** to open the Publish Confirm dialog.

The mobile client

You can install applications on your mobile device with the Application Center mobile client.

The Application Center mobile client is the application that runs on your Android, iOS, Windows Phone, Windows, or BlackBerry device. (Only Windows Phone 8 and BlackBerry OS 6 and OS 7 are supported by the current version of the Application Center.) You use the mobile client to list the catalog of available applications in the Application Center. You can install these applications on your device. The mobile client is sometimes referred to as the Application Center installer. This application must be present on your device if you want to install on your device applications from your private application repository.

Prerequisites

Your system administrator must give you a user name and password before you can download and install the mobile client. The user name and password are required whenever you start the mobile client on your device. For Windows Store applications, the user name and password are required for the mobile client only at run time. For security reasons, do not disseminate these credentials. These credentials are the same credentials used to log in to the Application Center console.

Installing the client on an Android mobile device

You can install the mobile client, or any signed application marked with the installer flag, on your Android mobile device by entering the access URL in your browser, entering your credentials, and completing the required steps.

Procedure

1. Start the browser on your mobile device.
2. Enter the following access URL in the address text field: `http://hostname:portnumber/applicationcenter/installers.html`

Where *hostname* is the address of the server and *portnumber* is the number of the port where the Application Center is installed. Your system administrator can provide this information.

The Application Center also provides an alternative URL for installing the client on a mobile device: `http://hostname:portnumber/applicationcenter/inst.html`. The page of this URL works better with some older or some nonstandard mobile web browsers. If the page `installers.html` does not work on your mobile device, you can use `inst.html`. This page is provided in English only and is not translated into other languages.

If you try to open the page with HTTPS and use self-signed certificates, older Android browsers cannot open the page. In this case, you must use a non self-signed certificate or use another browser on the Android device, such as Firefox, Chrome, or Opera. In Android 4 and later, the Android browser displays a security warning about the SSL certificate, but lets you proceed to the website after confirmation that you consent to an unsafe connection.

3. Enter your user name and password.

See *Prerequisites* in “The mobile client” on page 13-121.

When your user name and password are validated, the list of compatible installer applications for your device is displayed in the browser. Normally, only one application, the mobile client, appears in this list.

If you open the page with HTTPS:

- If the web server uses a real SSL certificate provided by a trusted certificate authority, proceed to step 5 on page 13-123.
 - If the web server uses a self-signed CA certificate, proceed to step 4.
4. If the web server uses a self-signed CA certificate, install the certificate at least once on the device.

The Application Center administrator should provide the certificate; see “Managing and installing self-signed CA certificates in an Application Center test environment” on page 6-304 for details.

- a. Tap the **SSL-Certificate** tab and select the certificate.
- b. Tap **Install**. You must only perform this action once for the device. You can verify whether the certificate is installed by looking in **Settings > Security > Trusted Credentials > User** on the device. This view shows the SSL certificates that the user has installed on the device. If the self-signed CA certificate is not installed on the device, the Android operating system prevents you from downloading the mobile client in the following steps.

Before you can see the mobile client in the list of available applications, the Application Center administrator must install the mobile client application. The administrator uploads the mobile client to Application Center and sets the **Installer** property to true. See “Application properties” on page 13-94.

Figure 13-26. List of available mobile client applications to install

5. Tap the **Installers** tab and select an item in the list to display the application details.

Typically, these details include the application name and its version number.

Figure 13-27. Application details

6. Tap **Install** to download the mobile client.
On newer Android devices, a question might request permission for Chrome to access media files on the device. Select **YES**. A warning about potential harmful files might be displayed. Select the option to keep the APK file anyway.
7. Launch the **Android Download** applications.
8. Select the Application Center client installer.
You can see the access granted to the application when you choose to install it.

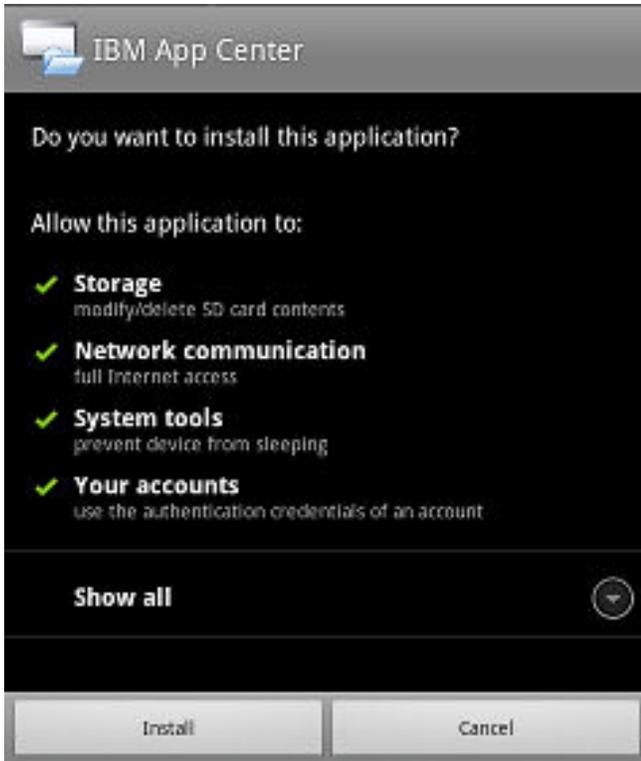

Figure 13-28. Installation of the mobile client on Android

9. Select **Install** to install the mobile client.
10. When the application is installed, select **Open** to open the mobile client or **Done** to close the Downloads application.

Results

The APK file might fail for one of the following reasons:

- The device does not have enough free memory.
- The SSL certificate of the server is not known to the device.

The first time that you install an app through the Downloads application, you might receive a request to confirm whether Google should regularly check the device activity for security problems. You can accept or decline according to your preference. The Application Center client is unaffected by your choice.

The installation might be blocked for one of the following reasons:

- The device does not permit installation from unknown sources. Go to **Settings > Security** on the device and enable **Unknown sources (Allow installation from unknown sources)**.
- The device has the same app already installed, but it was signed by a different certificate. In this case, you must remove the app before you install it on the device with another signed certificate.

Installing the client on an iOS mobile device

You can install the mobile client, or any signed application marked with the installer flag, on your iOS mobile device by entering the access URL in your browser, entering your credentials, and completing the required steps.

Before you begin

Important: To install applications on iOS devices, you must first configure the Application Center server with SSL. See “Configuring Secure Sockets Layer (SSL)” on page 6-301.

For experts

The **ibm.appcenter.ios.plist.onetimeurl** JNDI property of the IBM Application Center Services controls whether One-Time URLs are used when the mobile client is installed on an iOS mobile device. Set this property to `false` for maximal security. When you set this property to `false`, users must enter their credentials several times when they install the mobile client: once when they select the client and once when they install the client.

When you set the property to `true`, users enter their credentials only once. A temporary download URL with a cryptographic hash is generated when the user enters the credentials. This temporary download URL is valid for 1 hour and does not require further authentication. This solution is a compromise between security and ergonomics.

The steps to specify the **ibm.appcenter.ios.plist.onetimeurl** JNDI property are similar to the steps for the **ibm.appcenter.proxy.host** property. See “Defining the endpoint of the application resources” on page 6-296.

Procedure

Installing the mobile client on an iOS device is similar to installing it on Android, but with some differences. The installer is automatically started directly after download. Your user name and password credentials are requested for almost all the installation steps.

1. Start the browser on your mobile device.
2. Enter the following access URL in the address field: `http://hostname:portnumber/applicationcenter/installers.html`

Where *hostname* is the address of the server and *portnumber* is the number of the port where the Application Center is installed. Your system administrator can provide this information.

The Application Center also provides an alternative URL for installing the client on a mobile device: `http://hostname:portnumber/applicationcenter/inst.html`. The page of this URL works better with some older or some nonstandard mobile web browsers. If the page `installers.html` does not work on your mobile device, you can use `inst.html`. This page is provided in English only and is not translated into other languages.

If you open the page with HTTPS and use self-signed certificates, the browser displays a security warning about the SSL certificate, but lets you proceed to the website after confirmation that you consent to an unsafe connection.

3. Enter your user name and password.

See Prerequisites in “The mobile client” on page 13-121.

When your user name and password are validated, the list of compatible installer applications for your device is displayed in the browser. Normally, only one application, the mobile client, appears in this list.

If you open the page with https:

- If the web server uses a real SSL certificate that is provided by a trusted certificate authority, proceed to step 5.
 - If the web server uses a self-signed CA certificate, proceed to step 4.
4. If the web server uses a self-signed CA certificate, install the certificate at least once on the device.

The Application Center administrator provides the certificate. See “Managing and installing self-signed CA certificates in an Application Center test environment” on page 6-304 for details.

- a. Tap the **SSL-Certificate** tab and select the certificate.
- b. Tap **Install**. You do this only once for the device. You can verify whether the certificate is installed by looking in **Settings > General > Profiles** on the device. This view shows the SSL certificates that the user installed on the device. If the self-signed CA certificate is not installed on the device, the iOS operating system prevents you from downloading the mobile client in the following steps.

Before you can see the mobile client in the list of available applications, the Application Center administrator must install the mobile client application. The administrator uploads the mobile client to the Application Center and sets the **Installer** property to **true**. See “Application properties” on page 13-94.

5. Tap the **Installers** tab and select an item in the list to display the application details.
6. Tap **Install** to download the mobile client.
7. Enter your credentials to authorize the downloader transaction.
8. To authorize the download, tap **Install**.

Figure 13-29. Confirm app to be installed

9. Enter your credentials to authorize the installation.
10. Close the browser.

The app icon appears on the home screen and you can watch the download progress on the home screen.

Results

Note: Installing an application on a device requires a provisioning profile that enables the application to be installed on the selected device. If you accidentally try to install an application that is not valid for your device, some versions of iOS might try to install the application in an endless loop without ever succeeding or indicating any error. The application icon that shows the progress of the installation appears on the home screen, but, because of the endless loop, it is difficult to delete this application icon to stop the endless loop. A workaround is to put the device into Airplane mode. In this mode, the endless loop is stopped and you can delete the application icon by following the normal steps to delete apps on iOS devices.

The installation might be blocked for one of the following reasons:

- The provisioning profile of the application is not valid for the device. The application must be signed with a different provisioning profile.

- The device has no access to Apple servers to confirm the validity of the provisioning profile.
- The SSL certificate of the server is not known to the device.

What to do next

After the mobile client is installed on the device, you can open it.

In general, iOS applications can be installed on the device only if they are signed with a provisioning profile. See “Importing and building the project (Android, iOS, Windows Phone)” on page 13-73.

Since iOS 9, when a company application is opened, depending on the type of the provisioning profile, an Untrusted Enterprise Developer message might display. This message explains that the provisioning profile is not yet trusted on this device. In this case, the application does not open, unless trust is established for this provisioning profile. Establishing trust must be done only once per provisioning profile.

To establish trust for a provisioning profile after the application is installed:

Until iOS 9.1

1. Go to **Settings > General > Profiles**.
Under the **Enterprise apps** heading, you see the provisioning profile of the app.
2. Tap on the profile and confirm the trust.

Since iOS 9.2

1. Go to **Settings > General > Profiles > Device Management** or **Profiles & Device Management**.
Under the **Enterprise apps** heading, you see the provisioning profile of the app.
2. Tap on the profile and confirm the trust.

After the trust is confirmed, no application that uses that provisioning profile shows the Untrusted Enterprise Developer message. For more information, see the Apple web site at <https://support.apple.com/en-us/HT204460>.

Installing the client on a BlackBerry mobile device

You can install the mobile client, or any signed application marked with the installer flag, on your BlackBerry mobile device by entering the access URL in your browser, entering your credentials, and completing the required steps.

About this task

Support for BlackBerry platform OS versions 6 and 7 is deprecated and might be removed in future versions; it continues to work in this version of Application Center.

Procedure

The installer is automatically launched directly after download. Your user name and password credentials are requested for almost all the installation steps.

1. Start the browser on your mobile device.

2. Enter the following access URL in the address text field: `http://hostname:portnumber/applicationcenter/installers.html`.
Where *hostname* is the address of the server and *portnumber* is the number of the port where the Application Center is installed. Your system administrator can provide this information.
The Application Center also provides an alternative URL for installing the client on a mobile device: `http://hostname:portnumber/applicationcenter/inst.html`. The page of this URL works better with some older or some nonstandard mobile web browsers. If the page `installers.html` does not work on your mobile device, you can use `inst.html`. This page is provided in English only and is not translated into other languages.
3. Enter your credentials to authorize access to the server.
4. Select an item in the list of available applications to display the application details.
5. Tap **Install Now** to download the mobile client.
6. In the BlackBerry Over The Air Installation Screen, tap **Download** to complete the installation.

Figure 13-30. The installer in the BlackBerry browser

Note: BlackBerry OS 10 is not supported by the current version of the Application Center.

Installing the client on Windows Phone 8

You can install the mobile client, or any signed application marked with the installer flag, on Windows Phone 8 by entering the access URL in your browser, entering your credentials, and completing the required steps. The company account must be preinstalled on your mobile device.

Before you begin

Before you can install apps published by your company, you must add the company account to your mobile device. You must download an application enrollment token (AET) to your Windows Phone device. This AET must already be present on the IBM MobileFirst Platform Server. It is uploaded to the MobileFirst Server by using the Application Center console. See “Application enrollment tokens in Windows Phone 8” on page 13-111 for details.

Procedure

1. Start the browser on your mobile device.
2. Enter the following access URL in the address text field: `http://hostname:portnumber/applicationcenter/installers.html`.

Where *hostname* is the address of the server and *portnumber* is the number of the port where the Application Center is installed. Your system administrator can provide this information.

The Application Center also provides an alternative URL for installing the client on a mobile device: `http://hostname:portnumber/applicationcenter/inst.html`. The page of this URL works better with some older or some nonstandard mobile web browsers. If the page `installers.html` does not work on your mobile device, you can use `inst.html`. This page is provided in English only and is not translated into other languages.

3. Enter your credentials to authorize access to the server.

In the lower part of the screen, a toolbar contains **Installers** tab and **Tokens** tab.

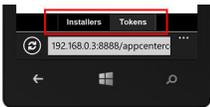

Figure 13-31. Preparing to install tokens and applications on a Windows Phone device

4. Tap **Tokens** and select an application enrollment token in the list of available tokens to display the token details.

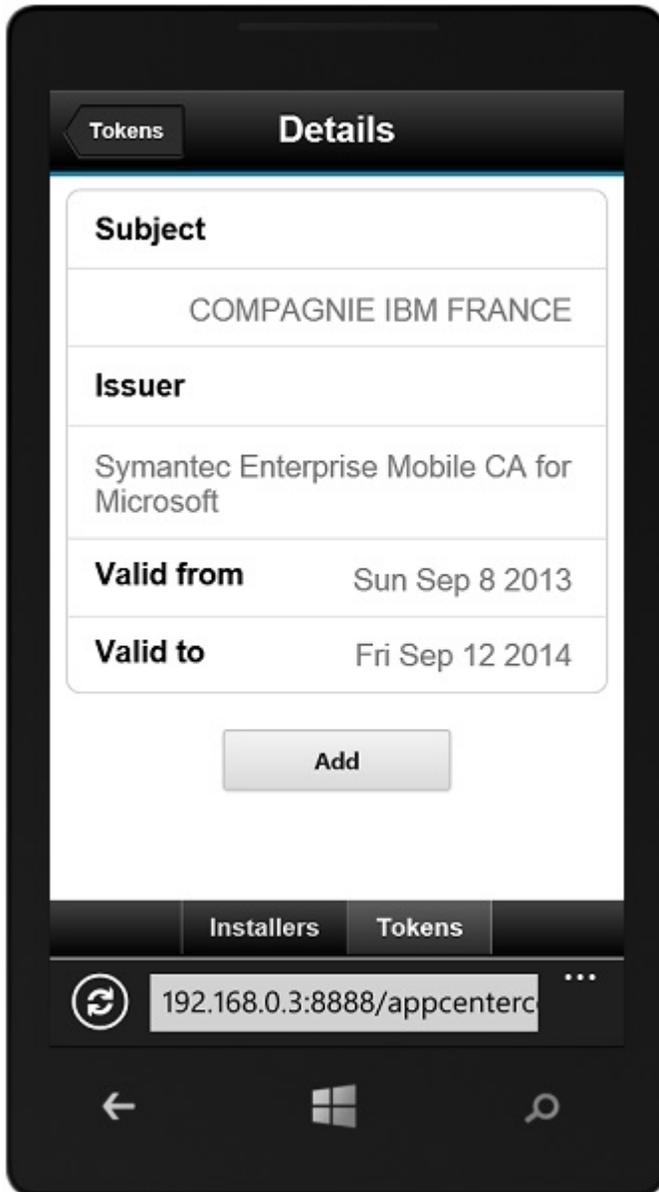

Figure 13-32. AET details on a Windows Phone device

5. Tap **Add** to download the application enrollment token.
6. Tap **Add** to add the company account.

Figure 13-33. Adding a company account in Windows Phone 8

Windows Phone 8 does not provide any feedback about adding the company account.

7. Tap the Back icon to return to the details of application enrollment tokens.

8. Tap **Installers** and select the mobile client application in the list of available applications. The application details are displayed.
9. Tap **Install** to download the selected application.

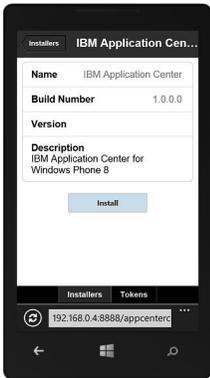

Figure 13-34. The application selected to download on a Windows Phone device

10. Tap **Install** to install the application.

Figure 13-35. Installing the downloaded application on a Windows Phone device

Windows Phone 8 does not provide any feedback about installing the application.

Tip: When you install a company application on a device, the device must connect to the Microsoft server to verify the application signature. Sometimes, the Microsoft server does not respond. In this case, you can try the installation again a few minutes later. See “Installing an application on a Windows Phone device” on page 13-143 for the possible error messages.

Results

When the installation is finished, the mobile client application should be available in your applications list in Windows Phone.

The Login view

In the Login view, you can access the fields that are required to connect to the server to view the list of applications available for your device.

Use the **Login** view to enter your credentials to connect to the Application Center server to view the list of applications available for your device.

The **Login** view presents all the mandatory fields for the information required to connect to the server.

When the application is started the Login page is displayed. The login credentials are required to connect to the server.

On iOS devices, the credentials are saved in the keychain. After you successfully log in to the Application Center server, when you start the application subsequently, the login page is not displayed and the previous credentials are used. If the login cannot be performed, the login view is displayed.

User name and password

Enter your credentials for access to the server. These are the same user name and password granted by your system administrator for downloading and installing the mobile client.

Application Center server address

The Application Center server address is composed of:

- Host name or IP address.
- Port, which is optional if the default port is used.
- Context, which is optional if the Application Center is installed at the root of the server.

On a phone, a field is available for each part of the address.

On a tablet, a single field that contains a preformatted example address is displayed. Use it as a model for entering the correct server address to avoid formatting errors. See “Preparations for using the mobile client” on page 13-71 for information on filling parts of the address in advance, or hardcode the address and hide the associated fields.

Secure Socket Layer (SSL)

SSL is mandatory on iOS devices. Therefore, this option is not displayed in the login view.

On the other supported operating systems, select SSL to turn on the SSL protocol for communications over the network. (Tapping this field again when SSL is selected switches SSL off.)

SSL selection is available for cases where the Application Center server is configured to run over an SSL connection. Selecting SSL when the server is not configured to handle an SSL layer prevents you from connecting to the server. Your system administrator can inform you whether the Application Center runs over an SSL connection.

Complex input on BlackBerry devices

If you have non-Latin characters to enter in the text field, such as Chinese and Japanese user names, select **Complex input** on a BlackBerry device. Selecting **Complex input** switches to the BlackBerry complex input mode in all text fields of the application.

Figure 13-36. Login view on BlackBerry devices

Connecting to the server

To connect to the server:

1. Enter your user name and password.
2. Enter your Application Center server address.
3. If your configuration of the Application Center runs over the SSL protocol, select **SSL**.
4. Tap **Log in** to connect to the server.

If this login is successful, the user name and server address are saved to fill the fields when you subsequently start the client.

Views in the Application Center client

The client provides views that are adapted to the various tasks that you want to perform.

After a successful login, you can choose among these views.

Figure 13-37. Views in the client application (Android, iOS, and Windows Phone operating systems)

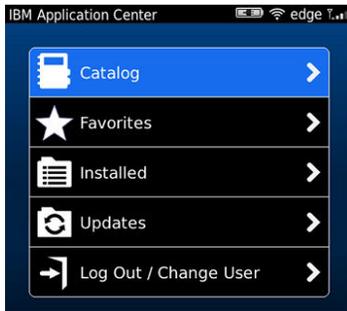

Figure 13-38. Views in the client application (BlackBerry devices)

These views enable you to communicate with a server to send or retrieve information about applications or to manage the applications located on your device.

The Windows 8 client home screen displays up to six applications in each category. On the Windows 8 client, if you want the full list of applications in a category, click the title of the category.

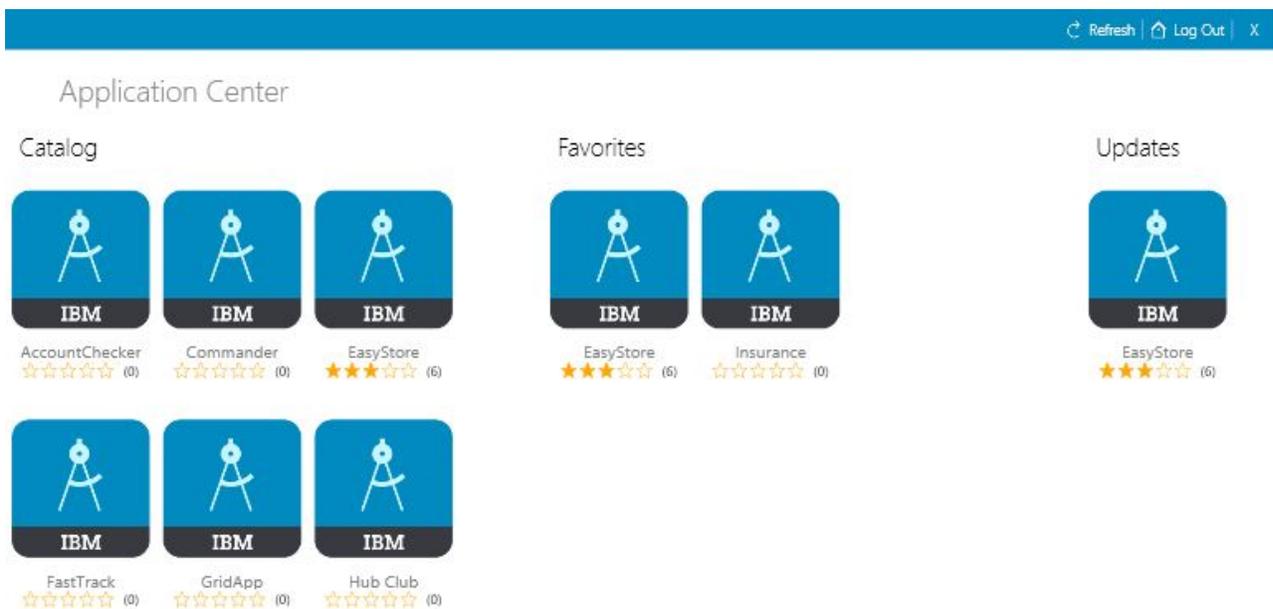

Figure 13-39. Client home screen on Windows 8

Here are descriptions of the different views.

Catalog

This view shows the applications that can be installed on a device.

Favorites

This view shows the list of applications that you marked as favorites.

Installed on BlackBerry version.

This view shows the applications installed on your mobile device. This view is not available on Android, iOS, Windows Phone, or Windows 8 versions of the client.

Updates

This view shows all applications that you marked as favorite apps and that have a later version available in Application Center than the version, if any, installed on the device.

When you first start the mobile client, it opens the **Login** view for you to enter your user name, password, and the address of the Application Center server. This information is mandatory.

Displays on different device types

The layout of the views is specific to the Android, iOS, Windows Phone, Windows 8, or BlackBerry environment, even though the common functions that you can perform in the views are the same for all operating systems. Different device types might have quite different page displays. On the phone, a list is displayed. On a tablet, a grid of applications is used.

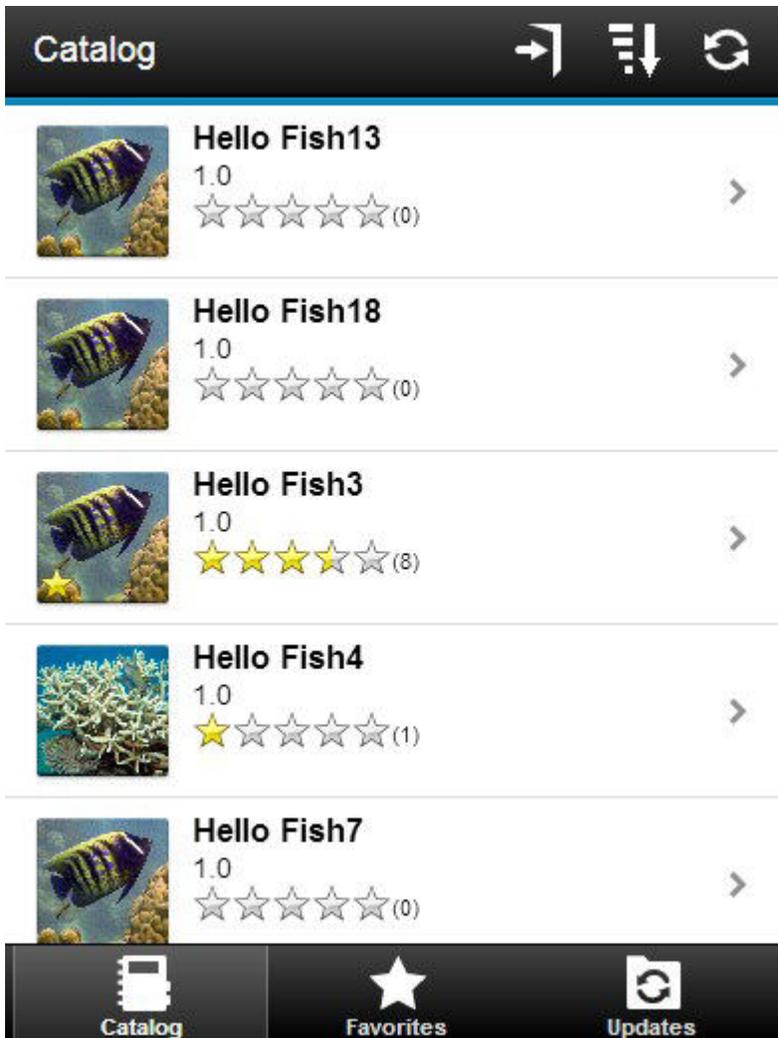

Figure 13-40. Catalog view on a phone

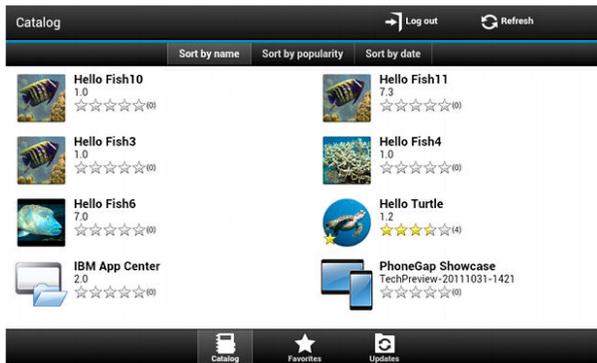

Figure 13-41. Catalog view on a tablet

Features of the views

On an Android or iOS tablet, you can sort the lists by tapping one of the sort criteria.

On a Windows Phone, an Android, iOS, or BlackBerry phone, sort criteria are available through the sort button. 

On BlackBerry devices, if the list of applications is too long, you can use the search field to find an application that contains the search string in its name.

On the Windows 8 client, you can sort the list of applications within a category. To sort the applications, select from the list of sort criteria in the “Sort By” field.

Applications that are marked as favorites are indicated by a star superposed on the application icon.

The average rating of the latest version of an application is shown by using a number of stars and the number of ratings received. See “Preparations for using the mobile client” on page 13-71 for how to show the rating of all versions of the application instead of the latest version only.

Tapping an application in the list navigates to the Details view of the latest installed version of this application.

To refresh the view, tap the refresh button:  or, on Windows 8,

To return to the login page:

- In Android, iOS, and Windows Phone applications, tap the logout button. 
- In the Windows 8 version of the client, tap the logout button.

- In the BlackBerry version of the client, tap the return button.  Then tap **Log out/Change User**.

The Details view

Tapping an application in the Catalog, Favorites, or Updates view navigates to the Details view where you can see details of the application properties. Details of the application version are displayed in this view.

On Android, iOS, Windows Phone, and BlackBerry clients, the following details of the application version are displayed:

- The name of the application.
- Commercial version: the published version of the application.
- Internal version: on Android, the internal version identification of the application; on iOS, the build number of the application; on BlackBerry, the version of the application and the same as the commercial version. See “Application properties” on page 13-94 for technical details concerning this property on all operating systems.
- Update date.
- Approximate size of the application file.
- Rating of the version and number of ratings received.
- Description of the application.

On Windows 8 client the following details of the application version are displayed:

- Application name.
- Version.
- Vendor name.
- Update date.
- Rating of the version and the number of ratings received.
- Existing reviews of either the current version or of all the versions of the current application.

You can perform several actions in this view.

- Install, upgrade, downgrade, or uninstall an application version.
- Cancel the current operation in progress (if available).
- Rate the application version if it is installed on the device.
- List the reviews of the this version or of all versions of the application.
- Show details of a previous version.
- Mark or unmark the application as a favorite app.
- Refresh the view with the latest changes from the Application Center server.

Installing an application on an Android device

From the **Details** view, you can install an application on your Android device.

About this task

In the **Details** view, if a previous version of the application is not installed, you can install this application version on your Android device.

Figure 13-42. Details view of an app version shown on your Android device

Procedure

1. In the **Details** view, tap **Install**.

The application is downloaded. You can tap **Cancel** in the **Details** view at any time during the download to cancel the download. (The **Cancel** button appears only during the installation steps.) If you let the download complete, you will see the rights that are granted to the application.

Figure 13-43. Application rights on your Android device

2. Tap **Install** to confirm installation of the application or **Cancel** to cancel installation..

Depending on the action taken, the application is installed or not. When the application is successfully installed, it is also marked as a favorite app.

If you selected **Cancel**, in the application rights confirmation panel, you can tap **Cancel** in the **Details** view at any time to notify the application that the installation has been canceled. The **Cancel** button appears in the **Details** view only during the installation steps.

Installing an application on an iOS device

From the **Details** view, you can install an application version on your iOS mobile device.

About this task

Figure 13-44. Details view of an app version shown on your iOS device

Important: To install applications on iOS devices, you must first configure the Application Center server with SSL. See “Configuring Secure Sockets Layer (SSL)” on page 6-301.

Procedure

1. In the **Details** view, tap **Install**. You are requested to confirm the download and installation of the application version.
2. Tap **Install** to confirm download and installation of the application version or **Cancel** to cancel the installation.

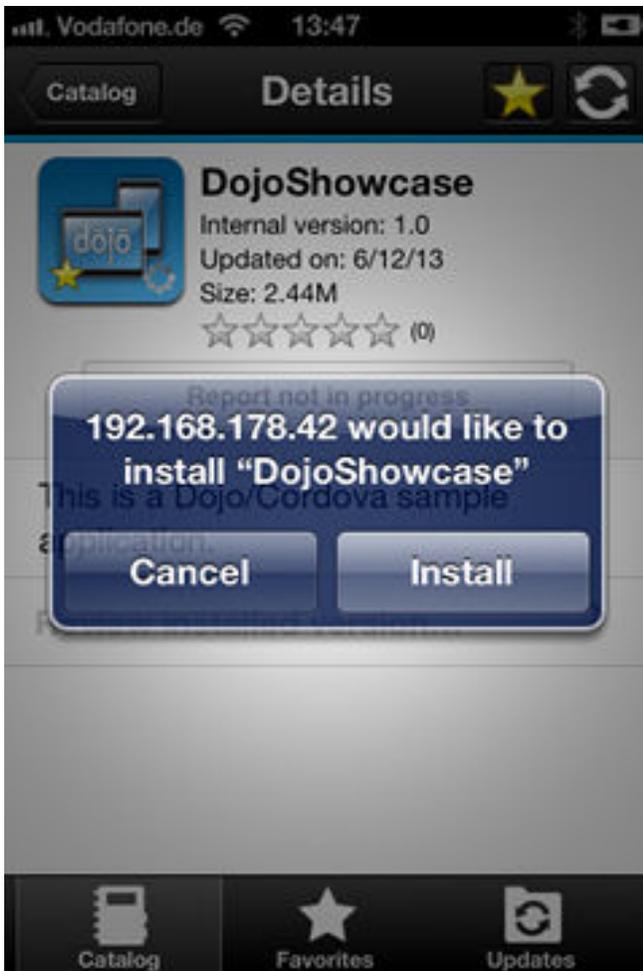

Figure 13-45. Canceling application installation on your iOS device

Depending on the action that is taken, the application is installed or not. When the application is successfully installed, it is also marked as a favorite app.

Installing an application on a device requires a provisioning profile that enables the application to be installed on the selected device. If you accidentally try to install an application that is not valid for your device, iOS 6 (deprecated) or earlier gives an error message.

Results

Unlike the Android client, after the installation is finished, the **Install** button in the Details view does not change its label to **Uninstall**. In iOS, there is no **Uninstall** button. It is only possible to uninstall applications through the home screen.

Some versions of iOS 7 might try to install the application in an endless loop without ever succeeding or indicating any error. The application icon that shows the progress of the installation appears on the home screen, but, because of the endless loop, it is difficult to delete this application icon to stop the endless loop. A workaround is to put the device into Airplane mode. In this mode, the endless loop is stopped and you can delete the application icon by following the normal steps to delete apps on iOS devices.

What to do next

After the application is installed on the device, you can open it.

In general, iOS applications can be installed on the device only if they are signed with a provisioning profile. See “Importing and building the project (Android, iOS, Windows Phone)” on page 13-73.

Since iOS 9, when a company application is opened, depending on the type of the provisioning profile, an Untrusted Enterprise Developer message might display. This message explains that the provisioning profile is not yet trusted on this device. In this case, the application does not open, unless trust is established for this provisioning profile. Establishing trust must be done only once per provisioning profile.

To establish trust for a provisioning profile after the application is installed:

Until iOS 9.1

1. Go to **Settings > General > Profiles**.

Under the **Enterprise apps** heading, you see the provisioning profile of the app.

2. Tap on the profile and confirm the trust.

Since iOS 9.2

1. Go to **Settings > General > Profiles > Device Management or Profiles & Device Management**.

Under the **Enterprise apps** heading, you see the provisioning profile of the app.

2. Tap on the profile and confirm the trust.

After the trust is confirmed, no application that uses that provisioning profile shows the Untrusted Enterprise Developer message. For more information, see the Apple web site at <https://support.apple.com/en-us/HT204460>.

Installing an application on a Windows Phone device

From the Details view, you can install a company application on your Windows phone device.

About this task

The Details view of the selected application displays information about the application that you want to install.

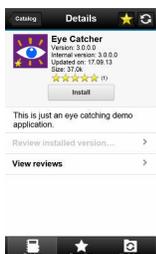

Figure 13-46. Details view of a version of a company application for installation on a Windows Phone device

Procedure

1. In the **Details** view, tap **Install**. The application is downloaded and installed. You can tap **Cancel** at any time during the downloading of the application to cancel the activity. **Cancel** appears only during the downloading step of the installation process.

At the beginning of the installation process, you are requested to confirm whether you want to add the company application to the applications installed on your mobile device.

2. Tap **Install** to confirm installation of the application or **Cancel** to cancel the installation.

The application is marked as a favorite app.

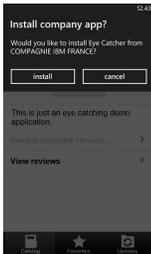

Figure 13-47. Confirming or canceling installation of a company application on a Windows Phone device

Tip: When you install a company application on a device, the device must connect to the Microsoft server to verify the application signature. Sometimes, the Microsoft server does not respond. In this case, you can try the installation again a few minutes later.

The possible error messages are:

- There's a problem with this company app. Contact your company's support person for help.

You are probably using an unsigned Windows Phone application package (.xap) file. You must sign application package (.xap) files before using them in the Application Center. This message might also occur if the Microsoft server does not respond and the signature of the company application cannot be validated. In this case, try the installation again a few minutes later.

- Before you install this app, you need to add ... company account.

The Windows Phone application package (.xap) file is signed, but the device is not enrolled for company applications. You must first install on the device the application enrollment token of the company.

- We haven't been able to contact the *company* account to make sure you can install this app. ...

Either the company account is expired or blocked, or the Microsoft server is temporarily not responding. Make sure that your device is connected to the internet and connected to the Microsoft server, and try again.

Note: If a device is registered with several company accounts, the Windows Phone operating system might display the wrong company account in the message *Would you like to install application from company name?*. This message is outside the control of the Application Center. This situation is a display problem only and does not affect the functionality.

Results

Depending on the action that you take, the application is installed or not.

Tip: The install process will not work if the PFX certificate used to code sign the application package (.xap) file of the application that you want to install has expired. Windows Phone operating system returns an error with HRESULT 0x81030110. When you renew your PFX certificate, you must code sign again with this new certificate all the deployed applications that you have in your Application Center catalog.

When you renew your PFX code-signing certificate, you must also renew the enrollment token and deploy it on the Application Center console. Devices must also be re-enrolled to the company account with this new token. Users of devices enrolled with an expired token cannot install any applications.

In Windows Phone 8.1, if the Application Center client is not code signed (for example, when you debug it in Visual Studio), you cannot install any application by using this unsigned client. In this case, the Windows Phone operating system returns an error with HRESULT 0x800703F0. Before installing applications in Windows Phone 8.1, you must code sign the application package (.xap) file of the client.

Installing a Windows Store application on a Windows device

Use sideloading to install Windows Store apps through Application Center.

Before you begin

You must check that your configuration satisfies the application sideloading prerequisites that are described in Prepare to Sideload Apps.

The device user needs administrator rights on the device to execute the Application Center client.

About this task

Installing APPX packages through Application Center is done by a process called sideloading. As part of Windows 8.1 Update, sideloading is enabled for all Windows 8.1 Pro devices that are part of an Active Directory domain, which matches the current behavior of Windows 8.1 Enterprise. If you use either of those product versions and the device is part of an Active Directory domain, you have no concerns about sideloading keys or activating sideloading.

When you develop a Windows Store application, Microsoft Visual Studio automatically generates a self-signed certificate and uses it to code sign the application package. To be able to install the application later by using Application Center, you must import this certificate into the “Trusted Root Certification Authorities” store of the “Local Machine”. Importing the certificate is a manual procedure.

Note: Manual installation of a certificate is only required for the development phase, because APPX code signing relies on a self-signed certificate generated by Microsoft Visual Studio. In production, your APPX file must be signed by a genuine certificate purchased from a recognized root certificate authority.

Procedure

The first step of this procedure tells you how to install the certificate before you can install the application through Application Center.

1. Import this certificate into the “Trusted Root Certification Authorities” store of the “Local Machine”.
 - a. After you have generated an APPX file by using Visual Studio, place this file in your file system. In the folder of the APPX file, you can see a certificate (.cer) file that contains the self-signed certificate that you must import.

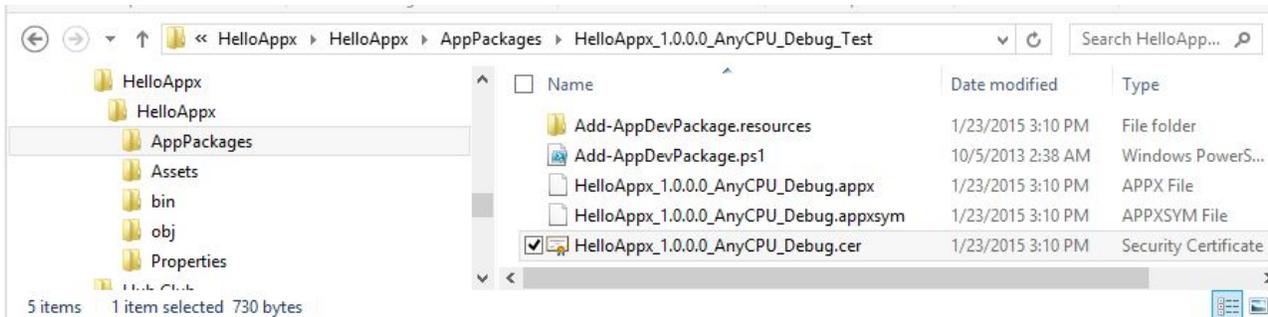

Figure 13-48. Certificate file in the application package folder

- b. To open the certificate, double-click the CER file.
 - c. Click **Install Certificate**.

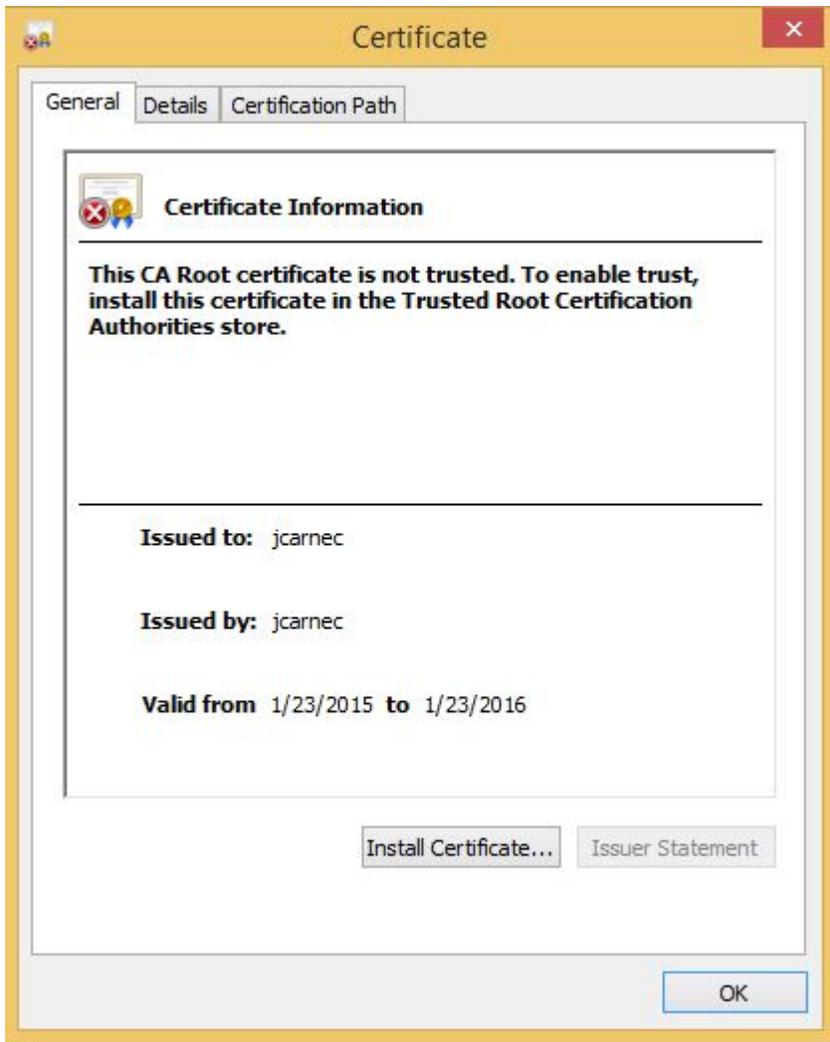

Figure 13-49. General information about the certificate

- d. Select "Local Machine" and click Next.

Figure 13-50. Specifying the local machine in the Certificate Import Wizard

- e. Select “Place all certificate in the following store” and then browse to select “Trusted Root Certification Authorities”.

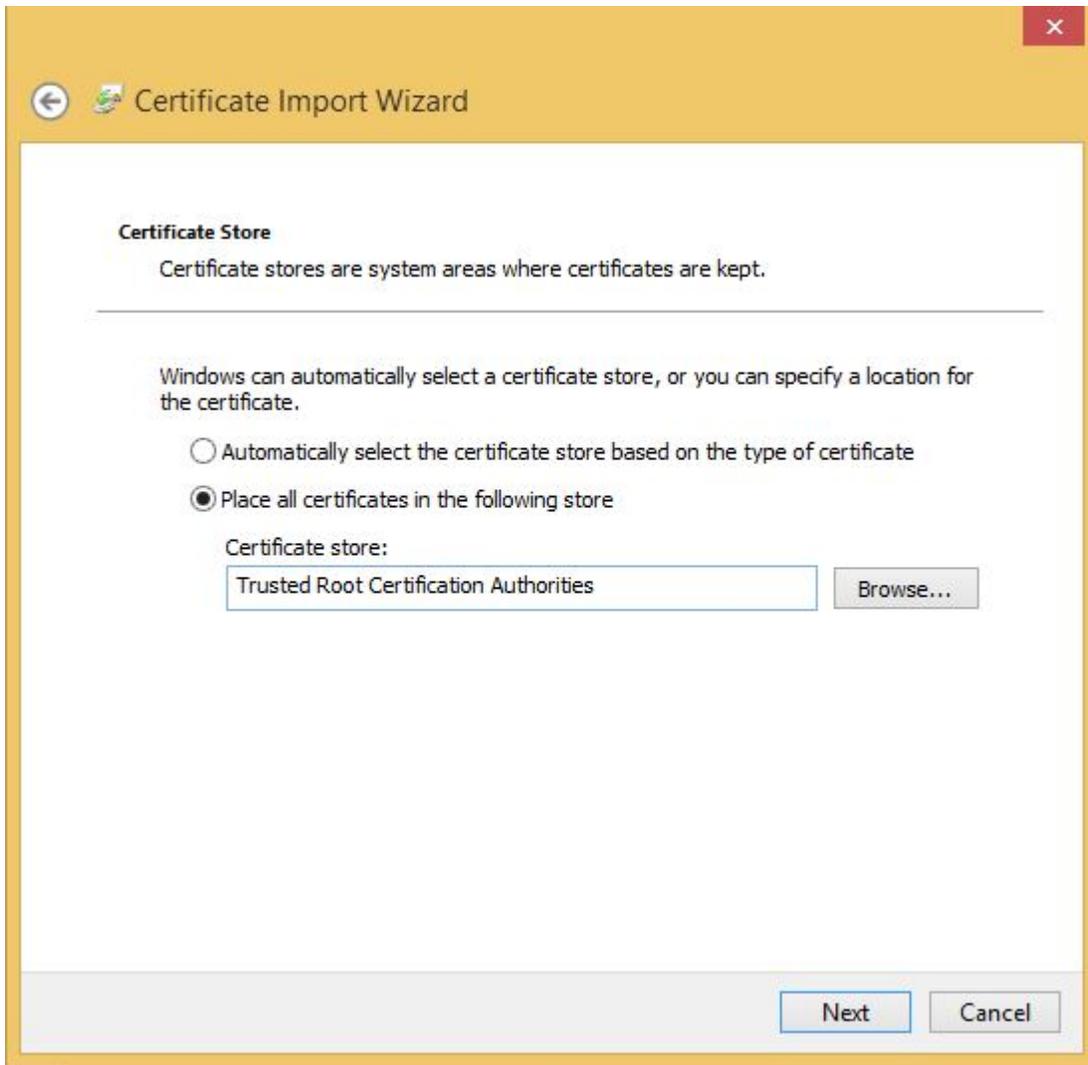

Figure 13-51. Placing the certificate in “Trusted Root Certification Authorities”

- f. Click **Next** and then **Finish**. The successful import of the certificate should be confirmed.

The following steps describe how to perform the installation of a Windows Store application on a Windows device by using Application Center.

2. Log in to the Application Center mobile client for Windows Store applications.
3. Select the application that you want to install to access its details.

Task Splitter

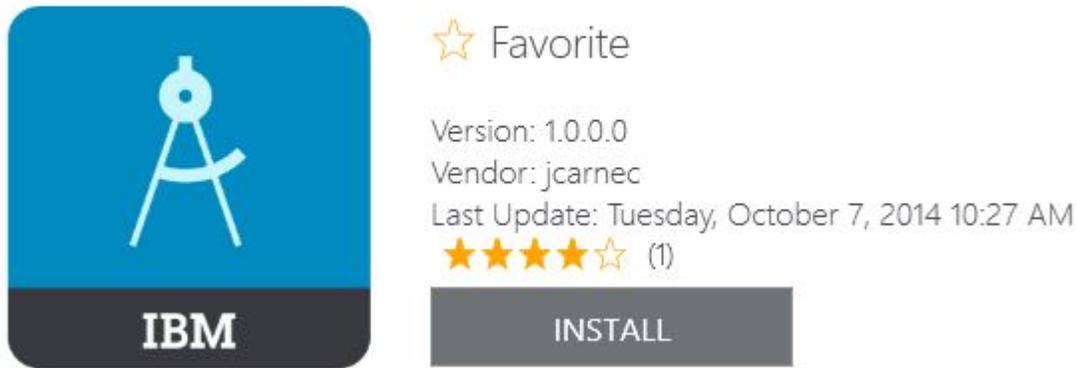

Figure 13-52. Details view for installing a Windows Store app

4. To install the application, tap **Install**. If the application is already installed and other versions are available, you can decide to update to a higher version or to revert to a lower version.

Installing an application on a BlackBerry device

From the **Details** view, you can install or reinstall an application version on your BlackBerry device.

About this task

Support for Δ BlackBerry platform OS versions 6 and 7 is deprecated and might be removed in future versions; it continues to work in this version of Application Center.

Procedure

1. In the **Details** view, tap **Install** or **Reinstall**. You are requested to confirm the download and installation of the application version.
2. Optional: During the installation, a progress bar is displayed; tap or click the red cross next to the progress bar to cancel the installation while the application is being downloaded. When the download of the application is complete, the installation can no longer be canceled. When the application is successfully installed, it is also marked as a favorite app.

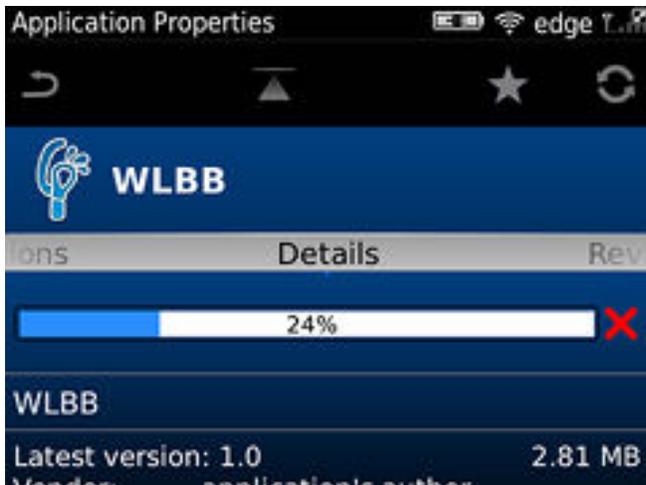

Figure 13-53. Downloading an application to a BlackBerry device

Updating or reverting an application often results in a request for a reboot. If you choose to reboot later, the list of installed applications displayed in the mobile client might temporarily become unsynchronized until the next reboot.

Installing applications through public app stores

You can link from the mobile client to applications that are stored in supported public app stores and install these applications on your compatible device by following the normal procedure of the public app store.

About this task

The Application Center administrator can create links to selected applications stored in supported public app stores and make them available to users of the Application Center mobile client on the operating systems that match these applications. See “Adding an application from a public app store” on page 13-91. You can install these applications through the mobile client on your compatible device.

Links to Android applications stored in Google play and to iOS applications stored in Apple iTunes are listed in the application list on the device along with the binary files of private applications created within your enterprise.

Procedure

1. Select an application stored in a public app store from the application list to see the application details. Instead of **Install**, you see **Go to Store**.
2. Tap **Go to Store** to open Google play or Apple iTunes.

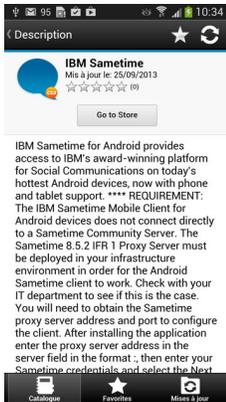

Figure 13-54. Accessing an application in Google play from the mobile client on the device

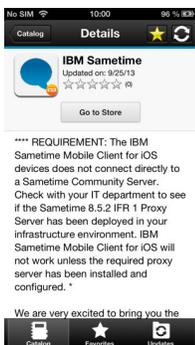

Figure 13-55. Accessing an application in Apple iTunes from the mobile client on the device

3. Follow the usual procedure of the public app store to install the application.

Removing an installed application

You can remove an application that is installed on your mobile device.

Procedure

1. Start the removal procedure that is valid for the operating system of your device.
 - Android: See the procedure in step 2.
 - iOS: You can remove applications only from the iOS Home screen, and not through the Application Center client. Use the normal iOS procedure for removing an application.
 - Windows Phone: You can remove applications only from the Windows Phone Home screen, and not through the Application Center client. Use the normal Windows Phone procedure for removing an application.
 - Windows Store: You can remove applications either from the Application Center mobile client or from the Windows home screen.
 - BlackBerry: See the procedure in step 3 on page 13-153.
2. **Android only:** Remove an application from an Android device.
 - a. In the **Details** view of any version of the application, tap **Uninstall**. The **Uninstall** button appears in the **Details** view only when a version of the application is installed. You are requested to confirm that the application version is to be uninstalled.

- b. Tap **Uninstall** to uninstall the application version or **Cancel** to notify the application that the uninstallation command has been canceled.
3. **BlackBerry only:** Remove an application from a BlackBerry device.
 - a. In the **Details** view of any version of the application, tap **Uninstall**. The **Uninstall** button appears in the **Details** view only when this version of the application is installed. You are requested to confirm that the application version is to be uninstalled.
 - b. Tap **Uninstall** to uninstall the application version or **Cancel** to cancel the uninstallation command. Removing an installed application often results in a reboot request. If you choose to reboot later, the list of installed applications displayed in the mobile client might temporarily become unsynchronized until the next reboot.

Showing details of a specific application version

Select a version of an application to show its details.

About this task

You can show the details of the selected version of an application by following the appropriate procedure for an Android or iOS phone or tablet, a Windows Phone device, a Windows device, or a BlackBerry device.

Procedure

1. Show details of a specific application version on a mobile device by selecting the appropriate procedure to follow for your device.
 - A Windows Phone, Android, or iOS phone; see step 2.
 - A BlackBerry phone; see step 3.
 - A Windows device; see step 4 on page 13-154
 - A tablet; see step 5 on page 13-154.
2. **Windows Phone, Android, iOS only:** Show details of a specific application version on a Windows Phone, Android, or iOS phone.
 - a. Tap **Select a version** to navigate to the version list view.

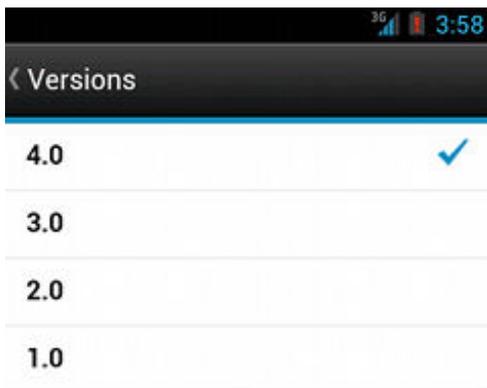

Figure 13-56. Specific version of an application selected in the list of versions on a Windows Phone, Android, or iOS phone

- b. Tap the required version of the application. The **Details** view is updated and shows the details of the selected application version.
3. **BlackBerry only:** Show details of a specific application version on a BlackBerry phone.

- a. Slide to the **Versions** pane.

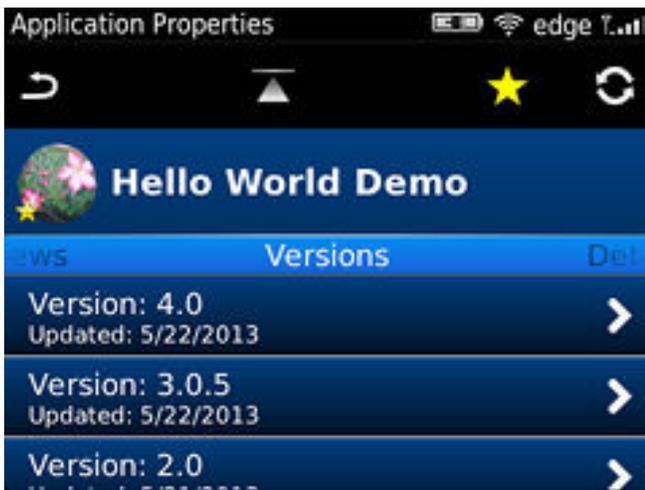

Figure 13-57. List of versions of an application on a BlackBerry phone

- b. Tap the required version of the application. The **Details** view is updated and shows the details of the selected application version.
4. **Windows only:** Show details of a specific Windows Store application version on a Windows device. If more than one version is available for the Windows Store application, then you can select which version that you want to install.
 - a. Tap the required version of the application. The **Details** view is updated and shows the details of the selected application version.
5. **Tablet devices only:** Show details of a specific application version on a tablet.
 - a. Tap **Select version**.
 - b. In the pop-up menu, select the required version of the application. The **Details** view is updated and shows the details of the selected application version.

Updating an application

You can update an application that is installed on your device if a new version is available in the Application Center.

About this task

Follow this procedure to make the latest versions of favorite and recommended apps available on your device. Applications that are marked as favorites and that have an updated version are listed in the **Updates** view. The applications that are marked as recommended by the Application Center server administrator are also listed in the **Updates** view, even if they are not favorites.

If a more up-to-date version of an installed application is available on the server, it is listed under **Update or Recommended**.

Procedure

1. In the **Updates** view, navigate to the **Details** view.
2. In the **Details** view, select a more recent version of the application or take the latest available version.
3. **Android, Windows Phone, Windows 8, and BlackBerry only:** On Android, Windows Phone, Windows 8, and BlackBerry devices, tap **Update**.

4. **iOS only:** On iOS devices, tap **Install latest**.
5. Follow the appropriate application installation procedure.
 - “Installing an application on an Android device” on page 13-139
 - “Installing an application on an iOS device” on page 13-141
 - “Installing an application on a Windows Phone device” on page 13-143
 - “Installing a Windows Store application on a Windows device” on page 13-145
 - “Installing an application on a BlackBerry device” on page 13-150

Upgrading the Application Center client automatically

You can enable automatic detection of new versions of the client application. Then, you can choose whether to download and install the new version on your mobile device. This feature is supported for iOS, Android, and Windows Phone.

Before you begin

Start the Application Center client.

About this task

New versions of the mobile client application that are available on the Application Center server can be detected automatically. When this feature is enabled, a more recent version of the application, if it exists, can be detected at start up or each time that the Available applications view is refreshed.

If a later version of the application is detected, you are requested to download and install the later version.

Automatic upgrade of the Application Center client application is enabled by default with the **appCenterAutoUpgrade** property set to true. This property is located in the MobileFirst project for the Application Center: `IBMAppCenter/apps/AppCenter/common/js/appcenter/config.json`.

If you want to disable automatic upgrade, you must set this property to false and rebuild the project for the required platforms.

Procedure

1. When a later version of the client is detected, tap **OK** to start the download and installation sequence.

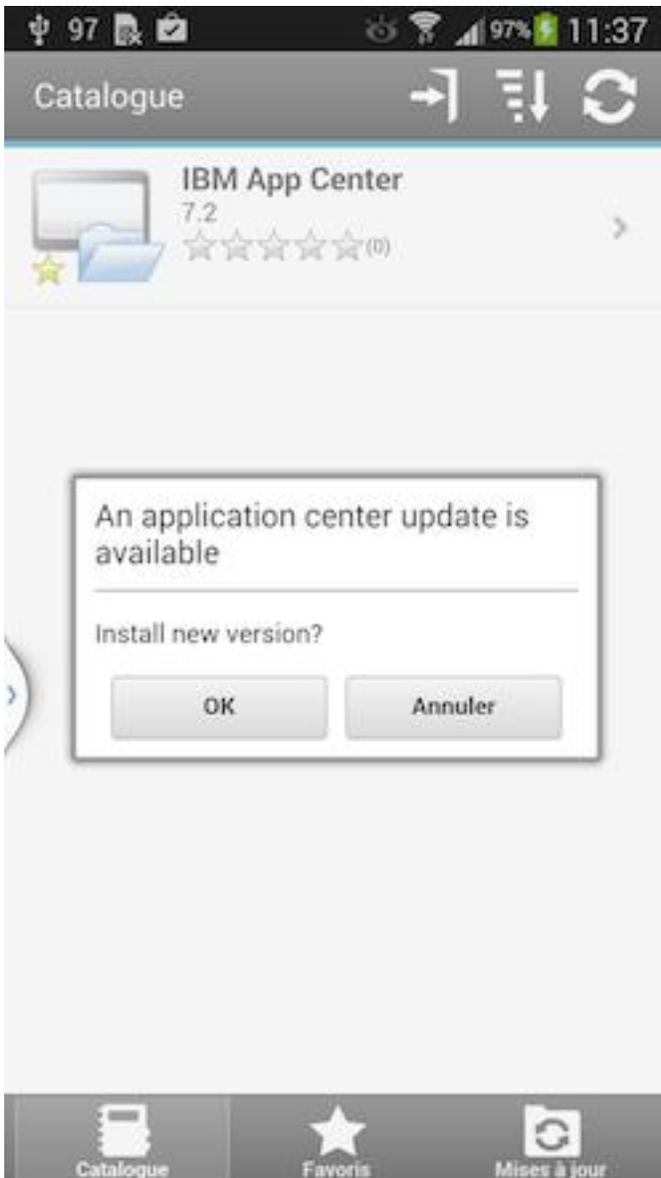

Figure 13-58. Detection of a later version of the client application available on the server

2. Tap **Install** to install the later version of the application.

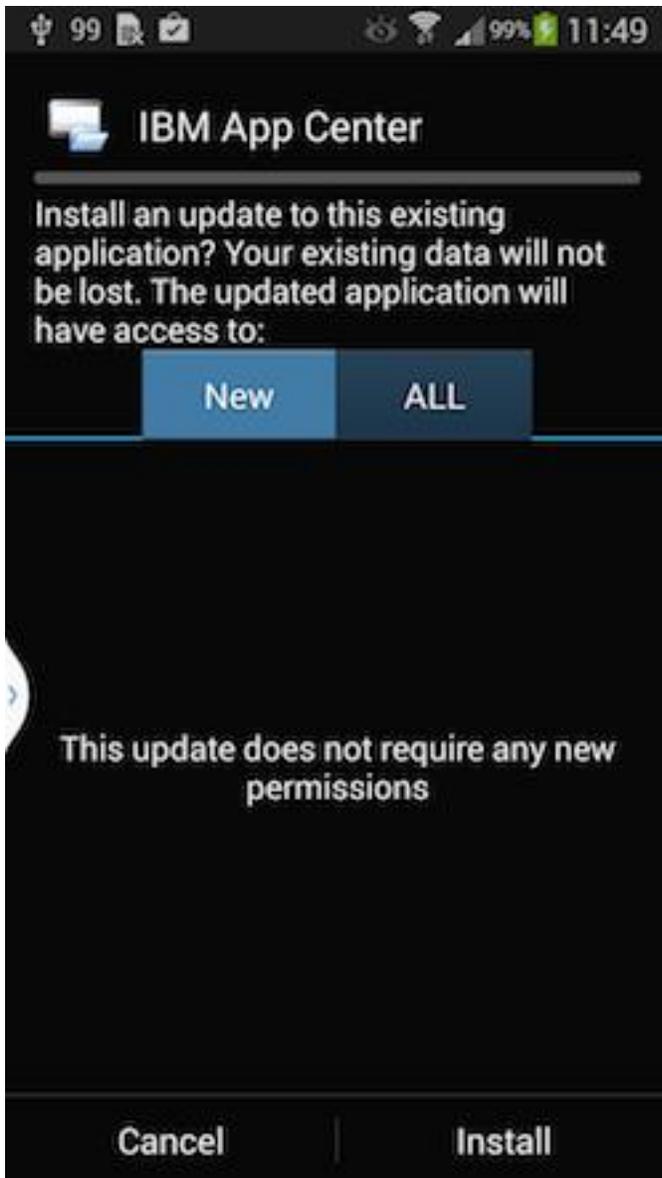

Figure 13-59. Confirm installation of the updated version of the application

3. Tap **Open** to start the updated application.

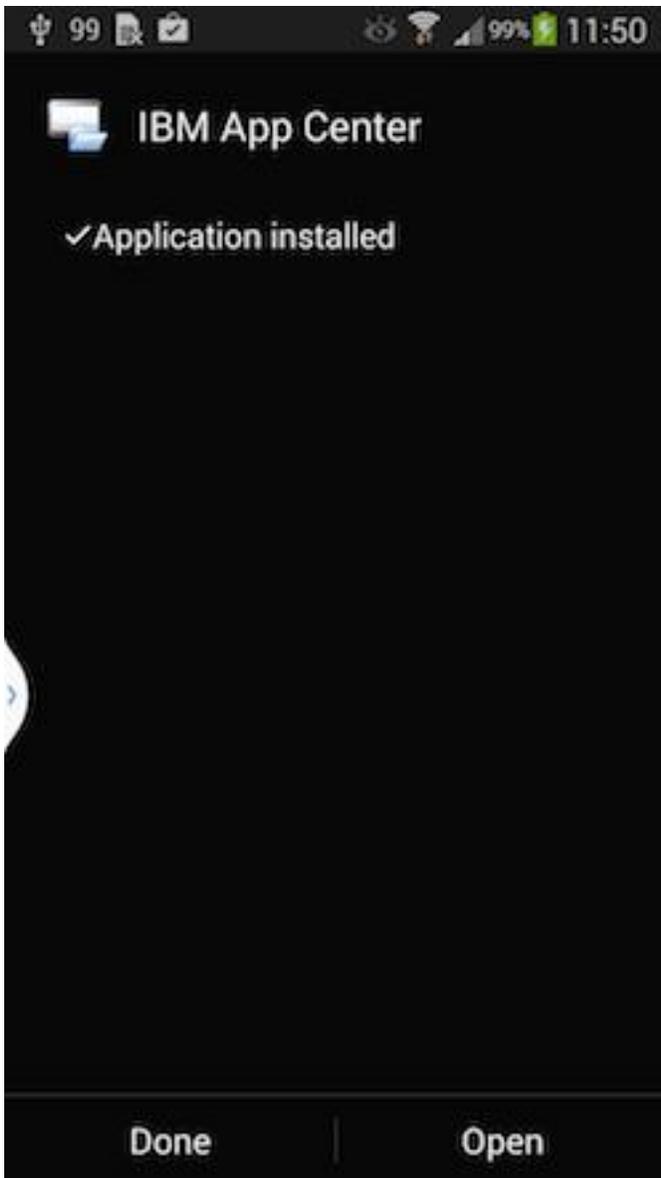

Figure 13-60. Starting the updated application

Results

You must log in to the updated version of the application to run it.

Figure 13-61. Logging in to the new version of the client application

Note: To upgrade the Application Center client, the following conditions apply:

- The new Application Center client must use the same package name or bundle identifier as the old client.
- On iOS, the new Application Center client must be signed with the same provisioning profile as the old client.
- On Android, the new Application Center client must have the same signature as the old client.
- On Windows Phone, the new Application Center client must be signed with the same company account as the old client.

Reverting an installed application

You can revert the version of an installed application if an earlier version exists on the server.

Purpose

To replace the currently installed version of an application with an earlier version, from the **Catalog**, **Updates**, or **Favorites** view, navigate to the **Details** view. In the **Details** view, select an earlier version. See “Showing details of a specific application version” on page 13-153 for information about how to display details of a specific application version on a mobile device.

See “Preparations for using the mobile client” on page 13-71 for information about how to disable reverting to earlier versions of an application.

On Android

If the installed version of the Android operating system is earlier than 4.2.2, tap **Revert**.

If the installed version of the Android operating system is 4.2.2 or later, you must uninstall the version currently installed before you can install the earlier version.

Then, follow the procedure documented in “Installing an application on an Android device” on page 13-139.

On iOS

Use the normal procedure of the operating system to remove the application.

Tap **Install** to install the earlier version of the application. Follow the procedure documented in “Installing an application on an iOS device” on page 13-141.

On Windows Phone

Tap **Revert**. Follow the procedure documented in “Installing an application on a Windows Phone device” on page 13-143.

On BlackBerry

Tap or click **Revert**. Follow the procedure documented in “Installing an application on a BlackBerry device” on page 13-150.

Marking or unmarking a favorite app

Mark your favorite apps or unmark an app to have it removed from the favorites list.

An application that is marked as a favorite on your device indicates that you are interested in this application. This application is then listed in the list of favorite apps to make locating it easier. This application is displayed on every device belonging to you that is compatible with the application. If a later version of the app is available in the Application Center, the application is listed in the **Updates** view.

To mark or unmark an application as a favorite app, tap the **Favorites** icon  in the header of the **Details** view.

An installed application is automatically marked as a favorite app.

Submitting a review for an installed application

You can review an application version installed on your mobile device; the review must include a rating and a comment.

About this task

You can only submit a review of a version of an application if that version is installed on your mobile device.

Procedure

1. In the **Details** view, initiate your review:
 - On iOS phones and tablets, tap **Review version X**.
 - On Android phones and tablets, tap **Review version X**.
 - On BlackBerry phones, slide to the **Reviews** pane and select **Write Review**.
2. Enter a nonzero star rating:
 - On mobile devices with touch screens, tap a star, from 1 to 5, to represent your approval rating of the version of the application.
 - On BlackBerry devices without touch screen, use the trackpad to slide and select the number of stars.

One star represents the lowest level of appreciation and five stars represent the highest level of appreciation.

3. Enter a comment about this version of the application.
4. Tap **Submit** to send your review to the Application Center.

Viewing reviews

You can view reviews of a specific version of an application or of all versions of an application.

Purpose

To view reviews of application versions; reviews are displayed in descending order from the most recent review. If the number of reviews fills more than one screen, tap **Load more** to show more reviews. On Android, iOS, and Windows Phone devices, the review details are visible in the list. On BlackBerry devices, select a review to view the review details.

Viewing reviews of a specific version

The **Details** view always shows the details of a specific version. On a phone, the reviews are for that version.

In the **Details** view of an application version:

On a Windows Phone, Android, or iOS phone

Tap **View Reviews** to navigate to the **Reviews** view.

On a BlackBerry phone

Slide to the **Reviews** pane.

On a tablet

Tap **Reviews xx**, where *xx* is the displayed version of the application.

Viewing reviews of all versions of an application

In the **Details** view of an application version:

On a Windows Phone, Android, or iOS phone

Tap **View Reviews** to navigate to the **Reviews** view. Then tap the settings

icon , tap **All versions**, and confirm the selection.

On a BlackBerry phone

Viewing reviews of all versions is only available when the details of the latest version are displayed. This action is not available when the details of another specific version are displayed. Slide to the **Reviews** pane, select the settings icon, select **All versions**, and confirm the selection.

On a tablet

Tap **All Reviews**.

Advanced information for BlackBerry users

You have a choice of connection suffixes for manual connection between the mobile client and BlackBerry.

Note: Support for ΔBlackBerry platform OS versions 6 and 7 is deprecated and might be removed in future versions; it continues to work in this version of Application Center.

Purpose

Sometimes you might have to set up the connection between the Application Center mobile client and BlackBerry service manually. This information helps you to set the correct connection.

The mobile client connects to the Application Center Server through HTTP. BlackBerry offers a wide range of HTTP connection modes that can be controlled by a connection suffix. The Application Center mobile client tries to detect the connection mode automatically. By default, the mobile client tries WiFi, then WAP 2.0, and then direct TCP over the mobile carrier (GPRS, 3G, and so on).

Note: BlackBerry OS 10 is not supported by the current version of the Application Center.

Setup of a manual connection

In rare cases, it might be necessary to set up the connection suffix manually.

On the BlackBerry home screen:

1. Open **Options**.
2. Open **Third Party Application**.
3. Open **IBM Application Center**.

You can then specify the connection suffix and the connection timeout parameter.

The table shows the possible connection suffixes. For corporate-owned devices, you might need to contact your network administrator for the correct connection suffix. Corporate-owned devices might disallow certain connection modes in the service book of the device.

See <http://supportforums.blackberry.com/t5/Java-Development/Network-Transports/ta-p/482457> for more details.

Table 13-113. Details for manual connection.

Connection suffix	User type	Conditions	Connection path
interface=wifi	All users	WiFi must be enabled. The device service book must allow WiFi. The device must be connected to a WiFi access point.	Device > Wifi access point > Internet > IBM Application Center Server
deviceside=true	All users	The mobile carrier must allow data connections. The device service book must allow direct TCP. The mobile carrier's APN must be set up.	Device > Mobile carrier > Internet > IBM Application Center Server
deviceside=true;apn=xyz		Similar to deviceside=true, but uses the specified APN.	
deviceside=true;apn=xyz;TunnelAuthUsername=user;TunnelAuthPassword=password		Similar to deviceside=true, but uses the specified APN and user name and password.	
deviceside=true;ConnectionUID=xyz	All users	The mobile carrier must allow data connections. The device service book must allow WAP 2.0. The WAP 2.0 connection details for the UID must be set up in the service book.	Device > Mobile carrier > WAP 2.0 Gateway > Internet > IBM Application Center Server
deviceside=true;WapGatewayIP=127.0.0.1;WapGatewayAPN=xyz	All users	The mobile carrier must allow data connections. The device service book must allow WAP 1.0/1.1.	Device > Mobile carrier > WAP 1.0 /1.1 Gateway > Internet > IBM Application Center Server

Table 13-113. Details for manual connection (continued).

Connection suffix	User type	Conditions	Connection path
deviceside=false	Corporate users	Your corporate entity must set up a BlackBerry Enterprise Server (BES) for mobile device services (MDS). The MDS connection UID must be set up in the service book.	Device > Wifi or Mobile carrier > Blackberry Infrastructure Network Operation Center (NOC) > Corporate BES > IBM Application Center Server
deviceside=false;ConnectionUID=xyz		Similar to deviceside=false, but uses the specified UID. This setting is useful when your corporate entity has set up multiple BES.	
A secret connection suffix.	BlackBerry Alliance members	You must be a member of the BlackBerry Alliance. In this case, you have received your own connection suffix. Instead of a corporate BES, you connect to the central Internet Service Browsing Server (BIS-B) of BlackBerry.	Device > Wifi or Mobile carrier > Blackberry Infrastructure Network Operation Center (NOC) > BIS-B > IBM Application Center Server
EndToEndRequired	All users	SSL connections only; use this suffix in combination with the other connection suffixes.	Device > ... > IBM Application Center Server is fully SSL encrypted
EndToEndDesired	All users	SSL connections only; use this suffix in combination with the other connection suffixes.	Device > ... > (BES or BIS-B does not necessarily use SSL) BES or BIS-B > ... > IBM Application Center Server uses SSL

Federal standards support in IBM MobileFirst Platform Foundation

IBM MobileFirst Platform Foundation supports Federal Desktop Core Configuration (FDCC), and United States Government Configuration Baseline (USGCB) specifications. IBM MobileFirst Platform Foundation also supports the Federal Information Processing Standards (FIPS) 140-2, which is a security standard that is used to accredit cryptographic modules.

For more information about the Federal Desktop Core Configuration and United States Government Configuration Baseline, see FDCC and USGCB.

For more information about the Federal Information Processing Standards 140-2, see FIPS 140-2 support.

FDCC and USGCB support

The United States federal government mandates that federal agency desktops that run on Microsoft Windows platforms adopt Federal Desktop Core Configuration (FDCC) or the newer United States Government Configuration Baseline (USGCB) security settings.

IBM Worklight V5.0.6 was tested by using the USGCB and FDCC security settings via a self-certification process. Testing includes a reasonable level of testing to ensure that installation and core features function on this configuration.

References

For more information, see USGCB.

FIPS 140-2 support

Federal Information Processing Standards (FIPS) are standards and guidelines that are issued by the United States National Institute of Standards and Technology (NIST) for federal government computer systems. FIPS Publication 140-2 is a security standard that is used to accredit cryptographic modules.

FIPS 140-2 on the MobileFirst Server, and SSL communications with the MobileFirst Server

The IBM MobileFirst Platform Foundation server runs in an application server, such as the WebSphere Application Server. The WebSphere Application Server can be configured to enforce the use of FIPS 140-2 validated cryptographic modules for inbound and outbound Secure Socket Layer (SSL) connections. The cryptographic modules are also used for the cryptographic operations that are performed by the applications by using the Java™ Cryptography Extension (JCE). Since the MobileFirst Server is an application that runs on the application server, it uses the FIPS 140-2 validated cryptographic modules for the inbound and outbound SSL connections.

When an IBM MobileFirst Platform Foundation client transacts a Secure Socket Layer (SSL) connection to a MobileFirst Server, which is running on an application server that is using the FIPS 140-2 mode, the results are the successful use of the FIPS 140-2 approved cipher suite. If the client platform does not support one of the FIPS 140-2 approved cipher suites, the SSL transaction fails and the client is not able to establish an SSL connection to the server. If successful, the client uses a FIPS 140-2 approved cipher suite.

Note: The cryptographic module instances that are used on the client are not necessarily FIPS 140-2 validated. For options to use FIPS 140-2 validated libraries on client devices, see “FIPS 140-2 on the MobileFirst client device for protection of data at rest in JSONStore and data in motion when using HTTPS communications.”

Specifically, the client and server are using the same cipher suite (SSL_RSA_WITH_AES_128_CBC_SHA for example), but the client side cryptographic module perhaps did not go through the FIPS 140-2 validation process, whereas the server side is using FIPS 140-2 certified modules.

See “References” on page 13-167 for links to documentation to enable FIPS 140-2 mode in WebSphere Application Server.

FIPS 140-2 on the MobileFirst client device for protection of data at rest in JSONStore and data in motion when using HTTPS communications

Protection of data at rest on the client device is provided by the JSONStore feature of IBM MobileFirst Platform Foundation. Protection of data in motion is provided by the use of HTTPS communication between the MobileFirst client and the MobileFirst Server. By default, these features use non-FIPS 140-2 validated libraries. But for iOS and Android devices, there is an option to use FIPS 140-2 validated libraries for the protection (encryption and decryption) of the local data that is stored by JSONStore and for the HTTPS communication to the MobileFirst Server. This support is achieved by using an OpenSSL library that achieved FIPS 140-2 validation (Certificate #1747). To enable this option in a MobileFirst client project, select the FIPS 140-2 optional feature in the MobileFirst Studio.

Note: There are some restrictions to be aware of:

- This FIPS 140-2 validated mode applies only to the protection (encryption) of local data that is stored by the JSONStore feature and protection of HTTPS communications between the MobileFirst client and the MobileFirst Server.
- This feature is only supported on the iOS and Android platforms.
 - On Android, this feature is only supported on devices or simulators that use the **x86** or **armv7** architectures. It is not supported on Android using **armv5** or **armv6** architectures. The reason is because the OpenSSL library used did not obtain FIPS 140-2 validation for **armv5** or **armv6** on Android. FIPS 140-2 is not supported on 64-bit architecture even though the MobileFirst library does support 64-bit architecture. FIPS 140-2 can be run on 64-bit devices if there are only 32-bit native NDK libraries in the project.
 - On iOS, it is supported on **i386**, **armv7**, and **armv7s** architectures.
- It only works with hybrid applications (not native).
- For HTTPS communications:
 - Only the communications between the MobileFirst client and the MobileFirst Server use the FIPS 140-2 libraries on the client. Direct connections to other servers or services do not use the FIPS 140-2 libraries.
 - The MobileFirst client can only communicate with a MobileFirst Server that runs in supported environments, which are listed in the System Requirements. If the MobileFirst Server runs in a non-supported environment, the HTTPS connection might fail with a key size too small error. This error does not occur with HTTP communications.
- The use of the User Certificate Authentication feature is not supported with the FIPS 140-2 feature.

- IBM MobileFirst Platform Application Center client does not support the FIPS 140-2 feature.
- The use of the Direct Update feature occurs over a non-FIPS 140-2 protected channel. If you want to use only a FIPS 140-2 protected channel, you must disable the Direct Update feature. To disable the Direct Update feature, you can override the mobile security test in the authenticationConfig.xml file in your server/conf directory.

```
<mobileSecurityTest name="mobileTests">
  <testDirectUpdate mode="disabled" />
</mobileSecurityTest>
```

Use this mobile security test for Android and iOS environments as follows:

```
<android securityTest="mobileTests" version="1.0">
```

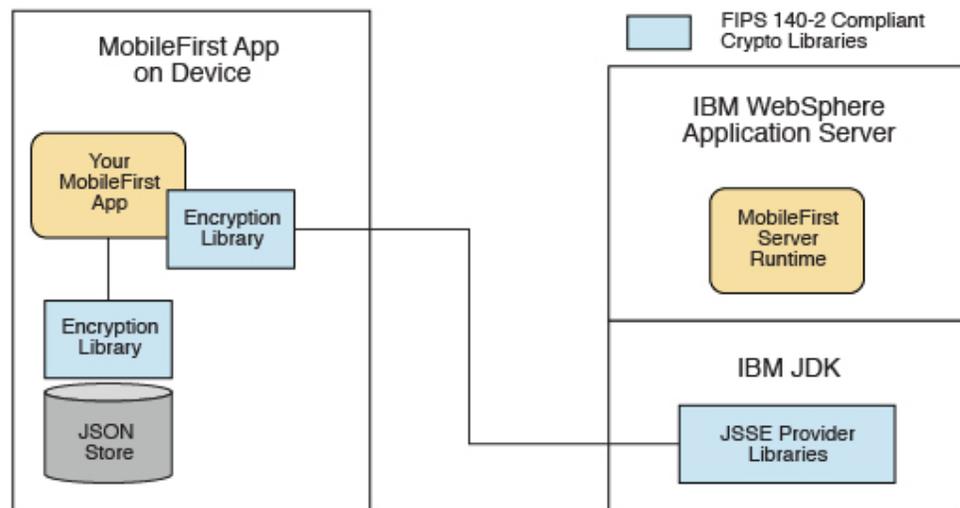

or

```
<iphone bundleId="com.TestHybridApp" version="1.0" securityTest="mobileTests">
```

The FIPS 140-2 optional feature supersedes the changes that were described in tutorial *JSONStore - Encrypting sensitive data with FIPS 140-2* that was available for IBM MobileFirst Platform Foundation V6.0.0 and earlier, *Advanced client side development*. This tutorial is available in the Advanced client side development category on the Getting Started page of the Developer Center.

If you previously made the changes that are described in the tutorial, you must first save any other environment-specific changes that you made, and then delete and re-create your Android or iOS environments.

Figure 13-62. Example

For more information about JSONStore, see “JSONStore overview” on page 8-416.

References

For information about how to enable FIPS 140-2 mode in WebSphere Application Server, see Federal Information Processing Standard support.

For the WebSphere Application Server Liberty profile, no option is available in the administrative console to enable FIPS 140-2 mode. But you can enable FIPS 140-2 by configuring the Java runtime environment to use the FIPS 140-2 validated modules. For more information, see Java Secure Socket Extension (JSSE) IBMJSSE2 Provider Reference Guide.

Enabling FIPS 140-2

To use the FIPS 140-2 feature in IBM Worklight V6.1.0, you must first enable the optional feature.

About this task

To enable this option in a MobileFirst client project, select the FIPS 140-2 optional feature in the IBM MobileFirst Platform Studio. After the optional feature is enabled, it must then be configured as described in the *What to do next* section. After the FIPS 140-2 optional feature is enabled and configured, this feature applies both to HTTPS and JSONStore data encryption.

Note: FIPS 140-2 is only supported on Android and iOS, and only for **i386**, **armv7**, and **armv7s** architectures.

Note: On Android, FIPS 140-2 is not supported on 64-bit architecture even though the MobileFirst library does support 64-bit architecture. When you use FIPS 140-2 on a 64-bit device, you might see the following error:

```
java.lang.UnsatisfiedLinkError: dlopen failed: "... is 32-bit instead of 64-bit
```

This error means that you have 64-bit native libraries in your Android project, and FIPS 140-2 does not currently work when you use these libraries. To confirm, go to `src/main/libs` or `src/main/jniLibs` under your Android project, and check whether you have the `x86_64` or `arm64-v8a` folders. If you do, delete these folders, and FIPS 140-2 can work again.

The FIPS 140-2 feature is an optional feature in IBM Worklight V6.1.0. To use the FIPS 140-2 feature, you must enable it by modifying the `application-descriptor.xml` file.

Procedure

1. Double-click the `application-descriptor.xml` file to open it in the Application Descriptor Editor.
2. Click the **Design** tab.
3. Under **Overview**, expand Application [your application's name].
4. Click **Optional Features**.
5. Click **Add**.
6. Select **FIPS 140-2**.
7. Click **OK**.

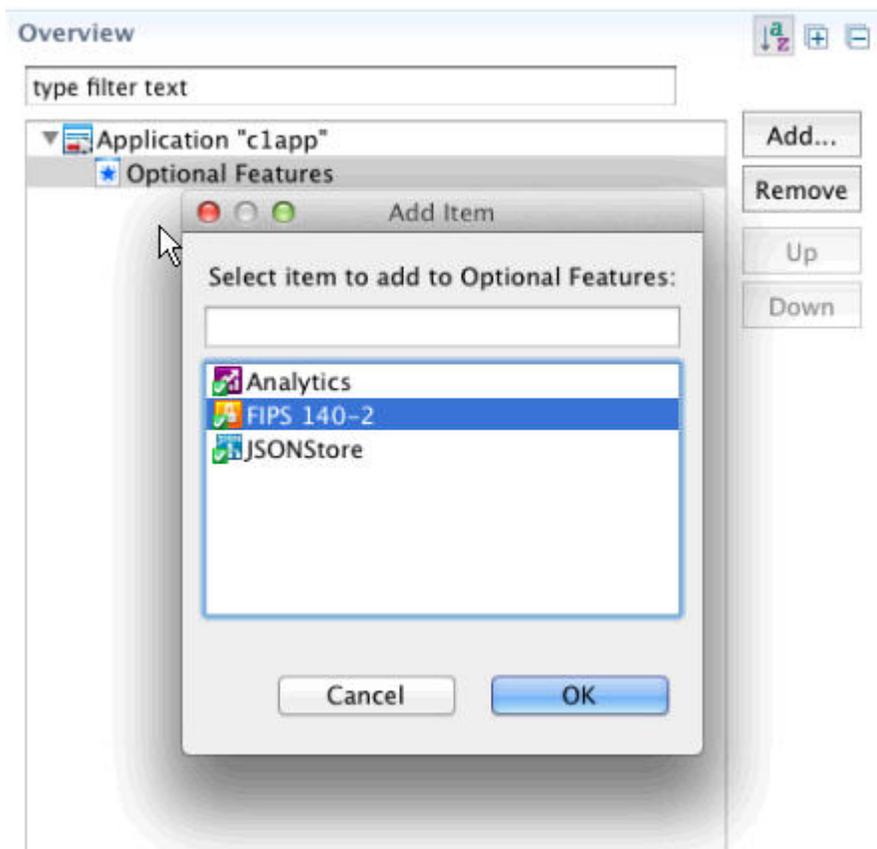

Figure 13-63. Installing the FIPS 140-2 optional feature

What to do next

“Configure FIPS 140-2 mode for HTTPS and JSONStore encryption”

Configure FIPS 140-2 mode for HTTPS and JSONStore encryption

Learn about settings to configure FIPS 140-2 for encrypting data for HTTPS and JSONStore.

The following code snippet is populated into a new IBM MobileFirst Platform Foundation application in the `initOptions.js` file for configuring FIPS 140-2:

```
var wlInitOptions = {
  ...
  // # Enable FIPS 140-2 for data-in-motion (network) and data-at-rest (JSONStore) on iOS or Android.
  // Requires the FIPS 140-2 optional feature to be enabled also.
  // enableFIPS : false
  ...
};
```

Notice the default value of `enableFIPS` is false. To enable FIPS 140-2 for both HTTPS and JSONStore data encryption, uncomment and set the option to true. After you set the value of `enableFIPS` to true, you should listen for the FIPS ready JavaScript event.

The following example assumes that you are using jQuery 1.7 or later, or WLJQ (jQuery that is included with IBM MobileFirst Platform Foundation).

```

$(document).on('WL/FIPS/READY', function(evt, obj) {
  //evt - Contains information about the event
  //obj - JavaScript object sent after the attempt to enable FIPS completes
  // if successfully enabled, object will be {enabled: true}
  // if enablement failed, object will be {enabled: false, msg: "message
  // indicating cause of the failure to enable"}
});

```

After you set the value of the `enableFIPS` property, create an Android, iPhone, or iPad environment, and build those environments.

Note: You must enable the FIPS 140-2 optional feature before you set the `enableFIPS` property to `true`. Otherwise, a warning message is logged that states the `initOption` value is set but the optional feature was not found. The FIPS 140-2 and JSONStore features are both optional. FIPS 140-2 affects JSONStore data encryption only if the JSONStore optional feature is also enabled. If JSONStore is not enabled, then FIPS 140-2 does not affect JSONStore.

```
[WARN] FIPShttp feature not found, but initOptions enables it on startup
```

For more information about installing the FIPS 140-2 optional feature, see “Enabling FIPS 140-2” on page 13-168.

Configuring FIPS 140-2 for existing applications

You must modify applications that were created in earlier versions of IBM MobileFirst Platform Foundation to enable the FIPS 140-2 feature.

Before you begin

The FIPS 140-2 optional feature is not enabled by default. To enable the FIPS 140-2 optional feature, see “Enabling FIPS 140-2” on page 13-168. After the optional feature is enabled, you can configure FIPS 140-2.

About this task

After you completed the steps that are described in “Enabling FIPS 140-2” on page 13-168, you must configure FIPS 140-2 by modifying the `initOptions.js` file to add the FIPS configuration property.

Note: For JSONStore FIPS 140-2 users – Starting with IBM Worklight V6.1.0, the FIPS 140-2 feature, combined with the JSONStore feature, enables FIPS 140-2 support for JSONStore. This combination supersedes what was indicated in tutorial *JSONStore - Encrypting sensitive data with FIPS 140-2* that was available for IBM Worklight V6.0 or earlier. If you previously modified an application by following the instructions in this tutorial, delete and re-create its iPhone, iPad, and Android environments. Because any environment-specific changes that you previously made are lost when you delete an environment, make sure to back up any such changes before you delete any environment. After the environment is re-created, you can reapply those changes to the new environment.

Procedure

1. Add the following lines of code to the `initOptions` object found in the `appFolder/common/js/initOptions.js` file.

```
enableFIPS : true
```
2. Rebuild and deploy your app.

Monitoring and mobile operations

IBM MobileFirst Platform Foundation includes a range of operational analytics and reporting mechanisms for collecting, viewing, and analyzing data from your IBM MobileFirst Platform Foundation applications and servers, and for monitoring server health.

Logging and monitoring mechanisms

IBM MobileFirst Platform Foundation reports errors, warnings, and informational messages into a log file. The underlying logging mechanism varies by application server.

IBM MobileFirst Platform Server

MobileFirst Server uses the standard `java.util.logging` package. By default, all MobileFirst logging goes into the application server log files. You can control MobileFirst Server logging by using the standard tools available in each application server. If, for example, you want to activate trace logging in Liberty, add a trace element to the `server.xml` file. To activate trace logging in WebSphere Application Server, use the logging screen in the console and enable trace for MobileFirst logs. MobileFirst logs all begin with "com.worklight".

Application Center logs begin with "com.ibm.puremeap".

For information on sending logging information from packages outside of the MobileFirst package (`com.worklight`), see [Adding additional logger packages](#).

For more information about the logging models of each server platform, including the location of the log files, see the documentation for the relevant platform, as shown in the following table.

Table 14-1. Documentation for different server platforms

Server platform	Location of documentation
Apache Tomcat	http://tomcat.apache.org/tomcat-7.0-doc/logging.html#Using_java.util.logging_(default)
WebSphere Application Server Version 7.0	http://ibm.biz/knowctr#SSEQTP_7.0.0/com.ibm.websphere.base.doc/info/aes/ae/ttrb_trcover.html
WebSphere Application Server Version 8.0	http://ibm.biz/knowctr#SSEQTP_8.0.0/com.ibm.websphere.base.doc/info/aes/ae/ttrb_trcover.html
WebSphere Application Server Version 8.5 full profile	http://ibm.biz/knowctr#SSEQTP_8.5.5/com.ibm.websphere.base.doc/ae/ttrb_trcover.html
WebSphere Application Server Version 8.5 Liberty profile	https://www.ibm.com/support/knowledgecenter/SSEQTP_8.5.5/com.ibm.websphere.wlp.doc/ae/rwlp_logging.html

Log level mappings

MobileFirst Server uses `java util logging`. The logging levels map to the following levels:

- WL.Logger.debug: FINE
- WL.Logger.info: INFO
- WL.Logger.warn: WARNING
- WL.Logger.error: SEVERE

Log monitoring tools

For Apache Tomcat, you can use IBM Operations Analytics - Log Analysis or other industry standard log file monitoring tools to monitor logs and highlight errors and warnings.

For WebSphere Application Server, use the log viewing facilities that are described in the IBM Knowledge Center at the URLs that are listed in the table in the MobileFirst Server section.

Back-end connectivity

To enable trace to monitor back-end connectivity, see the documentation for your specific application server platform in the table in the MobileFirst Server section. The packages to be enabled for trace are `com.worklight.adapters` and `com.worklight.integration`. Set the log level to FINEST for each package.

Audit log for administration operations

MobileFirst Operations Console stores an audit log for login, logout, and for all administration operations, such as deploying apps or adapters or locking apps. The audit log can be disabled by setting the JNDI property `ibm.worklight.admin.audit` on the web application of the MobileFirst Administration service (`worklightadmin.war`) to false.

When the audit log is enabled, you can download it from MobileFirst Operations Console by clicking the **Audit log** link in the footer of the page.

Audit logs for adapters

To write log information for auditing adapter calls, activate the audit logs by setting `audit="true"` in your `adapter.xml` file in the procedure definition.

Login and authentication issues

To diagnose login and authentication issues, enable the package `com.worklight.auth` for trace and set the log level to FINEST.

Vitality queries for checking server health

Use MobileFirst vitality queries to run a health check of your server, and determine the vitality status of your server.

You generally use the MobileFirst vitality queries from a load balancer or from a monitoring app (for example, Patrol).

You can run vitality queries for the server as a whole, for a specific adapter, for a specific app, or for a combination of. The following table shows some examples of vitality queries.

Table 14-2. Examples of queries that help determine server vitality

Query	Purpose
http://<server>:<port>/<publicWorkLightContext>/ws/rest/vitality	Checks the server as a whole.
http://<server>:<port>/<publicWorkLightContext>/ws/rest/vitality?app=MyApp	Checks the server and the MyApp application.
http://<server>:<port>/<publicWorkLightContext>/ws/rest/vitality?app=MyApp&adapter=MyAdapter	Checks the server, the MyApp application, and the MyAdapter adapter.

Note: Do not include the /<publicWorkLightContext> part of the URL if you use IBM MobileFirst Platform Foundation Developer Edition. You must add this part of the URL only if MobileFirst Server is running on another application server, such as Apache Tomcat or WebSphere Application Server (full profile or Liberty profile).

Vitality queries return an XML content that contains a series of <ALERT> tags, one for each test.

Example query and response

By running the http://<server>:<port>/ws/rest/vitality?app=MyApp query, you might have the following successful response, with an <ALERT> tag for each of the three tests:

```
<ROOT>
  <ALERT>
    <DATE> 2011-05-17T15:31:35.583+0300 </DATE>
    <EVENTID>0</EVENTID>
    <SUBJECT>SRV</SUBJECT>
    <TYPE>I</TYPE>
    <COMPUTER>worklight.acme.com</COMPUTER>
    <DESCRIPTION>Server is running</DESCRIPTION>
  </ALERT>
  <ALERT>
    <DATE> 2011-05-17T15:31:35.640+0300 </DATE>
    <EVENTID>0</EVENTID>
    <SUBJECT>APPL</SUBJECT>
    <TYPE>I</TYPE>
    <COMPUTER>worklight.acme.com</COMPUTER>
    <DESCRIPTION>Application 'MyApp' is deployed</DESCRIPTION>
  </ALERT>
  <ALERT>
    <DATE>2014-07-08T11:39:42.622+0300</DATE>
    <EVENTID>0</EVENTID>
    <SYSTEM>WRKL</SYSTEM>
    <SUBJECT>BUILD</SUBJECT>
    <COMPUTER>192.168.218.1</COMPUTER>
    <DESCRIPTION>6.2.0.00.20140707-1736</DESCRIPTION>
  </ALERT>
</ROOT>
```

Return values

The following table lists the attributes that might be returned, and their possible values.

Table 14-3. Return values and values

Return attribute	Possible values
DATE	Date value in JavaScript™ format
EVENTID	0 for the running server, deployed adapter, or deployed application 1 for not deployed adapter 2 for not deployed application 3 for malfunctioning server
SUBJECT	SRV for MobileFirst Server ADPT for adapter APPL for application BUILD for the version of the MobileFirst Server
TYPE	I – valid E – error
COMPUTER	Reporting computer name
DESCRIPTION	Status description in plain text

The returning XML contains more attributes, which are undocumented constants that you must not use.

Configuring logging in the development server

Information about the default logging settings for the embedded development server, and procedures for changing them.

When you are trying to diagnose problems in the MobileFirst Studio embedded test server (for example, when debugging a custom login module), it is important to be able to see log messages. The default settings for server logging are described in this section, along with the procedures for changing them if you must see finer levels of messages.

In previous releases of MobileFirst Studio, the embedded Jetty test server did not allow viewing the server logs. In Worklight Studio V6.0.0, the test server was replaced with an instance of the WebSphere Application Server Liberty profile server and is now referred to as the MobileFirst Development Server.

Logging levels for the MobileFirst Studio plugin and builder can be configured with a new file named `logging.properties`. This file is in the `.metadata` folder of your Eclipse workspace.

For example, if your MobileFirst Studio workspace is `/usr/workspace` (on UNIX) or `C:\workspace` (on Windows), the corresponding logging configuration file is `/usr/workspace/.metadata/logging.properties` or `C:\workspace\.metadata\logging.properties`.

This file contains the following default settings:

```
handlers = java.util.logging.FileHandler
.level = WARNING
com.worklight.level = INFO
```

Changing the MobileFirst Operations Console logging levels

To change the logging level for all packages in this instance of Eclipse, edit the `.level = line`. To change the logging level only for MobileFirst Studio, edit the `com.worklight.level = line`.

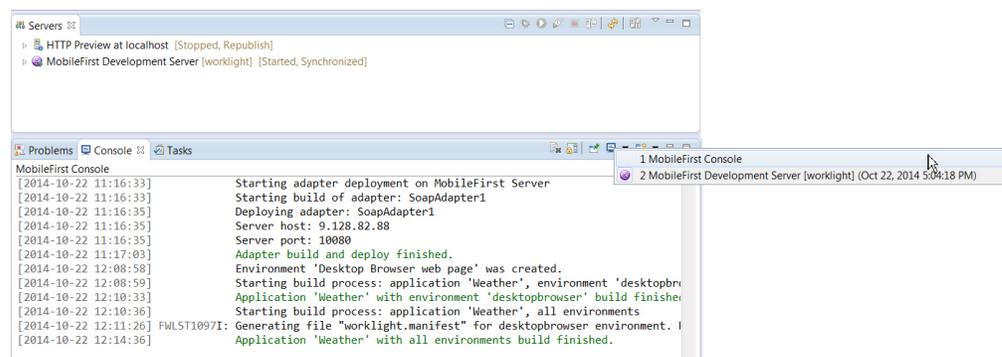

The available setting levels for `com.worklight.level = are:`

- SEVERE (highest value)
- WARNING
- INFO
- CONFIG
- FINE
- FINER
- FINEST (lowest value)

In addition, there is an ALL level that specifies logging of all messages, and an OFF level that turns off logging.

If you edit the `logging.properties` file to change the logging level, you must restart MobileFirst Studio before the change takes effect.

Whatever the logging level, the messages are displayed in MobileFirst Studio in its console view with the name **MobileFirst Console**, as shown in the following screen capture:

Changing the logging levels of a web application in Liberty profile

Changing the logging properties for individual application server types is done with those servers' administration tools.

To provide two examples for WebSphere Application Server Liberty profile, the `server.xml` file can be modified by appending the new logging element:

- To enable the INFO logging level for the server console, the following line is added to the `server.xml` file:

```
<logging consoleLogLevel="INFO"/>
```
- To enable trace log files, the following line is added to the `server.xml` file:

```
<logging traceSpecification="*=audit=enabled:com.worklight.*=info=enabled" />
```

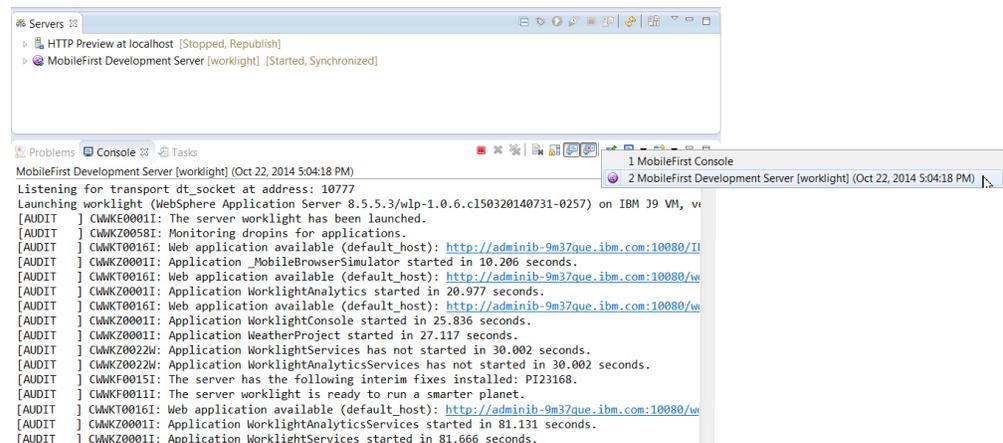

The available setting levels for `consoleLogLevel` are:

- INFO
- AUDIT
- WARNING
- ERROR
- OFF

This parameter does not support DEBUG level logging.

No server restart is necessary after you modify these settings.

Whatever the logging level, the messages are displayed in MobileFirst Studio in its console view with the name **MobileFirst Development Server**, as shown in the following screen capture:

This console view allows you to see messages from the MobileFirst Development Server, but with some known limitations:

- Localized log messages are shown incorrectly. For more information about this issue, see Liberty profile: Trace and logging.
- Setting the value of `consoleLogLevel` to WARNING, ERROR, or OFF causes the server not to start from MobileFirst Studio using the Eclipse servers view.

Trace log messages are written to the `trace.log` file only. This logging trace is optional and supports fine-tuning such as packaging and more precise reporting levels, and is mainly used for debugging.

The `trace*.log` file is found under your Eclipse workspace in the folder `WorklightServerConfig\servers\worklight\logs\`.

For example, if your MobileFirst Studio workspace is `/usr/workspace` (on UNIX) or `C:\workspace` (on Windows), the log files are created under `/usr/workspace/WorklightServerConfig/servers/worklight/logs/` or `C:\workspace\WorklightServerConfig\servers\worklight\logs\`.

The available setting levels for `<logging traceSpecification="*=audit=enabled:com.worklight.*=info=enabled" />` are:

- Off - No events are logged.
- Fatal - Task cannot continue and component cannot function.
- Severe - Task cannot continue, but component can still function.

- Warning - Potential error or impending error.
- Audit - Significant event affecting server state or resources.
- Info - General information outlining overall task progress.
- Config - Configuration change or status.
- Detail - General information detailing subtask progress.
- Fine - Trace information - General trace.
- Finer - Trace information - Detailed trace + method entry / exit / return values.
- Finest - Trace information - A more detailed trace - Includes all the detail that is needed to debug problems.
- All - All events are logged. If you create custom levels, All includes your custom levels, and can provide a more detailed trace than Finest.

For more information about WebSphere Application Server Liberty profile logging configuration, see Liberty profile: Trace and logging.

Setting logging and tracing for Application Center on the application server

You can set logging and trace parameters for particular application servers and use JNDI properties to control output on all supported application servers.

You can set the logging levels and the output file for tracing operations for Application Center in ways that are specific to particular application servers. In addition, IBM MobileFirst Platform Foundation provides Java Naming and Directory Interface (JNDI) properties to control the formatting and redirection of trace output, and to print generated SQL statements.

Enabling logging and tracing in WebSphere Application Server full profile

You can set the logging levels and the output file for tracing operations on the application server.

About this task

When you try to diagnose problems in the Application Center (or other components of IBM MobileFirst Platform Foundation), it is important to be able to see the log messages. To print readable log messages in log files, you must specify the applicable settings as Java virtual machine (JVM) properties.

Procedure

1. Open the administrative console of WebSphere Application Server.
2. Select **Troubleshooting > Logs and Trace**.
3. In "Logging and tracing", select the appropriate application server and then select "Change log detail levels".
4. Select the required packages and their corresponding detail level. For example, in this way you can select following packages and set the detail level. This example enables logging for IBM MobileFirst Platform Foundation, including Application Center, with level FINEST (equivalent to ALL)

```
com.ibm.puremeap.*=all
com.ibm.worklight.*=all
com.worklight.*=all
```

Where:

- com.ibm.puremeap.* is for Application Center.

- `com.ibm.worklight.*` and `com.worklight.*` are for other MobileFirst components.

The traces are sent to a file called `trace.log`. Note that they are not sent to `SystemOut.log` or to `SystemErr.log`.

For more details, see [Configuring Java logging using the administrative console](#).

Enabling logging and tracing in WebSphere Application Server Liberty profile

You can set the logging levels and the output file for tracing operations for Application Center on the Liberty profile application server.

When you try to diagnose problems in the Application Center, it is important to be able to see the log messages. To print readable log messages in log files, you must specify the applicable settings.

To enable logging for IBM MobileFirst Platform Foundation, including Application Center, with level `FINEST` (equivalent to `ALL`), add a line to the `server.xml` file.

For example:

```
<logging traceSpecification="com.ibm.puremap.*=all:com.ibm.worklight.*=all:com.worklight.*=all"/>
```

Where multiple entries of a package and its logging level are separated by a colon (:).

The traces are sent to a file called `trace.log`. Note that they are not sent to `messages.log` or to `console.log`.

For more details, see [Liberty profile: Logging and Trace](#).

Enabling logging and tracing in Apache Tomcat

You can set the logging levels and the output file for tracing operations undertaken on the Apache Tomcat application server.

When you try to diagnose problems in the Application Center, it is important to be able to see the log messages. To print readable log messages in log files, you must specify the applicable settings.

To enable logging for IBM MobileFirst Platform Foundation, including Application Center, with level `FINEST` (equivalent to `ALL`), edit the `conf/logging.properties` file. For example, add lines similar to these lines:

```
com.ibm.puremap.level = ALL
com.ibm.worklight.level = ALL
com.worklight.level = ALL
```

For more details, see [Logging in Tomcat](#).

JNDI properties for controlling trace output

On all supported platforms, you can use Java Naming and Directory Interface (JNDI) properties to format and redirect trace output for Application Center, and to print generated SQL statements.

The following table shows the applicable properties and settings.

Table 14-4. JNDI property settings for controlling trace output

Property settings	Description
ibm.appcenter.logging.formatjson=true	This setting uses white space to format the JSON output for easier reading in log files.
ibm.appcenter.logging.tosystemerror=true	This setting prints all log messages to system error in log files. It enables you to turn on logging globally.
ibm.appcenter.openjpa.Log=DefaultLevel=WARN, Runtime=INFO, Tool=INFO, SQL=TRACE	This setting prints all the generated SQL statements in the log files.

Operational analytics

The operational analytics feature enables searching across apps, services, devices, and other sources to collect data about usage or detect problems. The operational analytics platform collects data about applications, adapters, devices, and logs to give a high-level view of the client interaction with the MobileFirst Server and to enable problem detection.

IBM MobileFirst Platform Foundation includes a scalable operational analytics feature that is accessible from the MobileFirst Operations Console. The analytics feature enables enterprises to search across logs and events that are collected from devices, apps, and servers for patterns, problems, and platform usage statistics.

The data for operational analytics includes the following sources:

- Interactions of any app-to-server activity (anything that is supported by the MobileFirst client/server protocol, including push notification).
- Client-side logs and crashes.
- Server-side logs that are captured in traditional MobileFirst log files.

The data for operational analytics includes the following sources:

- Crash events of an application on iOS and Android devices (crash events for native code and JavaScript errors).
- Interactions of any application-to-server activity (anything that is supported by the MobileFirst client/server protocol, including push notification).
- Server-side logs that are captured in traditional MobileFirst log files.

The operational analytics feature is accessible from the MobileFirst Operations Console and includes the following capabilities:

- Near real-time analytics for client activity with the MobileFirst Server.
- Analytics for adapter hits.
- Network latency analytics.
- Client log search and download.
- Server log search and download.
- Crash and stack trace search.

All data collected by the analytics platform can be visualized through the Operational Analytics console. The console also provides the ability to create custom charts based on data collected by the analytics platform. In addition to an at-a-glance view of your mobile and web application analytics, the analytics feature

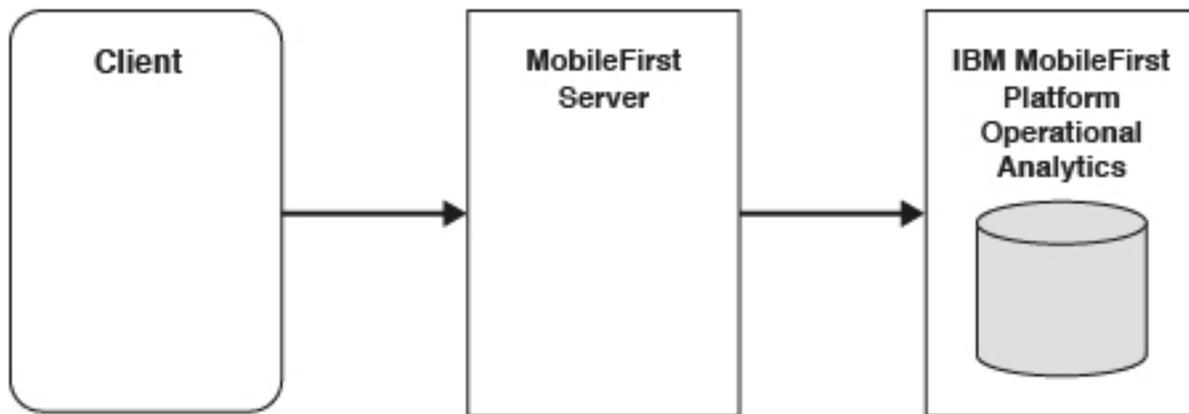

includes the capability to perform a raw search against server and client logs, captured client crash data, and any extra data you explicitly provide through client and server API function calls that feed into the IBM MobileFirst Platform Operational Analytics.

Data capture

When the IBM MobileFirst Platform Operational Analytics is deployed and the MobileFirst Server is properly configured, data begins to flow from the MobileFirst Server to the IBM MobileFirst Platform Operational Analytics. Some types of data are captured automatically without extra client or server configurations. Some types of data require changes to be made in the client application to capture or forward the data to the MobileFirst Server.

Analytics event types

The following image shows the analytics data flow:

All data that is sent from the MobileFirst Server to the IBM MobileFirst Platform Operational Analytics is categorized by its type. This section briefly describes the different types of analytics data that is captured and analyzed.

App Activities

All IBM MobileFirst Platform Foundation client/server network communication is considered to be an app activity. An app activity is sent to the IBM MobileFirst Platform Operational Analytics when:

- A client device begins a new session with the MobileFirst Server.
- A client device makes an adapter request.

When the client communicates with the MobileFirst Server through one of the previously mentioned events, it also sends metadata about the device, including:

- Device environment (iOS, Android, Windows Phone, and so on).
- Device model (iPhone3,3, iPad4,4, Nexus, and so on).

Note: MobileFirst Operational Analytics logs the iPhone model number. On iOS, two different values are reported for the device model: the generation and the hardware identifier string. The hardware identifier string comes from Cordova, while the generation comes from the app

instance registration. Due to this difference, you might see some iOS device models in the Analytics Console being referred to by either string.

- Device OS version (6.2, 4.2.2, and so on).

Extra information that is captured during a client/network communication includes:

- Response times for adapter calls.
- Response payload sizes for adapter calls.

Server Logs

Normal MobileFirst Server activity produces log messages that are saved to the disk. These messages are also forwarded to the MobileFirst Server IBM MobileFirst Platform Operational Analytics and can be searched.

Client Logs

Client devices can be configured to capture log data and crash events to be forwarded to the MobileFirst Server. For more information, see “Manually captured data.”

Notification Activities

Upon a successful push notification, a notification activity is automatically sent to the IBM MobileFirst Platform Operational Analytics.

Manually captured data

The following data must be captured manually by changing the client application.

Client Logs

The following examples show how to create client logs to be sent to the IBM MobileFirst Platform Operational Analytics.

Hybrid applications (JavaScript):

```
// Set logging level (default level is FATAL).
WL.Logger.config({level: "DEBUG"});

// Log the message.
WL.Logger.debug("This message is persisted locally until it is sent to the server");

// Call the 'send' method explicitly to send the logs to the MobileFirst Server.
WL.Logger.send();
```

Native iOS applications:

```
#import "OCLogger.h"

// Set logging level (default level is FATAL).
[OCLogger setLevel:OCLogger_DEBUG];

// Create a new instance of the logger and log the message.
OCLogger *logger = [OCLogger getInstanceWithPackage:@"MyPackage"];
[logger debug:@"This message is persisted locally until it is sent to the server"];

// Call the 'send' method explicitly to send the logs to the MobileFirst Server
[OCLogger send];
```

Native Android applications:

```
import com.worklight.common.Logger;

// Set logging level (default level is FATAL).
Logger.setLevel(LEVEL.DEBUG);

// Create a new instance of the logger and log the message.
Logger logger = Logger.getInstance("MyPackage");
```

```

logger.debug("This message is persisted locally until it is sent to the server");

// Call the 'send' method explicitly to send the logs to the MobileFirst Server
Logger.send();

```

For more information about capturing client-side logs, see “Client-side log capture configuration from MobileFirst Operations Console” on page 8-688.

All persisted client-side logs are sent automatically upon a successful initialization (successful session start) with the MobileFirst Server. An explicit API is provided if you want to send the logs more frequently.

Client Network Activities

Network activities for client devices are captured and persisted on the device automatically. However, they are only sent when the client successfully initializes with the MobileFirst Server (successful session start) and when the client calls the `send()` method.

Collecting Analytics for Network Connections to other servers

All network communications to the MobileFirst Server are logged and collected for analytics as part of MobileFirst Operational Analytics. To enable collection of network analytics to servers other than the MobileFirst Server, use `WLResourceRequest` provided in IBM MobileFirst Platform Foundation. This API exists for native iOS, native Android, and hybrid applications. For example:

```

//Android

WLResourceRequest resourceRequest = null;

try{

    /**
     * No java.util.logging.Logger method calls are captured until the
     * com.worklight.common.Logger.setContext(Context) method is called
     */

    //Logger.setContext(activity);

    resourceRequest = new WLResourceRequest(new URI("http://myserverurl.com/"), "GET");

    resourceRequest.send(new WLHttpServletResponse() {
        @Override
        public void onSuccess(HttpResponse httpResponse) {

            String responseBody = null;

            try {

                responseBody = EntityUtils.toString(httpResponse.getEntity());

            } catch (IOException e) {}

        }

        @Override
        public void onFailure(HttpResponse httpResponse, Exception e) {
            // request completed with an error
        });

    } catch (URISyntaxException e) {}

```

Analytics Logging

The client-logging feature enables developers to create logs to help debug problems and capture errors. A separate API exists for creating logs that are not meant for problem detection and capture:

```
WL.Analytics.log( object, message );
WL.Analytics.send();
```

For example:

```
WL.Analytics.log( { "hello": "world" } , "This is an analytics log" );
WL.Analytics.send();
```

Logs that are created by the client-side logger are only captured based on the logging level that is set. For example, DEBUG logs are not captured when the logging level is set to FATAL. However, logs that are produced by `WL.Analytics.log` are always captured, despite the current logging level. These logs are sent to the Analytics Server only after `WL.Analytics.send()` is called.

The metadata object that is passed into this method is searchable. However, the Analytics Console does not make further use of the object beyond the custom activities that are shown next. The primary purpose of the metadata object is to allow you to log custom JSON objects if you want to export analytics data into their own custom tool.

Crash reports

If you want uncaught exceptions recorded and sent to IBM MobileFirst Platform Operational Analytics in your native iOS application, you can do so by registering an uncaught exception handler.

```
NSSetUncaughtExceptionHandler(&unCaughtExceptionHandler);
```

Then you can implement your uncaught exception handler, utilizing `OCLogger` to record information about the exception.

```
static void unCaughtExceptionHandler(NSException *e) {
    [[OCLogger getInstanceWithPackage:@"example.package"] fatal:@"Uncaught Exception: %@. Reason: %@", e.name, e.reason];
}
```

Note that the logs are not sent to the server until the application is restarted and connects to the MobileFirst Server.

Custom Activities

The Analytics Console provides a page to view analytics for custom activities. These activities can be created on the client-side by the `WL.Analytics` API. Using the `_activity` key in the object for the `WL.Analytics` call creates a new activity on the server. For example:

```
WL.Analytics.log( { "_activity" : "myCustomActivity" } );
```

creates a new activity in the IBM MobileFirst Platform Operational Analytics that can be searched on the Activities page of the AnalyticsConsole.

JSONStore Analytics

For more information about configuring the client to send analytics data for JSONStore, see “JSONStore analytics” on page 8-466.

Client configurations

No additional client configurations are needed for client devices to forward analytics data to the MobileFirst Server.

The Analytics Optional Feature is not required to be enabled on the client for analytics in IBM MobileFirst Platform Foundation V7.1.0.

The analyticsEnabled flag in the initOptions.js file is not required to be enabled on the client for analytics in IBM MobileFirst Platform Foundation V7.1.0.

These configurations are only necessary if you are using the previous analytics platform (IBM SmartCloud Analytics Embedded). If you are using the new IBM MobileFirst Platform Operational Analytics in IBM MobileFirst Platform Foundation V7.1.0, then these properties can be ignored.

Event types

Data that is sent to the MobileFirst Operational Analytics is categorized into an event type.

MobileFirst Operational Analytics contains the following event types:

- Custom Data
- Devices
- Device App Logs
- Device App Network Transactions
- Device App Push Action
- If you are using the latest interim fix of MobileFirst: “Device App Session” on page 14-17
- Mobile Users
- Server Logs
- Server Network Transactions
- Server Push Notifications
- Server Push Subscriptions

Custom Data

Table 14-5. Custom Data Properties.

Property Name	Description
appID	Unique Bluemix application identifier
clientID	Unique client identifier
deviceAppName	Name of the MobileFirst application
deviceAppVersion	Version of the MobileFirst application
deviceID	Unique device identifier
deviceModel	Device model name. For example: iPhone3,3, Galaxy
deviceOS	Device environment. For example: iPhone, Android
deviceOSversion	Device operating system version. For example: 7.0
hostname	Host name of the MobileFirst Analytics server
serverIpAddress	IP address of the MobileFirst Analytics server
timestamp	Time the event was reported, represented as epoch time stamp in milliseconds
timezone	The difference between UTC and local time, in minutes

In addition to the default properties that are logged, any custom events that are sent to MobileFirst Operational Analytics by the `WL.Analytics.log` method also become a property of the custom data event.

Devices

Table 14-6. Devices Properties.

Property Name	Description
appID	Unique Bluemix application identifier
clientID	Unique client identifier
deviceAppName	Name of the MobileFirst application
deviceAppVersion	Version of the MobileFirst application
deviceID	Unique device identifier
deviceModel	Device model name. For example: iPhone3,3, Galaxy
deviceOS	Device environment. For example: iPhone, Android
deviceOSversion	Device operating system version. For example: 7.0
firstAccessTimestamp	Time stamp of the device's first access to a specific version of a MobileFirst application

Device App Logs

Table 14-7. Device App Logs Properties.

Property Name	Description
appID	Unique Bluemix application identifier
clientID	Unique client identifier
deviceAppName	Name of the MobileFirst application
deviceAppVersion	Version of the MobileFirst application
deviceID	Unique device identifier
deviceModel	Device model name. For example: iPhone3,3, Galaxy
deviceOS	Device environment. For example: iPhone, Android
deviceOSversion	Device operating system version. For example: 7.0
file	File name of the code that recorded this log entry
level	Level at which the log was recorded. For example: WARN, DEBUG
line	Line number of the code that recorded this log entry
pkg	Name of the logger instance that recorded this log entry
method	Name of the method that recorded this log entry

Table 14-7. Device App Logs Properties (continued).

Property Name	Description
message	Message content of the log
stacktrace	Stack trace that is associated with the log
timestamp	Time the event was reported, represented as epoch time stamp in milliseconds
timezone	The difference between UTC and local time, in minutes
userID	Unique user identifier
wifiAPS	Wireless access points
wifiConnectedMAC	MAC address of the connected wireless network
wifiConnectedSSID	Name of the connected wireless network
wifiTimestamp	Last recorded time that the client connected to the wireless network

Device App Network Transactions

Table 14-8. Device App Network Transactions Properties.

Property Name	Description
appID	Unique Bluemix application identifier
bytesReceived	Number of bytes that were received
bytesSent	Number of bytes that were sent
clientID	Unique client identifier
deviceAppName	Name of the MobileFirst application
deviceAppVersion	Version of the MobileFirst application
deviceID	Unique device identifier
deviceIpAddress	IP address of the device
deviceModel	Device model name. For example: iPhone3,3, Galaxy
deviceOS	Device environment. For example: iPhone, Android
deviceOSversion	Device operating system version. For example: 7.0
inboundTimestamp	Time when the client receives a response to a network request
networkType	Type of network connection that was used. For example: Wi-Fi, 3G
outboundTimestamp	Time when the client sends a network request
resourceURL	URL of the requested resource
responseCode	Response or status code for the network request
roundTripTime	Total duration of the transaction
timestamp	Time the event was reported, represented as epoch time stamp in milliseconds

Table 14-8. Device App Network Transactions Properties (continued).

Property Name	Description
timezone	The difference between UTC and local time, in minutes
trackingID	Unique tracking identifier
userID	Unique user identifier
userAgent	Value of the User-Agent header
wifiAPS	Wireless access points
wifiConnectedMAC	MAC address of the connected wireless network
wifiConnectedSSID	Name of the connected wireless network
wifiTimestamp	Last recorded time that the client connected to the wireless network

Device App Push Action

Table 14-9. Device App Push Action Properties.

Property Name	Description
appID	Unique Bluemix application identifier
clientID	Unique client identifier
deviceAppName	Name of the MobileFirst application
deviceAppVersion	Version of the MobileFirst application
deviceID	Unique device identifier
deviceModel	Device model name. For example: iPhone3,3, Galaxy
deviceOS	Device environment. For example: iPhone, Android
deviceOSversion	Device operating system version. For example: 7.0
notificationAction	The action that was taken by the application that received the push notification. For example: open, received, seen
notificationID	Unique push notification identifier
timestamp	Time the event was reported, represented as epoch time stamp in milliseconds
timezone	The difference between UTC and local time, in minutes
userID	Unique user identifier

Device App Session

Table 14-10. Device App Session Properties.

Property Name	Description
closedBy	Indicates what caused the end of the session. Valid values are USER and CRASH.
deviceID	Unique device identifier

Table 14-10. Device App Session Properties (continued).

Property Name	Description
deviceModel	Device model name. For example: iPhone3,3, Galaxy
deviceOS	Device environment. For example: iPhone, Android
deviceOSversion	Device operating system version. For example: 7.0
duration	The length of the usage session in milliseconds
mfpAppName	Name of the MobileFirst application
mfpAppVersion	Version of the MobileFirst application
timestamp	Time the session started, represented as epoch time stamp in milliseconds

Mobile Users

Table 14-11. Mobile Users Properties.

Property Name	Description
appID	Unique Bluemix application identifier
clientID	Unique client identifier
deviceAppName	Name of the MobileFirst application
deviceAppVersion	Version of the MobileFirst application
deviceID	Unique device identifier
deviceModel	Device model name. For example: iPhone3,3, Galaxy
deviceOS	Device environment. For example: iPhone, Android
deviceOSversion	Device operating system version. For example: 7.0
firstAccessTimestamp	Timestamp of the user's first access to a specific version of a MobileFirst application
timezone	The difference between UTC and local time, in minutes
userAuthBy	Name of the realm that the user authenticated with
userDisplayName	The display name of the user
userID	Unique user identifier

Server Logs

Table 14-12. Server Logs Properties.

Property Name	Description
appID	Unique Bluemix application identifier
hostname	Host name of the MobileFirst Analytics server

Table 14-12. Server Logs Properties (continued).

Property Name	Description
level	Level at which the log was recorded. For example: WARN, DEBUG
loggerName	Name of the logger
message	Message content of the log
serverIpAddress	IP address of the MobileFirst Analytics server
sourceClass	Name of the class that recorded the log
sourceMethodName	Name of the method that recorded the log
stacktrace	Stack trace that is associated with the log
stacktraceMessage	The message that was output by the exception that caused the stack trace
threadID	Identifier of the thread that recorded the log, only captured on Android
timestamp	Time the event was reported, represented as epoch time stamp in milliseconds
timezone	The difference between UTC and local time, in minutes
trackingID	Unique tracking identifier

Server Network Transactions

Table 14-13. Server Network Transactions Properties.

Property Name	Description
adapterName	Name of the adapter that was used
appID	Unique Bluemix application identifier
bytesReceived	Number of bytes that were received
bytesSent	Number of bytes that were sent
clientID	Unique client identifier
compressed	Boolean value that indicates whether the network payload was compressed
deviceAppName	Name of the MobileFirst application
deviceAppVersion	Version of the MobileFirst application
deviceID	Unique device identifier
deviceModel	Device model name. For example: iPhone3,3, Galaxy
deviceOS	Device environment. For example: iPhone, Android
deviceOSversion	Device operating system version. For example: 7.0
hostname	Host name of the MobileFirst Analytics server
inboundRequestURL	URL of the inbound request
inboundTimestamp	Time when the reporting server received the client network request

Table 14-13. Server Network Transactions Properties (continued).

Property Name	Description
outboundTimestamp	Time when the reporting server responds to the client network request
procedureName	Name of the adapter procedure
serverIpAddress	IP address of the MobileFirst Analytics server
serverProcessingTime	Total amount of time the server took to respond
sessionID	Unique session identifier
timestamp	Time the event was reported, represented as epoch time stamp in milliseconds
timezone	The difference between UTC and local time, in minutes
trackingID	Unique tracking identifier
userAgent	Value of the User-Agent header
userAuthBy	Name of the realm that the user authenticated with
userDisplayName	The display name of the user
userID	Unique user identifier

Server Push Notifications

Table 14-14. Server Push Notifications Properties.

Property Name	Description
appID	Unique Bluemix application identifier
clientID	Unique client identifier
destNumber	Phone number of the target recipient
deviceAppName	Name of the MobileFirst application
deviceAppVersion	Version of the MobileFirst application
deviceID	Unique device identifier
deviceModel	Device model name. For example: iPhone3,3, Galaxy
deviceOS	Device environment. For example: iPhone, Android
deviceOSversion	Device operating system version. For example: 7.0
eventSource	The push notification channel that generated the push notification
hostname	Host name of the MobileFirst Analytics server
mediator	Entity that processed the notification
messagePushTimestamp	Timestamp when the push notification was sent from the server
messageText	Message content of the push notification

Table 14-14. Server Push Notifications Properties (continued).

Property Name	Description
notificationCountAndroid	Number of push notifications that target recipients for Android
notificationCountIOS	Number of push notifications that target recipients for iOS
notificationCountWindows	Number of push notifications that target recipients for Windows
notificationCountWeb	Number of push notifications that target recipients for Web
notificationID	Unique push notification identifier
senderID	Identifier of the user who initiated the push notification
serverIpAddress	IP address of the MobileFirst Analytics server
timestamp	Time the event was reported, represented as epoch time stamp in milliseconds
timezone	The difference between UTC and local time, in minutes

Server Push Subscriptions

Table 14-15. Server Push Subscriptions Properties.

Property Name	Description
appID	Unique Bluemix application identifier
clientID	Unique client identifier
deviceAppName	Name of the MobileFirst application
deviceAppVersion	Version of the MobileFirst application
deviceID	Unique device identifier
deviceModel	Device model name. For example: iPhone3,3, Galaxy
deviceOS	Device environment. For example: iPhone, Android
deviceOSversion	Device operating system version. For example: 7.0
sessionID	Unique session identifier
timestamp	Time the event was reported, represented as epoch time stamp in milliseconds
timezone	The difference between UTC and local time, in minutes
userID	Unique user identifier

Navigating the Analytics Console

Learn how to use features that are provided by the MobileFirst Analytics Console.

Administration

Learn about the administrative aspects of the IBM MobileFirst Platform Operational Analytics.

Cluster Information:

The **Cluster Information** section of the **Cluster and Node** tab provides a list of properties about the state of the cluster.

Table 14-16. **Cluster Information** properties

Property Name	Description
Cluster Name	The unique name of the cluster that this node is a member of. Any node that joins the cluster must have the same cluster name set.
Cluster Status	Indicates the status of the cluster as GREEN, YELLOW, or RED. Green means that all shards and replicas are assigned and allocated. Yellow indicates that all primary shards are allocated, but some replicas are not. Red indicates that a shard is not allocated in the cluster.
Number of Nodes	Total number of nodes in the cluster.
Number of Master Nodes	Total number of master eligible nodes in the cluster.
Number of Data Nodes	Total number of non-master eligible nodes in the cluster (holds only data and processes queries, cannot be elected as a master node).
Number of Active Shards	Number of primary and replica shards that are assigned.
Number of Primary Shards	Number of primary shards (not including replicas).
Number of Unassigned Shards	Number of shards that are not yet allocated. This number is greater than zero if there are too many replica shards.

Update Settings:

The **Update Settings** page allows you to change settings dynamically. Typically these settings would need to be set via JNDI properties and require a server restart.

You can change these settings dynamically:

- Settings
- Documents Time To Live

The following table lists the **Settings** settings and their default values.

Table 14-17. **Settings** settings for the Analytics Console Administration page. This table lists the **Settings** settings and their default values for the Analytics Console Administration page.

Name	Default value
Ignore custom data	False
Ignore MFP application logs	False
Ignore MFP application push action	False
Ignore server logs	False

Table 14-17. Settings settings for the Analytics Console Administration page (continued). This table lists the **Settings** settings and their default values for the Analytics Console Administration page.

Name	Default value
Ignore server network transactions	False
Ignore server push notifications	False
Ignore server push subscriptions	False
Ignore devices	False
Ignore mobile users	False
Default tenant	worklight
Number of replicas	1

For more information about the **Settings** settings, see “Properties and configurations” on page 14-95.

The following table lists the **Documents Time To Live** settings.

Table 14-18. Documents Time To Live settings for the Analytics Console Administration page. This table lists the **Documents Time To Live** settings for the Analytics Console Administration page.

Event Type	Time To Live	Time To Live Unit
AnalyticsConfiguration	0	Minutes
CustomData	0	Minutes
MfpAppLogs	0	Minutes
ServerLogs	0	Minutes
ServerNetworkTransactions	0	Minutes
ServerPushNotifications	0	Minutes
ServerPushSubscriptions	0	Minutes

For more information about the **Documents Time To Live** settings, see “Data purging” on page 14-24.

Multi-tenancy:

Learn about multi-tenancy in the IBM MobileFirst Platform Operational Analytics.

Several MobileFirst Server instances can be configured to send analytics data to the same analytics cluster. All of the data is indexed together, which means that all charts and queries that are performed on the analytics server reflect data that was sent from every MobileFirst Server. If you want to use the same analytics cluster for multiple MobileFirst Server instances, but also want the data to be indexed separately so that it can be searched and viewed separately, you can add a tenant.

Servers can be configured to send their data to a new tenant on the analytics cluster so that the data can be viewed separately, even though all of the data lives on the same cluster.

To forward data to a different tenant, append the following format to the `wl.analytics.url` property on the MobileFirst Server:

?tenant=<tenant-name>

For example, if you want to send data to the default tenant, set the `wl.analytics.url` property as follows:

```
wl.analytics.url=http://<host name>/analytics-service/data
```

If you want to send data to a new tenant that is named `test`, set the `wl.analytics.url` property as follows:

```
wl.analytics.url=http://<host name>/analytics-service/data?tenant=test
```

To view the analytics data for a specific tenant, choose the tenant name from the drop-down list in the Analytics Console.

```
http://<host name>/analytics/console
```

Data purging:

Learn about purging data in the IBM MobileFirst Platform Operational Analytics.

By default, data that is stored in the Analytics Platform is not automatically deleted. To enable automatic purging of data, the time to live (TTL) property must be set for each data type.

The TTL for analytics data types that are stored in the Analytics Platform can be set by using JNDI properties. For more information about analytics data types, see “Operational analytics” on page 14-9.

The following table shows the TTL properties:

Table 14-19. TTL properties for purging data that is stored in the Analytics Platform. This table lists TTL property names and description for purging data that is stored in the Analytics Platform.

Property Name	Description
TTL_CustomData	Time to live for custom data.
TTL_MfpAppLogs	Time to live for client logs, such as client-side captured logs, and stack traces.
TTL_MfpAppPushAction	Time to live for application push actions.
TTL_ServerLogs	Time to live for server logs.
TTL_ServerNetworkTransactions	Time to live for server network transactions.
TTL_ServerPushNotifications	Time to live for server push notifications.
TTL_ServerPushSubscriptions	Time to live for server push subscriptions.

Note: All JNDI properties must be preceded with the `analytics/` string. For more information about JNDI properties, see “JNDI properties” on page 14-95.

Three document types are not configured with a TTL property and therefore documents of this type are automatically purged:

- CustomCharts
- Devices
- MobileUsers

You can also set some of the TTL values in the Admin tab in the Analytics Console. Do not use both JNDI property and changing the setting in the console at

the same time. A restart of the Analytics server reads and uses the JNDI property, which removes the previous value that was set in the console.

By default, the format for the TTL is in milliseconds. TTL can also be set by using a number followed by a character that represents the time interval:

- d (days)
- m (minutes)
- h (hours)
- ms (milliseconds)
- w (weeks)

The following example shows how to set the custom data TTL to one day in milliseconds:

```
<jndiEntry jndiName="analytics/TTL_CustomData" value="86400000" />
```

The following example shows how to set the client logs data TTL to five days:

```
<jndiEntry jndiName="analytics/TTL_MfpAppLogs" value="5d" />
```

The following example shows how to set the server logs TTL to one week:

```
<jndiEntry jndiName="analytics/TTL_ServerLogs" value="1w" />
```

Note: The TTL properties are not applied to data that exists in the Analytics Platform. You must set the TTL properties before you add data.

Exporting raw reports:

Learn about exporting raw reports in the IBM MobileFirst Platform Operational Analytics.

Exporting from the Administration page

The **Administration** page allows you to export all of the data stored in the analytics platform in one of the following formats:

- JSON
- CSV
- XML

This page is a user interface that displays the export feature and allows for the following options:

Table 14-20. Options for the export feature.

Option name	Description
Event Type	Name of the event that data will be exported from. For specific information about each of the events, see "Event types" on page 14-14.
Date Range	Start and end date for exporting data.
Limit	Number of analytics documents returned.
Offset	Number of documents to skip before exporting.
Data Format	Format data is exported in (JSON, CSV, or XML).

When an event type is selected from the user interface, you will have the option to select **Advanced Settings**. These settings allow you to apply additional filters to the data you are exporting.

Exporting custom data

The following example shows the format for exporting analytics data for custom data in JSON:

```
/administration/apps/{tenant}/export?query={"event":"CustomData","format":"json","limit":10,"offset":0,"startDate":"*","endDate":"*","mfpAppName":"*","mfpAppVersion":*
```

If the analytics console is hosted here:

```
http://hostname.ibm.com:9080
```

by using the curl command-line tool, the following curl command exports data from the worklight tenant for all versions of the TestApp application. Data is returned for only data for the iPhone environment, for all models of the iPhone, and only for iOS 7.0. The first 100 results that are found and start with the first result (limit = 100, offset = 0) are returned.

```
curl -XGET -G 'http://hostname.ibm.com:9080/analytics-service/data/administration/apps/worklight/export' --data-urlencode 'query={"event":"ServerLogs","format":"json","limit":10,"offset":0,"startDate":"*","endDate":"*","serverIpAddress":"*","level":"*"}' -u <username>
```

Replace the relevant values:

- **<username>**:<password>: your MobileFirst admin user name and password.
- **<output_file_name>**: the output file name.

Note: The default tenant is worklight. If you did not configure a specific tenant for the IBM MobileFirst Platform Operational Analytics, then you can use the worklight tenant. If you want to see data that occurred in a specific time range, specify a startDate time stamp in milliseconds and an endDate time stamp in milliseconds.

Exporting server push notifications

The following example shows the format for exporting analytics data for server push notifications:

```
/administration/apps/{tenant}/export?query={"event":"ServerPushNotifications","format":"json","limit":10,"offset":0,"startDate":"*","endDate":"*","mfpAppName":"*","mfpAppVersion":*
```

For example, by using the curl command-line tool, the following curl command exports data:

```
curl -XGET -G 'http://hostname.ibm.com:9080/analytics-service/data/administration/apps/worklight/export' --data-urlencode 'query={"event":"ServerPushNotifications","format":"json","limit":10,"offset":0,"startDate":"*","endDate":"*","mfpAppName":"*","mfpAppVersion":"*","mediator":"*","serverIpAddress":"*"}' -u <username>
```

Exporting server logs

The following example shows the format for exporting analytics data for server logs:

```
/administration/apps/{tenant}/export?query={"event":"ServerLogs","format":"json","limit":10,"offset":0,"startDate":"*","endDate":"*","serverIpAddress":"*","level":"*"}' -u <username>
```

For example, by using the curl command-line tool, the following curl command exports data:

```
curl -XGET -G 'http://hostname.ibm.com:9080/analytics-service/data/administration/apps/worklight/export' --data-urlencode 'query={"event":"ServerLogs","format":"json","limit":10,"offset":0,"startDate":"*","endDate":"*","serverIpAddress":"*","level":"*"}' -u <username>:<password> -o <output_file_name>
```

Note: Valid log levels for server logs include: FATAL, ERROR, WARN, INFO, LOG, DEBUG, and TRACE.

Exporting client logs

The following example shows the format for exporting analytics data for client logs:

```
/administration/apps/{tenant}/export?query={"event":"MfpAppLogs","format":"json","limit":10,"offset":0,"startDate":"*","endDate":"*","mfpAppName":"*","mfpAppVersion":"*","deviceOS":"*","de
```

For example, by using the curl command-line tool, the following curl command exports data:

```
curl -XGET -G 'http://hostname.ibm.com:9080/analytics-service/data/administration/apps/worklight/export ' --data-urlencode 'query={"event":"MfpAppLogs","format":"json","limit":10,"offset":0,"startDate":"*","endDate":"*","mfpAppName":"*","mfpAppVersion":"*","deviceOS":"*","deviceOSVersion":"*","deviceModel":"*"
```

Note: Valid log levels for client logs include: ANALYTICS, FATAL, ERROR, WARN, INFO, LOG, DEBUG, and TRACE.

Exporting server network transactions

The following example shows the format for exporting analytics data for server network transactions:

```
/administration/apps/{tenant}/export?query={"event":"ServerNetworkTransactions","format":"json","limit":10,"offset":0,"startDate":"*","endDate":"*","mfpAppName":"*","mfpAppVersion":"*","de
```

For example, by using the curl command-line tool, the following curl command exports data:

```
curl -XGET -G 'http://hostname.ibm.com:9080/analytics-service/data/administration/apps/worklight/export ' --data-urlencode 'query={"event":"ServerNetworkTransactions","format":"json","limit":10,"offset":0,"startDate":"*","endDate":"*","mfpAppName":"*","mfpAppVersion":"*","deviceOS":"*","deviceOSVersion":"*","de
```

Note: Valid log levels for client logs include: ANALYTICS, FATAL, ERROR, WARN, INFO, LOG, DEBUG, and TRACE.

Alerts:

If you are using the latest interim fix of MobileFirst, you can set thresholds in alert definitions in the IBM MobileFirst Analytics Console to better monitor your activities.

You can configure thresholds, which if exceeded, trigger alerts to notify the MobileFirst Analytics Console monitor. The triggered alerts can be visualized on the console, or the alerts can be handled by a custom webhook. This feature provides a proactive means of detecting client log errors, server log errors, extended periods of network latency, and authentication failures. Reactive thresholds and alerts keep you from having to sift through your data and set thresholds at a wide spectrum of granularity.

Creating an alert definition for client logs:

You can create an alert definition based on client logs.

Before you begin

Ensure that the IBM MobileFirst Platform Operational Analytics Server is started and ready to receive client logs.

About this task

In this example, you use client log data to create an alert definition. The alert monitors all client logs that were received in the last 5 minutes, and continues to check every 5 minutes, until the alert definition is disabled or deleted. An alert is

triggered for each device that sent 3 or more client error logs with the same app name and version.

Procedure

1. In the MobileFirst Analytics Console, click the **Alerts** icon. This action brings up the Alert Log page.
2. Click the **Alert Management** tab and click **Create Alert**.
3. Provide the following values:
 - **Alert Name:** Alert for Client Logs
 - **Message:** Error Message Alert
 - **Query Frequency:** 5 Minutes
 - **Event Type:** Client Logs
 - **Property:** Log Level
 - **Value:** Error
 - **Threshold**
 - **Threshold Type:** Total for Application Instance

Note: If you choose the **Average for Application** option, the client logs are averaged by the number of devices. For example, if you have two devices, and one device sends six client logs while the other device sends three client logs, the average is 4.5 client logs.

- **Operator:** is greater than or equals 3

The following image shows the alert definition tab:

Alert Definition

Distribution Method

Alert Name

An optional name of this alert

Message

Error Message Alert

An optional description for this alert. The description is shown in the alert log table when an alert is available

Query Frequency *

Minutes
▼

How frequently the analytics data is analyzed to check if this alert criteria has been met.

Event Type *

Client Logs
▼

Property *

Log Level
▼

Value *

Error
▼

Threshold *

Total for Application Instance
▼

is greater than or equals
▼

4. Click the **Distribution Method** tab, and provide the following value:

- **Method:** Analytics Console Only

Note: Choose the **Analytics Console and Network Post** option if you want to additionally send a POST message with a JSON payload to your customized URL. The following fields are available if you choose this option:

- **Network Post Url** (required)
- **Headers** (optional)
- **Authentication Type** (required)

5. Click **Save**.

Results

You created an alert definition to trigger an alert at the end of each 5-minute interval if the number of client logs reached your threshold of 3 or more error logs.

Creating an alert definition for server logs:

You can set an alert based on server logs.

Before you begin

Ensure that the IBM MobileFirst Platform Operational Analytics Server is started and ready to receive logs.

About this task

In this example, you use server log data to create an alert definition. The alert monitors all server logs that were received in the last 5 minutes, and continues to check every 5 minutes, until the alert definition is disabled or deleted. An alert is triggered if there are 2 or more server warn logs.

Procedure

1. In the MobileFirst Analytics Console, click the **Alerts** icon. This action brings up the Alert Log page.
2. Click the **Alert Management** tab and click **Create Alert**.
3. Provide the following values:
 - **Alert Name:** Alert for Server Logs
 - **Message:** Warn Message Alert
 - **Query Frequency:** 5 Minutes
 - **Event Type:** Server Logs
 - **Property:** Log Level
 - **Value:** Warn
 - **Threshold**
 - **Threshold Type:** Count
 - **Operator:** is greater than or equals 2

You created an alert definition to trigger an alert at the end of each 5-minute interval if the number of server logs reached your threshold of 2 or more warn logs.

Creating an alert definition for network transactions:

You can create an alert definition based on server network transactions.

Before you begin

Ensure that the IBM MobileFirst Platform Operational Analytics Server is started and ready to receive analytics data.

About this task

In this example, you use server network transaction data to create an alert definition. The alert monitors all network transactions in the last 10 minutes, and continues to check every 10 minutes. An alert is triggered when the average round-trip time exceeds 5 seconds, until the alert is disabled or deleted.

Procedure

1. In the MobileFirst Analytics Console, click the **Alerts** icon. This action brings up the Alert Log page.
2. Click the **Alert Management** tab and click **Create Alert**.
3. Provide the following values:
 - **Alert Name:** Alert for Network Transactions
 - **Message:** Round Trip Time Alert
 - **Query Frequency:** 10 Minutes
 - **Event Type:** Network Transactions
 - **Network Transaction Type:** All Network Requests

Note: You can also choose **All Adapter Requests** or **Specific Adapter Requests**. If you choose **Specific Adapter Requests**, you must also provide a value for **Adapter**.

- **Property:** Round Trip Time
 - **Threshold**
 - **Threshold Type:** Average
 - **Operator:** is greater than or equals 5000 ms

5. Click **Save**.

Results

You created an alert definition to trigger an alert at the end of each 10-minute interval when the average round-trip time for all network requests reached your threshold of 5 or more seconds.

Creating an alert definition for authorization failures:

You can create an alert definition based on authorization failures.

Before you begin

Ensure that the IBM MobileFirst Platform Operational Analytics Server is started and ready to receive logs.

About this task

In this example, you use validation code data to create an alert definition. The alert monitors all network transactions in the last minute, and continues to check every minute, until the alert definition is disabled or deleted. An alert is triggered when the number of failed authorizations exceeds 5.

Procedure

1. In the MobileFirst Analytics Console, click the **Alerts** icon. This action brings up the Alert Log page.
2. Click the **Alert Management** tab and click **Create Alert**.
3. Provide the following values:
 - **Alert Name:** Alert for Failed Authorization
 - **Message:** This client had more than 5 challenges issued in a 1 minute period. This might indicate that someone is trying to guess the app password on this device.
 - **Query Frequency:** 1 Minutes
 - **Event Type:** Network Transactions
 - **Network Transaction Type:** All Network Requests

Note: You can also choose **All Adapter Requests** or **Specific Adapter Requests**. If you choose **Specific Adapter Requests**, you must also provide a value for **Adapter**.

- **Property:** Validation Code
 - **Value:**
AUTHORIZATION_FAILED_CLIENT_INTERACTION_REQUIRED
 - **Threshold**
 - **Threshold Type:** Count
 - **Operator:** is greater than or equals 5

```

Creating an alert definition for application crashes:

You can create an alert definition based on application crashes.

Before you begin

Ensure that the IBM MobileFirst Platform Operational Analytics Server is started and ready to receive client logs.

About this task

In this example, you use app crash data to create an alert definition. The alert monitors all app crashes in the last 2 minutes, and continues to check every 2 minutes, until the alert definition is disabled or deleted. An alert is triggered for each application that crashed 5 or more times.

Procedure

1. In the MobileFirst Analytics Console, click the **Alerts** icon. This action brings up the Alert Log page.
2. Click the **Alert Management** tab and click **Create Alert**.
3. Provide the following values:
 - **Alert Name:** Alert for App Crashes
 - **Message:** App Crash Alert
 - **Query Frequency:** 2 Minutes
 - **Event Type:** Application Crashes
 - **Application Name:** Any Application

- **Application Version:** Any Version
- **Threshold**
 - **Threshold Type:** Crash Count
 - **Operator:** is greater than or equals 5

The following image shows the alert definition tab:

The screenshot shows the 'Alert Definition' tab of a configuration interface. It contains the following fields and their values:

- Alert Name:** Alert for App Crashes
- Message:** App Crash Alert
- Query Frequency:** 2 Minutes
- Event Type:** Application Crashes
- Application Name:** Any Application
- Application Version:** Any Version
- Threshold:** Crash Count, is greater than or equals, 5

At the bottom right, there are three buttons: Save, Next, and Cancel.

4. Click the **Distribution Method** tab, and provide the following value:

- **Method:** Analytics Console Only

Note: Choose the **Analytics Console and Network Post** option if you want to additionally send a POST message with a JSON payload to your customized URL. The following fields are available if you choose this option:

- **Network Post Url** (required)
- **Headers** (optional)
- **Authentication Type** (required)

5. Click **Save**.

Results

You created an alert definition to trigger an alert at the end of each 2-minute interval if the number of app crashes reached your threshold of 5 or more crashes.

Managing alert definitions:

You can manage your alert definitions.

Before you begin

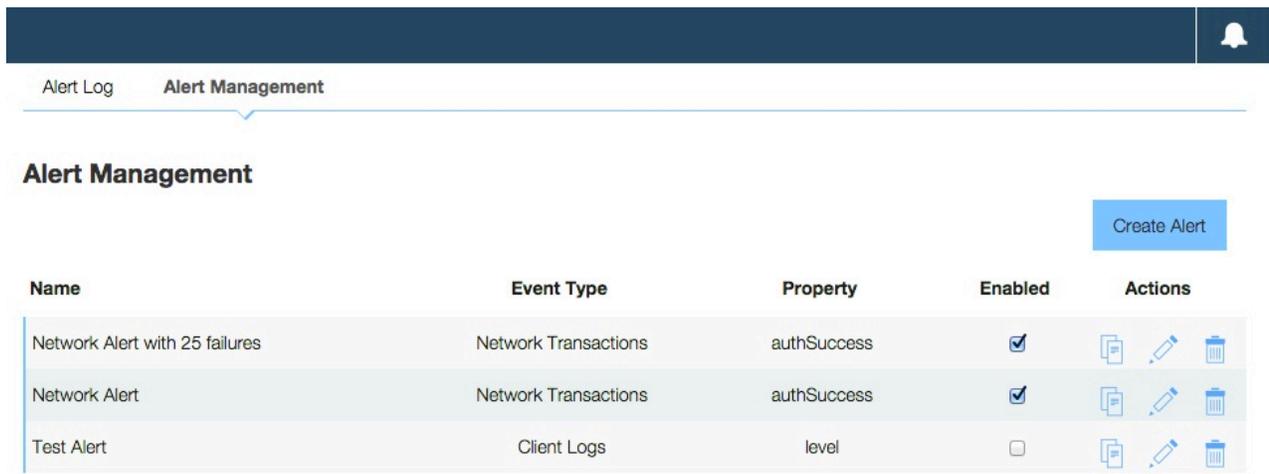

Ensure that the IBM MobileFirst Platform Operational Analytics Server is started and ready to receive analytics data.

About this task

In this example, you manage your alert definitions from the Alert Management page.

Procedure

1. In the MobileFirst Analytics Console, click the **Alerts** icon. This action brings up the Alert Log page.
2. Click the **Alert Management** tab. The following image shows the Alert Management page:

The screenshot shows the 'Alert Management' page in the MobileFirst Analytics Console. The page has a dark blue header with 'Alert Log' and 'Alert Management' tabs, and a notification bell icon. Below the header, the 'Alert Management' section is displayed. It features a 'Create Alert' button in the top right corner. A table lists three alert definitions:

Name	Event Type	Property	Enabled	Actions
Network Alert with 25 failures	Network Transactions	authSuccess	<input checked="" type="checkbox"/>	  
Network Alert	Network Transactions	authSuccess	<input checked="" type="checkbox"/>	  
Test Alert	Client Logs	level	<input type="checkbox"/>	  

3. Optional: Toggle the check-box under the **Enabled** column to enable or disable a specific alert definition.
4. Optional: Click the **Duplicate** icon if you want to create a copy of an alert definition and change some values.
5. Optional: Click the **Pencil** icon if you want to edit an alert definition.
6. Optional: Click the **Trash** icon if you want to delete an alert definition.

Results

You managed your alert definitions.

Viewing alert details:

You can view the details of your triggered alerts.

Before you begin

Ensure that the IBM MobileFirst Platform Operational Analytics Server is started and ready to receive analytics data.

About this task

In this example, you view the details of your triggered alerts from the Alert Log page.

Procedure

1. In the MobileFirst Analytics Console, click the **Alerts** icon. This action brings up the Alert Log page. The following image shows the Alert Log page:

	Count	Date	Alert Name	Event type	
<input type="checkbox"/>	1	Oct 23, 2015	AlertDefinition name 026c0aad-b54c-4280-863f-ddf5643e...	Network Transactions	<input type="checkbox"/>
<input type="checkbox"/>	2	Oct 23, 2015	AlertDefinition name 1f59e7aa-2052-4774-8249-d0fe40f9...	Network Transactions	<input type="checkbox"/>

2. Click the + icon for any of the alerts. This action displays the **Alert Definition** and **Alert Instances** sections. The following image shows the **Alert Definition** and **Alert Instances** sections:

Note: If the corresponding alert definition was not deleted or modified, you can edit the alert definition by clicking **Edit Alert**. Otherwise, the **Edit Alert** button is unavailable and the following message is displayed:

This alert definition has since been modified or deleted.

- Optional: Select an alert and click the **Trash** icon to delete the alert.

Results

You viewed more details about your alerts.

Application crashes:

If you are using the latest interim fix of MobileFirst, you can view information about your application crashes in the IBM MobileFirst Analytics Console to better monitor and troubleshoot your applications.

Application crash monitoring:

You can quickly see information about your app crashes in the Dashboard page of the IBM MobileFirst Analytics Console.

Two new charts are available: **Crash Overview** and **Crashes**.

The **Crash Overview** table shows the following data columns:

- **Application:** application name
- **Crashes:** total number of crashes for that application
- **Total Uses:** total number of times a user opens and closes that application
- **Crash Rate:** percentage of crashes per use

The **Crashes** bar graph shows a histogram of crashes over time. The data can be shown in two ways:

- **Display crash rate:** crash rate over time
- **Display total crashes:** total crashes over time

Note: Both charts query against the MfpAppSession documents. You must instrument your application to collect app uses and crashes for data to appear in the charts. If MfpAppSession data is not collected, then MfpAppLog documents are queried. In this case, the charts can count the number of crashes, but cannot compute a crash rate because the number of app uses is unknown, which results in the following limitations:

- The **Crash Overview** table has empty columns for **Total Uses** and **Crash Rate**.
- The **Crashes** bar graph displays no data when **Display Crash Rate** is selected.

To instrument crash data, see the following tasks for your environment:

- “Instrumenting your iOS application for application crash data” on page 14-42
- “Instrumenting your Android application for application crash data” on page 14-42
- “Instrumenting your hybrid application for application crash data” on page 14-43

Application crash troubleshooting:

You can view the **Crash Summary** tab in the Dashboard page of the IBM MobileFirst Analytics Console to better administer your applications.

The **Crash Summary** tab displays a sortable table with the following data columns:

- **Crashes**
- **Devices**
- **Last Crash**
- **Application**
- **OS**
- **Message**

You can click on the + icon next to any entry to display the **Crash Details** table, which includes the following columns:

- **Time Crashed**
- **Application Version**
- **OS Version**
- **Device Model**
- **Device ID**
- **Download:** link to download the logs that led up to the crash

You can expand any entry in the **Crash Details** table to get more details, including a stacktrace.

Note: The data for the **Crash Summary** tab is populated by querying the fatal level client logs. If your application does not collect fatal client logs, no data is available.

Instrumenting your iOS application for application crash data:

You must instrument your iOS application code to collect application crash data.

Before you begin

To capture sessions that are closed by a crash and by the user, you must use the iOS Logger API in the application. You must also send both analytics and logs with the OCLogger and WAnalytics APIs.

About this task

In this example, you instrument your iOS application to collect app crash data.

Procedure

Add the following call to the beginning of your application code in `application:didFinishLaunchingWithOptions:` in the app delegate.

```
[[WAnalytics sharedInstance] startRecordingApplicationLifecycleEvents]
```

Results

You instrumented your iOS application for app crash data.

Instrumenting your Android application for application crash data:

You must instrument your Android application code to collect application crash data.

Before you begin

You must create a class that extends the Android Application class. The name of your class must also be added to the `application` tag in the `AndroidManifest.xml`.

About this task

In this example, you instrument your Android application to collect app crash data.

Procedure

1. If you are using Android API 14 or higher, add the following line of code to your application `onCreate` method:

```
@Override
public void onCreate() {
    super.onCreate();
    WAnalytics.startRecordingActivityLifecycleEvents(this);
}
```

- a. If you already implemented your own life cycle activity callbacks and do not want to overwrite them, you must add the following lines of code to your `onActivityPaused` and `onActivityResumed` methods:

```
public void onActivityPaused(Activity activity) {
    WLifecycleHelper.getInstance().onPause();
}

public void onActivityResumed(Activity activity) {
    WLifecycleHelper.getInstance().onResume();
}
```

2. If you are using lower than API 14, the application developer is responsible for instrumenting the application. The following methods are required:
 - `WAnalytics.logAppForeground()`; - Use this method when the application enters the foreground for the first time. A timestamp is recorded to denote the start of an application use.
 - `WAnalytics.logAppBackground()`; - Use this method when the application enters the background, which means that the user successfully closes the application. An app use is recorded.
- Capturing application crashes happens behind the scenes. If `WAnalytics.logAppForeground()` is called, which denotes the start of an app use, and a crash occurs, the crash is logged without any further instrumentation from the application developer.

Results

You instrumented your Android application for app crash data.

Instrumenting your hybrid application for application crash data:

You must instrument your hybrid application code to collect application crash data.

About this task

By default, hybrid apps record foreground and background session events automatically. Crash events are considered background session events. You must report the session events and send crash logs though.

Procedure

1. To report the session events, call the `WAnalytics.send()` method.
2. To send the crash logs, call the `WLogger.send()` method.

Results

You instrumented your hybrid application for app crash data.

Custom Analytics

Starting with V7.0.0, you can visualize the collected analytics data in your analytics repository. This visualization is a powerful way to inspect data for specific use cases. You can create charts with data already collected by Operational Analytics in addition to custom data you report.

The ability to report custom data (custom key-value pairs) from the IBM MobileFirst Platform Foundation was present since V6.1.0. Now you can extract that data in raw form, and render custom charts from that raw data.

Creating a custom chart:

MobileFirst Operational Analytics has several pre-made charts with useful visualizations. Starting with V7.1.0, you can create a different chart type or run a specific query to render into a table.

About this task

In this scenario, you create a bar chart for all active Android Galaxy devices.

Procedure

1. Click the **Custom Charts** tab from the Dashboard page of the MobileFirst Analytics Console.

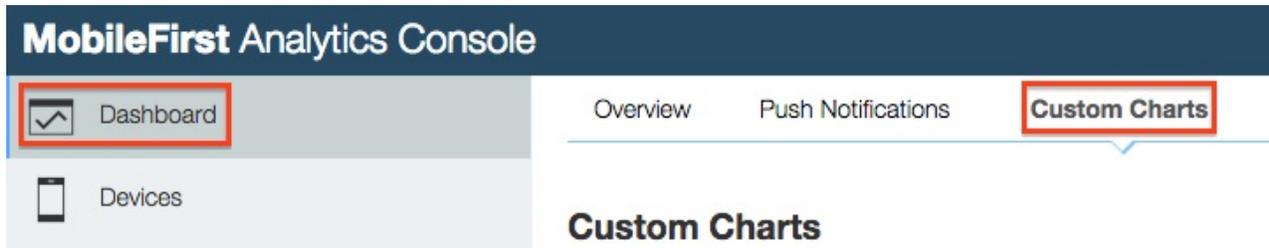

Figure 14-1. Analytics Dashboard

2. Click **Create Chart**. This action opens a **General Settings** tab where you specify your chart title and event type.

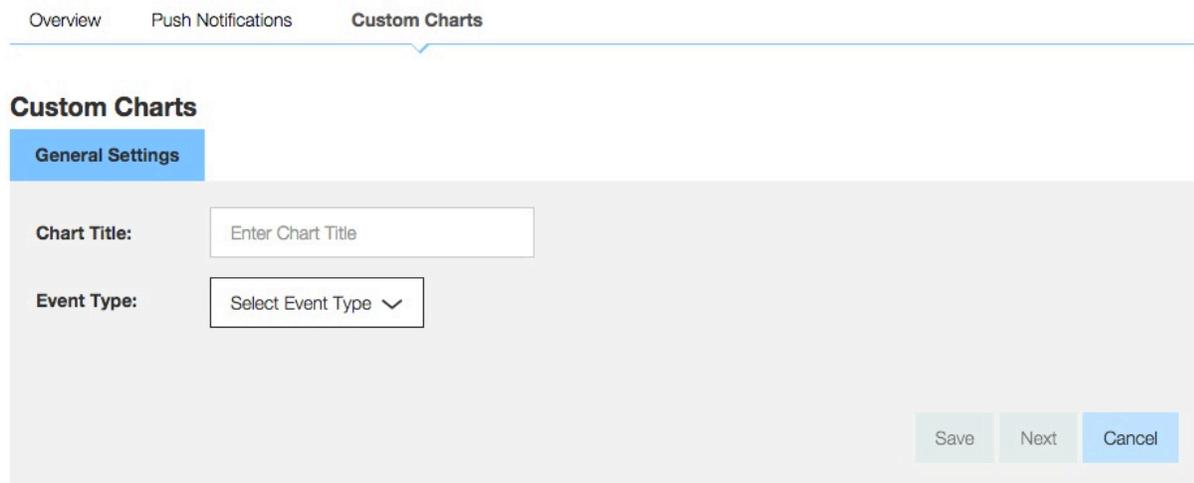

Figure 14-2. General Settings

- a. Enter a chart title.
 - b. Choose the event type. For this scenario, choose **Server Network Transactions**.
 - c. Choose a chart type. For this scenario, choose **Bar Graph**.
3. Click the **Chart Definition** tab.

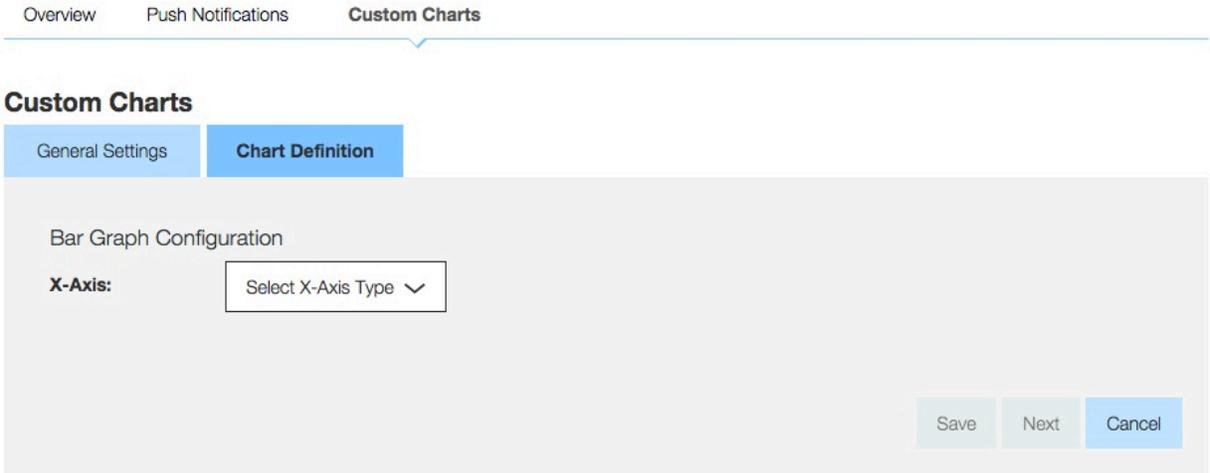

Figure 14-3. Chart Definition

- a. Select **Axis by Timeline** for the x-axis.
 - b. Select **Unique** for the y-axis.
 - c. Select **Device Id** for the property.
4. Click the **Chart Filters** tab to specify filters for the data.

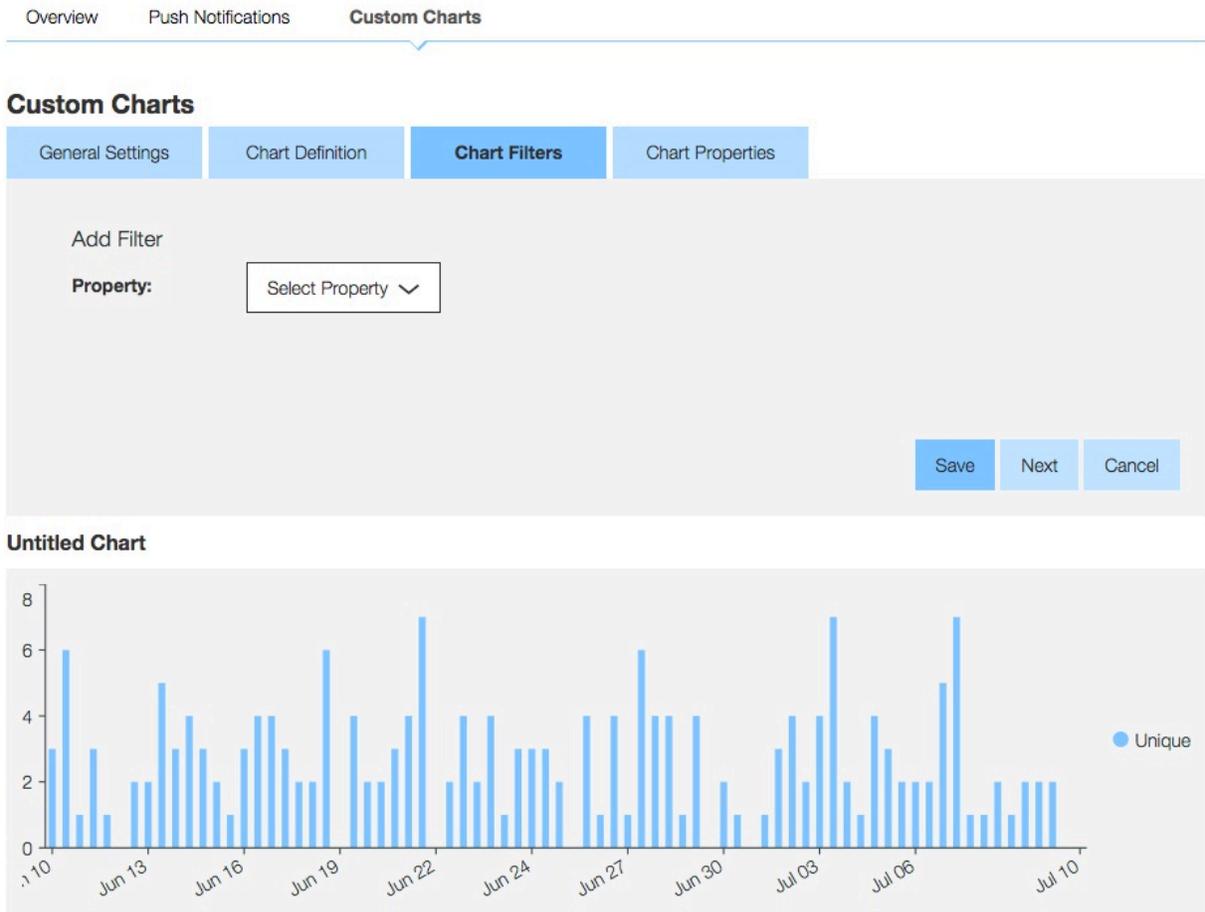

Figure 14-4. Chart Filters

- a. Select the property to filter. For this scenario, choose **Device Model**.
- b. Select the operator to filter. For this scenario, choose **Equals**.
- c. Select the value to filter on. For this scenario, choose **galaxy**.
- d. Click **Add Filter**.

6. Click **Save**. Repeat steps 1-5 for all filters that you want to apply.

What to do next

For more advanced usage, see “Patterns for visualizing custom data” on page 14-60.

Custom chart types:

The MobileFirst Analytics Console offers the following chart types for data visualization.

- Bar Graph
- Flow Chart
- Line Graph
- Metric Group
- Pie Chart

- Table

Note: The following sections contain only information about custom chart types that might not be familiar.

Flow Chart:

The flow chart can be used to show relationships between two different properties.

Three selections must be made to use the flow chart:

- A source
- A destination
- A value from either the source or destination

If you want to see the relationship between an adapter and its procedures, you select **Adapter Name** as the source and **Procedure Name** as the destination. You then select one of the adapters as the value.

Custom Charts

The screenshot shows a web interface for configuring custom charts. At the top, there are three tabs: 'General Settings', 'Chart Definition' (which is active), and 'Chart Filters'. Below the tabs is a 'Flow Chart Configuration' section. It contains three rows, each with a label and a dropdown menu:

- Source:** Adapter Name
- Destination:** Procedure Name
- Property:** RegistrationAdapter

At the bottom right of the configuration area, there are three buttons: 'Save', 'Next', and 'Cancel'.

Figure 14-7. Adapter-Procedure chart definition

Untitled Chart

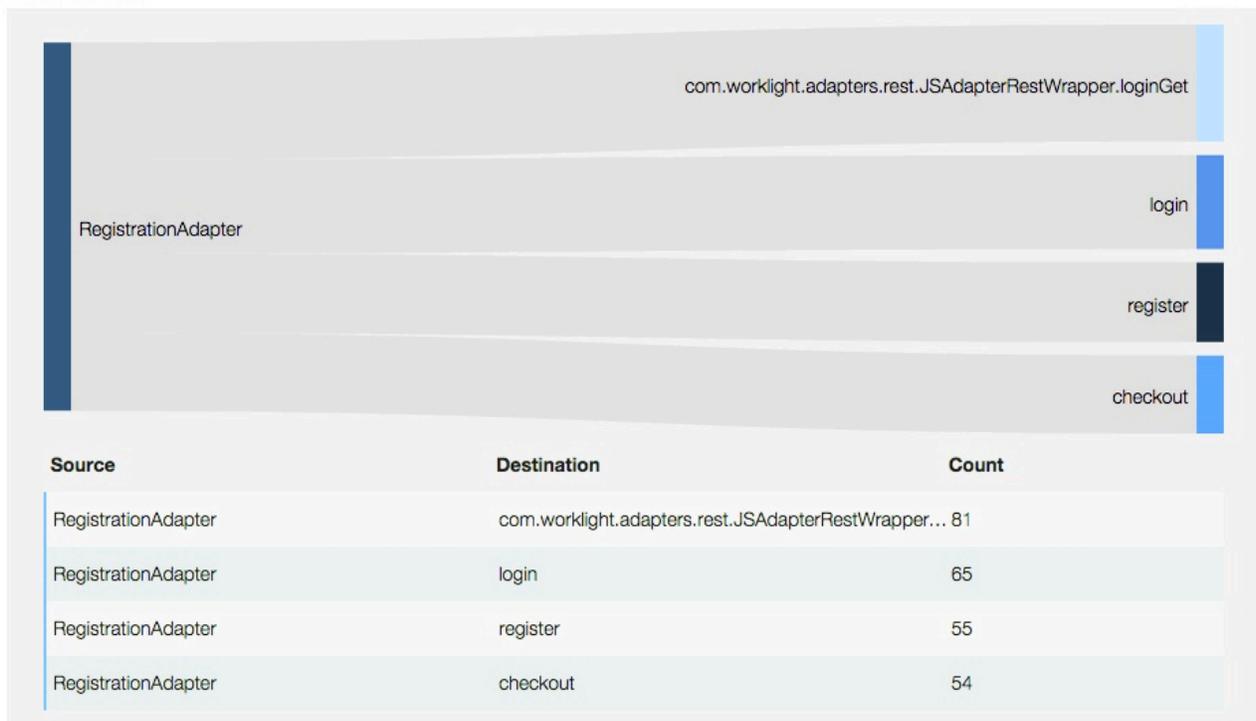

Figure 14-8. Adapter-Procedure Flow Chart

The RegistrationAdapter adapter is the source on the left and its four procedures are on the right. The line next to each procedure represents a relationship between the source and each of its destinations. The length of this line is relative to the frequency at which that procedure was called. In this case, all four of the RegistrationAdapter procedures were called about the same number of times. A table is displayed following the flow chart with the exact values of each relationship.

Metric Group:

The Metric Group chart is used to display a single numerical value.

This value can be:

- A total or sum of events
- An average of a specified property
- A unique count

If you want to see an at-a-glance view of how many unique devices contacted your server, you can make the following selections.

Custom Charts

Title	Type	Property
Unique Devices	Unique	Device Id

Figure 14-9. Unique Devices chart definition

The following chart is created:

Untitled Chart

Figure 14-10. Unique Devices Metric Group Chart

Filters:

When you create a custom chart, you can apply filters to the results from the **Filters** tab.

As discussed in “Event types” on page 14-14, each event type has a set of properties. You can apply the following filters for any of these properties:

- Equals/Not Equals
- Exists/Not Exists
- Greater Than/Greater Than or Equal
- Less Than/Less Than or Equal

You can create a bar graph chart to display the number of application activities for each day. You want to see the number of activities that were made by iPhone 4 devices. You can apply the **Equals** filter to your chart:

Custom Charts

General Settings | Chart Definition | **Chart Filters** | Chart Properties

Add Filter

Property: Device Model ▾

Operator: Equals ▾

Value: iPhone 4 ▾

Add Filter

Save Next Cancel

Figure 14-11. Device Model Filter

Custom Filters

Several filters can be applied to the same chart, but all of these filters are applied together. For example, if you want to see application activities for iPhone 4 and iPhone 5 devices, and you cannot add an Equals filter for both device model values. If you do, the resulting query searches for activities where the device model is iPhone 4 and iPhone 5. This query returns zero results since each activity can have only one device model property. To create more complex predicates for queries, you must use the custom filters feature.

Custom Charts

General Settings | Chart Definition | **Chart Filters** | Chart Properties

Add Filter

Property: Custom Filter ▾

Query: doc.['deviceModel'].value=='iPhone'

Add Filter

Filter Configuration

Property	Operator	Value
Custom Filter		doc.['deviceMod...

Save Next Cancel

Figure 14-12. Custom Filters

The following filter selects only the documents where the device model is iPhone 4:

```
doc['deviceModel'].value=='iPhone 4'
```

Conversely, this filter does the opposite and selects only the documents where the environment is not iPhone 4:

```
doc['deviceModel'].value!='iPhone 4'
```

You can do other logical comparisons, like the greater than and less than comparisons:

```
doc['timestamp'].value<1418277600000
```

In addition to logical expressions, you can combine filters by using Boolean expressions. You can filter on documents where the environment is Android or iPhone:

```
doc['deviceModel'].value=='iPhone 4' || doc['deviceModel'].value=='iPhone 5'
```

You can further group these filters by using parenthesis. You can combine the last filter with a limitation to retrieve all documents before a certain date:

```
doc['timestamp'].value<1418277600000 && (doc['deviceModel'].value=='iPhone 4' || doc['deviceModel'].value=='iPhone 5')
```

You can extract other data from a document field besides its value. For example, `doc['field_name'].values` is the native array values of the field, and `doc['field_name'].empty` is a Boolean indicating if the field has no values within the document. For a detailed description of all the documents and their fields, refer to. For a list of all available expressions, see Elastic Search scripting documentation

Note: When you create a custom filter for a custom chart, the query of a custom filter does not use Unicode Normalization Forms C (NFC) for comparison. The query does not consider language sensitivity such as normal matching, accent-insensitive, case-insensitive, and 1-to-2 mapping for search function to run correctly in different languages. The message property uses NFC and considers language sensitivity though. For fuzzy searches, only right like searches are compatible with the message query.

Patterns for creating custom charts:

Each of the following sections contains a subsection that explains how to populate data, which typically involves calling some APIs on the client.

For more information about the different types of data that is collected, see “Event types” on page 14-14.

Note: Some APIs, such as `connect` and `invokeProcedure` send analytics information automatically without having to use the analytics send API. However, this behavior is only true if you call `connect` and `invokeProcedure` 60 seconds apart. This implementation limits the number of requests to the server. For example, when you call multiple adapters in the span of a single minute, it is better to “batch send” the analytics information. For testing purposes, it is better to always call the analytics send API explicitly.

Client Logs:

Client logs contain log information sent with the platform's Logger API. This also includes contextual information about the device, including environment, application name, and application version.

Before you begin

If you are using the `WL.Client.logActivity` API, replace those calls with `WL.Analytics.log`. Otherwise you cannot create custom charts from the information you are logging.

Note: The steps that follow use JavaScript APIs. If you are using a native application, you must use the native versions of these APIs.

About this task

In this example, you use client log data to create a flow chart. The final graph shows the distribution of log levels in a specific application. You also have the following data available to show in a chart:

- Specific data
 - Log level
- Message data
 - Timestamp
- Device OS Contextual data
 - Application name
 - Application version
 - Device OS
- Device Contextual data
 - Device Id
 - Device model
 - Device OS version

Procedure

1. Create a new hybrid application.
2. Populate data by calling `WL.Logger.log('Hello world!')` or any of the other `Logger` APIs. Then call `WL.Logger.send()`.
3. In the MobileFirst Analytics Console, click the **Custom Charts** tab on the Dashboard page. You can create a chart based on the analytics messages that were sent to the server.
4. Click **Create Chart** to create a new custom chart.
5. Provide the following values:
 - **Chart Title:** Application and Log Levels
 - **Event Type:** Client Logs
 - **Chart Type:** Flow Chart
6. Click the **Chart Definition** tab.
7. Provide the following values:
 - **Source:** Application Name
 - **Destination:** Level
 - **Property:** your application name
8. Click **Save**.

Application and Log Levels

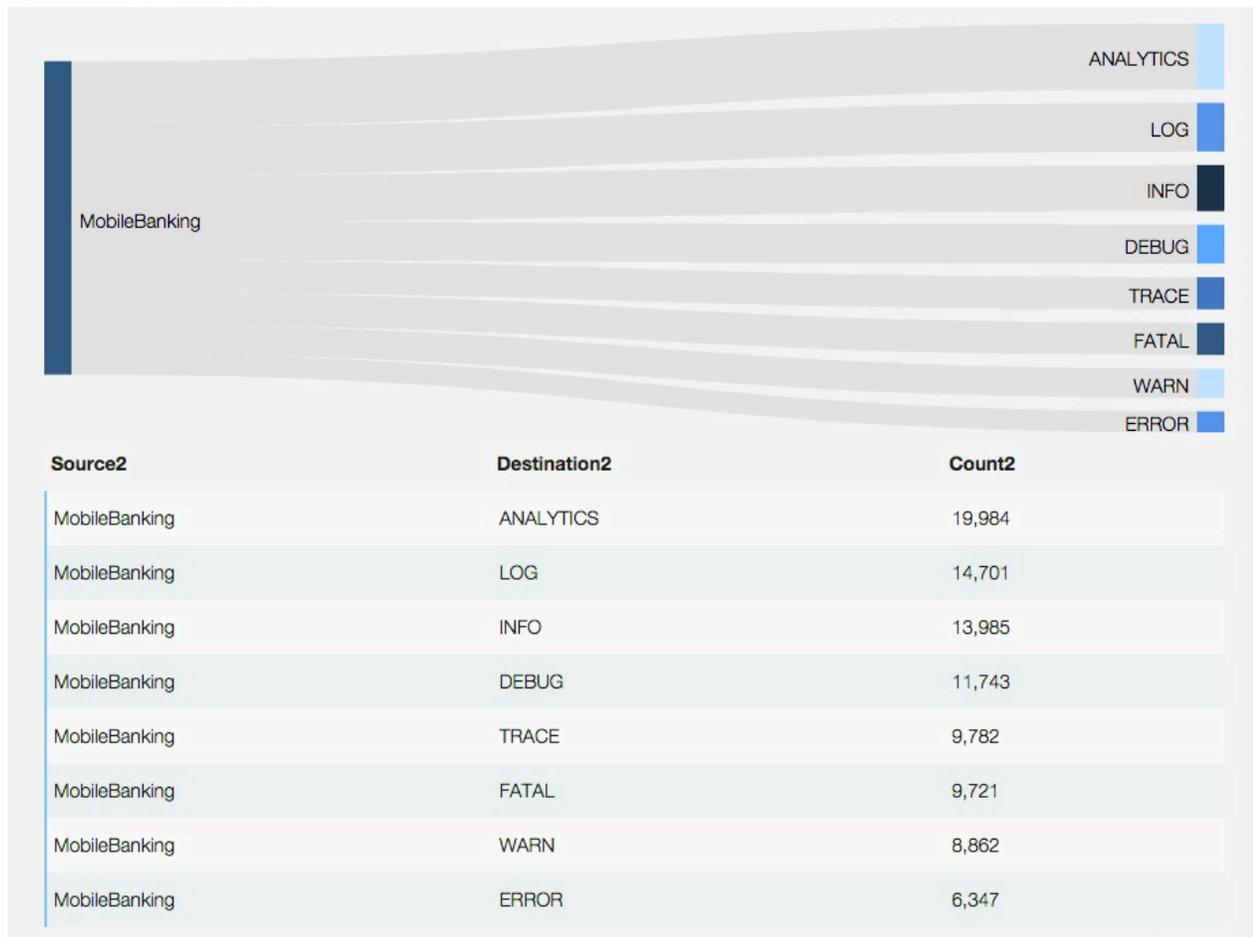

Figure 14-13. Application and Log Levels

Server Network Transactions:

Server network activities contain information about network requests such as network request time and bytes received by the client. This event type also includes contextual information about the device, such as environment, application name, and application version.

About this task

In this example, you use server network activity data to create a line chart. The graph shows the average bytes that are received. All the values in a single day are averaged. You also have the following data available to show in a chart:

- Specific data
 - Adapter name
 - Procedure name
 - Adapter response time (in milliseconds)
 - Bytes received
 - Server (for example: `dallas.ibm.com/9.64.77.98`)

- URL path (for example: /w1proj/apps/services/api/w1app/iphone/query)
- Authenticator Name
- Success status
- Login Module Name
- Login Module Class
- Tracking ID
- Realm Name
- Session Id
- Validation Code
- Client Id
- Message data
 - Timestamp
- Device OS Contextual data
 - Application name
 - Application version
 - Device OS
- Device Contextual data
 - Device Id
 - Device model
 - Device OS version

Procedure

1. Create a new hybrid application.
2. Populate data.
 - a. Call `WL.Client.connect()`.
 - b. Create an adapter with a procedure.
 - `helloWorldAdapter-impl.js`

```
function sayHello() {
  return {hello: 'world'};
}
```
 - `helloWorldAdapter.xml`

```
<procedure name="sayHello"/>
```
 - c. Call `WL.Client.invokeProcedure()` to call a procedure on the newly created adapter. The parameters include anything that is required to contact your adapter. The following example uses an adapter that returns a simple `{hello: 'world'}` object.
 - `main.js`

```
WL.Client.invokeProcedure({
  adapter : 'helloWorldAdapter',
  procedure : 'sayHello',
  parameters : []
})
.then(function (res) {
  console.log(JSON.stringify(res, null, ' '));
})
```
 - d. Call `WL.Analytics.send()`.
3. In the MobileFirst Analytics Console, click the **Custom Charts** tab on the Dashboard page. You can create a chart based on the analytics messages that were sent to the server.

4. Click **Create Chart** to create a new custom chart.
5. Provide the following values:
 - **Chart Title:** Average Bytes Received
 - **Event Type:** Server Network Activities
 - **Chart Type:** Line Graph
6. Click the **Chart Definition** tab.
7. Provide the following values:
 - **Measure:** Average
 - **Property:** Bytes Received
8. Click **Save**.

Results

Average Bytes Received

Push Notifications:

Push notifications contain information about push notifications.

About this task

In this example, you use the notification activities information to create a table. The table shows an application name and the mediator (for example, APNS is Apple Push Notification Service). You also have the following data available to show in a chart:

- Event source
- Application version
- Mediator
- Application name

Procedure

1. Create a new hybrid application.
2. Set up push notifications. For more information, see “Setting up push notifications” on page 8-499.
3. In the MobileFirst Analytics Console, click the **Custom Charts** tab on the Dashboard page. You can create a chart based on the analytics messages that were sent to the server.

4. Click **Create Chart** to create a new custom chart.
5. Provide the following values:
 - **Chart Title:** Push Notifications
 - **Event Type:** Push Notifications
 - **Chart Type:** Table
6. Click the **Chart Definition** tab.
7. Add the following columns: Application Name and Mediator
8. Click **Save**.

Server Logs:

Server logs contain internal server logs.

About this task

In this example, you use the server log information to create a metric group. The metric shows the number of log messages on the server that are categorized as debug by their corresponding log level property. You also have the following data available to show in a chart:

- Specific data
 - Log level
 - Message
 - Logger name
 - Source class

- Server (for example: dallas.ibm.com/9.64.77.98)
- Source
- Source method
- Thread Id
- URL path (for example: /w1proj/apps/services/api/w1app/iphone/query)
- Message data
 - Timestamp

Procedure

1. Create a new hybrid application.
2. Populate data
 - a. Call `WL.Client.connect()`.
 - b. Create an adapter with a procedure.
 - `helloWorldAdapter-impl.js`

```
function sayHello() {
  return {hello: 'world'};
}
```
 - `helloWorldAdapter.xml`

```
<procedure name="sayHello"/>
```
 - c. Call `WL.Client.invokeProcedure()` to call a procedure on the newly created adapter. The parameters include anything that is required to contact your adapter. The following example uses an adapter that returns a simple `{hello: 'world'}` object when called from the client.
 - `main.js`

```
WL.Client.invokeProcedure({
  adapter : 'helloWorldAdapter',
  procedure : 'sayHello',
  parameters : []
})
.then(function (res) {
  console.log(JSON.stringify(res, null, ' '));
})
```
 - d. Call `WL.Analytics.send()`.
3. In the MobileFirst Analytics Console, click the **Custom Charts** tab on the Dashboard page. You can create a chart based on the analytics messages that were sent to the server.
4. Click **Create Chart** to create a new custom chart.
5. Provide the following values:
 - **Chart Title:** Server Logs
 - **Event Type:** Server Logs
 - **Chart Type:** Metric Group
6. Click the **Chart Definition** tab.
7. Provide the following values:
 - **Metric Title:** Total DEBUG Log Count
 - **Measure:** Total
8. Click **Add Metric**.
9. Click the **Chart Filters** tab and select the following options:
 - **Filter:** Level
 - **Operator:** Equals

- **Value:** DEBUG
10. Click **Add Filter**.
 11. Click **Save**.

Creating a custom chart with custom data:

To collect custom data, configure your application codebase with the Analytics API.

About this task

In this scenario, you create a pie chart that represents the relative frequency of user button clicks.

Procedure

1. Create a MobileFirst application. For this scenario, attach functions to the JavaScript `onClick` event listeners for buttons in your user interface. These functions are instrumented to report analytics. The `WL.Analytics.log` method takes an object and a message as parameters. The message is used for searching for this custom event in the **Search** page of the Analytics Console. The object is used to collect data for custom analytics charting.

```
function buttonA(){
  var event = {buttonPress: 'buttona'};
  WL.Analytics.log(event, 'Custom event for button A press');
}

function buttonB(){
  var event = {buttonPress: 'buttonb'};
  WL.Analytics.log(event, 'Custom event for button B press');
}

function buttonC(){
  var event = {buttonPress: 'buttonc'};
  WL.Analytics.log(event, 'Custom event for button C press');
}

function sendAnalytics(){
  WL.Analytics.send();
}
```

The `sendAnalytics` function is a convenience for demonstration purposes only. The values for keys that are passed to the `WL.Analytics.log` method can be strings and numbers only. Objects and arrays can be passed as values, but are not used during custom charts creation. The event object in each method is used to create custom charts. The `buttonPress` key is used to generate data for each chart. The values for this key are `buttona`, `buttonb`, and `buttonc`.

2. Create a custom chart. For more information about custom charts, see “Creating a custom chart” on page 14-43.
When a device sends the analytics to the server, the key becomes available in

Custom Button Presses

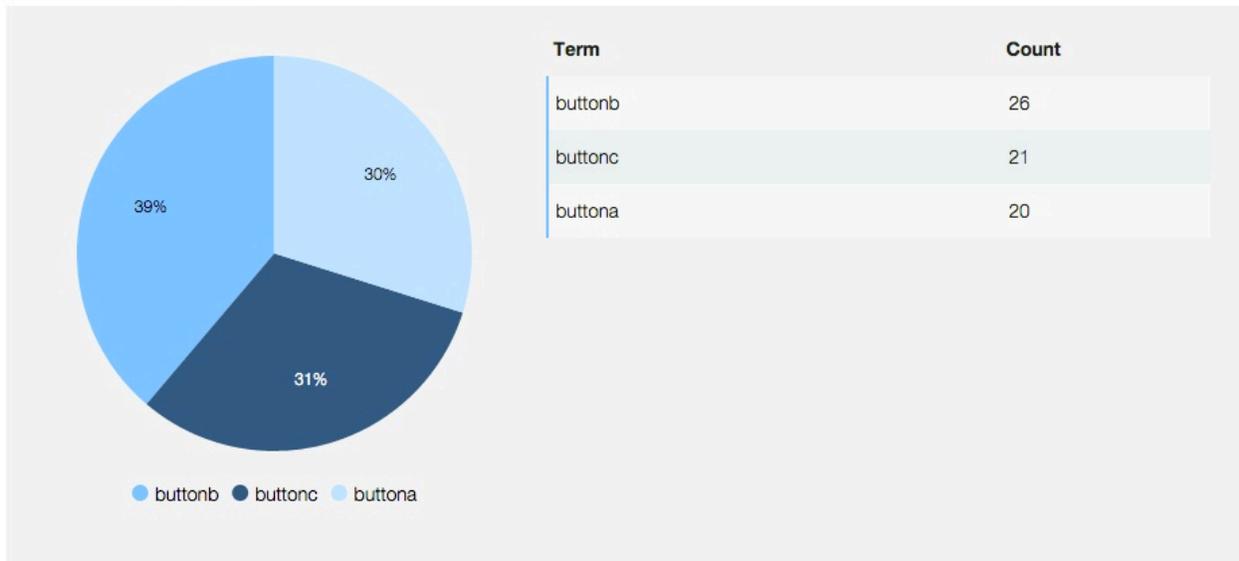

Figure 14-17. Chart Definition

the **Select Property** field for chart creation and filters.

Patterns for visualizing custom data:

You can instrument your IBM MobileFirst Platform Foundation V7.1.0 applications to collect and visualize analytics data, so you can continuously understand application usage and target improvements.

Prerequisites

Ensure that you are familiar with the WL.Analytics API and “Operational analytics” on page 14-9.

Patterns

When you develop mobile applications, you can track key actions over time that can provide useful insight. The following patterns explain how to track various interesting data points and chart them in different ways.

Many visualizations can be created following two patterns. The first pattern involves recording and sending information as it gets created. For example, a user completes a registration form. The second pattern involves accumulating and calculating information on the client-side before you call the analytics API to record and send that information to the server. For example, the amount of time that is elapsed between two actions.

Single events:

The single event pattern involves sending a single piece of information as it becomes available.

One example of a single event pattern is tracking new user registrations. After the user successfully completed the application's registration form, tracking this data gives insight about how many people are registering for your application over time.

Creating a line graph chart for new user registrations over time:

You can create a line graph chart to represent new registered users over time.

Procedure

1. Create a MobileFirst hybrid application. These instructions use the JavaScript versions of the log and send APIs. If you want to work with a native application instead, use the native versions of log and send.
2. Write the following code to generate four newSignup events:

```
WL.Analytics.log({ newSignup: 'username' + Math.random(), _activity: "customActivity" }, 'newS  
WL.Analytics.log({ newSignup: 'username' + Math.random(), _activity: "customActivity" }, 'newS  
WL.Analytics.log({ newSignup: 'username' + Math.random(), _activity: "customActivity" }, 'newS  
WL.Analytics.log({ newSignup: 'username' + Math.random(), _activity: "customActivity" }, 'newS
```

This code locally stores a JSON object with information about the new registrations, which is a few random user names in this case. The second parameter in the log function is a useful string to search for log messages. However, for the creation of custom charts, this parameter is irrelevant. The example uses the same key as the object that is being recorded.

3. Send analytics data to the server with the following function:

```
WL.Analytics.send();
```

This function detects all analytics messages that are locally stored, sends them to the server, and removes the local copy after successfully sending them.

4. In the MobileFirst Analytics Console, click the **Custom Charts** tab on the Dashboard page. You can create a chart based on the analytics messages that were sent to the server.
5. Click **Create Chart** to create a new custom chart.
6. Provide the following values:
 - **Chart Title:** New Registrations
 - **Event Type:** Custom Data
 - **Chart Type:** Line Graph
7. Click the **Chart Definition** tab.
8. Provide the following values:
 - **Measure:** Unique
 - **Property:** newSignup
9. Click **Save**.

Results

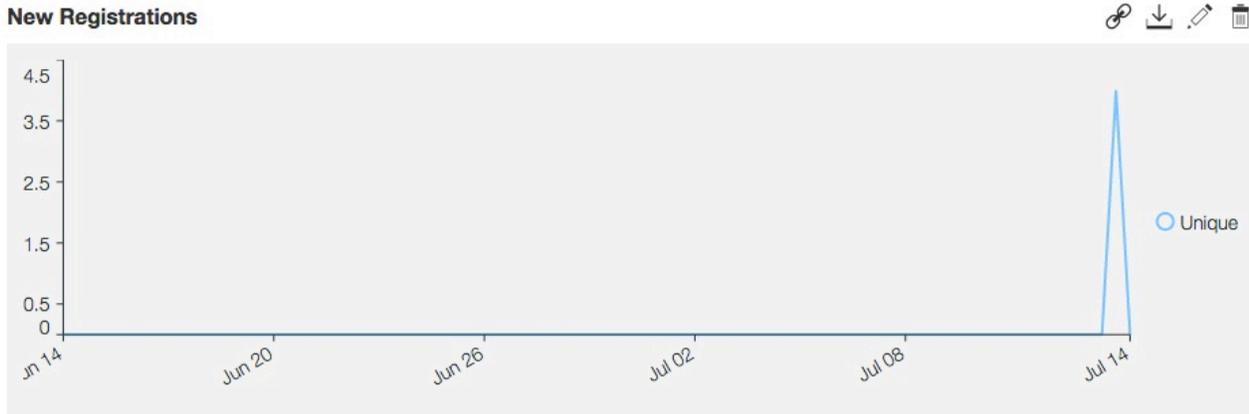

Figure 14-18. New User Registrations Over Time

Creating a table chart for new registrations and device OS:

You can create a table chart to represent new registered users and what device OS they are using.

Before you begin

Complete steps 1-5 in “Creating a line graph chart for new user registrations over time” on page 14-61.

About this task

In this example, you create a table of new registered users and what device OS they are using.

Procedure

1. Provide the following values when you add the new chart:
 - **Chart Title:** New Registrations and Device OS Table
 - **Event Type:** Custom Data
 - **Chart Type:** Table
2. Click the **Chart Definition** tab.
3. Add the following columns to the table: newSignup and Device OS
4. Click **Save**.

Results

Figure 14-19. New Registrations and Device OS Table

What to do next

You can export the data that is shown in the table to use with other applications. For more information about exporting data, see “Exporting custom data” on page 14-70.

Creating a metric group chart for new registrations:

You can create a metric group chart to represent new user registration data.

Before you begin

Complete steps 1-5 in “Creating a line graph chart for new user registrations over time” on page 14-61.

About this task

In this example, you create a metric group chart of new registrations.

Procedure

1. Provide the following values when you add the new chart:
 - **Chart Title:** New Registrations Metric Group
 - **Event Type:** Custom Data
 - **Chart Type:** Metric Group
2. Click the **Chart Definition** tab.
3. Add the following Metric information:
 - **Metric Title:** Registrations
 - **Metric Type:** Unique
 - **Metric Property:** newSignup
4. Click **Add Metric**.
5. Click **Save New Chart**.

Results

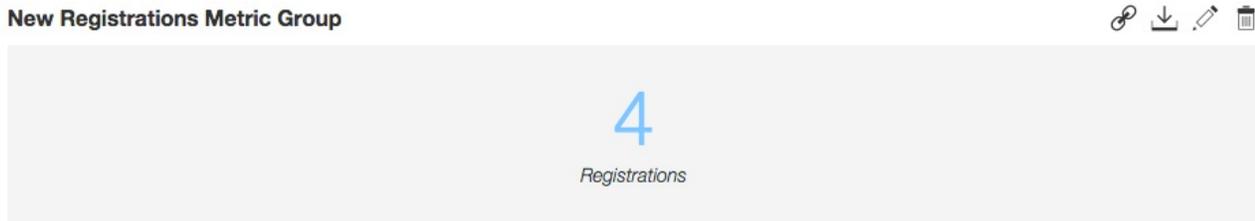

Figure 14-20. New Registrations Metric Group

Creating a pie chart for check-out results:

You can create a pie chart to represent check-out successes and failures.

About this task

You can visualize data as a pie chart. This example shows the percentage of check-out successes and failures.

Procedure

1. Create a MobileFirst hybrid application.
2. Write the following code to generate four successful check-out events and two failures:

```
WL.Analytics.log({checkout: 'success', _activity: "customActivity"}, 'checkout');  
WL.Analytics.log({checkout: 'failure', _activity: "customActivity"}, 'checkout');  
WL.Analytics.log({checkout: 'failure', _activity: "customActivity"}, 'checkout');
```

3. Provide the following values when you add the new chart:
 - **Chart Title:** Check-out Result
 - **Event Type:** Custom Data
 - **Chart Type:** Pie Chart
4. Click the **Chart Definition** tab.
5. Provide the following values:
 - **Property:** checkout
6. Click **Save**.

Results

Check-out Result

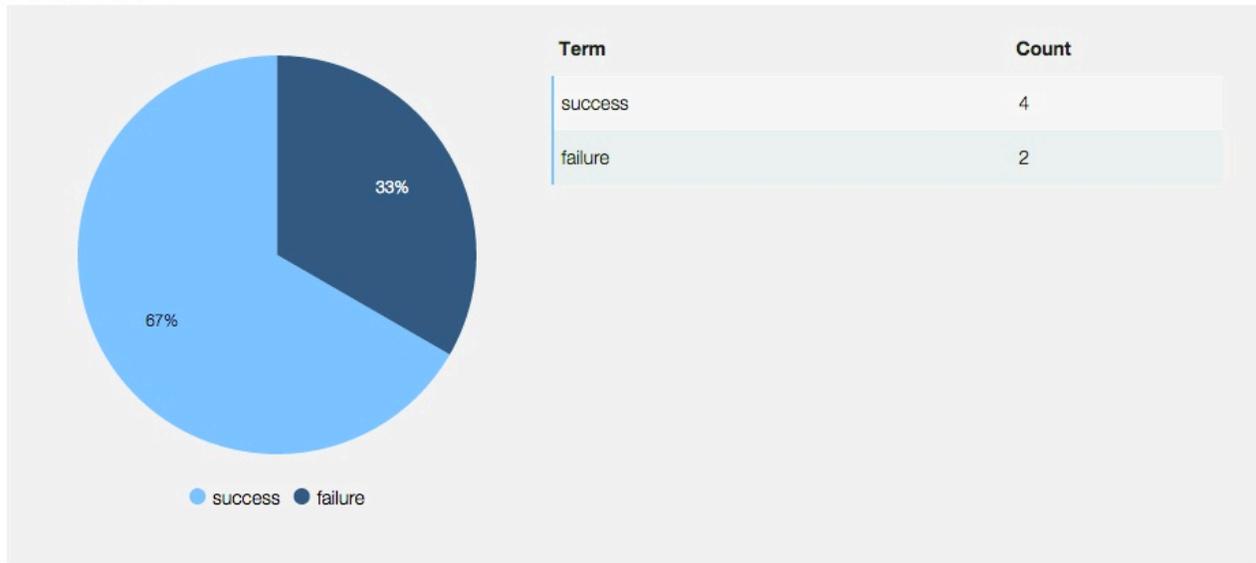

Figure 14-21. Check-out Results

Composed events:

Some pieces of information are only meaningful after you do certain calculations on them.

Examples of composed events are tracking the length of a user session and how long it took a user to complete a specific task. The client portion of the application must record an initial value, such as the current date, wait for the user to complete the task of interest, and then record the amount of time that passed between the initial value and the final value. The client then sends the result of that computation to the server.

The key difference between composed events and single events is that you cannot log `sessionStartTime` and `sessionEndTime` as they occur and have the server calculate the time that is spent between the two intervals to generate a meaningful chart.

In addition to time-based information, another use case for composed events is recording the source and destination page of a user's navigation through the application.

You can also record information about the user and augment analytics events that are sent to the server. For example, recording the users that used the application more than a certain number of times are considered active users. You can send information about the session, such as what country the user is in, and then filter by active users.

Session Length:

You can plot average session lengths and define a threshold to visualize how often the sessions lengths exceed your threshold.

About this task

In this example, you take all the values that are recorded in a single day, calculate the average, and plot them on a graph.

Procedure

1. Define what you consider a session. A session can be defined as the time interval that starts when the user logs in until the user logs out. Another way to define a session is to start the session when the user begins a process and end the session when the process is complete. For this example, a session starts when the application enters the foreground and ends when the application goes into the background.
2. The application lifecycle callback methods depend on which environments you want to support. You can use the native versions of Analytics API for those environments. For simplicity, this example logs the amount of time that is spent on the session that uses the JavaScript API.
3. Add this code to your application:

```
function getSessionTotalTime(currentTime, startTime) {  
    return currentTime - startTime;  
}
```

```
// startTime and endTime can be retrieved through app lifecycle event listeners
```

```
WL.Analytics.log({'totalSessionTime' : getSessionTotalTime(endTime, startTime)}, 'totalSessionTime');
```

4. Send the analytics data to the server:

```
WL.Analytics.send();
```
5. From the **Custom Charts** tab of the Dashboard page in the Analytics Console, click **Create Chart**.
6. Provide the following values:
 - **Chart Title:** Average Session Times
 - **Event Type:** Custom Data
 - **Chart Type:** Bar Graph
7. Click the **Chart Definition** tab and provide the following values:
 - **X-Axis:** Axis By Timeline
 - **Y-Axis:** Average
 - **Property:** totalSessionTime
8. Click the **Chart Properties** tab and add a threshold line with the following values:
 - **Threshold Label:** SessionTimeGoal
 - **Threshold Value:** 300

This threshold creates a line at the value that is specified with the label. The goal is to show the daily average session time that is greater than 300 units of time.

9. Click **Save**.

Results

Average Session Times

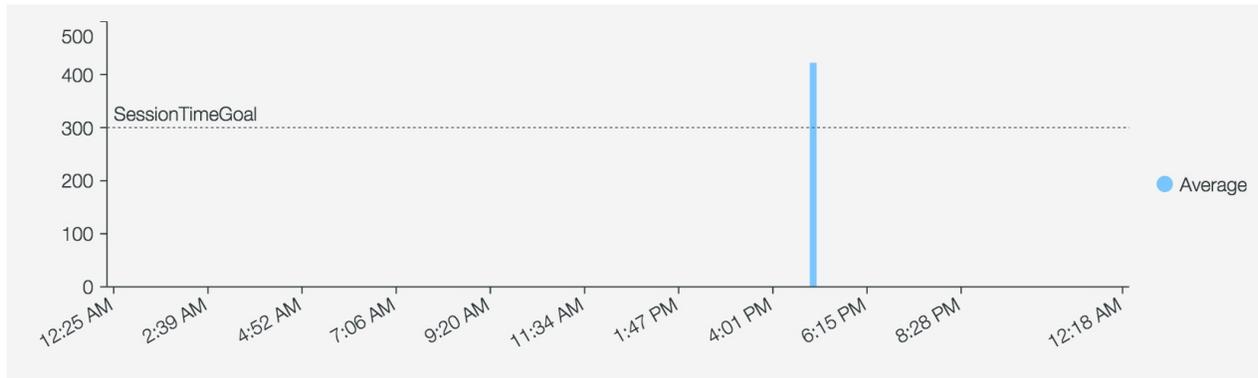

Figure 14-22. Session Length

Page Flow:

You can gain insight about how users of your application reach and leave certain pages by tracking the source page and the destination page.

About this task

In this example, you record how users reach the cart page of an application, and what pages users moves to after they leave that page.

Procedure

1. Create a new hybrid application.
2. Make the following calls to the log function.

```
WL.Analytics.log({sourcePage : 'home', destinationPage: 'cart'}, 'pageFlow');
WL.Analytics.log({sourcePage : 'home', destinationPage: 'cart'}, 'pageFlow');
WL.Analytics.log({sourcePage : 'product', destinationPage: 'cart'}, 'pageFlow');
WL.Analytics.log({sourcePage : 'product', destinationPage: 'cart'}, 'pageFlow');
WL.Analytics.log({sourcePage : 'cart', destinationPage: 'home'}, 'pageFlow');
WL.Analytics.log({sourcePage : 'cart', destinationPage: 'checkout'}, 'pageFlow');
```
3. In the MobileFirst Analytics Console, click the **Custom Charts** tab on the Dashboard page. You can create a chart based on the analytics messages that were sent to the server.
4. Click **Create Chart** to create a new custom chart.
5. Provide the following values:
 - **Chart Title:** Cart Page Flow
 - **Event Type:** Custom Data
 - **Chart Type:** Flow Chart
6. Click the **Chart Definition** tab.
7. Provide the following values:
 - **Source:** sourcePage
 - **Destination:** destinationPage
 - **Property:** cart
8. Click **Save**.

Results

Figure 14-23. Cart Page Flow

Regular Users and Geolocation:

You can view the geographical locations for regular users of your application.

About this task

In this example, you show the geographical locations of an application's regular users.

Procedure

1. Define different types of users that are relevant to your application. For this example, use the following types of users:
 - New: The user used the application less than 5 times.
 - Regular: The user used the application 5 or more times.
2. When the application is started, you need to persist a counter with how many times the user opened the application. This example uses HTML5 local storage, but you can use something more powerful, such as JSONStore. Use the following code to obtain the type of user:

```
var userVisit = localStorage.getItem('userVisit');
localStorage.setItem('userVisit', userVisit + 1);
var typeOfUser = (userVisit > 5) ? 'Regular' : 'New';
```

3. Send the following log messages:

```
WL.Analytics.log({type : 'New', geographicLocation: 'USA'}, 'visit');
WL.Analytics.log({type : 'New', geographicLocation: 'Mexico'}, 'visit');
WL.Analytics.log({type : 'New', geographicLocation: 'USA'}, 'visit');
WL.Analytics.log({type : 'Regular', geographicLocation: 'Mexico'}, 'visit');
```

```
WL.Analytics.log({type : 'Regular', geographicLocation: 'Canada'}, 'visit');
WL.Analytics.log({type : 'Regular', geographicLocation: 'USA'}, 'visit');
WL.Analytics.log({type : 'Regular', geographicLocation: 'USA'}, 'visit');
```

In a real application, do not hardcode values for type and geographicLocation. When you get the location, use strings instead of latitude longitude values.

4. From the **Custom Charts** tab of the Dashboard page in the Analytics Console, click **Create Chart**.
5. Provide the following values:
 - **Chart Title:** Regular Users and Location
 - **Event Type:** Custom Data
 - **Chart Type:** Flow Chart
6. Click the **Chart Definition** tab and provide the following values:
 - **Source:** type
 - **Destination:** geographicLocation
 - **Property:** Regular
7. Click **Save**.

Results

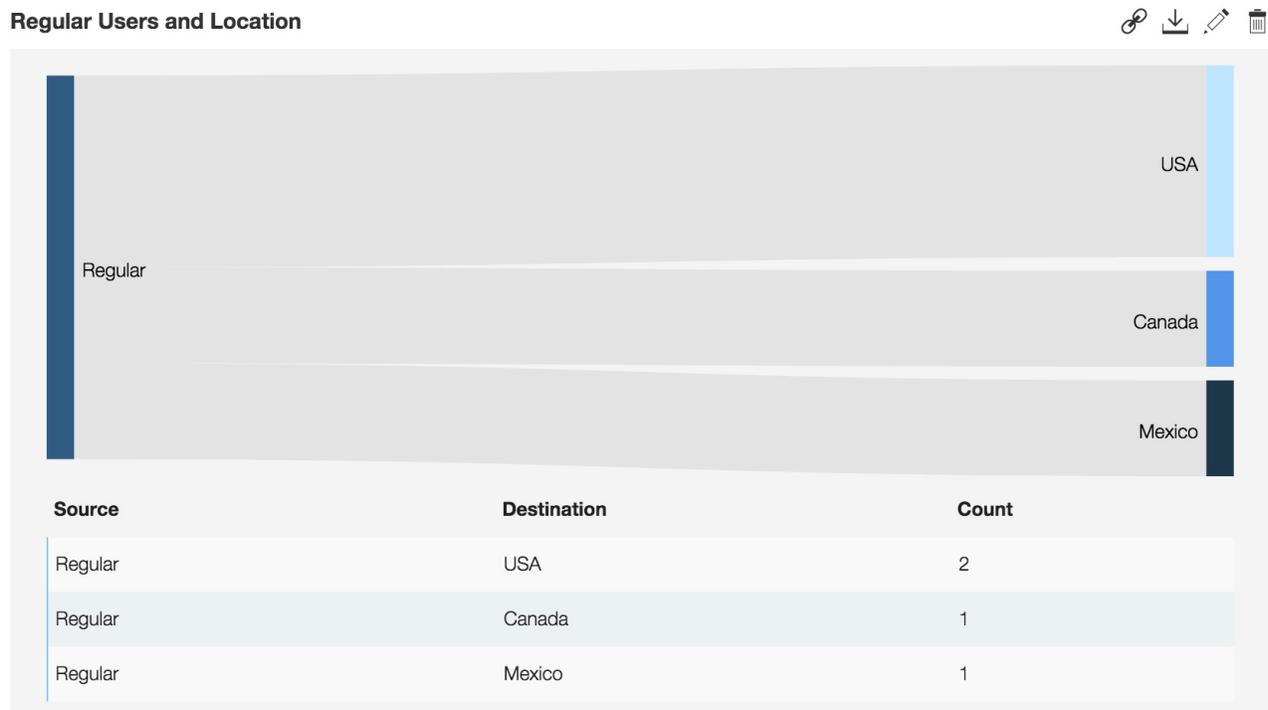

Figure 14-24. Regular Users and Location

New Users and Location:

You can use filters with a pie chart to show new users and their geographic location instead of regular users.

About this task

In this example, the chart uses the same information that is presented in “Regular Users and Geolocation” on page 14-68, but shows new users instead of regular users. Unlike that task, this example uses filters to limit the amount of information that is shown and uses a pie chart instead of a flow chart.

Procedure

1. Follow steps 1-3 from “Regular Users and Geolocation” on page 14-68.
2. From the **Custom Charts** tab of the Dashboard page in the Analytics Console, click **Create Chart**.
3. Provide the following values:
 - **Chart Title:** New Users and Location
 - **Event Type:** Custom Data
 - **Chart Type:** Pie Chart
4. Click the **Chart Definition** tab and provide the following values:
 - **Property:** geographicLocation
5. Click the **Chart Filters** tab and provide the following values:
 - **Property:** type
 - **Operator:** Equals
 - **Value:** New
6. Click **Save**.

Results

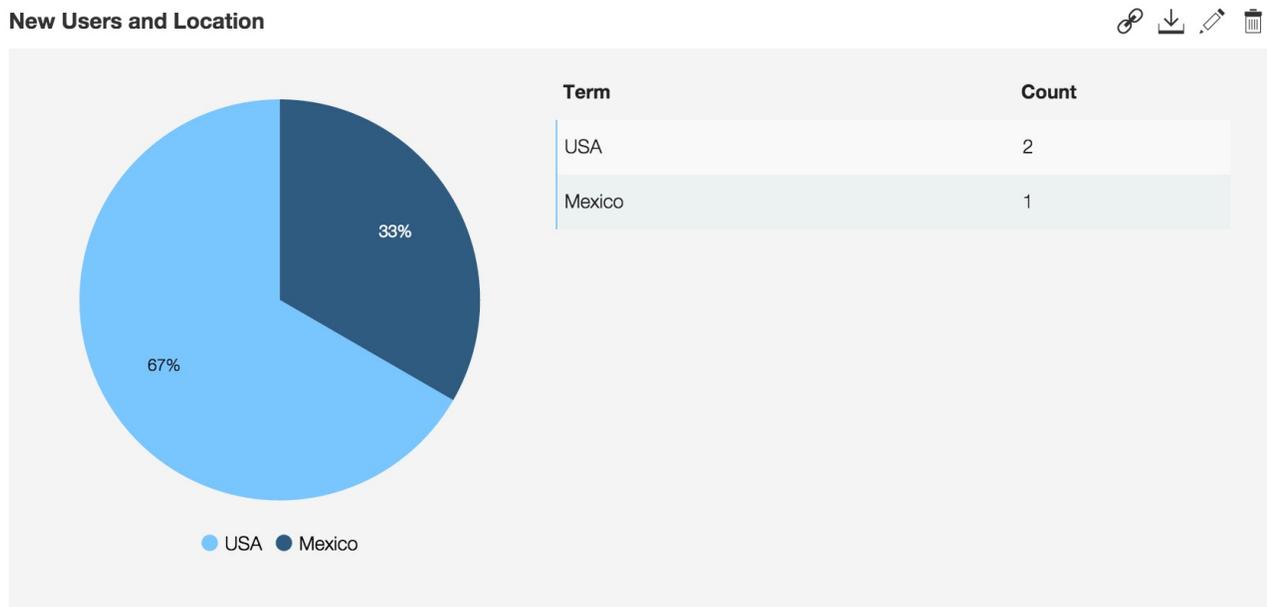

Figure 14-25. New Users and Location

Exporting custom data:

The data from each custom chart can be exported into JSON, XML, or CSV format.

The structure of the exported data depends on the chart that is being exported. To export data, click the export icon at the upper right of the custom chart.

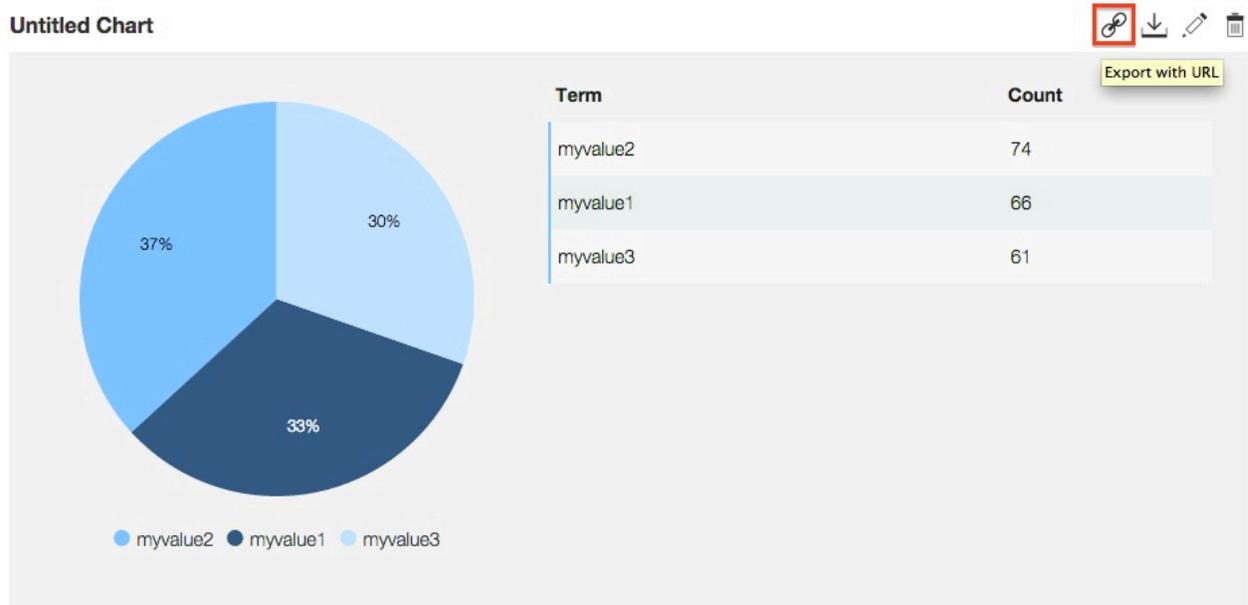

Figure 14-26. Exporting chart data

Exporting and importing custom chart definitions:

If you are using the latest interim fix of MobileFirst, you can import and export custom chart definitions programmatically or manually in the IBM MobileFirst Platform Operational Analytics Console.

Before you begin

Ensure that you have at least one custom chart in the IBM MobileFirst Analytics Console.

About this task

In this example, you manually export and import custom chart definitions.

Procedure

1. In the MobileFirst Analytics Console, click the **Custom Charts** tab in the Dashboard page.
2. To export the custom chart definitions, click **Export Charts**. This action displays a dialog to save a `customChartsDefinition.json` file.
3. Choose a location to save the file.
4. Click the **Delete Chart** icon next to each custom chart to delete all custom charts.
5. To import a custom chart definition, click **Import Charts**. This action displays a dialog to choose a file.
6. Choose the `customChartsDefinition.json` file that you previously exported to open.

Results

You exported and imported a custom chart definition manually in the MobileFirst Analytics Console.

What to do next

You can also export and import custom chart definitions programmatically by using your HTTP client of choice (for example, CURL or postman). The GET endpoint for export is `http://<hostname>:<port>/analytics-service/data/customCharts/apps/{appId}`. The POST endpoint for import is `http://<hostname>:<port>/analytics-service/data/customCharts/apps/{appid}/import`. For example, if the context root was not changed from the default of `analytics-service`, the export endpoint is `http://myHost.com:9080/analytics-service/data/customCharts/apps/{appid}` and the import endpoint is `http://myHost.com:9080/analytics-service/data/customCharts/apps/{appid}/import`. If the application is protected by basic authorization, all security requirements apply.

Note: If you import a custom chart definition that exists, you end up with duplicate definitions, which also means that the MobileFirst Analytics Console shows duplicate custom charts.

Security Analytics

Starting with V7.0.0, the MobileFirst Operational Analytics includes a **Security** tab.

Overview of IBM MobileFirst Platform Foundation security

Applications and adapter procedures can be protected by a security test. The test includes one or more realms. Each Realm represents a specific security check. Some realms are already provided. For example, `wl_antiXSRFRealm` is used to avoid cross-site request forgery attacks. Other realms are defined by the developer based on their security needs.

The realms contain two key pieces of functionality: an Authenticator and a Login Module. The Authenticator gets some information from the user or device, such as a user name and password. The Login Module gets information from the Authenticator and validates it. An example of validation is checking the user name and password against a user registry.

For more information about security, see “MobileFirst security overview” on page 12-90.

Example use case

1. A developer creates an adapter procedure. The procedure returns account information for a specific user.
2. Only valid users can access account information, so the developer protects the procedure with a security test. That adapter procedure is now a protected resource.
3. You can determine if a user is valid by contacting a user registry. The developer creates a realm and makes the authenticator the `FormBasedAuthenticator`. That authenticator will send a login form to the client and expect a response with the user name and password.

4. The Login Module is a Java class implemented by the developer. It contains code to contact a user registry on the backend using the credentials gathered by the `FormBasedAuthenticator`. There are two possible outcomes now:
 - a. If the user is valid, the security test passes and access to the protected resource (account information for the user) is granted.
 - b. If the security test fails, then the user is unable to access the protected resource. The cause of the failure might be incorrect credentials, failure to access the user registry due to a network error, exception on the server, or other causes.
5. If the user is valid, the security test passes and access to the protected resource (i.e. account information for the user) is granted. b) If the security test fails then the user is unable to access the protected resource. The cause of the failure might be one of the following: wrong credentials, failure to access the user registry due to a network error, exception on the server, among others.

Potential use cases

The platform can be used to develop a banking application. The application allows users to log in using their bank's credentials. Successfully authenticated users can access their account information and perform various actions (such as transferring money between accounts). This authentication flow is similar to the flow described in the previous section.

Network issues

If an application gets popular, more people are trying to access a protected resource (such as their account information). Using the **Security** tab of the Operational Analytics console, you notice a high failure rate on one of the realms. That realm is part of the security test used to allow users to log in and view their account information. The most common error under **Authenticator Failures** is an internal server error. One reason for this error is that the backend infrastructure (the number of servers) needs improvement to meet the increase in demand.

Security threats

You notice that there is a high failure rate on one of the protected resources (such as account information). Looking at the **Authenticator Failures**, you notice the most common error is invalid credentials. That error gets returned when the client supplies an invalid user name or password. This might mean a hacker is attempting to access a protected resource by trying different credentials within short time intervals. Based on this information, you conclude that you should not allow users to try different credentials indefinitely. With the data provided by the analytics console, you decide to let users attempt 5 wrong credentials before asking users to wait a specific amount of time before allowing them to try again. The goal is to limit the effectiveness of a brute force attack.

Application usability issues

In addition to using their user name and password to access the application and view their account balances, users also need to supply their bank's pin number to transfer money between accounts. You notice a high failure rate in the realm that asks for the pin number. Looking at the **Authenticator Failures**, you notice the most common error is client interaction required. This means the server is expecting credentials (the pin number) but is not receiving them. This can be caused by a high percentage of users inability to understand the user interface. The

users are not noticing that they need to send their pin number. Based on these findings, the page should be redesigned to solve that issue.

Development defects

You are viewing security information from the last 24 hours and notice the failure rate for one of the realms is 100%, meaning that it always fails. This might result from a recent change introducing a regression that broke one of the realms. Another possibility, based on the realms provided by the platform, is that `wl_directUpdateRealm` is failing. This happens because of an issue with direct update. A third possibility is evident when an entry with [Unknown Realm] is displayed in the list of realms. This happens when there is a failure before one of the realms is reached. Having this information is especially useful when running an application in production.

Securing the Operational Analytics server

Learn about security with the IBM MobileFirst Platform Operational Analytics.

Protecting the analytics data entry point with basic authentication

IBM MobileFirst Platform Operational Analytics is configured to protect the data entry point by using basic authentication.

Default path protection

Data is sent from the MobileFirst Server to the IBM MobileFirst Platform Operational Analytics when the following IBM MobileFirst Platform Foundation property is set:

```
wl.analytics.url=http://<hostname>:<port>/analytics-service/data
```

The IBM MobileFirst Platform Operational Analytics exposes this path and it is protected by default using basic authentication (user name and password).

Configuration of basic authentication

In the `analytics-service` WAR file, basic authentication is configured in the `WEB-INF/web.xml` file. The default configuration has the following structure:

```
<!-- SECURITY ROLES -->
<security-role>
  <role-name>worklightadmin</role-name>
</security-role>
<security-role>
  <role-name>worklightdeployer</role-name>
</security-role>
<security-role>
  <role-name>worklightmonitor</role-name>
</security-role>
<security-role>
  <role-name>worklightoperator</role-name>
</security-role>

<!-- SECURITY CONSTRAINTS -->
<security-constraint>
  <web-resource-collection>
    <web-resource-name>allAccess</web-resource-name>
    <url-pattern>/data/*</url-pattern>
  </web-resource-collection>
  <auth-constraint>
    <role-name>worklightadmin</role-name>
```

```

    <role-name>worklightdeployer</role-name>
    <role-name>worklightmonitor</role-name>
    <role-name>worklightoperator</role-name>
  </auth-constraint>
  <user-data-constraint>
    <transport-guarantee>NONE</transport-guarantee>
  </user-data-constraint>
</security-constraint>

<!-- AUTHENTICATION METHOD: basic auth -->
<login-config>
  <auth-method>BASIC</auth-method>
  <realm-name>worklightRealm</realm-name>
</login-config>

```

Four roles are created (worklightadmin, worklightdeployer, worklightmonitor, worklightoperator) and the data endpoint is protected from all requests made by authenticated users not belonging to one of these roles.

Note: These role names also exist in the analytics-ui WAR file, which must also be edited if roles are added or changed.

Basic authentication credentials

In the worklight.properties file, set the wl.analytics.username and wl.analytics.password values for basic authentication. For more information about encrypting sensitive information in the worklight.properties file, see “Storing properties in encrypted format” on page 12-62. After this configuration, the IBM MobileFirst Platform Operational Analytics will not accept any incoming data unless the request also contains the correct credentials. When the wl.analytics.username and wl.analytics.password values are set, the MobileFirst Server uses these credentials when it forwards data to the IBM MobileFirst Platform Operational Analytics. For more information about IBM MobileFirst Platform Foundation properties, see “MobileFirst properties” on page 14-95.

Note: This configuration protects only the /data path that accepts incoming data. It does not protect the console.

Ports that are used by the IBM MobileFirst Platform Operational Analytics

When the IBM MobileFirst Platform Operational Analytics is started, it listens on port 9600.

Port 9500 - HTTP Port

This port can be used for HTTP requests that are made directly to the IBM MobileFirst Platform Operational Analytics. It is not required to be open and should not be accessible from outside the cluster. It is important to protect this port because foreign commands can be sent directly to the IBM MobileFirst Platform Operational Analytics through this port. This port is closed by default. You can open this port by setting the http.enabled JNDI property to true. For more information, see “Properties and configurations” on page 14-95.

Port 9600 - Transport Port

This port is used for communication between nodes in a cluster. This port should be open to other nodes in the cluster for node communication to work properly. This port should also not be accessible from outside the cluster. This port is open by default.

These ports can be changed by using the following JNDI properties:

- httpport
- transportport

The following example shows how you can modify the ports.

```
<jndiEntry jndiName="analytics/httpport" value="9700" />  
<jndiEntry jndiName="analytics/transportport" value="9800" />
```

Production deployment and clustering

Most of the clustering functionality and logic is handled by the IBM MobileFirst Platform Operational Analytics. It is not necessary to do any additional work to cluster the application server that the IBM MobileFirst Platform Operational Analytics is running on. The application servers are only necessary to host the IBM MobileFirst Platform Operational Analytics and do not require special configuration for clustering.

Creating an IBM MobileFirst Platform Operational Analytics cluster can be scoped down to the following steps:

1. Configure the master node or nodes.
2. Set the number of shards.
3. Set the number of replicas.
4. Add a node to the cluster.
5. Point the new node to the master node or nodes.

It is important to fully understand how the clustering works for the IBM MobileFirst Platform Operational Analytics before you create the cluster.

Clustering terminology

Learn about clustering terminology for the IBM MobileFirst Platform Operational Analytics.

Cluster

A collection of one or more master and data nodes.

Master Node

Coordinator of the cluster. Manages the distribution of shards and keeps track of all nodes in the cluster. There can be more than one master node. If a master node fails, then a new node that is marked as a master node is automatically elected as a new master node. The cluster cannot operate without at least one master node.

Data Node

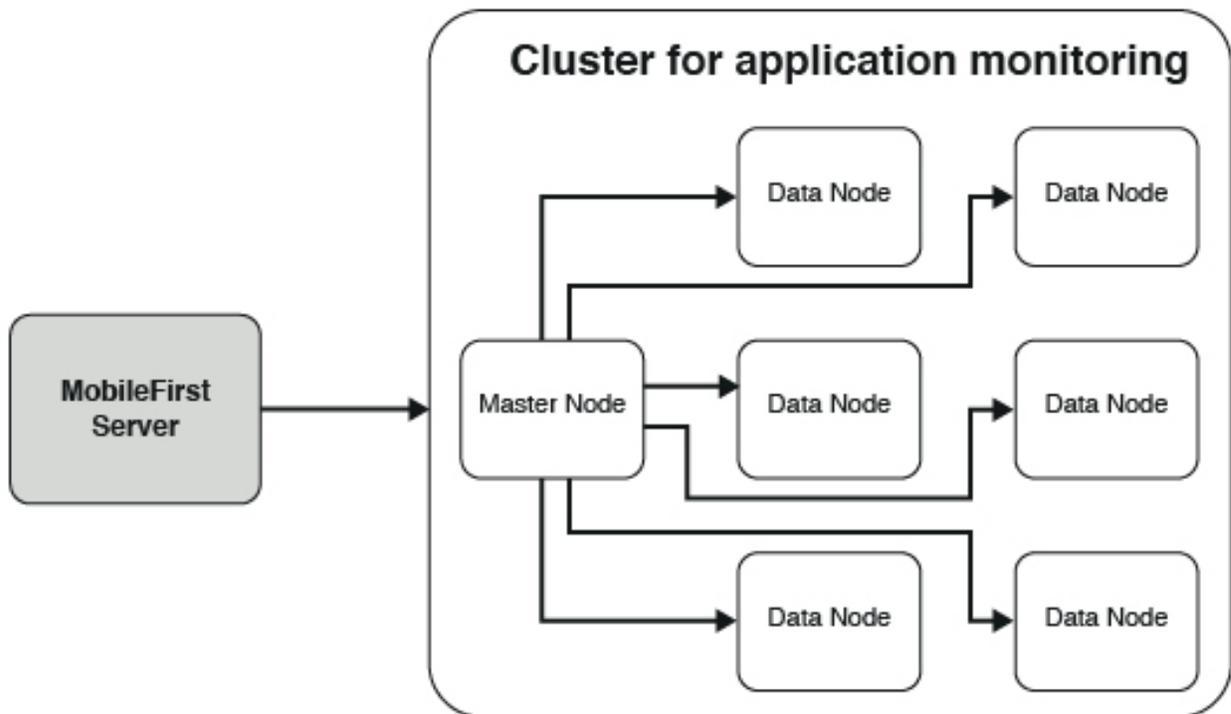

Workhorse of the cluster. Stores data and processes incoming search and index requests. A node can act as both a data node and a master node.

Shard Each data node stores data in a shard. For more information about shards, see “Understanding shards” on page 14-77.

Replica shard

Each shard can have any number of replicas. Replicas are used to ensure high availability in the case that a node is no longer available. For more information about replicas, see “Understanding replicas” on page 14-83.

The following image shows a basic clustering topology:

Note: Data can be forwarded from the MobileFirst Server to any node in the server. The MobileFirst Server does not have to point to a master node.

In development, a cluster that contains one node and one shard is sufficient. The single node acts as the master and data nodes.

In production, it is ideal to have multiple nodes that perform specific functions to ensure high availability and performance.

Understanding shards:

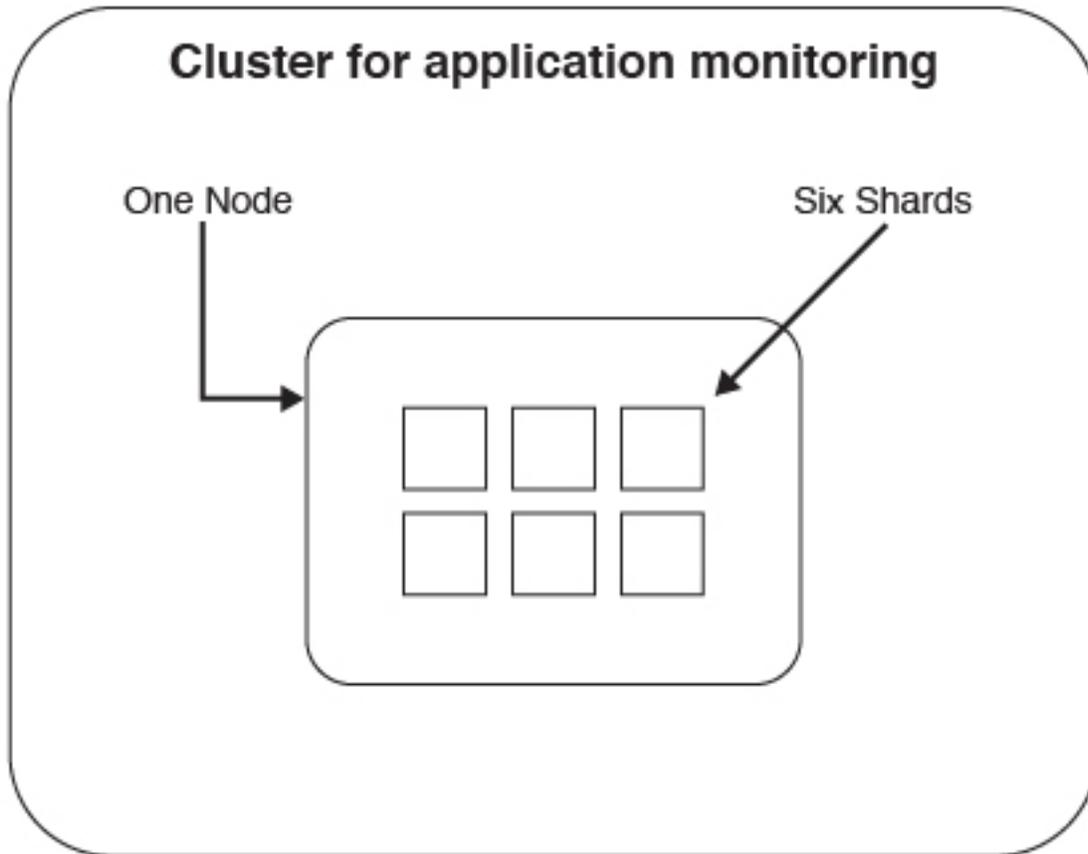

Learn about shards in the IBM MobileFirst Platform Operational Analytics.

It is important to carefully consider setting the number of shards when you set up a cluster. The number of shards can be set only once, by the first node in the cluster. If the number of shards must be changed later, you must completely reindex all of the data that is stores in the IBM MobileFirst Platform Operational Analytics.

Ideally, the number of shards is equal to the maximum number of nodes that the cluster eventually expands to. Because the maximum number of nodes that are needed is often unknown at installation time, it is a common practice to create more shards than needed.

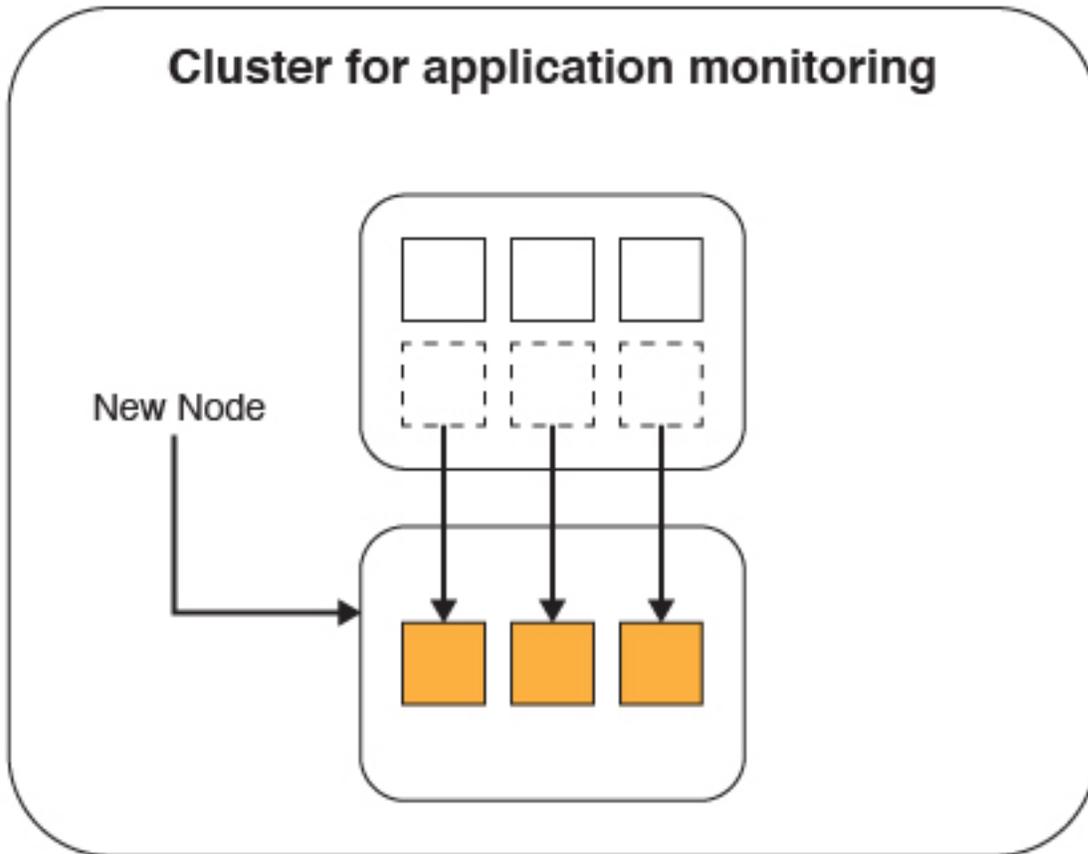

The following images show how sharding works.

Here is a cluster with one node and six shards. Because there is only one node, all six shards live on the same node. The single node handles all requests and data processing.

After several months of use, requests that are made to the cluster begin to perform poorly. It is determined that a single node is no longer adequate to handle processing for all of the incoming data. A new node is added to the cluster.

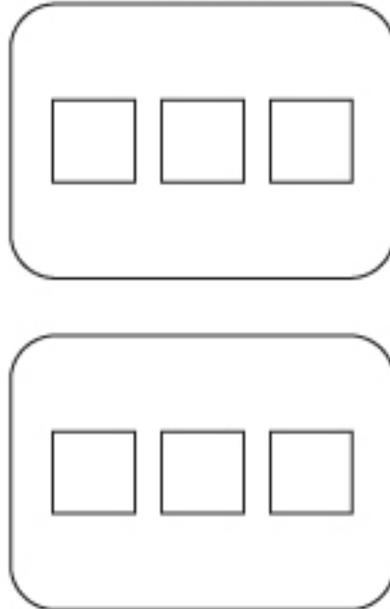

After a new node is added, the shards are automatically evenly distributed across all of the nodes.

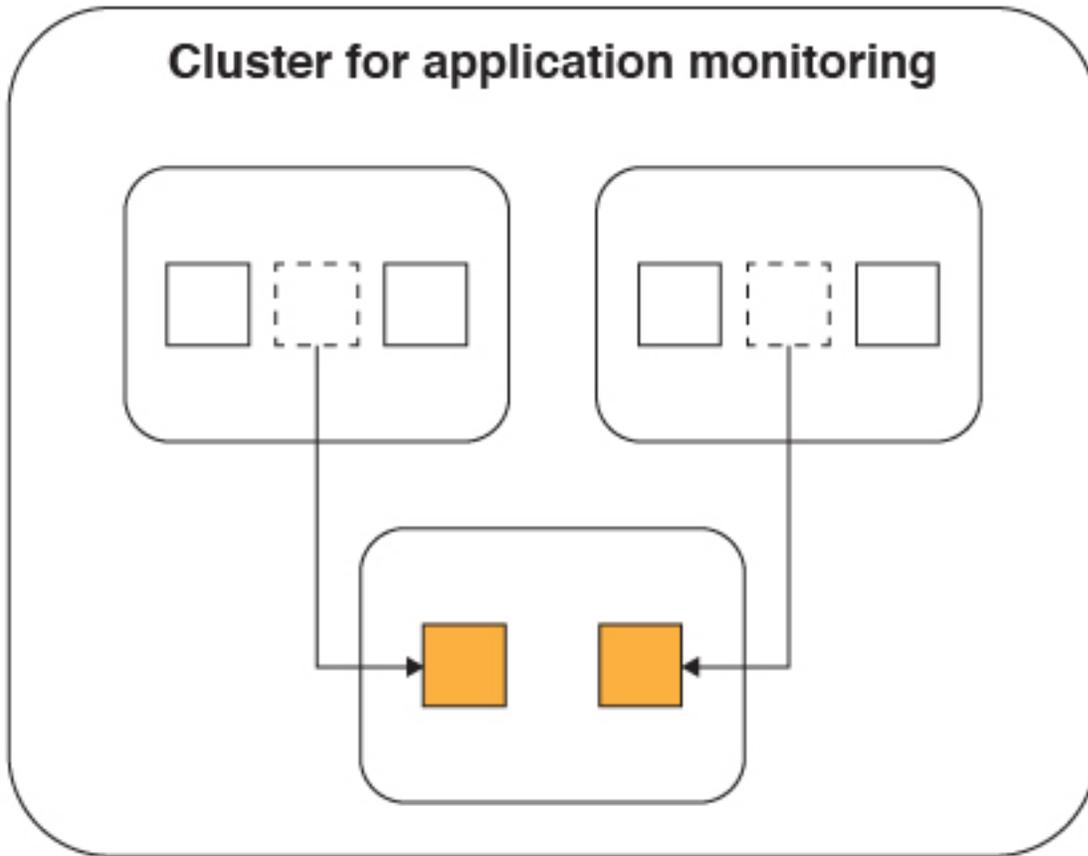

Now when a request comes in to either node, the request is forwarded to the node that has the shard that contains the data. The data indexing and processing is now split between the two nodes. Because the requests and data processing is now split between the nodes, the performance and response times improve.

Cluster for application monitoring

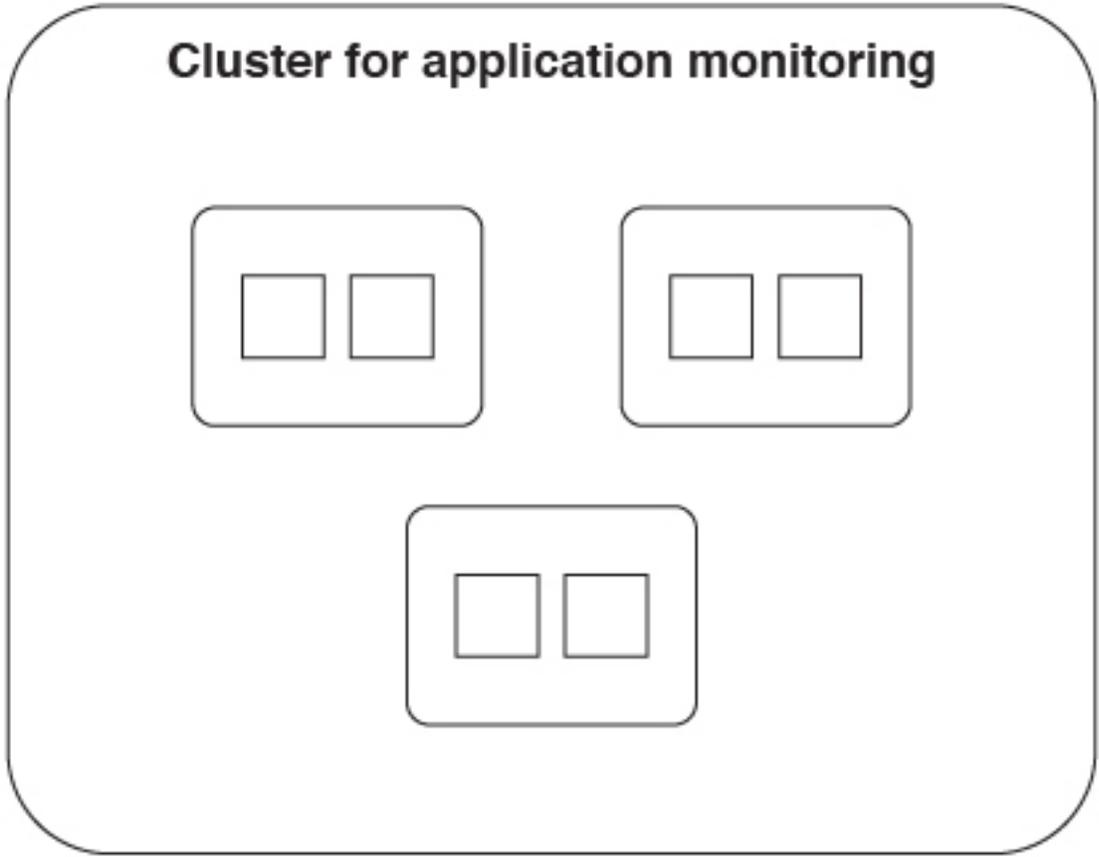

Requests split between the two nodes

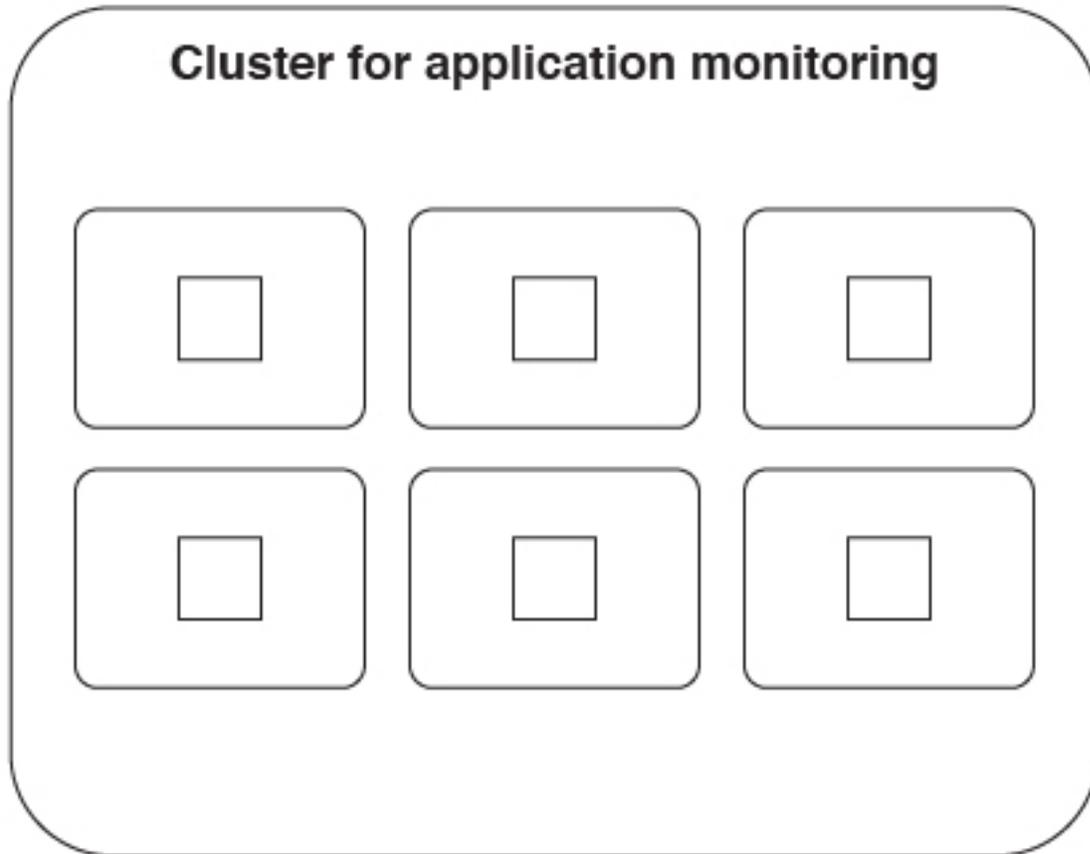

After several months, requests begin to slow down again, and it is determined that a third node is required.

The shards are split between the three nodes.

This process repeats itself until there are six nodes, which each contains one shard. It is now no longer possible to add more nodes because each shard contains only one node.

If it is determined that six nodes are no longer sufficient to handle the incoming data load, a new cluster must be set up. The data must then be reindexed with a larger shard limit.

It is important to understand that the distribution of the shards happens automatically. The only configuration that must be made for shards is specifying the number of shards at installation time.

A small performance hit comes with having more than one shard per node. Although this performance hit is often negligible, the cluster should not be configured with an arbitrarily large number of shards.

Understanding replicas:

Learn about replicas in the IBM MobileFirst Platform Operational Analytics.

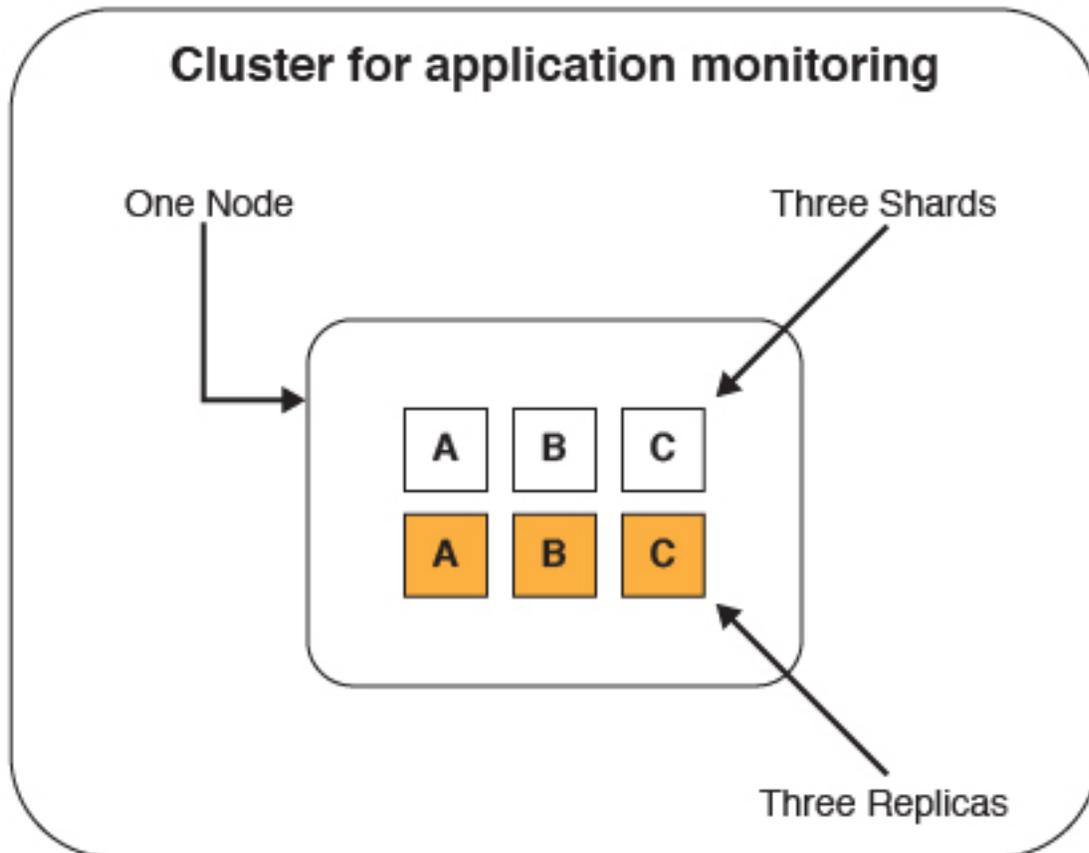

Shards contain the actual data that is sent from the MobileFirst Server. The master node keeps track of which shards are on which nodes so that it can evenly distribute incoming requests. Because of the way shards are distributed among nodes, performance can be increased by adding another node and allowing the shards to be distributed.

But what happens if a node fails? The data that was stored in the lost shards is no longer available. Incoming analytics data might no longer be indexable. Search requests for data on a particular shard fail. To increase shard availability to avoid these problems, you can create a replica of each shard. By using JNDI properties,

you can tell the IBM MobileFirst Platform Operational Analytics to create a specified number of replicas for each shard.

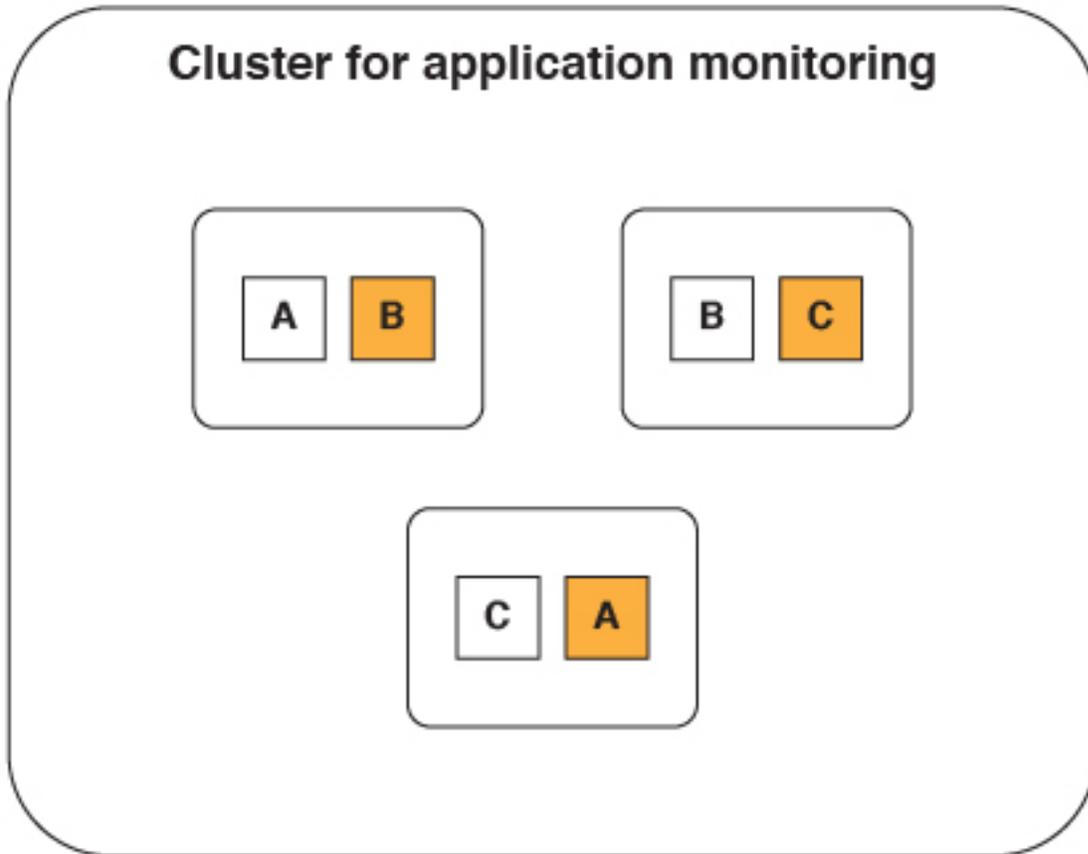

The following images show how replicas work.

Here is a cluster with one node, three shards, and one replica for each shard.

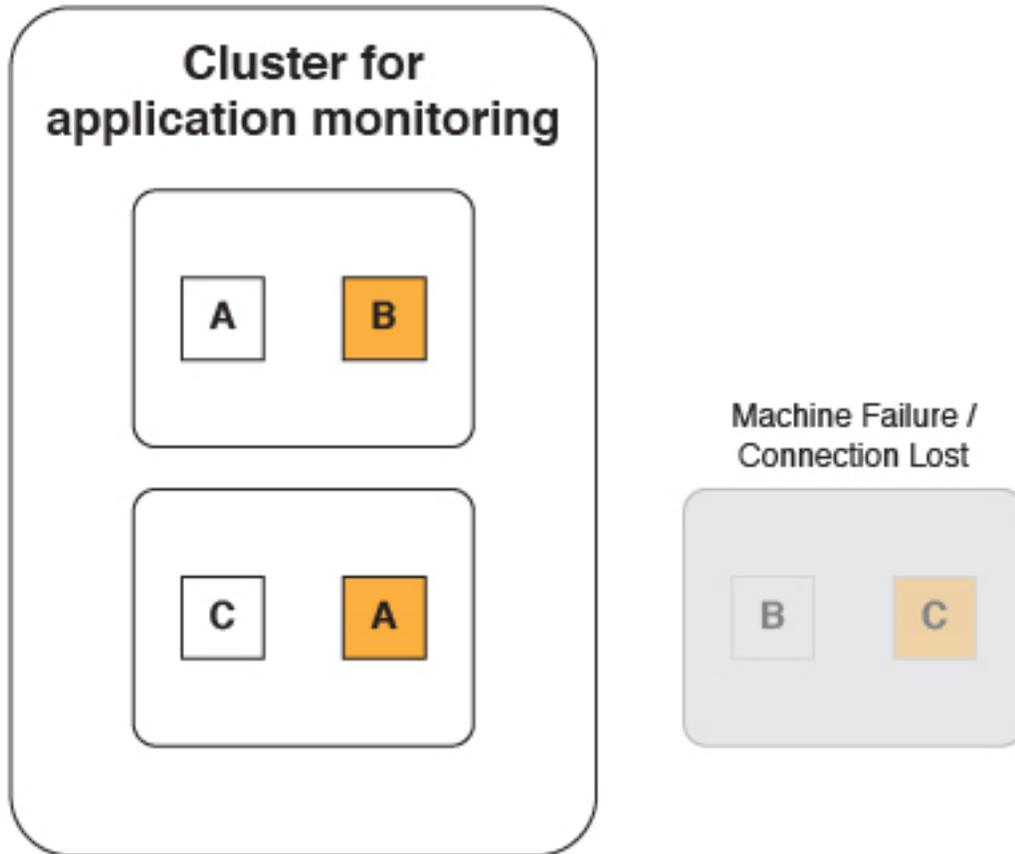

In this case, the replicas are redundant. Because there is only one node, having a replica exist on the same node does not accomplish anything. If the single node fails, the shards and replicas are all lost.

Now two more nodes are added to the cluster to improve performance:

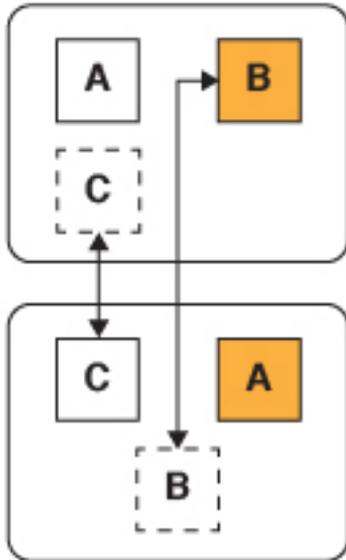

Notice that the shards and replicas are both automatically distributed evenly among the nodes. Now consider the scenario where a node fails due to a network or hardware issue.

The analytics cluster can still operate normally because a replica of the lost shards still exists on one of the remaining nodes.

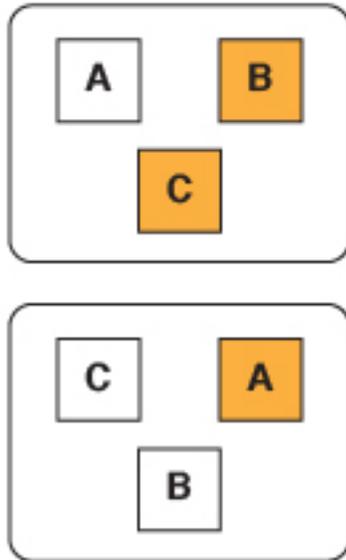

Cluster for application monitoring

Machine Failure /
Connection Lost

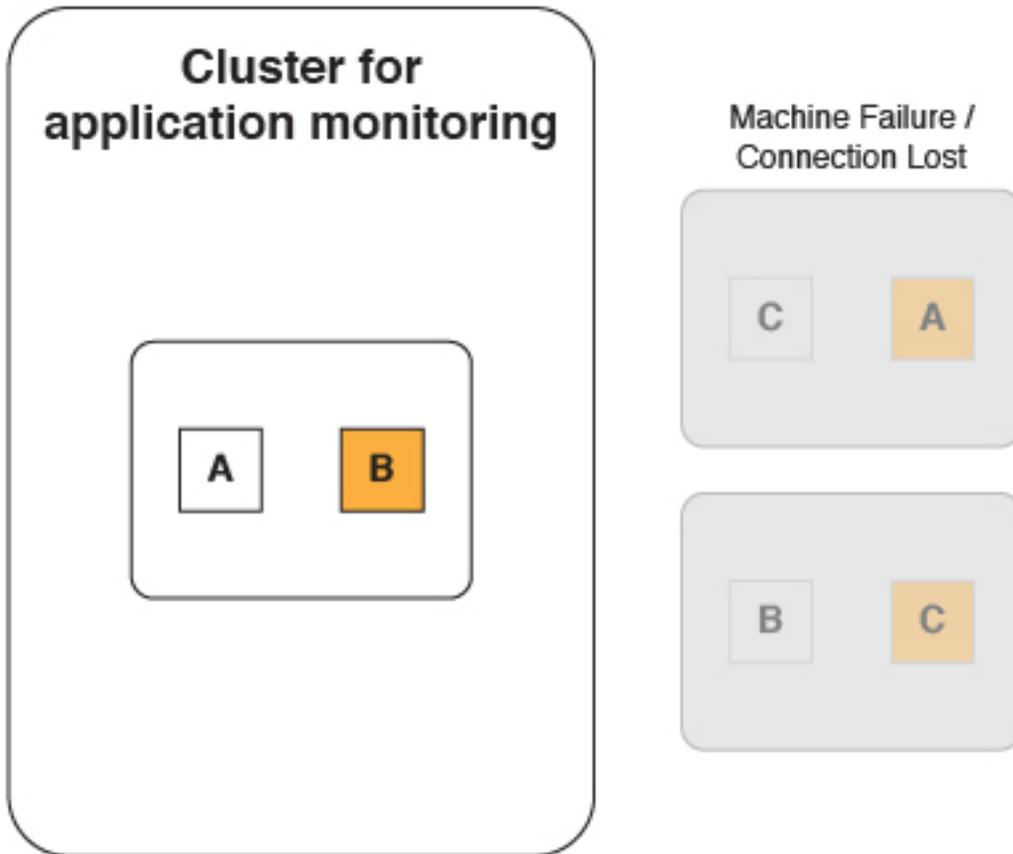

Cluster for application monitoring

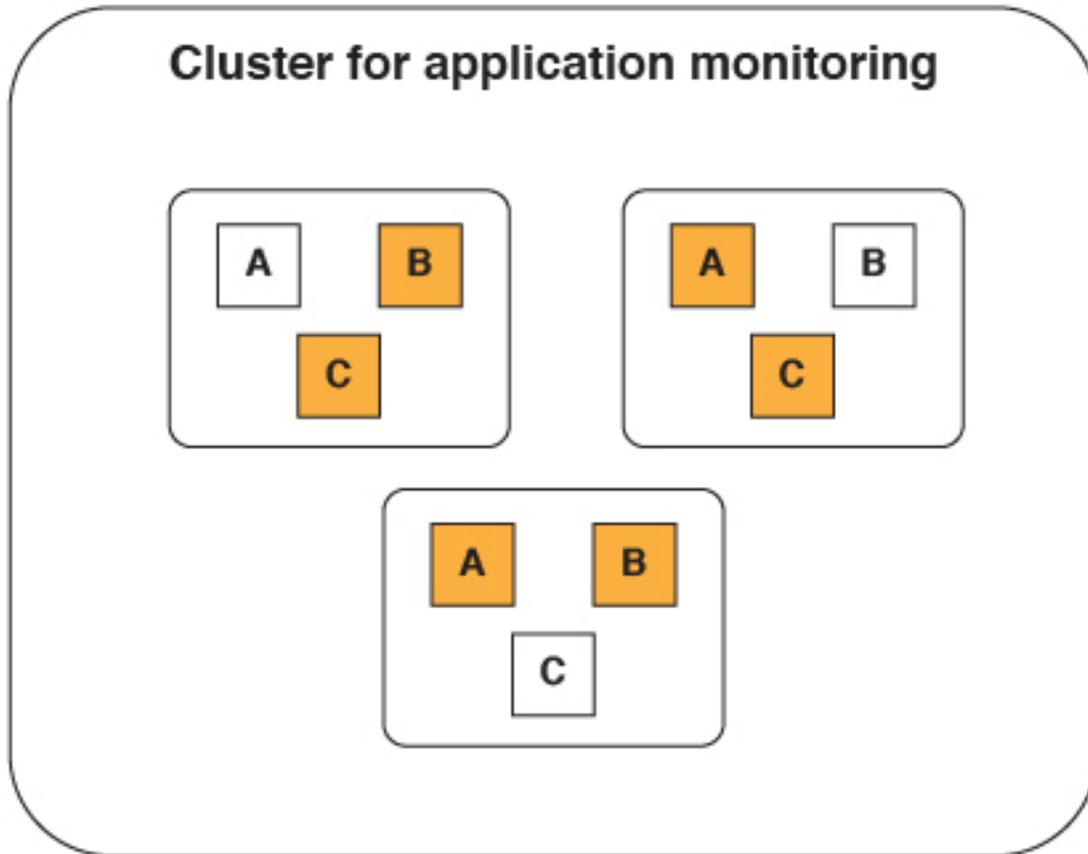

When the failed node comes back online and rejoins the cluster, the shards and replicas are again evenly distributed. The cluster returns to the state it was in before one of the nodes failed.

But what happens when two of the nodes fail simultaneously?

The cluster cannot operate normally. Even with one replica per shard, if two nodes were to fail, you would still lose information that was stored in the lost shards.

The answer to this problem is to use two replicas per shard.

Now even when two nodes fail, all of the data is available and the cluster can still operate normally.

Having replica shards can also increase performance because an incoming request can be handled by either a primary or replica shard.

The ideal number of replicas for each shard varies based on several factors such as:

- Hardware limitations.
- Availability requirements.
- Clustering topology.

Setting up a production cluster

You can set up a production cluster for operational analytics.

Before you begin

For a production cluster, do not run the IBM MobileFirst Platform Operational Analytics on the same server as the MobileFirst Server. The IBM MobileFirst Platform Operational Analytics uses a large amount of the computer's processor and memory resources. Each node should run on a separate server.

If you are deploying to a WebSphere Application Server cluster, also see "Deploying in a clustered WebSphere Application Server environment" on page 14-92.

About this task

To set up your production cluster, follow these steps.

Procedure

1. Set the heap size for the application server. The heap size has a very significant impact on the performance of the IBM MobileFirst Platform Operational Analytics. The heap size must be set on each application server that is hosting a node. The `-Xms` Java option sets the minimum heap size value. The `-Xmx` Java option sets the maximum heap size value. For example, to reserve 8 GB of memory for the IBM MobileFirst Platform Operational Analytics, set the following Java options:

```
-Xms8G -Xmx8G
```

Note:

- The minimum heap size for a production server is 8 GB.
- Do not allocate more than half of the system memory to the application server that is running the IBM MobileFirst Platform Operational Analytics.
- Set the minimum and maximum heap size to the same value for an application server that is hosting the IBM MobileFirst Platform Operational Analytics.
- To change the heap size on WebSphere Application Server, from the console, go to WebSphere Application Servers/<server name>/Java, and Process Management/Process definition/Java Virtual Machine. Then, restart the server for changes to be taken into account.

For an IBM MobileFirst Platform Operational Analytics that runs on a server with 32 GB of RAM, the optimal heap size is:

```
-Xms16G -Xmx16G
```

2. Configure the first node in the cluster. The first node in the cluster is important because some properties can be set only by this node. It is important to ensure that the settings for the node are present before you start the application servers. The first node in a cluster must be a master node. A master node can also act as a data node.
 - a. Configure the node to be a master node. Set the `nodetype` JNDI property to `master`.

```
<jndiEntry jndiName="analytics/nodetype" value="master" />
```

Note: By default, a node acts as a master and data node. If you want to create a node that acts as both a master and a data node, the node type does not need to be set.

- b. Set the number of shards. Set the `shards` JNDI property to the number of shards you want.
- c. Set the number of replicas. Set the `replicas_per_shard` JNDI property to the number of replicas you want.

```
<jndiEntry jndiName="analytics/shards" value="10" />
```

```
<jndiEntry jndiName="analytics/replicas_per_shard" value="2" />
```

After all of the JNDI properties are set, the application server can be started.

3. Add a node to an existing cluster.
 - a. Set the node type. Set the `nodetype` JNDI property to either `master` or `data`.

```
<jndiEntry jndiName="analytics/nodetype" value="master" />
```

```
<jndiEntry jndiName="analytics/nodetype" value="data" />
```

Note: By default, a node acts as a master and data node. If you want to create a node that acts as both a master and a data node, the node type does not need to be set.

Note: If you are deploying to a WebSphere Application Server cluster, do not set the nodetype JNDI property. All nodes in the WebSphere Application Server cluster must act as master and data nodes.

- b. Provide a list of the master nodes. Set the masternodes JNDI property to a comma delimited list of host names for the master node.

```
<host>:<transport-port>,<host>:<transport-port>
```

The default transport port is 9600. You can change this value by using a JNDI property. For more information about the transport port, see “Ports that are used by the IBM MobileFirst Platform Operational Analytics” on page 14-75.

For example:

```
<jndiEntry jndiName="analytics/masternodes"
          value="master1.ibm.com:9600,master2.ibm.com:9600" />
```

4. Configure the `worklight.properties` file. Set the `wl.analytics.url` property to point to any of the nodes (can point to a master or data node).

```
wl.analytics.url=http://<hostname>:<port>/analytics-service/data
```

Results

You have set up a production cluster.

Note:

A node that is set as a pure data node cannot run on its own without a master node. The masternodes JNDI property must be set and must point to an active master node.

A node that is set as a pure master node cannot store data. Any attempts to store or view data from a master node fails until a data node connects to it.

Data nodes are active, which makes them more prone to network and hardware failures. If a data node fails, the cluster can still operate normally if the other data nodes are alive. If the master node or nodes fail, then the cluster cannot operate. Data nodes can communicate with only each other through master nodes. This behavior is why it is important to consider having separate master nodes that can run on servers with fewer chances for failure.

The same version of Java must be installed on all nodes in the cluster. Using different versions of Java for different nodes causes the cluster to fail.

Deploying in a clustered WebSphere Application Server environment:

You can deploy the Analytics Platform in a clustered WebSphere Application Server environment.

Before you begin

Note: In previous topics, the term *node* is used as a general term to define a separate machine that runs an instance of the Analytics Platform. The term *node* is used here to identify a node in a WebSphere Application Server cluster.

About this task

All clustering is handled by the Analytics Platform regardless of the topology that is configured in WebSphere Application Server. You must determine which machines in the cluster you want to be the *master nodes* and define them through a JNDI property. The list of master nodes are passed down to the WAR file, where the distribution of analytics data within the cluster is handled.

To use the Analytics Platform in a clustered environment on WebSphere Application Server, follow these steps.

Procedure

1. Identify the machines in the cluster that you want to be the master nodes and record their IP addresses or host names.
2. Deploy the analytics WAR file to the WebSphere Application Server cluster. Do not start the web application yet.
3. Set the JNDI property for masternodes to a comma-separated list of the nodes in the cluster that you want to be the host name. The following example shows possible values for the JNDI property:

```
<hostname>:<port>,<hostname>:<port>,<hostname>:<port>
```

```
192.168.1.32:9600,192.168.1.8:9600
```

```
clusterhost1:9600,clusterhost2:9600,clusterhost3:9600
```

Note: The *port* value is the transport port, which by default is 9600. You can change this port through the JNDI property. For more information, see “Ports that are used by the IBM MobileFirst Platform Operational Analytics” on page 14-75.

The following image shows the environment entries for web modules:

Web module	URI	Name	Type	Description	Value
analytics	worklight-analytics-service.war,WEB-INF/web.xml	analytics/serviceProxyURL	String	[OPTIONAL] Proxy URL for analytics REST services.	<input type="text"/>
analytics	worklight-analytics-service.war,WEB-INF/web.xml	analytics/nodetype	String	[OPTIONAL] Defines the node type. Valid values are "master" and "data". If this JNDI property is not set, then by default, the node will act as a master node and a data node.	<input type="text"/>
analytics	worklight-analytics-service.war,WEB-INF/web.xml	analytics/shards	String	[OPTIONAL] The number of shards that the cluster will create. This value can only be set by the first node in a cluster. Default: 5	<input type="text"/>
analytics	worklight-analytics-service.war,WEB-INF/web.xml	analytics/replicas_per_shard	String	[OPTIONAL] The number of replicas for each shard in the cluster. This value can only be set on the first node in a cluster. Default: 1	<input type="text"/>
analytics	worklight-analytics-service.war,WEB-INF/web.xml	analytics/masternodes	String	[OPTIONAL] A comma delimited string containing the hostname and ports of the master nodes (hostname:transport-port,hostname:transport-port)	9.122.123.134:9600
analytics	worklight-analytics-service.war,WEB-INF/web.xml	analytics/clustername	String	[OPTIONAL] Name of the cluster. It is only necessary to set this value if you plan to have multiple clusters and wish to uniquely identify them. Default: "worklight"	<input type="text"/>
analytics	worklight-analytics-service.war,WEB-INF/web.xml	analytics/nodename	String	[OPTIONAL] Name of a node in a cluster. A node joining a cluster will randomly generate a name to uniquely identify it. You can specify your own name using this property. Default: (randomly generated)	<input type="text"/>
analytics	worklight-analytics-service.war,WEB-INF/web.xml	analytics/datapath	String	[OPTIONAL] The path that analytics data is saved to on the file system.	<input type="text"/>

- Set the remaining JNDI properties. For more information about the JNDI properties, see "Properties and configurations" on page 14-95.
- Open the analytics console page on each cluster. When the console is accessed, each node in the cluster establishes a connection with each node listed in the masternodes list.

Results

You deployed the Analytics Platform in a clustered WebSphere Application Server environment.

Note: When you install analytics on WebSphere Application Server, a profile can contain multiple servers. Each server can have multiple analytics WAR files. By default, each of these WAR files points to the same directory to store analytics data. Normally, a JNDI property is used to change the location of the directory that is used to store analytics data. However, in this case, each server shares the same JNDI property. Because of this scenario, you must use WebSphere Application Server variables to define the location of the data directory when you set the JNDI property for the analytics data folder. The following example shows how you can set the JNDI property with the variables:

```
${USER_INSTALL_ROOT}/MFPAnalyticsDir/${WAS_SERVER_NAME}/AnalyticsData
```

Performance tuning

Learn about performance tuning for the IBM MobileFirst Platform Operational Analytics.

Java virtual machine (JVM) swapping

The underlying technology that is used by the IBM MobileFirst Platform Operational Analytics is called Elasticsearch. Elasticsearch performs poorly when the JVM starts swapping. To ensure that the JVM never swaps, the following JNDI property can be set to true:

```
<jndiEntry jndiName="analytics/bootstrap.mlockall" value="true" />
```

Setting the Field Cache Size

The underlying technology used by the analytics platform loads several field values into memory to provide fast access to those documents. This is known as the field cache. By default, the amount of data loaded into memory by the field cache is unbounded. If the field cache becomes too large, it can cause an out of memory exception and crash the analytics platform. You can put an upper limit on the field cache to prevent this from happening. The field cache can be set using the following JNDI property:

```
<jndiEntry jndiName="analytics/indices fielddata.cache.size" value="80%"/>  
<jndiEntry jndiName="analytics/indices fielddata.cache.size" value="10GB"/>
```

Note: The field cache can be set using a hardcoded value (such as 10GB) or it can be set to a percentage of the heap (such as 80%).

Placing an upper limit on the cache will prevent the field cache from causing an out of memory exception. However, when the limit is reached, the analytics platform will begin to take longer to perform search queries. At this point, you can either add additional memory to your machine or add an additional node to your cluster.

Properties and configurations

Learn about the properties and configurations that are used for configuring the MobileFirst Server and IBM MobileFirst Platform Operational Analytics.

MobileFirst properties

These properties can be set on the MobileFirst Server in the `worklight.properties` file. The server must be restarted for these properties to take effect.

Note: All properties in the `worklight.properties` file can also be set by using JNDI properties. For more information about JNDI properties, see “JNDI environment entries for MobileFirst projects in production” on page 12-68.

For more information about the IBM MobileFirst Platform Operational Analytics properties, see “Analytics” on page 12-59.

JNDI properties

JNDI environment properties can be set on the application server. For a clustered environment, some properties can be set only on the first node in the cluster. For more information, see “Setting up a production cluster” on page 14-90. The Analytics runtime web application must be restarted for any changes in these properties to take effect. It is not necessary to restart the entire application server.

All JNDI properties are namespaced with `analytics/`.

The following example shows how to set the datapath JNDI property in Liberty:
`<jndiEntry jndiName="analytics/datapath" value="/opt/IBM/analytics/data" />`

The following example shows how to set the datapath JNDI property in Tomcat:

```
<Environment name="analytics/datapath"
  value="/opt/IBM/analytics/data"
  type="java.lang.String"
  override="false" />
```

Note: For Tomcat, the JNDI property must include the `override="false"` attribute to work properly.

The following table shows the JNDI properties:

Table 14-21. JNDI properties for the IBM MobileFirst Platform Operational Analytics. This table lists the JNDI property names, default values, and descriptions for the IBM MobileFirst Platform Operational Analytics.

Property Name	Default Value	Description
nodetype	None.	Defines the node type. Valid values are master and data. If this JNDI property is not set, then the node acts as a master node and a data node by default.
shards	5	The number of shards per index that the cluster creates. This value can be set only by the first node in a cluster. This value can never be changed after the first node in the cluster starts.
replicas_per_shard	1	The number of replicas for each shard in the cluster. This value can be set only by the first node in a cluster.
masternodes	None.	A comma-delimited string that contains the host name and ports of the master nodes. For more information about this property, see "Setting up a production cluster" on page 14-90.
clustername	worklight	Name of the cluster. Set this value if you plan to have multiple clusters and want to uniquely identify them.
nodename	Randomly generated.	Name of a node in a cluster. A node that joins a cluster randomly generates a name to uniquely identify itself. You can specify your own name by using this property.

Table 14-21. JNDI properties for the IBM MobileFirst Platform Operational Analytics (continued). This table lists the JNDI property names, default values, and descriptions for the IBM MobileFirst Platform Operational Analytics.

Property Name	Default Value	Description
datapath	./analyticsData	The path that analytics data is saved to on the file system. By default, a folder that is named analyticsData is created.
settingspath	None.	Specifies the path to an extra settings file. For more information, see “Elasticsearch properties” on page 14-98.
transportport	9600	Port that is used for node-to-node communication. For more information, see “Ports that are used by the IBM MobileFirst Platform Operational Analytics” on page 14-75.
httpport	9500	Port that is used for HTTP communication to the IBM MobileFirst Platform Operational Analytics. For more information, see “Ports that are used by the IBM MobileFirst Platform Operational Analytics” on page 14-75.
http.enabled	false	Controls whether Elasticsearch can be queried directly by using the HTTP Port. If false, the port that is specified by the JNDI value httpport is not opened, and Elasticsearch is not accessible by using HTTP.
app_activities_ttl	None.	The TTL for automatic deletion of app activities data.
notification_activities_ttl	None.	The TTL for automatic deletion of notification activities data.
client_logs_ttl	None.	The TTL for automatic deletion of client logs data.
server_logs_ttl	None.	The TTL for automatic deletion of server logs data.

Table 14-21. JNDI properties for the IBM MobileFirst Platform Operational Analytics (continued). This table lists the JNDI property names, default values, and descriptions for the IBM MobileFirst Platform Operational Analytics.

Property Name	Default Value	Description
serviceProxyURL	None	This property enables the IBM MobileFirst Platform Operational Analytics console to locate the Analytics REST services. The value of this property must be specified as the external address and context root of the worklight-analytics-service.war web application.
bootstrap.mlockall	true	This property prevents any Elasticsearch memory from being swapped out.
index.mapper.dynamic	false	This property allows for the dynamic creation of mappings for unmapped types to be disabled.
multicast	false	Enables or disables multicast ping discovery.
warmupFrequencyInSeconds	600	This property runs background queries immediately on start in the specified interval to force data query results into memory, improving web console performance. Negative value disables running the background warmup.
tenant	worklight	Name of the main Elasticsearch index.

Elasticsearch properties

Elasticsearch is the underlying technology that is used by IBM MobileFirst Platform Operational Analytics. Elasticsearch provides several extra properties for performance tuning. The JNDI properties that are exposed and documented here are abstractions around the properties that are provided by Elasticsearch. Normally, these properties are set in a custom settings file.

If you are familiar with Elasticsearch and the format of its properties files, you can specify the path to the settings file by using the `settingspath` JNDI property:

```
<jndiEntry jndiName="analytics/settingspath"
  value="/home/system/elasticsearch.yml" />
```

All properties that are provided by Elasticsearch can also be set by using a JNDI property with the `analytics/` string added before the property name. For example, `threadpool.search.queue_size` is a property that is provided by Elasticsearch that is used for performance tuning. This property can be set by using a JNDI property as follows:

```
<jndiEntry jndiName="analytics/threadpool.search.queue_size" value="100" />
```

Analytics Console properties

For more information about the settings that can be set in the **Update Settings** page of the Analytics Console, including TTL settings, see “Update Settings” on page 14-22 and “Data purging” on page 14-24.

Backing up Operational Analytics data

Learn about how to back up your MobileFirst Operational Analytics data.

The data for MobileFirst Operational Analytics is stored as a set of files on the MobileFirst Operational Analytics Server file system. The location of this folder is specified by the datapath JNDI property in the MobileFirst Operational Analytics Server configuration. For more information about the JNDI properties, see “Properties and configurations” on page 14-95.

The MobileFirst Operational Analytics Server configuration is also stored on the file system, and is called `server.xml`.

You can back up these files by using any existing server backup procedures that you might already have in place. No special procedure must be used when you back up these files, other than ensuring that the MobileFirst Operational Analytics Server is stopped. Otherwise, the data might change while the backup is occurring, and the data that is stored in memory might not yet be written to the file system. To avoid inconsistent data, stop the MobileFirst Operational Analytics Server before you start your backup.

(deprecated) Reports database

IBM MobileFirst Platform Foundation provides an extensible mechanism for enterprises to use to integrate reporting tools with IBM MobileFirst Platform Foundation.

Note: The Reports database and the sample BIRT Reports were deprecated in IBM MobileFirst Platform Foundation V7.0.0. Use “Operational analytics” on page 14-9 instead.

IBM MobileFirst Platform Foundation provides raw data reports and a number of device reports that are aggregated from the raw data report table. IBM MobileFirst Platform Foundation also comes bundled with a third-party Business Intelligence Report Tools (BIRT) feature, which provides a range of predefined report templates. To understand the similarities and differences between the existing reports feature and the new operational analytics feature, see “Comparison of operational analytics and reports features” on page 14-102.

Note: Enabling the BIRT feature is redundant if you already use the IBM MobileFirst Platform Operational Analytics.

IBM MobileFirst Platform Foundation provides three reporting mechanisms:

Raw data feeds

IBM MobileFirst Platform Foundation emits raw data, which enables an OLAP system to extract the required information and present it through corporate reporting mechanisms. For more information, see “Using raw data reports” on page 14-103.

Device usage reports

IBM MobileFirst Platform Foundation provides reports about device usage. Device usage reports are default aggregations that are based on raw data, and are provided for the benefit of organizations that do not have OLAP systems or choose not to integrate IBM MobileFirst Platform Foundation with an OLAP system. For more information, see “Device usage reports” on page 14-107.

Note: Device usage reports are functional only in IBM MobileFirst Platform Foundation Customer Edition and IBM MobileFirst Platform Foundation Enterprise Edition.

BIRT reports

IBM MobileFirst Platform Foundation comes bundled with predefined BIRT report to use either as they are or as templates to modify. For more information, see “Predefined BIRT Reports” on page 14-110.

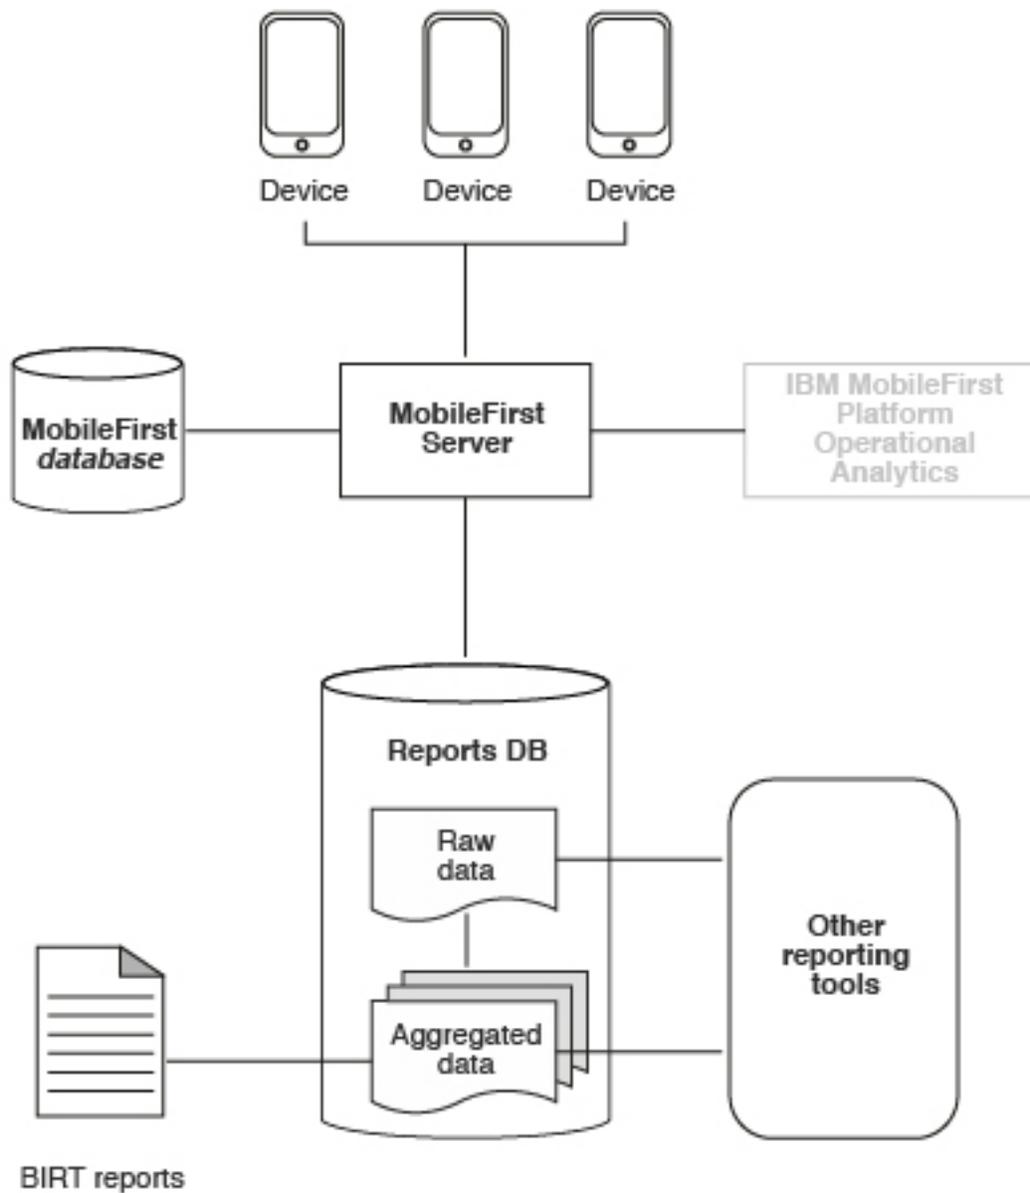

Figure 14-27. High-level overview of the reports architecture

The reports architecture diagram shows how the raw data feed comes from three devices into the MobileFirst Server and then into the IBM MobileFirst Platform Foundation database, the Reports database, or both. From the Reports database, data then becomes aggregated data and is filtered out into the BIRT reports or to other reporting tools.

Important: When you work with report generation, you must update the `.rptdesign` file with your reports database user name and password, which are considered sensitive information. You are responsible for protecting it against unauthorized access.

Comparison of operational analytics and reports features

Compare the reports and operational analytics features to know why and how to best use each.

Note: The Reports database and the sample BIRT Reports were deprecated in IBM MobileFirst Platform Foundation V7.0.0. Use “Operational analytics” on page 14-9 instead.

With the introduction of the IBM MobileFirst Platform Operational Analytics, enabling the BIRT feature is redundant. A comparison of the capabilities of these two features can help clarify the strengths of each, and help determine how you can best use them.

The data that is collected by the “(deprecated) Reports database” on page 14-99 feature is a subset of the total data that is collected as part of the “Operational analytics” on page 14-9 feature. You can use the reports database and the operational analytics feature simultaneously, but usage of both in a production environment is redundant. Use the reports feature in cases where you want direct access to the Reports database to run custom queries. An example of a scenario where direct database access is needed is the use of BIRT or a customized online analytics processing (OLAP) system that runs database queries directly against the Reports database.

Table 14-22. Comparison of analytics and reports features. This table lists a comparison of analytics and reports features.

	Operational analytics feature	Reports feature
Primary usage	Problem determination, device usage summary, geographic view of mobile activity	Device usage summary
Typical user	Administrator, operational support personnel, developer, analyst	Administrator, analyst
Data used in analytics	App crash from clients, MobileFirst Server log, MobileFirst app to server interaction activities	MobileFirst app to server interaction activities
Data storage mechanism	Files on the IBM MobileFirst Platform Operational Analytics	Relational database
Analytics mechanism	Each log event is treated as a JSON document. The data in the document is indexed so that it can be searched by keyword in the document and presented in a canonical form that shows the app, version, some device data, location (if enabled), time stamp, adapter (if present in the document) and other data.	Each log event is treated as a row in the raw Reports database table and then aggregated for statistics into the app_activities database table, summarized to app, device operating system, and time stamp relationships.

Table 14-22. Comparison of analytics and reports features (continued). This table lists a comparison of analytics and reports features.

	Operational analytics feature	Reports feature
Access mechanism	MobileFirst Operations Console	BIRT or other reporting tools that can understand data cubes
Extendable	Extending the published reports is not supported.	Data can be extracted from the database tables by using any means that you desire, including but not limited to, BIRT.
Search across logs	Yes	No
Optional	Yes	Yes

In addition to an at-a-glance view of your mobile and web application analytics, the operational analytics includes the capability to perform raw search against server logs, client activities, captured client crash data. The operational analytics feature can also search any additional data that you explicitly provide through client and server-side API function calls that feed into the IBM MobileFirst Platform Operational Analytics.

Using raw data reports

You can use the raw data reports feature to extract raw data to different databases and view it in the form of reporting tables.

About this task

Note: The Reports database and the sample BIRT Reports were deprecated in IBM MobileFirst Platform Foundation V7.0.0. Use “Operational analytics” on page 14-9 instead.

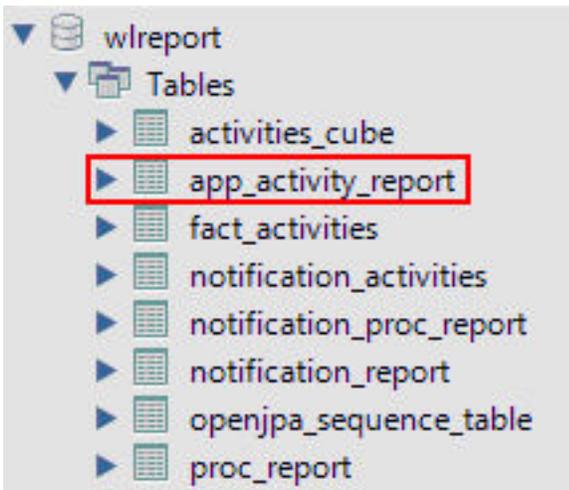

Raw data reports provide you with analytics information about your applications and adapter usage, such as activity type, device information, and application version. Use the following steps to enable the raw data reports feature:

Procedure

1. Ensure that the IBM MobileFirst Platform Server application server is not running.
2. Create a separate database or a new schema for reports. This action is not mandatory but is useful because the raw data table is rapidly populated. For information about creating databases in a development environment, see “Runtime database setup for development mode” on page 12-52. For information about creating databases and schemas in a production environment, see “Creating and configuring the databases manually” on page 12-20.
3. When you work in a development environment, complete the following steps.
 - a. Edit the `worklight.properties` file. Uncomment the `reports.exportRawData` property and set its value to `true`.
 - b. Modify the `wl.reports.db` properties to contain your database settings as shown in the following example.

```
#####
# Raw reports
#####
reports.exportRawData=true
# jndi name; empty value means Apache DBCP data source
#wl.reports.db.jndi.name=${wl.db.jndi.name}
# Default values for DBCP connection pool
#wl.reports.db.initialSize=${wl.db.initialSize}
#wl.reports.db.maxActive=${wl.db.maxActive}
#wl.reports.db.maxIdle=${wl.db.maxIdle}
#wl.reports.db.testOnBorrow=${wl.db.testOnBorrow}
wl.reports.db.url=jdbc:mysql://localhost:3306/wlreport
wl.reports.db.username=worklight
wl.reports.db.password=worklight
```

- c. Ensure that the **wl.reports.db.url** property contains the URL of the database you are planning to use for raw data.
4. When you work in a production environment, connect to the reports database by using JNDI environment entries in addition to editing the `worklight.properties` file, as described in the previous step. See “Configuring a MobileFirst project in production by using JNDI environment entries” on page 12-66.
5. Restart your application server.
The `app_activity_report` table of the raw data database is populated with data as you use your applications and adapters.

The raw data `app_activity_report` table contains the following information:

Column	Description
ACTIVITY_TIMESTAMP	UTC time of entry
GADGET_NAME	MobileFirst Application name
GADGET_VERSION	Application version
ACTIVITY	Activity type
ENVIRONMENT	Application environment name (Android, and so on)
SOURCE	User identifier
ADAPTER	MobileFirst adapter name
PROC	MobileFirst adapter procedure name

Column	Description
USERAGENT	User agent from HTTP header of client device
SESSION_ID	A unique identifier for the user's session on the server
IP_ADDRESS	IP address of the client
DEVICE_ID	A unique device ID
DEVICE_MODEL	Manufacturer model, for example Galaxy I9000
DEVICE_OS	Device operating system version
LONGITUDE	The longitude of the device. Requires that ongoing acquisition is enabled for Geo.
LATITUDE	The latitude of the device. Requires that ongoing acquisition is enabled for Geo.
POS_USER_TIME	The local time on the device when the latest position information (longitude and latitude) were updated. Requires that ongoing acquisition is enabled for Geo.
WIFI_APS	The access points visible on the device. Requires that ongoing acquisition is enabled for WiFi.
WIFI_CONNECTED_SSID	The SSID (network identification) of the connected WiFi access point. Requires that ongoing acquisition is enabled for WiFi.
WIFI_CONNECTED_MAC	The MAC address of the connected WiFi access point. Requires that ongoing acquisition is enabled for WiFi.
WIFI_USER_TIME	The local time on the device when the latest WiFi information was updated. Requires that ongoing acquisition is enabled for WiFi.
APP_CONTEXT	The application context, as set by <code>WL.Server.setApplicationContext</code> .

The following activities can be included in reports:

Activity	Description
Init	Application initialization
Login	Successful authentication in using the application
Adoption New	Not supported in IBM Worklight V5.0
Adoption	Not supported in IBM Worklight V5.0
Query	Procedure call to an adapter
Logout	User logout
Event	An event handler was called

In addition to predefined activity types, custom activities can be logged by using `WL.Client.logActivity("custom-string")` APIs.

When the activity is Event, the reporting information comes from the event device context instead of `WL.Server.getClientDeviceContext`. Also, when the activity is Event the **PROC** column gives the name of the event handler function that was called.

Important: MobileFirst raw data feed can increase rapidly. The data is typically used by a BI system such as Cognos® or Business Objects. It is the administrator's responsibility to purge built-in tables periodically. For example, the following commands delete Oracle database rows that are more than 30 days old from the `activities_cube` and `app_activity_report` tables. For other databases such as MySQL, modify the syntax appropriately.

To delete rows from `activities_cube` that are more than 30 days old (assuming `ACTIVITY_DATE` is a `DATE` type field):

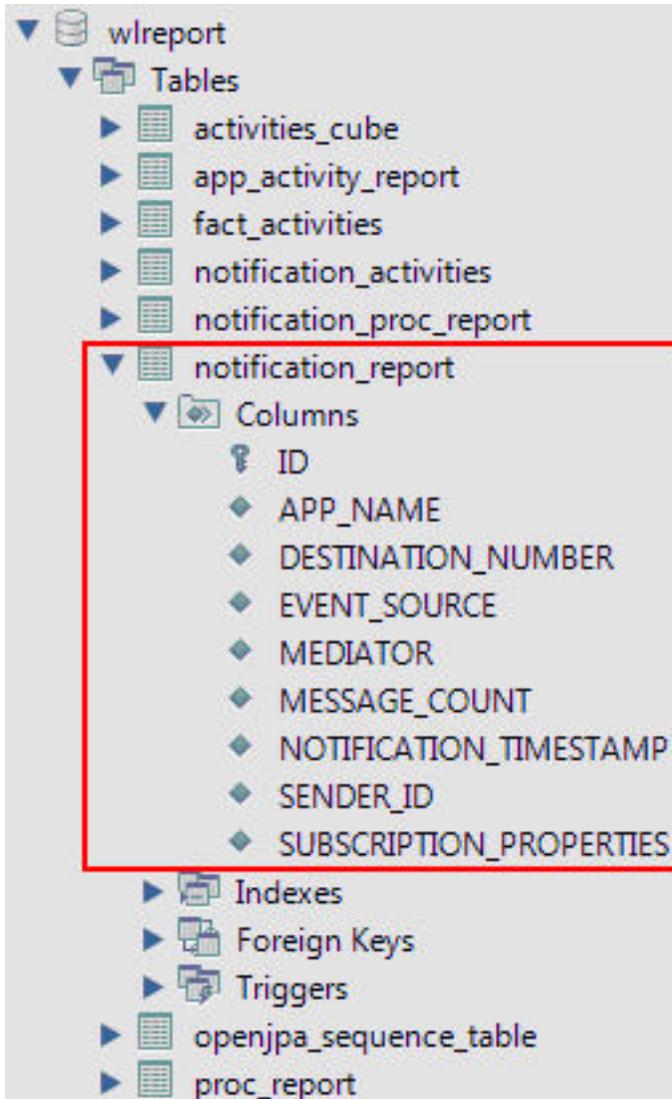

```
DELETE FROM ACTIVITIES_CUBE WHERE ACTIVITY_DATE <= TRUNC(SYSDATE) - 30
```

To delete rows from `app_activity_report` that are more than 30 days old (assuming `ACTIVITY_TIMESTAMP` is a `TIMESTAMP` type field):

```
DELETE FROM APP_ACTIVITY_REPORT WHERE ACTIVITY_TIMESTAMP <= TO_TIMESTAMP(TRUNC(SYSDATE) - 30)
```

Purging data by deleting rows might fail on heavily loaded systems. An alternative approach is to use database table partitions to facilitate the purging of accumulated data. For more information, see “Optimization of MobileFirst Server project databases” on page 6-153.

In addition to the `app_activity_report` table, the raw data engine also populates the `notification_report` table. This raw data table contains information about notifications that are sent from SMS event sources.

Device usage reports

For simpler and faster access to the reports data, IBM MobileFirst Platform Server runs an analytics data processor task at a default time interval of every 24 hours.

Note: The Reports database and the associated APP_ACTIVITY_REPORT table described below are deprecated in IBM MobileFirst Platform Foundation V7.1.0. Use “Operational analytics” on page 14-9 instead. Note that setting up the Reports database is optional in this release and earlier releases.

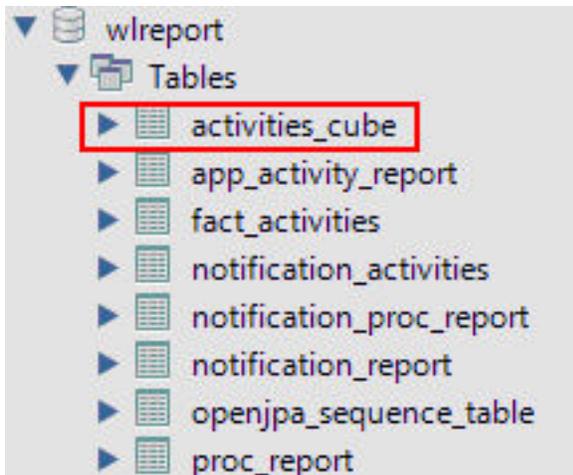

The analytics data processor task retrieves raw entries for the specified time interval from the app_activity_report table and processes them to populate the fact_activities table.

Note: The fact_activities table is only populated with usage data from hybrid and native applications from actual devices. Usage data from MobileFirst mobile web applications that are running on actual devices or from a browser, such as

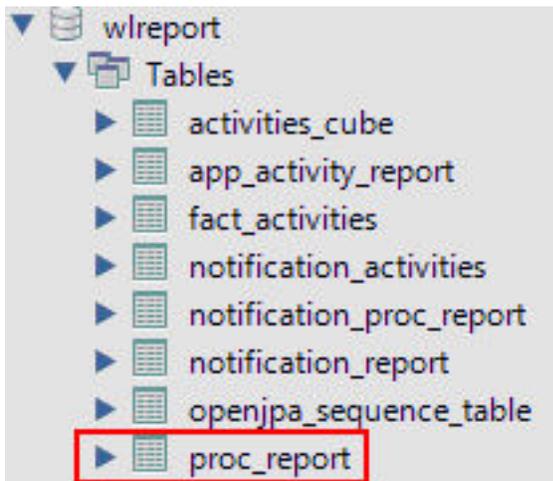

when you are using preview, is not populated into this table.

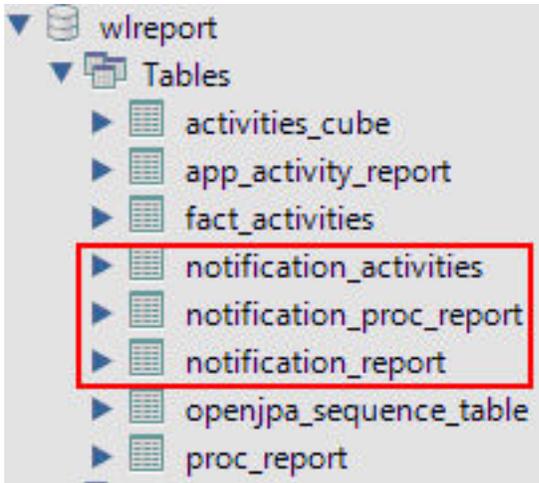

The fact_activities table contains a total activity count (number of logged actions) per application, application version, device, and environment. The fact_activities data is also processed and put into the activities_cube table. This table has the same structure as the fact_activities table and only contains records for the last 30 days.

Each time the data processing is done, a time stamp is added to a `proc_report` table with the processing result (time stamp and number of processed entries).

In addition, `notification_report` table data is also processed to populate the `notification_activities` table with consolidated data. The table is populated in the same way as the `fact_activities` table. Every time the `notification_report` table data is processed, an entry is added to the `notification_proc_report` table, which is similar to the `proc_report` table.

The processing interval can be modified by adding the following property to your `worklight.properties` file and setting the required interval in seconds.

```
# Default interval value for analytics processing task  
wl.db.factProcessingInterval=86400
```

The processing interval can also be disabled by setting this property to a negative value.

```
# Set to a negative value to disable the analytics processing task  
wl.db.factProcessingInterval=-1
```

Predefined BIRT Reports

You can use predefined BIRT reports to generate and display information about mobile devices and usage.

Note: The predefined BIRT reports and the Reports database and associated tables such as `APP_ACTIVITY_REPORT` are deprecated in IBM MobileFirst Platform Foundation V7.1.0. Use “Operational analytics” on page 14-9 instead. Note that setting up the Reports database is optional in this release and earlier releases.

IBM MobileFirst Platform Foundation generates raw reports, which are stored in an `app_activity_report` table. IBM MobileFirst Platform Foundation also includes device usage reports, which are aggregations of data from the `app_activity_report`, and are described in “Device usage reports” on page 14-107 and “Using raw data reports” on page 14-103. Users can view or extract data from the `app_activity_report` table or from the device usage reports, and process it using their own business intelligence systems.

For users with no existing business intelligence analysis system, IBM MobileFirst Platform Foundation provides a selection of predefined Business Intelligence Reporting Tool (BIRT) reports. BIRT is a third-party tool, and is not created or supported by IBM. IBM MobileFirst Platform Foundation provides several `*.rptdesign` files that contain logic to connect to the reports database, pull data from device usage tables, process, and display the data.

The IBM MobileFirst Platform Foundation editions containing MobileFirst Server include the following predefined BIRT reports:

Table 14-23. Predefined BIRT reports

Report Name	Description	Report file name
Active Users	Active users in last 30 days.	report_active_users.rptdesign
Daily Hits	The daily aggregated hits for last 30 days. Any action from the user/device that caused a request to the server is counted as a hit. This number, aggregated over a day, equals the daily hits.	report_daily_hits.rptdesign
Daily Visits	The number of discreet visits by separate user/device in last 30 days. All actions by a user/device that caused one or more requests to the server within a day is counted as a visit.	report_daily_visits.rptdesign
Environment Usage	Application version and application environment used: number of visits that were recorded in the last 30 days.	report_environment_usage.rptdesign
New Devices	A record of unique devices that were connected in the last 30 days.	report_new_devices.rptdesign
Notification Messages Per Day	Number of messages sent each day in the past 90 days per data source.	report_notification_messages_per_day.rptdesign
Notification Messages Per Source	Total number of messages that were sent in the last 90 days per data source.	report_notification_messages_per_source.rptdesign
License Total New Device Count	A record of unique devices that were connected over a specified period (90 days as default), for licensing purposes.	report_license_total_device_count.rptdesign

Total number of new devices detected in the last 90 days

New Device Count: 23

Device Details

Figure 14-28. An example of a report generated by BIRT, in this case report_license_total_device_count.rptdesign

There are several ways of viewing predefined reports, by using one of the following options.

- The Eclipse report designer plug-in. For instructions, see “BIRT in Eclipse” on page 14-119
- The BIRT Viewer application that is installed on your Tomcat, WebSphere Full Profile or WebSphere Liberty Profile application server.

Installing BIRT on Apache Tomcat

You can use the Business Intelligence Reporting Tool (BIRT) to generate and render report content. You can view this content either by using an Eclipse plug-in, or an application server and browser.

About this task

Note: The predefined BIRT reports and the Reports database and associated tables such as APP_ACTIVITY_REPORT are deprecated in IBM MobileFirst Platform Foundation V7.1.0. Use “Operational analytics” on page 14-9 instead. Note that setting up the Reports database is optional in this release and earlier releases.

The MobileFirst installation contains a number of predefined BIRT reports. These reports are configurable XML files that are designed to retrieve and present data from the MobileFirst reports database tables. These files have an .rptdesign extension.

Complete the following steps to set up the BIRT Reports for viewing in an Apache Tomcat application server. For information about how to set up the BIRT Reports on other application servers, refer to the BIRT Reports website at Birt Tools.

Procedure

1. Ensure that your Tomcat instance is not running.
2. Download the BIRT Reports runtime archive from Birt Report Downloads.

3. Extract the BIRT Reports runtime archive.
4. Copy the WebViewerExample folder to the webapps folder of your Tomcat server.
5. Rename the WebViewerExample folder to birt (this step is an option, and is just to simplify later execution).
6. Copy your database jdbc connector JAR file package to the Tomcat \lib folder (if you are using the same Tomcat instance that is running IBM MobileFirst Platform Server the jdbc connector package is already in the \lib folder).
7. In some cases, Tomcat might not have enough memory allocated to run BIRT Reports. To resolve this problem, edit the catalina.bat file under your Tomcat \bin folder and add the following line at the start of it. You might want to consult with your IT manager about exact settings.

```
set CATALINA_OPTS=-Xms512m -Xmx512m -XX:MaxPermSize=256m
```

8. Restart your Tomcat.
9. Go to the Tomcat manager application at <http://your-server/manager/> to verify that the BIRT Reports application started.

Applications					
Path	Version	Display Name	Running	Sessions	Commands
/birt	None specified	Eclipse BIRT Report Viewer	true	0	Start <input type="button" value="Stop"/> <input type="button" value="Reload"/> <input type="button" value="Undeploy"/> <input type="button" value="Expire sessions"/> with idle ≥ <input type="text" value="30"/> minutes

10. Your BIRT Reports viewer application is accessible at <http://your-server/birt/>.
11. You can test the BIRT Reports installation by going to http://your-server/birt/frameset?__report=test.rptdesign&sample=my+parameter.

Installing BIRT on WebSphere Application Server Liberty profile

Complete these steps to install Business Intelligence Reporting Tools on the WebSphere Application Server Liberty profile.

About this task

Note: The predefined BIRT reports and the Reports database and associated tables such as APP_ACTIVITY_REPORT are deprecated in IBM MobileFirst Platform

Foundation V7.1.0. Use “Operational analytics” on page 14-9 instead. Note that setting up the Reports database is optional in this release and earlier releases.

Procedure

1. Verify that your WebSphere Application Server Liberty profile instance is not running.
2. Go to your WebSphere Application Server Liberty profile folder and create two folders as follows:
 - apps
 - libs
3. Locate the jdbc connector driver that you are using and copy it to the libs folder.
4. Download the latest release of BIRT run time from <http://download.eclipse.org/birt/downloads/>
5. Extract the downloaded file and go to the extracted folder.
6. Rename WebViewerExample folder to birt.
7. Go to the folder `birt\WEB-INF\lib` and delete the following files.
 - `org.apache.xerces*.jar`
 - `org.apache.xml.resolver*.jar`
 - `org.apache.xml.serializer*.jar`

Set up the BIRT Viewer application on a Liberty instance by following these steps.

8. Copy the birt folder to `{your-liberty-instance}\usr\servers\{your-server-name}\apps\`
9. Update the `server.xml` file of your Liberty server profile.
10. Make sure that the JSP feature is enabled.
11. Add an application definition.
12. Add classloader definition with a `privateLibrary` definition that is configured to point to your JDBC connector driver.

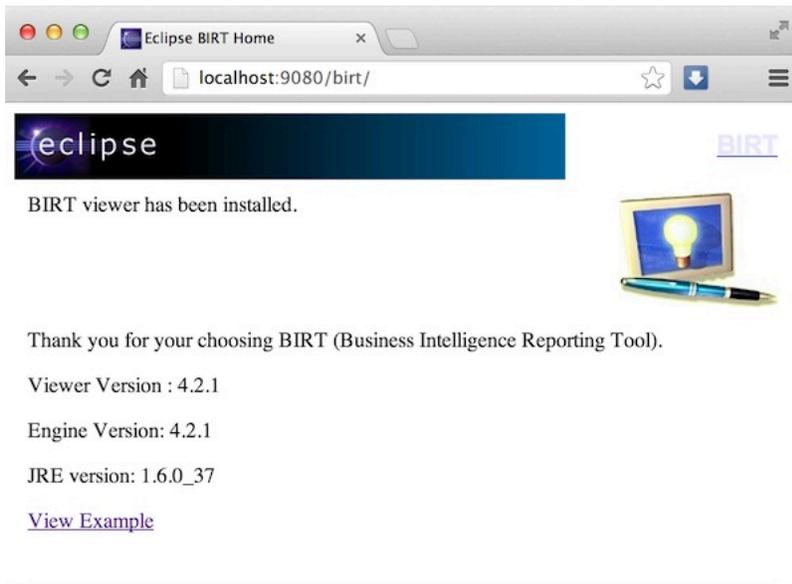

```
<server description="new server">
  <featureManager>
    <feature>jsp-2.2</feature>
  </featureManager>

  <httpEndpoint id="defaultHttpEndpoint"
    host="*"
    httpPort="9080"
    httpsPort="9443" />

  <application id="birt"
    name="birt"
    type="war"
    location="{server.config.dir}/apps/birt"
    context-root="/birt">
    <classloader delegation="parentLast">
      <privateLibrary>
        <fileset dir="{server.config.dir}/libs"
          includes="mysql-connector*.jar" />
      </privateLibrary>
    </classloader>
  </application>
</server>
```

13. Start your Liberty instance.

14. Browse to `http://server:port/birt`. The BIRT Viewer landing page opens.

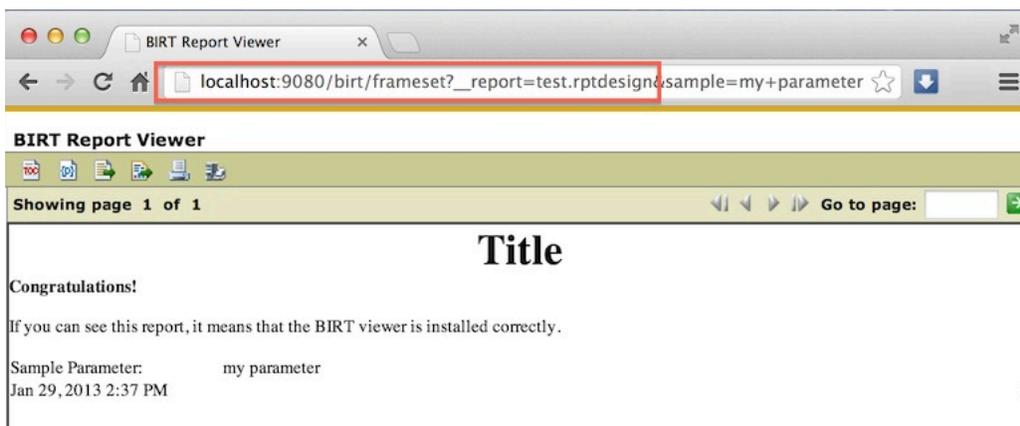

15. Click **View Example** link.

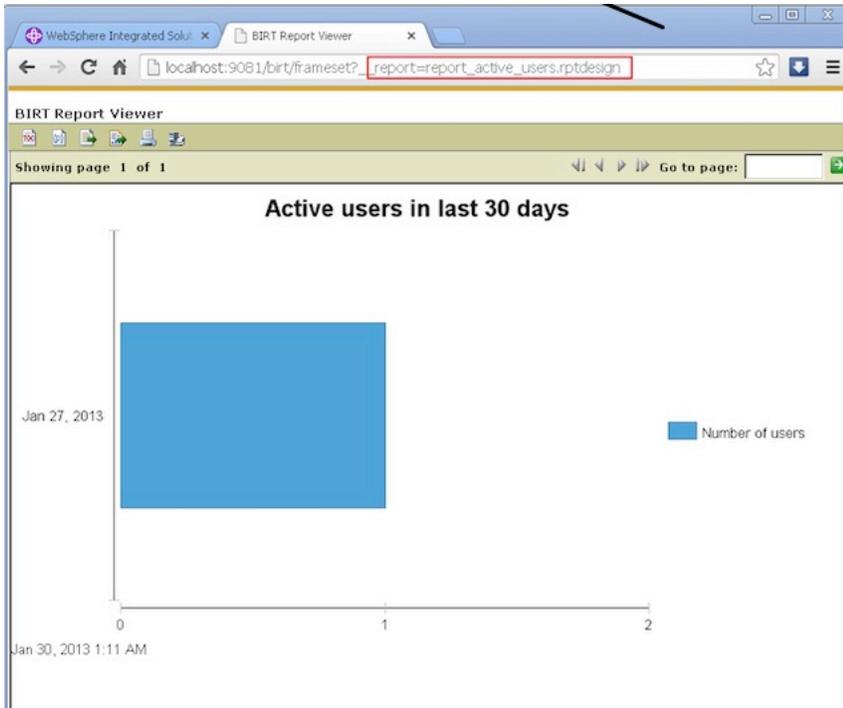

16. If you see the following error message, refresh your page.

17. The BIRT Viewer sample report appears.

Note `test.rptdesign` in the page URL. You can replace this text with the name of other **rptdesign** files, as shown here for example:

Installing BIRT on WebSphere Application Server full profile

Complete these steps to install Business Intelligence Reporting Tools (BIRT) on WebSphere Application Server full profile.

About this task

Note: The predefined BIRT reports and the Reports database and associated tables such as APP_ACTIVITY_REPORT are deprecated in IBM MobileFirst Platform Foundation V7.1.0. Use “Operational analytics” on page 14-9 instead. Note that setting up the Reports database is optional in this release and earlier releases.

Procedure

1. Download the BIRT package and extract the contents.
2. From the folder `birt-runtime-version\WebViewerExample\WEB-INF\lib`, delete (or remove) the following packages:
 - `org.apache.xerces.jar`
 - `org.apache.resolver.jar`
 - `org.apache.serializer.jar`

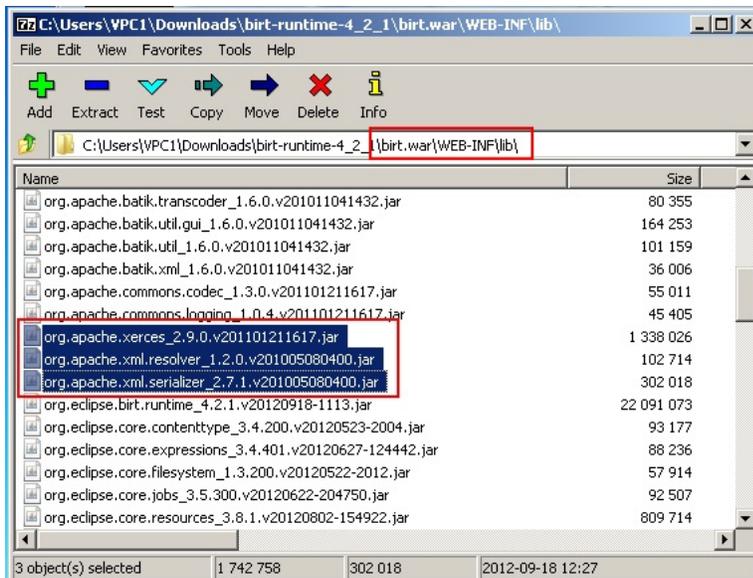

Figure 14-29. Deleting three files

3. Use a `.war` command to package the directory `WebViewerExample` into a WAR file named `birt.war`
4. Start the WebSphere Server.
5. Open the console web page.
6. Log in.
7. From the console, install BIRT package by installing `birt.war` from the runtime download.
8. Click **Enterprise Applications**.
9. Click the name of the deployed application, `birt_war`, to enter the configuration page.
10. Under the heading **Modules**, click **Manage Modules**.
11. In the Module list, click **Eclipse BIRT Report Viewer**.
12. In the **General Properties** page, under **Class loader order**, select the **Classes loaded with parent class loader first** option.
13. Click **OK**.
14. Save the Master Configuration.

Configuring BIRT reports for your application server by using Ant

You can update your BIRT reports with your web application server settings by using Ant.

About this task

Note: The predefined BIRT reports and the Reports database and associated tables such as `APP_ACTIVITY_REPORT` are deprecated in IBM MobileFirst Platform Foundation V7.1.0. Use “Operational analytics” on page 14-9 instead. Note that setting up the Reports database is optional in this release and earlier releases.

To use BIRT reports, you must update them with your web application server settings and install them in your server web applications folder. The easiest way to

do this is to specify a <reports> element in the Ant script that invokes the <configureapplicationserver> Ant task.

Procedure

1. Ensure that the <configureapplicationserver> invocation has the inner element <reports todir="web applications directory"/>. See “Ant tasks for installation of MobileFirst runtime environments” on page 16-42 for more details.
2. Invoke the Ant script, which copies the report templates from the WorklightServer/report-templates/ directory to the web applications directory, adjusting the <data-sources> element as needed.
3. Verify that the BIRT Viewer application is installed and running on your application server.
4. To view or edit a BIRT Report, go to the path `http://your-server/birt/frameset?__report=[report name].rptdesign.`, in which [report name].rptdesign represents one of the following files:
 - report_active_users.rptdesign
 - report_daily_hits.rptdesign
 - report_daily_visits.rptdesign
 - report_environment_usage.rptdesign
 - report_license_total_device_count.rptdesign
 - report_new_devices.rptdesign
 - report_notification_messages_per_day.rptdesign
 - report_notification_messages_per_source.rptdesign

Manually configuring BIRT Reports for your application server

To use BIRT reports, you must update them with your web application server settings.

About this task

Note: The predefined BIRT reports and the Reports database and associated tables such as APP_ACTIVITY_REPORT are deprecated in IBM MobileFirst Platform Foundation V7.1.0. Use “Operational analytics” on page 14-9 instead. Note that setting up the Reports database is optional in this release and earlier releases.

Before using the BIRT Viewer application to see predefined reports, you must edit them to adjust the reports database settings, and then copy the reports to a specific folder on the application server.

Procedure

1. Go to your IBM MobileFirst Platform Server installation folder created by the IBM Installation Manager.
2. Locate the \report-templates\ folder, which contains a set of .rptdesign files.
3. Copy all of the files with the .rptdesign extension from the \report-templates\ folder to your server web applications folder.
4. Edit each .rptdesign file as needed and adjust the <data-sources> element with the properties of your reports database.

```
<data-sources>
  <oda-data-source extensionID="org.eclipse.birt.report.data.oda.jdbc" ...>
    <list-property name="privateDriverProperties">
      <ex-property>
        <name>metadataBidiFormatStr</name>
        <value>ILYNN</value>
      </ex-property>
    </list-property>
  </oda-data-source>
</data-sources>
```

```

    <ex-property>
      <name>disabledMetadataBidiFormatStr</name>
    </ex-property>
    <ex-property>
      <name>contentBidiFormatStr</name>
      <value>ILYN</value>
    </ex-property>
    <ex-prperty>
      <name>disabledContentBidiFormatStr</name>
    </ex-property>
  </list-property>
  <property name="odaDriverClass">WLREPORT_DRIVER_CLASS</property>
  <property name="odaURL">WLREPORT_JDBC_URI</property>
  <property name="odaUser">WLREPORT_DBUSER</property>
  <encrypted-property name="odaPassword" encryptionID="base64">
    WLREPORT_DBPASSWORD_BASE64
  </encrypted-property>
</oda-data-source>
</data-sources>

```

5. Make sure that BIRT Viewer application is installed and running on your application server
6. To view or edit a BIRT Report, go to the path `http://your-server/birt/frameset?__report=[report name].rptdesign.`, where [report name].rptdesign represents one of the following files:
 - report_active_users.rptdesign
 - report_daily_hits.rptdesign
 - report_daily_visits.rptdesign
 - report_environment_usage.rptdesign
 - report_license_total_device_count.rptdesign
 - report_new_devices.rptdesign
 - report_notification_messages_per_day.rptdesign
 - report_notification_messages_per_source.rptdesign

BIRT in Eclipse

When BIRT is installed in Eclipse, it displays reports through the Eclipse interface.

Note: The predefined BIRT reports and the Reports database and associated tables such as APP_ACTIVITY_REPORT are deprecated in IBM MobileFirst Platform Foundation V7.1.0. Use “Operational analytics” on page 14-9 instead. Note that setting up the Reports database is optional in this release and earlier releases.

You can install Business Intelligence Reporting Tools (BIRT) as either a stand-alone instance of Eclipse, or as a plug-in added to your existing IBM MobileFirst Platform Foundation Eclipse instance, or any other instance of Eclipse. Each of these choices has potential advantages, depending on your needs.

Installing a stand-alone Eclipse instance means having a dedicated tool for creating reports. This option involves downloading an Eclipse installer that comes with BIRT included.

Installing BIRT as a plug-in to your existing Eclipse instance that is running IBM MobileFirst Platform Foundation can provide you with a more integrated interface, for both IBM MobileFirst Platform Foundation and reports. Use the following links to select the option you want to install.

Installing BIRT in stand-alone Eclipse

You can install BIRT including the BIRT Report Designer in a stand-alone instance of Eclipse as a dedicated reporting tool.

About this task

To use the BIRT Report Designer in a stand-alone, dedicated instance of Eclipse, follow these steps:

Procedure

1. In your web browser, go to <http://www.eclipse.org/downloads/>
2. Download the **Eclipse IDE for Java and Report Developers**
3. Follow the Eclipse installation instructions in the installation package. Eclipse and the BIRT components, including the Report Designer, are installed along with Eclipse.

Installing BIRT in MobileFirst Eclipse

You can install BIRT in the instance of Eclipse on which IBM MobileFirst Platform Foundation is running, and use the Report Designer as an integrated tool.

About this task

To install BIRT in the existing instance of Eclipse that is running IBM MobileFirst Platform Foundation, follow these steps:

Procedure

1. Click **Help > Install new software**
2. In **Work with...**, select http://download.eclipse.com/release/Eclipse_instance
3. Select Business Intelligence Reporting and Charting
4. Click **Next** and follow the installation instructions. When the installation is completed, you must install the reports.
5. Click **Window > Open perspective > Other...**
6. Select the **Report Design** perspective
7. Click **File > New > Project**
8. Select **Report project** and click **Next**
9. Enter a project name and click **Finish**
10. Using the import command, go to your MobileFirst Server installation folder created by IBM Installation Manager.
11. Locate the `\report-templates\` folder, which contains a set of `.rptdesign` files.
12. Import all files with the suffix `.rptdesign` from the `\report-templates\` folder into the Eclipse project. Eclipse comes with a bundled driver for Apache Derby database. If you use another database type, you must add a JDBC connector driver manually.
13. Click **Manage Drivers...**
14. Click **Add...** and add the JDBC connector driver package to communicate with your MobileFirst reports database
15. Select **Driver Class** and adjust the rest of your database settings
16. Click **Test Connection...** to validate that database settings are correct.

Viewing BIRT reports in Eclipse

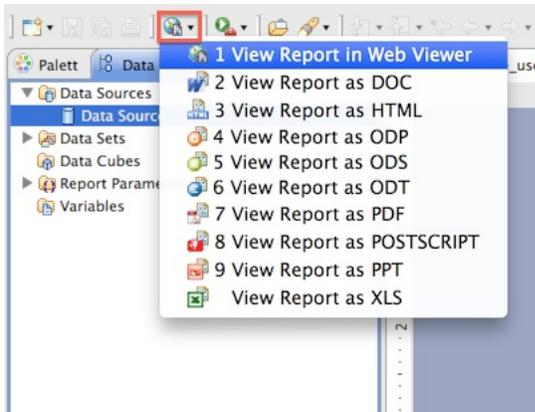

With BIRT installed in Eclipse, you can view reports through the Eclipse interface.

About this task

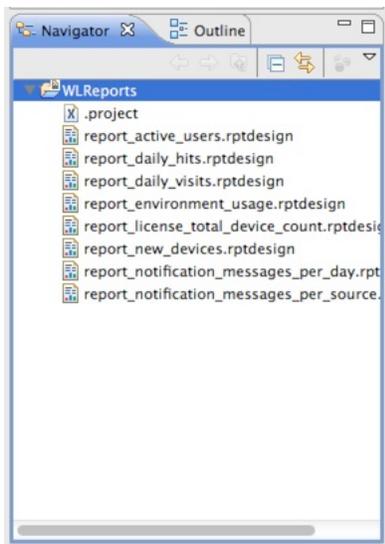

To view BIRT reports in Eclipse, follow these steps:

Procedure

1. Click the black arrow next to **View Report**.

2. Select the output format for your report
3. View the report.

Notification reports database schema

IBM MobileFirst Platform Foundation uses a database schema to store the notification reports data derived from the raw data.

Note: The predefined BIRT reports and the Reports database and associated tables such as NOTIFICATION_ACTIVITIES are deprecated in IBM MobileFirst Platform Foundation V7.1.0. Use “Operational analytics” on page 14-9 instead. Note that setting up the Reports database is optional in this release and earlier releases.

NOTIFICATION_ACTIVITIES	
SID varchar(255)	
NOTIFICATION_DATE	date
EVENT_SOURCE	varchar(255)
MEDIATOR	varchar(255)
TOTAL_NOTIFICATIONS	int(11)

Figure 14-30. NOTIFICATION_ACTIVITIES schema

A notification activities table is populated to simplify the use of report construction. This notification activities table, **NOTIFICATION_ACTIVITIES**, is populated as part of the analytics setup.

Manually creating and configuring the reports database

You can manually create and configure the reports databases.

The reports database WLREPORT is deprecated since IBM MobileFirst Platform Foundation V7.0.0. Use “Operational analytics” on page 14-9 instead.

If needed, you can still manually configure your reports database. See the topics in the section Creating and configuring the databases manually, and substitute the parameters and instructions for the runtime database with the instructions in the following topics, which are specific to the reports database.

Manually configuring the DB2 reports database

You can manually set up the reports database for DB2, and configure it according to your application server.

About this task

Set up your DB2 reports database and configure your application server. Depending on your application server, follow the steps for WebSphere Application Server Liberty profile, WebSphere Application Server full profile, or Apache Tomcat.

Procedure

- Set up your DB2 reports database manually.

```
CREATE DATABASE WLREPORT COLLATE USING SYSTEM PAGESIZE 32768
CONNECT TO WLREPORT
GRANT CONNECT ON DATABASE TO USER worklight
QUIT
```

```
db2 CONNECT TO WLREPORT USER worklight USING password
db2 SET CURRENT SCHEMA = 'WLRESCHM'
```

```
db2 -vf product_install_dir/WorklightServer/databases/create-worklightreports-db2.sql -t
```

Steps for WebSphere Application Server Liberty profile.

- Configure Liberty profile for DB2 manually.

```
<!-- Declare the reports database -->
<dataSource jndiName="worklight/jdbc/WorklightReportsDS" transactional="false">
  <jdbcDriver libraryRef="DB2Lib"/>
  <properties.db2.jcc databaseName="WLREPORT"
    currentSchema="WLRESCHM"
    serverName="db2server" portNumber="50000"
    user="worklight" password="password"/>
</dataSource>
```

Steps for WebSphere Application Server full profile.

- Configure WebSphere Application Server for DB2 manually.
 1. Set the **Data source name** to **Worklight Reports Database**.
 2. Set **JNDI Name** to **jdbc/WorklightReportsDS**.
 3. Click **Next**.
 4. Enter properties for the data source, for example:
 - **Database Name:** WLREPORT

Steps for Apache Tomcat.

- Configure Apache Tomcat for DB2 manually.

```
<Resource auth="Container"
  driverClassName="com.ibm.db2.jcc.DB2Driver"
  name="jdbc/WorklightReportsDS"
  username="worklight"
  password="password"
  type="javax.sql.DataSource"
  url="jdbc:db2://db2server:50000/WLREPORT:currentSchema=WLRESCHM;"/>
```

Manually configuring the Apache Derby reports database

You can manually set up the reports database for Apache Derby, and configure it according to your application server.

About this task

First, set up your Apache Derby reports database. Then, configure your application server. According to your application server, follow the steps for WebSphere Application Server Liberty profile, or WebSphere Application Server full profile, or Apache Tomcat.

Procedure

- Set up your Apache Derby reports database manually.

```
connect 'jdbc:derby:WLREPORT;user=WORKLIGHT;create=true';
run 'product_install_dir/WorklightServer/databases/create-worklightreports-derby.sql';
```

Steps for WebSphere Application Server Liberty profile.

- Configure Liberty profile for Derby manually.

```
<!-- Declare the reports database -->
<dataSource jndiName="worklight/jdbc/WorklightReportsDS" transactional="false" statementCacheSize="1000">
  <jdbcDriver libraryRef="derbyLib" javax.sql.ConnectionPoolDataSource="org.apache.derby.jdbc.EmbeddedDriver"
    <properties.derby.embedded databaseName="DERBY_DATABASES_DIR/WLREPORT" user="WORKLIGHT"
      shutdownDatabase="false"
      connectionAttributes="upgrade=true"/>
</dataSource>
<connectionManager connectionTimeout="180">
```

```

maxPoolSize="10" minPoolSize="1"
reapTime="180" maxIdleTime="1800"
agedTimeout="7200" purgePolicy="EntirePool" />
</dataSource>

```

Steps for WebSphere Application Server full profile.

- Configure WebSphere Application Server for Derby manually.
 1. Set **Data source name** to **Worklight Reports Database**.
 2. Set **JNDI name** to jdbc/WorklightReportsDS.

Steps for Apache Tomcat

- Configure Apache Tomcat for Derby manually.

```

<Resource auth="Container"
    driverClassName="org.apache.derby.jdbc.EmbeddedDriver"
    name="jdbc/WorklightReportsDS"
    username="WORKLIGHT"
    password=""
    type="javax.sql.DataSource"
    url="jdbc:derby:DERBY_DATABASES_DIR/WLREPORT"/>

```

Manually configuring the MySQL reports database

You can manually set up the reports database for MySQL, and configure it according to your application server.

About this task

First, set up your MySQL reports database. Then, configure your application server. According to your application server, follow the steps for WebSphere Application Server Liberty profile, or WebSphere Application Server full profile, or Apache Tomcat.

Procedure

- Set up your MySQL reports database manually.

```

CREATE DATABASE WLREPORT CHARACTER SET utf8 COLLATE utf8_general_ci;
GRANT ALL PRIVILEGES ON WLREPORT.* TO 'worklight'@'Worklight-host' IDENTIFIED BY 'worklight';
GRANT ALL PRIVILEGES ON WLREPORT.* TO 'worklight'@'localhost' IDENTIFIED BY 'worklight';
FLUSH PRIVILEGES;

USE WLREPORT; SOURCE product_install_dir/WorklightServer/databases/create-worklightreports-mysql.s

```

Steps for WebSphere Application Server Liberty profile

- Configure Liberty profile for MySQL manually.

```

<!-- Declare the reports database -->
<dataSource jndiName="worklight/jdbc/WorklightReportsDS" transactional="false">
  <jdbcDriver libraryRef="MySQLLib"/>
  <properties databaseName="WLREPORT"
    serverName="mysqlserver" portNumber="3306"
    user="worklight" password="password"/>
</dataSource>

```

Steps for WebSphere Application Server full profile

- Configure WebSphere Application Server for MySQL manually.
 1. Set **JNDI Name** to jdbc/WorklightReportsDS.
 2. Set the custom properties of the new data source.

```

databaseName = WLREPORT

```

Steps for Apache Tomcat

- Configure Apache Tomcat for MySQL manually.

```
<Resource name="jdbc/WorklightReportsDS"
  auth="Container"
  type="javax.sql.DataSource"
  maxActive="100"
  maxIdle="30"
  maxWait="10000"
  username="worklight"
  password="worklight"
  driverClassName="com.mysql.jdbc.Driver"
  url="jdbc:mysql://mysqlserver:3306/WLREPORT"/>
```

Manually configuring the Oracle reports database

You can manually set up the reports database for Oracle, and configure it according to your application server.

About this task

First, set up your Oracle reports database. Then, configure your application server. According to your application server, follow the steps for WebSphere Application Server Liberty profile, or WebSphere Application Server full profile, or Apache Tomcat.

Procedure

- Set up your Oracle reports database manually.

```
CONNECT SYSTEM/SYSTEM_password@ORCL
CREATE USER WORKLIGHTREPORTS IDENTIFIED BY WORKLIGHTREPORTS_password DEFAULT TABLESPACE USERS Q
GRANT CREATE SESSION, CREATE SEQUENCE, CREATE TABLE TO WORKLIGHTREPORTS;
DISCONNECT;

CONNECT WORKLIGHTREPORTS/<WORKLIGHTREPORTS_password>@ORCL
@product_install_dir/WorklightServer/databases/create-worklightreports-oracle.sql
DISCONNECT;
```

Steps for WebSphere Application Server Liberty profile

- Configure Liberty profile for Oracle manually.

```
<!-- Declare the reports database -->
<dataSource jndiName="worklight/jdbc/WorklightReportsDS" transactional="false">
  <jdbcDriver libraryRef="OracleLib"/>
  <properties.oracle driverType="thin" databaseName="ORCL"
    serverName="oserver" portNumber="1521"
    user="WORKLIGHTREPORTS" password="WORKLIGHTREPORTS_password"/>
</dataSource>
```

Steps for WebSphere Application Server full profile

- Configure WebSphere Application Server for Oracle manually.
 1. Set **JNDI name** to jdbc/WorklightReportsDS.
 2. Set **user = WORKLIGHTREPORTS**.

Steps for Apache Tomcat

- Configure Apache Tomcat for Oracle manually.

```
<Resource name="jdbc/WorklightReportsDS"
  auth="Container"
  type="javax.sql.DataSource"
  driverClassName="oracle.jdbc.driver.OracleDriver"
  url="jdbc:oracle:thin:@oserver:1521:ORCL"
  username="WORKLIGHTREPORTS"
  password="WORKLIGHTREPORTS_password"/>
```

Upgrading the reports database

If you still use the reports database and want to upgrade it to MobileFirst V7.1.0, you can upgrade with Ant tasks or manually.

The reports database WLREPORT is deprecated since IBM MobileFirst Platform Foundation V7.0.0. Use “Operational analytics” on page 14-9 instead. If needed, you can still have a reports database and upgrade it to V7.1.0. In this case, you have two options to upgrade. You can upgrade the reports database with Ant tasks, or manually.

Using Ant tasks to upgrade the reports database

You can choose to use Ant tasks to upgrade your reports database to IBM MobileFirst Platform Foundation V7.1.0. This is the preferred way.

Procedure

1. See the procedure at “Identify the MobileFirst WAR file and prepare the Ant deployment script” on page 7-30 to identify and specify the correct properties of the Ant sample that you use for your application server and your database, for example `configure-liberty-db2.xml` if you have WebSphere Application Server Liberty profile and a DB2 database.
2. After you identify and specify the properties, add the following properties about the reports database to your Ant sample, according to your database type.

- For DB2:

```
<property name="database.db2.worklightreports.password" value="*****"/>
<property name="database.db2.worklightreports.dbname" value="****UPDATE**** - Database name for
<property name="database.db2.worklightreports.schema" value="****UPDATE**** - Database Schema
<property name="database.db2.worklightreports.username" value="****UPDATE**** - DB2 user name
```

- For MySQL:

```
<property name="database.mysql.worklightreports.password" value="*****"/>
<property name="database.mysql.worklightreports.dbname" value="****UPDATE**** - Database name
<property name="database.mysql.worklightreports.username" value="****UPDATE**** - MySQL user na
```

- For Oracle:

```
<property name="database.oracle.worklightreports.password" value="*****"/>
<property name="database.oracle.worklightreports.dbname" value="****UPDATE**** - Database name
<property name="database.oracle.worklightreports.username" value="****UPDATE**** - User name fo
```

3. Modify the database target according to your database type. Find the `<target name="databases">` target in your Ant sample, and add the following element to that target:

- For DB2:

```
<configuredatabase kind="WorklightReports">
  <db2 database="${database.db2.worklightreports.dbname}"
    server="${database.db2.host}"
    instance="${database.db2.instance}"
    user="${database.db2.worklightreports.username}"
    port="${database.db2.port}"
    schema="${database.db2.worklightreports.schema}"
    password="${database.db2.worklightreports.password}">
  </db2>
  <driverclasspath>
    <fileset dir="${database.db2.driver.dir}">
      <include name="db2jcc4.jar"/>
      <include name="db2jcc_license_*.jar"/>
    </fileset>
  </driverclasspath>
</configuredatabase>
```

- For MySQL:

```

<configuredatabase kind="WorklightReports">
  <mysql database="${database.mysql.worklightreports.dbname}"
    server="${database.mysql.host}"
    port="${database.mysql.port}"
    user="${database.mysql.worklightreports.username}"
    password="${database.mysql.worklightreports.password}">
  </mysql>
  <driverclasspath>
    <pathelement location="${database.mysql.driver}"/>
  </driverclasspath>
</configuredatabase>

```

- For Oracle:

```

<configuredatabase kind="WorklightReports">
  <oracle database="${database.oracle.worklightreports.dbname}"
    server="${database.oracle.host}"
    port="${database.oracle.port}"
    user="${database.oracle.worklightreports.username}"
    password="${database.oracle.worklightreports.password}">
  </oracle>
  <driverclasspath>
    <pathelement location="${database.oracle.driver}"/>
  </driverclasspath>
</configuredatabase>

```

4. Modify the minimal-update target. Find the <target name="minimal-update"> target and the <updateapplicationserver> element, and change the useWorklightReports property to true:

```

<target name="minimal-update">
  <updateapplicationserver useWorklightReports="true"
    contextroot="${worklight.contextroot}">

```

5. According to your database type, add the following element to your <target name="minimal-update"> target:

- For DB2:

```

<database kind="WorklightReports">
  <db2 database="${database.db2.worklightreports.dbname}"
    server="${database.db2.host}"
    user="${database.db2.worklightreports.username}"
    port="${database.db2.port}"
    schema="${database.db2.worklightreports.schema}"
    password="${database.db2.worklightreports.password}">
  </db2>
  <driverclasspath>
    <fileset dir="${database.db2.driver.dir}">
      <include name="db2jcc4.jar"/>
      <include name="db2jcc_license_*.jar"/>
    </fileset>
  </driverclasspath>
</database>

```

- For MySQL:

```

<database kind="WorklightReports">
  <mysql database="${database.mysql.worklightreports.dbname}"
    server="${database.mysql.host}"
    port="${database.mysql.port}"
    user="${database.mysql.worklightreports.username}"
    password="${database.mysql.worklightreports.password}">
  </mysql>
  <driverclasspath>
    <pathelement location="${database.mysql.driver}"/>
  </driverclasspath>
</database>

```

- For Oracle:

```

<database kind="WorklightReports">
  <oracle database="${database.oracle.worklightreports.dbname}"
    server="${database.oracle.host}"
    port="${database.oracle.port}"
    user="${database.oracle.worklightreports.username}"
    password="${database.oracle.worklightreports.password}"/>
  <driverclasspath>
    <pathelement location="${database.oracle.driver}"/>
  </driverclasspath>
</database>

```

What to do next

After you complete these steps, you can resume the upgrade procedure in “Identify the MobileFirst WAR file and prepare the Ant deployment script” on page 7-30.

Manually upgrading the reports database

You can choose to manually upgrade your reports database to IBM MobileFirst Platform Foundation V7.1.0. You can use this option if you are not able to use the Ant tasks.

Procedure

- You must follow the procedure at “Manually upgrading the MobileFirst Server V7.1.0 databases” on page 7-71.
- Verify that a data source for your reports database is declared in your application server. For more information about how to add this data source, see “Manually creating and configuring the reports database” on page 14-122.
- Enable your reports database by setting the JNDI property `reports.exportRawData` to `true`. For more information, see “JNDI environment entries for MobileFirst projects in production” on page 12-68.

Mobile application management

The Mobile Application Management feature enables mobile operators and administrators to securely track, search, and control access to users through the mobile applications that are used on their devices, all from the MobileFirst Operations Console.

The MobileFirst Server runtime tracks devices that access your mobile infrastructure by the MobileFirst apps that are used by your users. Each user, whether employee, customers, suppliers, or business partners, can use several devices to access your mobile environment through one or more apps that you deployed. IBM MobileFirst Operations Console now provides a view into this mapping of user to devices through the apps that are used to access your MobileFirst Server. Mobile operators and administrators can use the console to not only search for registered users by name, but also block access to a specific app from a specific user's device. They can also block any MobileFirst App that is installed on the device from connecting to the MobileFirst Server.

When multiple applications from the same enterprise are installed to the same device, it is desirable to disable access for all of the applications at once when the device is lost, stolen, or its security compromised. When these applications on the same device are authenticated to and routing traffic through a MobileFirst Server, administrators can disable access for all MobileFirst applications on that device.

In some cases, it might not be desirable to block access for every MobileFirst application that is installed on the device. MobileFirst application management features allow the administrator to view each individual application that is installed on a user's device and select which applications to block access.

When a MobileFirst application requires a certificate from the user to authenticate, the serial number of the certificate is recorded on the MobileFirst Server. In addition to viewing each application installed on a device, the certificate serial number can also be viewed in the MobileFirst Operations Console. This feature allows administrators to revoke access to an application installed on the device by using the serial number to locate and revoke the certificate.

IBM MobileFirst Platform Foundation maintains a database table of device IDs, among other device-related metadata, to enable this feature. In addition to the device ID column in the database, a status column is also kept. The possible status values are:

- active
- lost
- stolen
- expired (the device has not connected to this MobileFirst Server in 90 days) - configurable
- disabled

When a MobileFirst application from a device attempts to connect through the MobileFirst Server, the device ID is stored in the in-memory session data on the server. This device ID is checked against the database before any further processing of the inbound message. If the status column for this device ID is any value other than active, a 401 forbidden is returned. If the status is lost, stolen, or disabled, only an administrator with access to the MobileFirst Operations Console or direct database access can restore the status to the active state.

User to device mapping and control

Starting in IBM Worklight V6.1.0, the MobileFirst Server tracks the devices that access the system as part of the core runtime database. You can now enable the user to device mapping feature, which provides the ability for mobile operators or administrators to query their mobile systems by user. A device friendly name can also be established to see the devices that are mapped to a user. Further, specific controls can be applied to a user-app-device mapping to either disable that link or reactivate that link to address common situations. For example, a user loses a device and must block all access from that device. Another example is the requirement to block access to an app across all devices, or block access to an app on a device, when a user changes departments. Reactivation is available for all of these disablement control actions.

For the user to device mapping feature to work, a security realm must exist that establishes the user identity. The user identity is then used to associate the MobileFirst Device ID with the user. Developers can create custom challenge handlers or specific API calls to set a device friendly name as preferred by the user, programmatically. This feature helps in querying the device by its friendly name.

The following list shows what a mobile operator or admin can do with this set of features:

- Search for a device by friendly name or search by user name.

- A matching search yields all devices that belong to that user or the single device and the associated user, along with device model and information.
- The apps that are used on the device to access this system are also displayed.

The following list shows the available actions that can be taken for a queried device:

- Disable the specific device, marking the state as lost or stolen so that access from any of the apps on that device is blocked.
- Re-enable a disabled device so that access from the device to the MobileFirst Server is allowed.
- Disable a specific app, marking the state as disabled so that access from the specific app on that device is blocked.
- Re-enable that specific app on the device so that access from the specific app on the device to the MobileFirst Server is allowed.

Device access management in the MobileFirst Operations Console

In the MobileFirst Operations Console, administrators can search for devices that access the MobileFirst Server and can manage access rights.

In the search field, devices can be searched for by either the user ID (the ID that was used to log in to the Authentication Realm), or the friendly name (a name that is associated with the device to distinguish it from other devices that share the user ID). The friendly name can be set on the client by using the client-side JavaScript APIs: `WL.Device.getFriendlyName` and `WL.Device.setFriendlyName`. For more information about the `getFriendlyName` API, see the `getFriendlyName` method, as defined in the `WL.Device` class. For more information about the `setFriendlyName` API, see `setFriendlyName` method, as defined in the `WL.Device` class.

When a valid device is found, all devices that match the user ID or friendly name are listed.

Devices

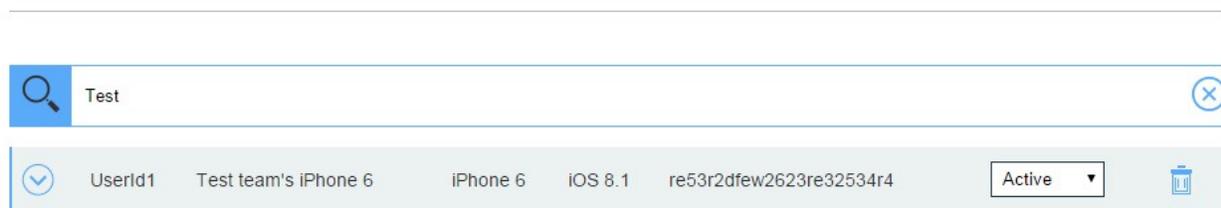

Figure 14-31. User or friendly name search

The Status column contains the current access rights of the device. Any device with the column marked as “Stolen”, “Lost”, or “Disabled” is not allowed to access MobileFirst Server. The “Expired” status is used only for licensing purposes. After successful connection to the server, any device with the status marked as “Expired” is allowed to access MobileFirst Server and its status is changed to “Active”. For more information about licensing, see “License Tracking report” on page 14-135.

Clicking the **expand arrow** icon in the column shows a list of all applications that this device accessed.

Devices

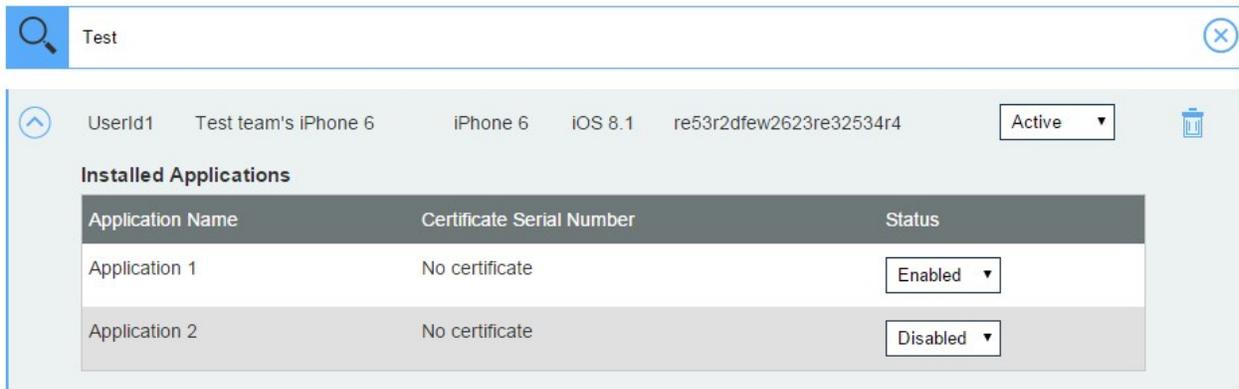

Figure 14-32. List of applications that are accessed by a device

Each row in the table contains the name of the application, the certificate serial number for this device-application pair (if enabled), and a status menu that is used to disable an application's access to the MobileFirst Server for this device.

Enabling the device access management features

All devices that access the MobileFirst Server are recorded in the runtime database without any additional configurations. However, IBM MobileFirst Platform Foundation does not enforce the device access settings that are set from the MobileFirst Operations Console unless you enable a property on the MobileFirst Server.

About this task

More processing is required on the MobileFirst Server when this property is enabled to enforce access management on devices. Appropriate performance testing must be done before production to measure how enabling this feature impacts the server's performance.

Procedure

1. Set the `wl.device.enableAccessManagement=true` property on the MobileFirst Server (this value is false by default). The `wl.device.tracking.enabled=true` property must also be set (this value is true by default).
2. Capture the UserID. The user ID is recorded for the device automatically when the user logs in to an authentication realm that is marked as `isInternalUserID`. The following example shows a sample authentication configuration file:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<tns:loginConfiguration xmlns:tns="http://www.worklight.com/auth/config"
                        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <!-- Licensed Materials - Property of IBM
       5725-G92 (C) Copyright IBM Corp. 2006, 2013. All Rights Reserved.
       US Government Users Restricted Rights - Use, duplication or
       disclosure restricted by GSA ADP Schedule Contract with IBM Corp. -->
```

```

<securityTests>
  <customSecurityTest name="DummyAdapter-securityTest">
    <test isInternalUserID="true" realm="SampleAppRealm" />
  </customSecurityTest>
</securityTests>

<realms>
  <realm loginModule="StrongDummy" name="SampleAppRealm">
    <className>com.worklight.core.auth.ext.FormBasedAuthenticator</className>
  </realm>
</realms>

<loginModules>
  <loginModule name="StrongDummy">
    <className>com.worklight.core.auth.ext.NonValidatingLoginModule</className>
  </loginModule>
</loginModules>

</tns:loginConfiguration>

```

Since a security test can include several realms that require a user ID, only the realm that has the `isInternalUserID` property is recorded for the device in the runtime database. For a `mobileSecurityTest`, the realm that is set by the `testUser` element is used. For more information about security tests, see “Security tests” on page 8-569.

If the user is authenticated through the `UserCertificateAuthenticator`, the serial number that is generated for the certificate that is sent to the device is automatically saved in the runtime database. For more information about the `UserCertificateAuthenticator` and serial number, see “User certificate authentication” on page 8-577.

Performance implications for the server

You must consider two questions when you measure the Mobile Application Management feature and its impact on performance.

1. Does IBM MobileFirst Platform Foundation save information about a device when it accesses the server?
2. Does IBM MobileFirst Platform Foundation enforce access rights when a device tries to access the server?

Saving device information

The MobileFirst administrator can control whether the server saves device information to the internal database when a device connects to the MobileFirst Server. This behavior is controlled by the following flag in the `worklight.properties` file:

```
wl.device.tracking.enabled=true
```

When this flag is enabled, the MobileFirst Server attempts to store information about the device each time a device begins a new session with the server. In terms of performance, this behavior results in a potential database write each time that a device starts a new session.

Note: This flag is enabled by default in production, and is used for license tracking. Do not disable this flag unless you fully understand the implications. For more information about licensing, see “License tracking” on page 14-133.

Enforcing access rights

The MobileFirst Server tries to save the device information only on the first request of a session from the device. However, IBM MobileFirst Platform Foundation must enforce access rights on every request that is made to the server from the device. This behavior ensures that the rights that are set by the MobileFirst administrator take effect immediately. This feature can be controlled by the following flag in the `worklight.properties` file:

```
wl.device.enableAccessManagement=true
```

From a performance perspective, this behavior results in an extra database read that occurs each time that the device tries to access a resource on the server. The performance hit for the read is smaller than the write for saving device information. Administrators must consider the fact that this read occurs every time that a device tries to connect to the server. When this flag is disabled, the administrator can still view the devices in the database from the MobileFirst Operations Console. However, they cannot block access from the device to the MobileFirst Server.

Space limitations for the database

Database administrators must consider how enabling the Mobile Application Management feature can affect the Worklight runtime database size. The Mobile Application Management feature does not affect the Worklight raw reports database. The following example shows a typical database row entry for a single device:

```
('db7abddf-3d5f-4b03-b3b8-f706e56e8306', 'Lucas', 'Tillman', '6.2', 'iPad2,5', '2013-10-08 15:12:32', 3)
```

For each application that the device uses, another entry is created as follows:

```
(db7abddf-3d5f-4b03-b3b8-f706e56e8306, 12, 0)
```

The size impact for each device is small. However, administrators must consider the potential size increases if their MobileFirst Server serves thousands of devices that use multiple applications that are hosted by the server. Devices can be deleted from the runtime database in the MobileFirst Operations Console, but each device entry has a Last Accessed time stamp column. That time stamp gives administrators the ability to clear out old rows that are no longer being used, by creating custom queries.

Note: Database rows that contain device information are used for licensing purposes. Database administrators must not delete data from these rows if the action of deleting the data affects licensing.

License tracking

IBM MobileFirst Platform Foundation is available in Enterprise (B2E) and Consumer (B2C) editions, and the license terms vary depending on which edition was sold.

License tracking is enabled by default in IBM MobileFirst Platform Foundation, which tracks metrics relevant to the licensing policy such as active client device, addressable devices, and installed apps.

This information helps determine if the current usage of IBM MobileFirst Platform Foundation is within the license entitlement levels and can prevent potential license violations.

Also, by tracking the usage of client devices, and determining whether the devices are active, MobileFirst administrators can decommission devices that are no longer accessing the IBM MobileFirst Platform. This situation might arise if an employee has left the company, for example. Addressable devices are only counted for the current calendar month. Devices that did not use an application in the current calendar month are not counted.

License tracking details are gathered by specifying configuration properties in JNDI, and the data that is gathered is displayed in a License Tracking report that is accessed from the IBM MobileFirst Platform Operations Console.

Configuring your license tracking details

Administrators can set Java Naming and Directory Interface (JNDI) configuration properties to gather data that relates to license terms for devices that are accessing the MobileFirst platform. This data can be displayed in the License Tracking report, which is accessed from the IBM MobileFirst Platform Operations Console.

About this task

Administrators can specify the following JNDI configuration properties, which enable the administrators to gather the required data:

wl.device.decommission.when

The number of days of inactivity after which a client device is decommissioned by the device decommissioning task. The default value is 90 days.

wl.device.archiveDecommissioned.when

A value, in days, that defines when client devices that were decommissioned will be placed in an archive file when the decommissioning task is run. The archived client devices are written to a file in the IBM MobileFirst Platform Server home\devices_archive directory. The name of the file contains the time stamp when the archive file is created. The default value is 90 days.

wl.device.tracking.enabled

A value that is used to enable or disable device tracking in IBM MobileFirst Platform Foundation. For performance reasons, you can disable this flag when IBM MobileFirst Platform Foundation is neither licensed by Client Device nor by Addressable Device. When device tracking is disabled, the license reports are also disabled and no license metrics are generated. In that case, only ILMT records for Application count are generated.

For more information about specifying JNDI properties, see [Configuring an IBM MobileFirst project in production by using JNDI environment entries](#).

The decommissioning task is run daily, as a MobileFirst Server task in the background. This task performs the following actions:

- Decommissions inactive devices, based on the **wl.device.decommission.when** setting.
- Optionally, archives older decommissioned devices, based on the **wl.device.archiveDecommissioned.when** setting.
- Generates the License Tracking report.

Active client devices are those devices whose status is not decommissioned; inactive client devices have a decommissioned status.

Procedure

1. Specify the required properties as JNDI properties.
2. View the data in the License Tracking report in the MobileFirst Operations Console. For more information, see “License Tracking report.”

License Tracking report

IBM MobileFirst Platform Foundation provides a report that shows how many client devices accessed the platform, and whether they are active or decommissioned. The report also provides historical data.

The License Tracking report shows the following data:

- The number of applications deployed in the IBM MobileFirst Platform Server
- The number of client devices, both active and decommissioned (see Note)
- The number of addressable devices in the current calendar month (see Note)
- The highest number of client devices reported over the last n days, where n is the number of days of inactivity after which a client device is decommissioned (see Note).

Note: The License Tracking report can track devices that run native or hybrid applications on iOS, Android, or Windows.

Administrators might want to analyze data further. For this purpose, the number of active client devices per application, the generated report details, the addressable devices per application in the last 12 months, and a historical listing of license metrics are captured in a CSV file that can be downloaded for further analysis.

The data is gathered by using the following JNDI configuration properties:

- `wl.device.decommission.when`
- `wl.device.archiveDecommissioned.when`
- `wl.device.tracking.enabled`

For more information, see [Configuring your license tracking details](#).

To access the License Tracking report, click the **License tracking** link in a runtime environment in the IBM MobileFirst Platform Operations Console.

Integration with IBM License Metric Tool

IBM MobileFirst Platform Foundation generates IBM Software License Metric Tag (SLMT) files. Versions of IBM License Metric Tool that support IBM Software License Metric Tag can generate License Consumption Reports. Read this section to interpret these reports for MobileFirst Server, and to configure the generation of the IBM Software License Metric Tag files.

If you have not installed a version of IBM License Metric Tool that supports IBM Software License Metric Tag, you can review the license usage with the License Tracking reports of MobileFirst Operations Console. For more information, see “License Tracking report” on page 14-135.

Each instance of a running MobileFirst runtime environment generates an IBM Software License Metric Tag file. The metrics monitored are CLIENT_DEVICE and APPLICATION. Their values are refreshed every 24 hours.

About the CLIENT_DEVICE metric

The CLIENT_DEVICE metric can have the following subtypes:

Active Devices

The number of client devices that used the MobileFirst runtime environment, or another MobileFirst runtime instance belonging to the same cluster or server farm, and that were not decommissioned. For more information about decommissioned devices, see “Configuring your license tracking details” on page 14-134.

Inactive Devices

The number of client devices that used the MobileFirst runtime environment, or another MobileFirst runtime instance belonging to the same cluster or server farm, and that were decommissioned. For more information about decommissioned devices, see “Configuring your license tracking details” on page 14-134.

The following cases are specific:

- If the decommissioning period of the device is set to a small period, the subtype “Inactive Devices” is replaced by the subtype “Active or Inactive Devices”.
- If device tracking was disabled, only one entry is generated for CLIENT_DEVICE, with the value 0, and the metric subtype “Device Tracking Disabled”.
- If the MobileFirst runtime environment is running in a development server, and device tracking is not disabled, only one entry is generated for CLIENT_DEVICE. This entry has the sum of active and decommissioned devices as its value, and “Development Server” as its metric subtype.

Note: The License Tracking report can track devices that run native or hybrid applications on iOS, Android, or Windows.

About the APPLICATION metric

The APPLICATION metric has no subtype unless the MobileFirst runtime environment is running in a development server.

The value reported for this metric is the number of applications that are deployed in the MobileFirst runtime environment. Each application is counted as one unit, whether it is a new application, an additional brand deployment, or an additional type of an existing application (for example native, hybrid, or web).

This number of applications is monitored even if `wl.device.tracking.enabled` is set to false.

The following cases are specific:

- If the MobileFirst runtime environment is running in a development server, the metric Application is reported with the subtype “Development Server”.

About the ADDRESSABLE_DEVICE metric

The ADDRESSABLE_DEVICE metric has the following subtype:

- Application: <applicationName>, Category: <targetCategory>

The target category of an application is B2C, B2E, or UNDEFINED. To define the target category of an application, see the following topics according to your operating system:

- For a hybrid application, see “The application descriptor” on page 8-50
- For a native Android application, see “Application Descriptor of Native API application for Android” on page 8-200
- For a native iOS application, see “Application descriptor of native API applications for iOS” on page 8-185
- For a native Windows 8 Universal application, see “Application Descriptor of native C# API application for Windows 8 Universal and Windows Phone 8 Universal” on page 8-219
- For a native Windows Phone Silverlight 8 application, see “Application descriptor of native C# API application for Windows Phone Silverlight 8” on page 8-214

The following cases are specific:

- If the decommissioning period of the device is set to less than 30 days, the warning “Short decommissioning period” is appended to the subtype.
- If device tracking was disabled, no addressable report is generated.
- If the MobileFirst runtime environment is running in a development server, and device tracking is not disabled, “Development Server” is appended to the subtype.

Note: The License Tracking report can track devices that run native or hybrid applications on iOS, Android, or Windows.

Configuring IBM License Metric Tool log files

By default, the IBM Software License Metric Tag files are in the following directories:

- On Windows: %ProgramFiles%\ibm\common\slm
- On UNIX and UNIX-like operating systems: /var/ibm/common/slm

If the directories are not writable, the files are created in the log directory of the application server that runs the MobileFirst runtime environment.

You can configure the location and management of those files with the following properties:

- `license.metric.logger.output.dir`: Location of the IBM Software License Metric Tag files
- `license.metric.logger.file.size`: Maximum size of an SLMT file before a rotation is performed. The default size is 1 MB.
- `license.metric.logger.file.number`: Maximum number of SLMT archive files to keep in rotations. The default number is 10.

To change the default values, you must create a Java property file, with the format `key=value`, and provide the path to the properties file through the `license_metric_logger_configuration` JVM property.

Related tasks:

“Configuring your license tracking details” on page 14-134

Administrators can set Java Naming and Directory Interface (JNDI) configuration properties to gather data that relates to license terms for devices that are accessing the MobileFirst platform. This data can be displayed in the License Tracking report,

which is accessed from the IBM MobileFirst Platform Operations Console.

Token license validation

IBM MobileFirst Platform Server validates licenses during various scenarios.

The various scenarios in which licenses are validated are:

On application deployment

Licenses are checked out only if sufficient number of tokens are available.

License validation might fail in the following cases:

- The Rational Common Licensing native library is not installed and configured.
- The JNDI properties for Administration Services are not configured.
- Rational License Key Server is not accessible.
- Sufficient tokens are not available.
- The license has expired.

On application undeployment

Licenses are checked in when an application is undeployed.

At server startup

The license is checked out for every deployed application only if enough number of tokens are available for all deployed applications.

License validation might fail in the following cases:

- The Rational Common Licensing native library is not installed and configured.
- The JNDI properties for Administration Services are not configured.
- Rational License Key Server is not accessible.
- Sufficient tokens are not available.
- The license has expired.

At server shutdown

The license is checked in for every deployed application, during a server shutdown.

Integrating with other IBM products

IBM MobileFirst Platform Foundation integrates with other IBM products.

You can find samples and more documentation about such integration for developers and administrators on the Integration page of the Developer Center website for IBM MobileFirst Platform.

Introduction to MobileFirst integration capabilities

As a developer or administrator, you can use IBM MobileFirst Platform Foundation integration capabilities to connect specific IBM products to existing back-end systems and other Internet or intranet sources.

IBM MobileFirst Platform Foundation provides capabilities to integrate with IBM Endpoint Manager for Mobile Devices and IBM WebSphere Cast Iron for enterprise and application security.

To implement integration to external resources, you use the product adapter technology. For more information about adapters, see “Overview of MobileFirst adapters” on page 8-231.

IBM MobileFirst Platform Foundation also provides a flexible authentication framework to support existing security requirements through authenticator or login modules. For more information, see “MobileFirst security framework” on page 8-527.

Figure 1 gives a high-level view of the topology context for an app on a device that connects to IBM MobileFirst Platform Foundation.

Figure 2 shows where other IBM products fit within the typical MobileFirst topology diagram in Figure 1.

Item	Description
A	App
D	Device
N	Network
I/i	Internet or intranet
MFP	IBM MobileFirst Platform Foundation
EBE	Existing back ends
I	Other Internet sources

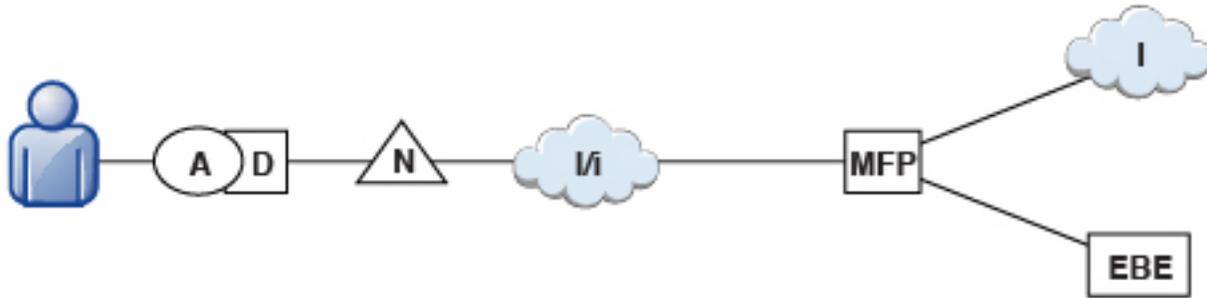

Figure 15-1. Overall Topology

Figure 15-2 shows where these products fit within the typical MobileFirst topology diagram in Figure 15-1.

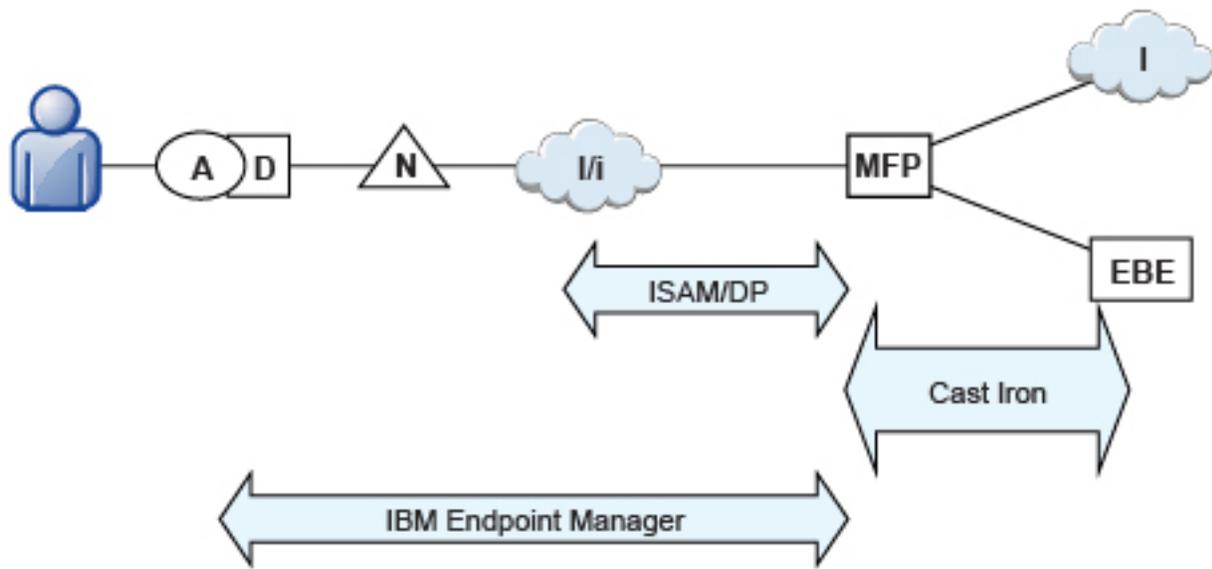

Figure 15-2. Integration Points

Integration with Cast Iron

You can use IBM WebSphere Cast Iron to enable enterprise connectivity within a MobileFirst environment.

IBM MobileFirst Platform Foundation supports the following adapters:

- SQL
- HTTP
- Cast Iron
- Java Message Service (JMS)

The Cast Iron adapter provides first-class integration with all of the cloud-based, hardware appliance, or software-based hypervisor editions of IBM WebSphere Cast Iron.

By using IBM WebSphere Cast Iron, companies can integrate applications, regardless of whether the applications are located on-premises or in public or private clouds. With WebSphere Cast Iron, you do not need any programming knowledge to integrate applications. You can build integration flows in WebSphere Cast Iron Studio, which is a graphical development environment that is installed on a personal computer. With Cast Iron Studio, you can create an integration project that contains one or more orchestrations. Each orchestration is built with a number of activities that define the flow of data. You can define the details of an activity from the configuration panes within Cast Iron Studio.

Figure 1 shows how the topology changes to reflect the use of Cast Iron.

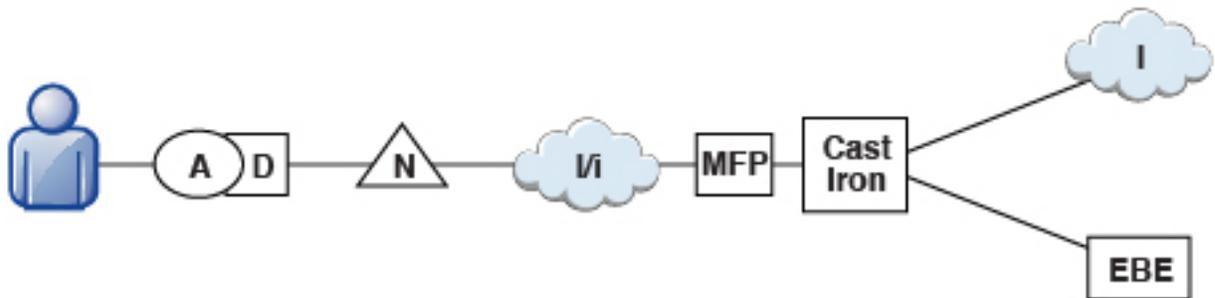

Figure 15-3. Integration with Cast Iron

For more information about Cast Iron adapters, see “Typical topologies of a MobileFirst instance in an extranet infrastructure” on page 6-327.

Integration and authentication with a reverse proxy

You can use a reverse proxy to enable enterprise connectivity within a MobileFirst environment and to provide authentication to IBM MobileFirst Platform Foundation.

General architecture

Reverse proxies typically front MobileFirst instances as part of the deployment, as shown in Figure 1, and follow the gateway pattern.

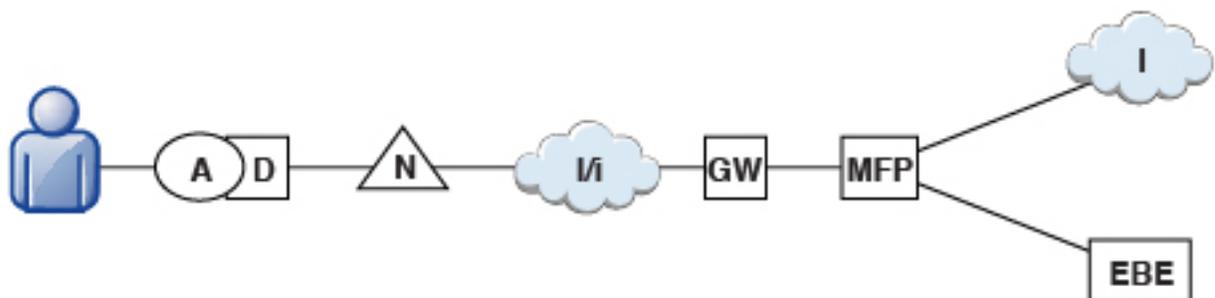

Figure 15-4. Integration with reverse proxy

The MFP icon represents an instance of MobileFirst Server. The GW icon represents a reverse-proxy gateway, such as IBM WebSphere DataPower or IBM Security Access Manager. In addition to protecting MobileFirst resources from the Internet, the

reverse proxy provides termination of HTTPS (SSL) connections and authentication. The reverse proxy can also act as a policy enforcement point (PEP).

When a gateway is used, an application (A) on a device (D) uses the public URI that is advertised by the gateway instead of the internal MobileFirst Server URI. The public URI can be exposed as a setting within the application, or can be built in during promotion of the application to production, before the application is published to public or private application stores.

Authentication at the gateway

If authentication ends at the gateway, IBM MobileFirst Platform Foundation can be informed of the authenticated user by a shared context, such as a custom HTTP header or a cookie. By using the extensible authentication framework, you can configure IBM MobileFirst Platform Foundation to use the user identity from one of these mechanisms and establish a successful log in. Figure 15-5 shows a typical authentication flow for this gateway topology.

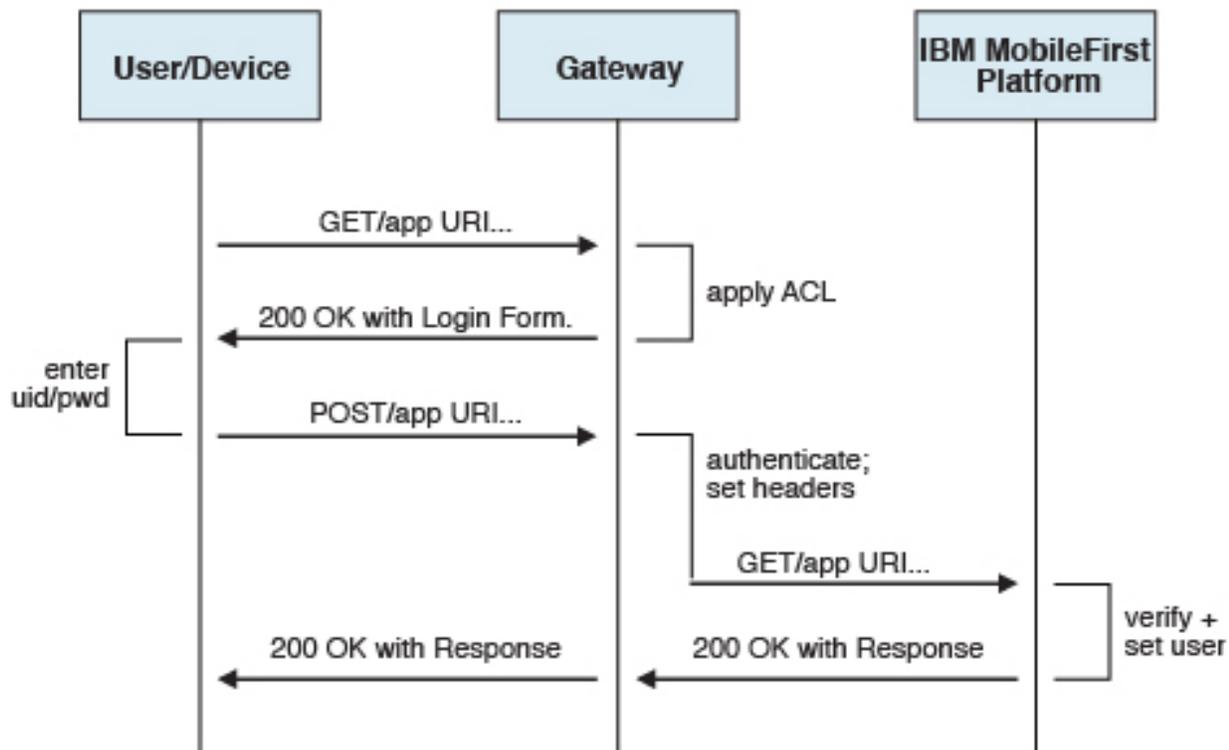

Figure 15-5. Authentication flow

This configuration was tested with DataPower and IBM Security Access Manager for header-based authentication and LTPA-based authentication.

Header-based authentication

- On successful authentication, the gateway forwards a custom HTTP header with the user name or ID to IBM MobileFirst Platform Foundation.
- IBM MobileFirst Platform Foundation is configured to use HeaderAuthenticator and HeaderLoginModule on either Tomcat or WebSphere Application Server.

LTPA-based authentication

- On successful authentication, the gateway forwards an LTPA token (in the form of an HTTP cookie) to IBM MobileFirst Platform Foundation, which validates the LTPA token and creates a caller principal.
- IBM MobileFirst Platform Foundation on WebSphere Application Server is configured to use the WebSphereFormBasedAuthenticator and WebSphereLoginModule classes. See “LTPA authenticator” on page 8-644 and “WASLTPAModule login module” on page 8-620.

For more information about using lightweight third-party authentication (LTPA) tokens with IBM MobileFirst Platform Foundation, see “MobileFirst Security and LTPA” on page 12-94.

For information about using WebSphere DataPower as a reverse proxy, see “Integrating with DataPower as a security gateway and reverse proxy” on page 6-169.

Hybrid applications note

The client's registration with MobileFirst Server, including any challenge that is sent during the registration stage, is executed only in native code. To ensure that a hybrid application's challenge handler is called during the client's registration with the server, the challenge handler must be implemented and registered within the application's native code. For more information, see “Challenge handling in a gateway topology” on page 8-558.

Related information

- “Integration with IBM WebSphere DataPower as a security gateway and reverse proxy” on page 6-168
- “Using a reverse proxy with server farm and WebSphere Application Server Network Deployment topologies” on page 6-29
- “Reverse proxy with LTPA” on page 12-100
- “Typical topologies of a MobileFirst instance in an extranet infrastructure” on page 6-327

Integration with IBM Endpoint Manager

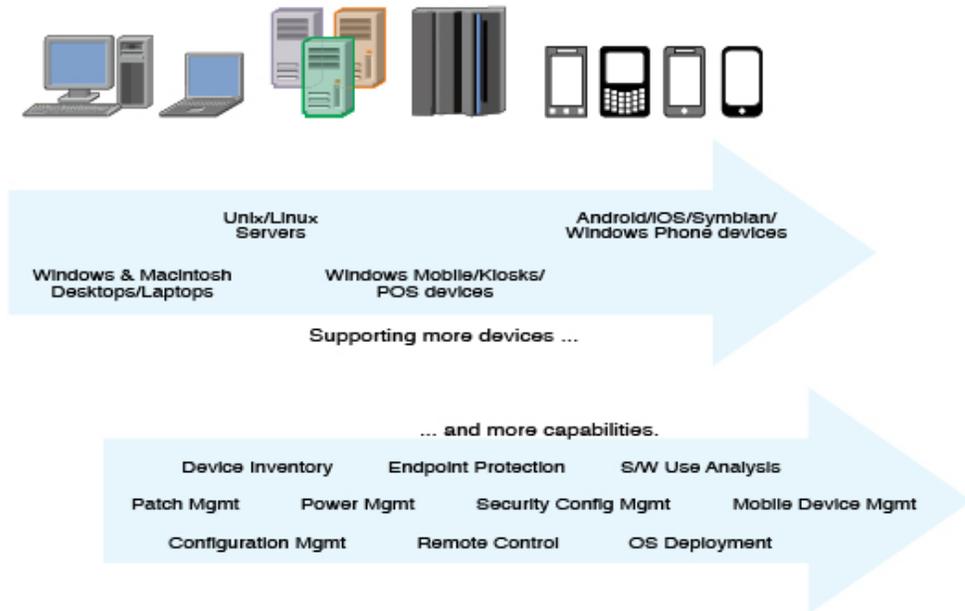

In a MobileFirst environment, you can implement an IBM Endpoint Manager architecture to make your enterprise devices and applications benefit from endpoint management features, such as data security, compliance, and unified infrastructure.

IBM Endpoint Manager for Mobile Devices

The features and architecture of IBM Endpoint Manager for Mobile Devices are described here.

Features

With IBM MobileFirst Platform Foundation, you can integrate the security features that IBM Endpoint Manager provides. The purpose of IBM Endpoint Manager is to deliver a unified solution for the management of systems and security, for all enterprise devices.

IBM Endpoint Manager for Mobile Devices provides security capabilities in the following areas:

- Enterprise Access Management: Configuration of email, VPN, and Wi-Fi.
- Policy and security management: Password policies, device encryption, jailbreak, and root detection.
- Management actions: Selective wipe, full wipe, deny email access, remote lock, user notification, clear passcode.
- Application management: Application inventory, enterprise app store, whitelisting, blacklisting, Apple Volume Purchase Program (VPP).
- Container solution: Enterpoid Divide provides a secure and manageable container for BYOD (Bring Your Own Device) devices. The Divide app provides a workspace that mimics device capabilities. Because this workspace is isolated from the rest of the device, Divide can manage information separately and safely.
- Personal Information Manager (PIM) – NitroDesk TouchDown is a PIM product that allows enterprise data such as email to be secured separately in a BYOD Android environment.
- Support for SAFE, Samsung's proprietary APIs that provide more security than standard Android.

Architecture

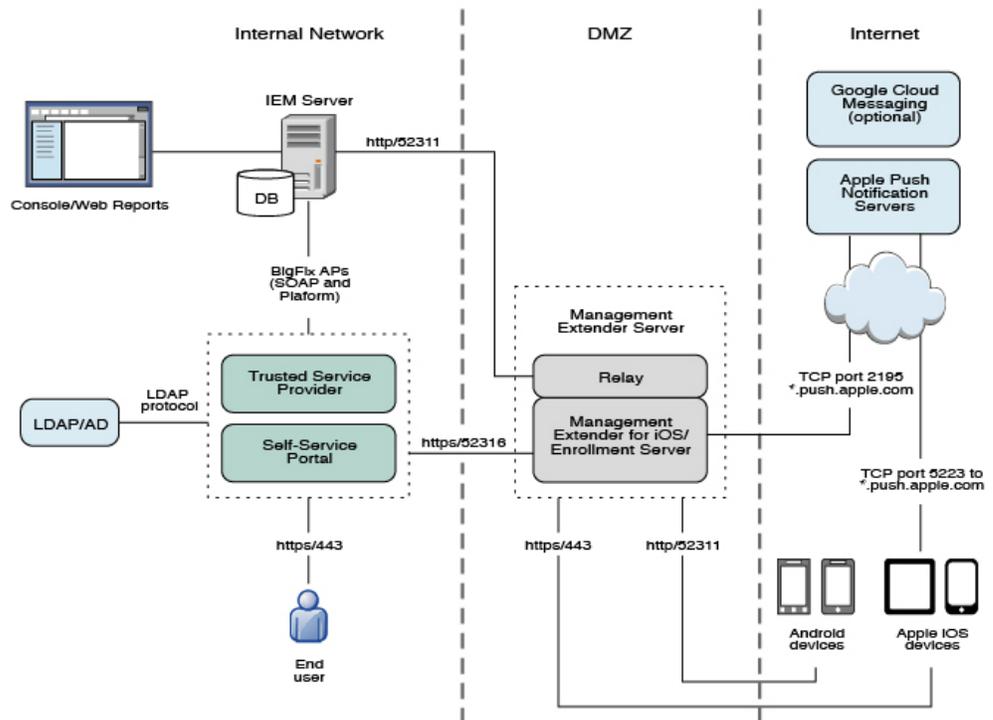

IBM Endpoint Manager for Mobile Devices uses two approaches to manage those devices:

- An agent-based, Mobile Device Management (MDM) API-based approach that is supported on Android and iOS devices through the IBM Mobile Client. This approach provides the full set of capabilities through either a native Agent on the Android platform or the usage of Apple's MDM APIs and the Push Notification Server infrastructure (APNS).
- An email-based management through Exchange (Active Sync) and Lotus® Traveler (IBM Sync). In this approach, Android, iOS, Windows Phone, and

Symbian are supported, but the functionality is limited and includes the ability to wipe a device, deny email access, and set password policies. You cannot see individual device details, perform application management, configure Wi-Fi or VPN connections, or provide advance restrictions as in the agent-based, MDM API-based approach.

- Container management is available through Enterploid Divide, as indicated in “Features” on page 15-5.
- PIM is available through NitroDesk TouchDown.

The following diagram shows an architectural overview of a production-level, agent-based, MDM API-based implementation with IBM Endpoint Manager for Mobile Devices.

End-point management with IBM Endpoint Manager

IBM Endpoint Manager for Mobile Devices provides features to manage devices in a MobileFirst environment.

IBM MobileFirst Platform Foundation provides app management capabilities as part of the platform. IBM Endpoint Manager provides specific device management capabilities. The app can also use certain device functions, which leads to an overlap in some of the management aspects between IBM MobileFirst Platform Foundation and IBM Endpoint Manager for Mobile Devices, as shown in Figure 15-6 on page 15-8.

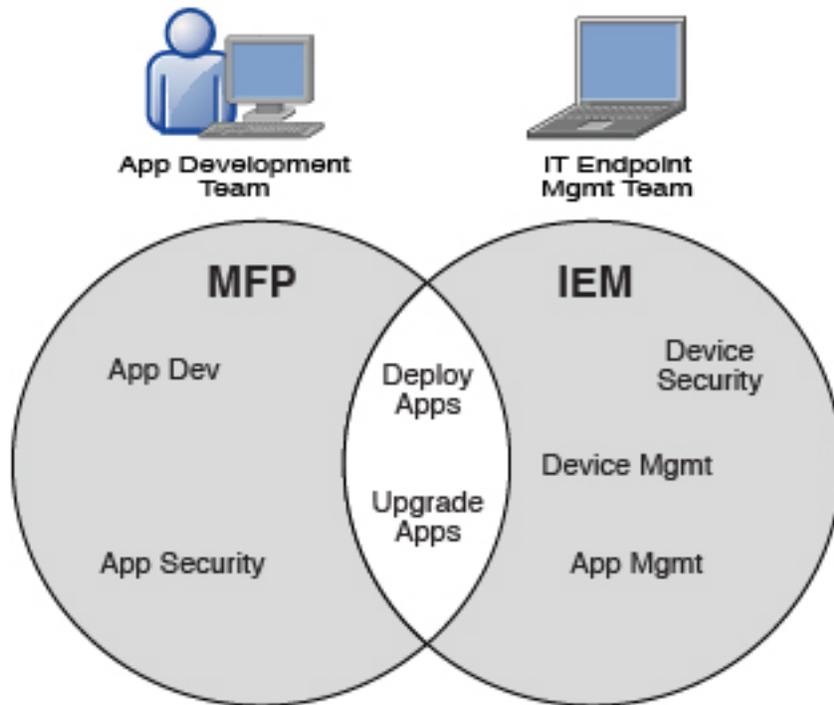

Figure 15-6. IBM MobileFirst Platform Foundation and IBM Endpoint Manager management capabilities

For devices that must be managed as enterprise assets and devices that must be controlled across applications, IBM Endpoint Manager provides the following mobile device management capabilities:

- Safeguard of enterprise data
- Flexible management
- Maintained compliance
- Unified infrastructure

Safeguard of enterprise data

- Selectively wipes enterprise data when devices are lost or stolen.
- Configures and enforces passcode policies, encryption, VPN, and more.

Flexible management

- Secures and manages employee-owned and corporate-owned mobile devices by a combination of email-based and agent-based management, while preserving the native device experience.

Maintained compliance

- Automatically identifies non-compliant devices.
- Denies email access or issues user notifications until corrective actions are implemented.

Unified infrastructure

- Uses a single infrastructure to manage and secure all your enterprise devices; that is, smartphones, tablets, desktops, notebooks, and servers.

Integration with IBM Tealeaf

The use of IBM Tealeaf is described here.

IBM Tealeaf CX Mobile helps customers apply the power of Tealeaf powerful solutions for customer experience management to their mobile websites, hybrid applications, and native applications, including support for HTML5. IBM Tealeaf gives customers visibility where they do not have it today, helping to deliver winning mobile services. IBM Tealeaf CX Mobile is an add-on to the Tealeaf CX platform. IBM Tealeaf is provided as a set of libraries. To use it, you must take steps on both your client and your server.

For more information, see the Product Integration pages.

IBM Tealeaf client-side integration

To make the IBM Tealeaf client SDK available for development, you can use MobileFirst Studio to place the libraries and configuration files in the appropriate location of your MobileFirst project file system for each supported environment.

About this task

Integrating the IBM Tealeaf client SDK into your application is meaningful only when you also have an IBM Tealeaf CX server to which the clients send their collected data. Use the MobileFirst Studio `application-descriptor.xml` editor to manage the optional feature.

Procedure

1. Find and double-click the `application-descriptor.xml` file to open the Application Descriptor editor view.
2. Find and click **Optional Features**.
3. Click **Add**.
4. Click **IBM Tealeaf SDK**.
5. Click **OK**.

Results

After the libraries and configuration files are in the correct directory, the IBM Tealeaf client-side API is on your Java class path and available in XCode (Objective-C), and the TLT global variable is available in your JavaScript code.

Important:

Be aware of the following effects:

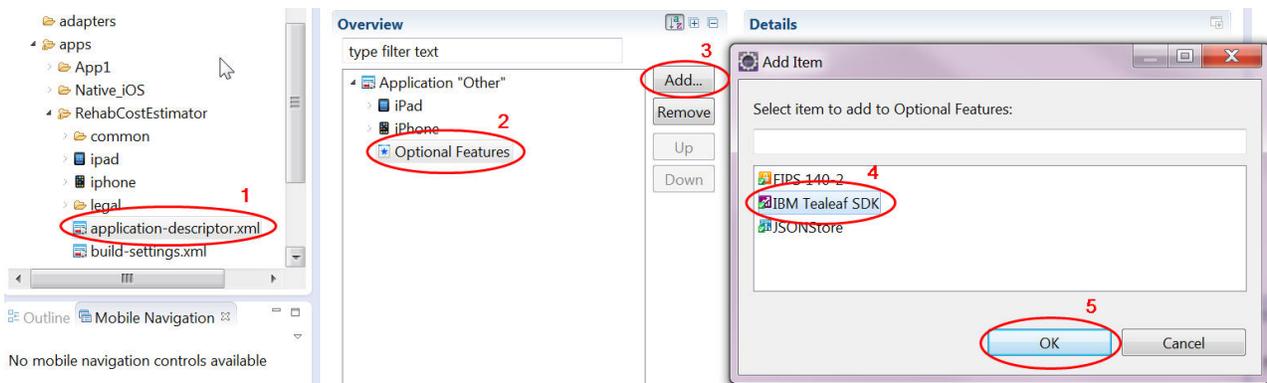

- Selecting the IBM Tealeaf SDK for inclusion in your application in MobileFirst Studio does not overwrite existing IBM Tealeaf artifacts.
- Removing the IBM Tealeaf SDK from inclusion in your application by removing the optional feature item removes existing IBM Tealeaf artifacts from your project, including any you placed manually.

Therefore, you can place specific versions of the IBM Tealeaf SDK artifacts manually and avoid managing the placement of IBM Tealeaf artifacts in your project in the application descriptor editor.

For more information about how to edit the properties file (Android), the plist file (iOS), or the configuration object (JavaScript), and how to use the IBM Tealeaf CX Mobile API, see the Tealeaf documentation indicated in the Tealeaf CX Mobile page of the Developer Center website for IBM MobileFirst Platform.

Example

The following figure shows the Application Descriptor editor view. The steps are highlighted:

IBM Tealeaf server-side integration

To aggregate the data that is collected in client applications by the IBM Tealeaf client SDK, you must install the IBM Tealeaf Mobile CX server.

For more information about installation, configuration, and usage, see Tealeaf CX Mobile.

Integration with IBM Trusteer

You can use IBM Trusteer to collect mobile device risk factors. By providing these to your mobile app, you can restrict mobile app functionality by risk levels.

IBM MobileFirst Platform Foundation supports the following versions of IBM Trusteer Mobile SDK:

- IBM Trusteer Mobile SDK Version 3.6 and later fix packs
- IBM Trusteer Mobile SDK Version 4.0 and later fix packs

IBM MobileFirst Platform Foundation supports full integration with the IBM Trusteer Mobile SDK for Android and iOS applications only.

After the Trusteer Mobile SDK is installed, you must configure MobileFirst Server to support it:

- “MobileFirst security overview” on page 12-90 and “MobileFirst security configuration” on page 12-92 provide an overview of general MobileFirst security configuration.
- “Configuring the MobileFirst Server for Trusteer” on page 12-100 provides steps for configuring MobileFirst Server to support Trusteer.

For more information, see Trusteer for iOS and Trusteer for Android in the Development Center.

Integrating IBM Trusteer for iOS

You might want to integrate Trusteer with IBM MobileFirst Platform Foundation.

Before you begin

- If you are using a Trusteer compressed archive:
 1. Make sure that you have the following files:
 - Trusteer Mobile iOS library: `libtas_full.a`.
 - A MobileFirst-compatible Trusteer license file: `tas.license`
 - A Trusteer configuration package: `default_conf.rpkg`
 - A Trusteer Application Security Manifest: `manifest.rpkg`

Note: You might need to generate the manifest manually. For more information, see the Trusteer documentation.

If any of these items is missing, consult your local IBM representative.

 2. In your file system, create a `tas` folder and place in it the files that are listed previously.
 3. Continue from step 1.
- If you are using a Trusteer MobileFirst component, first follow the instructions in “Adding application components to MobileFirst projects” on page 8-412, then continue from step 1.

Note: Starting with its version 4.0, Trusteer supports the arm64 architecture. Earlier versions of Trusteer do not.

Procedure

1. In your Xcode project, drag the folder onto your project navigator.
2. Select the check box **Copy items into destination group's folder (if needed)**.
3. Select the option **Create folder references for any added folders**.
4. Make sure that your target is selected, then click **Finish**.
5. Click the project name at the top of the tree in the **Project Navigator**, then click **Build Phases**.
6. To link your project with the Trusteer library, drag the `libtas_full.a` file from the **Project Navigator** to the **Link Binary With Libraries** list.
7. In **Build Settings > Linking > Other Linker Flags**, add: `-force_load "$(SRCROOT)/tas/libtas_full.a"`.
8. In **Build Settings > Linking > Dead Code Stripping**, select **NO**.
9. In **Build Settings > Deployment**, set **Strip Linked Product** to **NO**.
10. In the Xcode **Project Navigator**, drag `tas.license` into the **Resources** group.
11. In the dialog box that opens, click **Finish**.
12. Open the `tas.license` file and check that the values for `vendorId`, `clientId`, and `clientKey` match the licensing information that was provided by Trusteer.
13. Initialize the Trusteer Mobile SDK. By default, the Trusteer Mobile SDK is initialized automatically when you integrate the SDK into a MobileFirst project. However, to provide more flexibility and eliminate potential initialization failure, it is recommended that you disable the automatic SDK initialization and instead initialize the SDK manually:
 - a. Disable the automatic initialization of the Trusteer Mobile SDK by setting the **TRUSTEER_AUTO_INIT** property in your client properties file (`worklight.plist`) to `false`:

```
<key>TRUSTEER_AUTO_INIT</key>
<false/>
```

- b. Manually initialize the SDK. You can do this either by using the Trusteer Mobile SDK according to the Trusteer documentation, or by using the MobileFirst Trusteer API from your application's native iOS code or hybrid JavaScript code:
 - In your native iOS code, call the init method of the WLTrusteer sharedInstance class method:

```
[[WLTrusteer sharedInstance] init];
```
 - In your hybrid JavaScript code, call the init method of the WL.Trusteer class:

```
WL.Trusteer.init(onSuccess,onFailure);
```

Integrating IBM Trusteer for Android

You can integrate Trusteer with IBM MobileFirst Platform Foundation for Android apps by using either a MobileFirst component or a zipped archive.

Procedure

1. Install the Trusteer Mobile SDK and integrate it with you MobileFirst project by following the instructions for your preferred integration method:
 - “Integrating IBM Trusteer for Android by using a MobileFirst component”
 - “Integrating IBM Trusteer for Android from a zipped archive” on page 15-13
2. Initialize the Trusteer Mobile SDK. By default, the Trusteer Mobile SDK is initialized automatically when you integrate the SDK into a MobileFirst project. However, to provide more flexibility and eliminate potential initialization failure, it is recommended that you disable the automatic SDK initialization and instead initialize the SDK manually:
 - a. Disable the automatic initialization of the Trusteer Mobile SDK by setting the **TRUSTEER_AUTO_INIT** property in your client properties file (`wlclient.properties`) to `false`:

```
TRUSTEER_AUTO_INIT=false
```
 - b. Manually initialize the SDK. You can do this either by using the Trusteer Mobile SDK according to the Trusteer documentation, or by using the MobileFirst Trusteer API from your application's native Android code or hybrid JavaScript code:
 - In your native Android code, call the `createInstance` method of the `WLTrusteer` class (where *context* refers to your Android context):

```
WLTrusteer.createInstance(context);
```
 - In your hybrid JavaScript code, call the `init` method of the `WL.Trusteer` class:

```
WL.Trusteer.init(onSuccess,onFailure);
```

Integrating IBM Trusteer for Android by using a MobileFirst component

You can integrate Trusteer with IBM MobileFirst Platform Foundation for Android apps by using a MobileFirst component.

Procedure

1. Make sure that you have obtained a Trusteer MobileFirst Component.
2. Add the Trusteer MobileFirst component to your MobileFirst project, by following the procedures in “Adding application components to MobileFirst projects” on page 8-412.

3. In the **Project Navigator**, under your application, navigate to **nativeResources > assets**.
4. Open the `tas.license` file and check that the values for `vendorId`, `clientId` and `clientKey` match the licensing information that was provided by Trusteer.

Integrating IBM Trusteer for Android from a zipped archive

You might want to integrate Trusteer with IBM MobileFirst Platform Foundation for Android apps by using a zipped archive.

Procedure

1. Make sure that Trusteer has provided you with the following:
 - a. Trusteer Mobile Android native libraries (`libtaz_full.so` and `libgnustl_shared.so`).
 - b. Trusteer Mobile Android Java Libraries (`taz.jar` and `reflectutils.jar`).
 - c. MobileFirst-compatible Trusteer license file (`tas.license`).
 - d. Trusteer configuration package (`default_conf.rpkg`).

If any of these items is missing, consult your local IBM representative.

2. In your file system, create two folders: `libs/armeabi` and `libs/armeabi-v7a`.
3. Copy the Trusteer Mobile Android native libraries to the two folders.
4. Copy the Trusteer Mobile Android Java Libraries to the `libs` folder.
5. Copy the Trusteer configuration package (`default_conf.rpkg`) to the `Assets` folder.
6. Copy the MobileFirst-compatible Trusteer license file (`tas.license`) to the `Assets` folder.
7. Add the following permissions to the application manifest file (`androidManifest.xml`):

```
<uses-permission android:name="android.permission.INTERNET" />
<uses-permission android:name="android.permission.READ_PHONE_STATE" />
<uses-permission android:name="android.permission.ACCESS_WIFI_STATE" />
```

8. If you use Trusteer Mobile SDK V4.0 or later, add the following permissions to the application manifest file (`androidManifest.xml`):

```
<uses-permission android:name="android.permission.ACCESS_FINE_LOCATION" />
<uses-permission android:name="android.permission.ACCESS_NETWORK_STATE" />
<uses-permission android:name="android.permission.RECEIVE_BOOT_COMPLETED" />
```

9. Optional: Add the following permission to the application manifest file (`androidManifest.xml`):

```
<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />
```

10. If you use Trusteer Mobile SDK V4.0 or later, add the following tags to the `<application>` section of the application manifest file (`androidManifest.xml`):

```
<service android:name="com.trusteer.taz.service.TasService"/>

<receiver android:name="com.trusteer.taz.service.TasIntentReceiver" >
  <intent-filter>
    <action android:name="android.intent.action.BOOT_COMPLETED" />
  </intent-filter>
</receiver>
```

Integration with IBM WebSphere DataPower

Use IBM WebSphere DataPower as a reverse proxy and security gateway for handling inbound mobile traffic, or as a proxy and gateway for handling outbound traffic to a notification mediator.

IBM WebSphere DataPower (DataPower) SOA appliances are built for simplified deployment and hardened security, bridging multiple protocols, and performing conversions at wire speed. These capabilities help an organization to achieve and maintain its security and operational policies.

DataPower can act as a reverse proxy and security gateway for handling inbound traffic into an enterprise and authenticating mobile clients. For information about configuring DataPower as a reverse proxy and security gateway between MobileFirst applications and MobileFirst Server, see “Integration with IBM WebSphere DataPower as a security gateway and reverse proxy” on page 6-168.

DataPower can also be used as a gateway for monitoring and routing outbound connections when required by corporate policy. For information about configuring DataPower as a proxy between MobileFirst Server and a notification mediator (Apple Push Notification Service or Google Cloud Messaging servers) for pushing notifications to mobile applications, see “Integrating with WebSphere DataPower as a push notification proxy.”.

Related information

- “Integration with IBM WebSphere DataPower as a security gateway and reverse proxy” on page 6-168
- “Integrating IBM WebSphere DataPower with a cluster of instances of MobileFirst Server” on page 6-347

Integrating with WebSphere DataPower as a push notification proxy

Use IBM WebSphere DataPower as a gateway and proxy for pushing outbound notifications from MobileFirst Server to a notification mediator.

About this task

IBM MobileFirst Platform Foundation makes outbound connections to a notification mediator, APNS (Apple Push Notification Service) or GCM (Google Cloud Messaging servers), to push notifications to mobile applications. You can configure IBM WebSphere DataPower (DataPower) as a proxy between MobileFirst Server and your notification mediator.

Procedure

- You must configure both DataPower and MobileFirst Server, regardless of your notification mediator.
- For GCM, there are two possible DataPower configurations that enable it to act as a GCM proxy for IBM MobileFirst Platform Foundation: a TCP proxy configuration and a web application firewall configuration.
- For more information and detailed step-by-step instructions, see the developerWorks article Using WebSphere DataPower as a push notification proxy for MobileFirst mobile applications.

Related information

Integration with IBM WebSphere DataPower as a security gateway and reverse proxy

Protect your mobile-application traffic by using IBM WebSphere DataPower as a reverse proxy and security gateway in the DMZ between client applications and MobileFirst Server.

Integrating IBM WebSphere DataPower with a cluster of instances of MobileFirst Server

You can use IBM WebSphere DataPower as a gateway for all incoming connections for IBM MobileFirst Platform Foundation and Application Center, and IBM HTTP Server (IHS) for load-balancing MobileFirst Server that are deployed on an IBM WebSphere Application Server 8.5 cluster or a Liberty profile server farm.

More about integration

More resources on integration with IBM WebSphere Cast Iron, IBM Endpoint Manager, IBM WebSphere DataPower, and IBM Security Access Manager are available from the product websites and IBM Redbooks® website.

CLI Commands

You can use IBM MobileFirst Platform Command Line Interface to create apps from the command line.

adapter add

Creates a new adapter, which is generated in the **adapters** folder of the current project.

Syntax

```
mfp adapter add [<name> --type|-t <type> [--jsonstore|-j] [--ussd|-u]
[--package|-p <package>]]
```

Parameters

<name>

The name of the generated adapter.

<type>

The type of adapter. Valid values: castiron, http, java, jco, jms, sap, and sql.

[--jsonstore|-j]

Your choice of JSONStore procedures. JSONStore procedures are not valid for JCo and Java adapters.

[--ussd|-u]

The option for the Unstructured Supplementary Service Data (USSD) communication technology.

[--package|-p <package>]

The name of the package that contains the Java adapter classes. Package option is valid only for Java adapters.

adapter call

Calls an adapter procedure on the MobileFirst Server.

Syntax

Choose one of the following syntaxes.

```
mfp adapter call [<adapter>/<procedure> [--type|-t get|post] [--file|-f
<args.json>]]
```

```
mfp adapter call [<adapter>/<procedure>
```

```
  [--type|-t get|post]
```

```
  [--form|-fp <form_parameters>]
```

```
  [--header|-h <header_parameters>]
```

[--query|-q <query_parameters>]

]

Parameters

[--file|-f]

The JSON file that contains the required arguments.

[--type|-t]

Indicates the request type. Valid options: **get** or **post**. If you are using Java adapters, the type also includes **put** and **delete**.

Note: If the **type** parameter is not defined, the adapter call command uses **get** by default. Type cannot be passed in a JSON file.

[--form|-fp]

The form parameters to pass with the procedure. For Java Adapters and Direct Mode use only. Example: `--form "username:user"`.

[--header|-h]

The header parameters to pass with the procedure. For Java Adapters and Direct Mode use only. Example: `--header "password:pass"`.

[--query|-q]

The query parameters to pass with the procedure. For Java Adapters and Direct Mode use only. Example: `--query "date:01/01/2015"`.

Usage

You can use the adapter call command in interactive mode or in direct mode.

Note: In direct mode, any string parameters, such as "stringParameter" in these examples, must have their quotation marks escaped, even if the string object is within an Array or Object object. Escaping string parameters is not necessary in interactive mode.

- Interactive: **\$ mfp adapter call**, then follow the prompts by using the arrow keys.
- Direct with no parameters: **\$ mfp adapter call adapterName/procedure**.
- Direct with multiple parameters: **\$ mfp adapter call adapterName/procedure \"stringParameter\", 2, true**.
- Direct with an array: **\$ mfp adapter call adapterName/procedure [\"stringParameter\", 2, true]**
- Direct with a JSON file parameter: **\$ mfp adapter call adapterName/procedure --file ./myArgs.json**

JSON file

```
[  
  "world"  
]
```

JSON file for Java adapter

```
{  
  "FORM":{"username":"user","password":"pass"},  
  "QUERY":{"index":6},  
  "HEADER":{"Date":"01/01/2015"}  
}
```

- Direct with POST method: **\$ mfp adapter call adapterName/procedure/ {path_parameter} -fp "username:user1" --type post**. To use the **path**

parameters, add them to the adapter/procedure path. Replace the {path_parameter} with your value. For example:

- Before: `myAdapter/users/{username}`
- After: `myAdapter/users/StanLee`
- Direct with Java adapter: `$ mfp adapter call "adapterName/procedure/{pathParameter with space}" --form "username:user" --header "Date:01/01/2015" --query "index:6" --type post`

Important: If the certificate of the server is not recognized as a trusted certificate, the following error is displayed when you run this command: Failed to retrieve runtime information: CERT_UNTRUSTED. To add your certificate to the list of trusted certificates, see "Specifying a trusted SSL certificate" on page 6-199.

add adapter

Deprecated in V7.0.0. Use `adapter add` instead. Creates a new adapter, which is generated into the `adapters` folder of your project.

Syntax

```
mfp add adapter [<name> --type|-t <adapertype> [--jsonstore|-j]
[--ussd|-u] [--package|-p]]
```

Parameters

<name>

The name that you want for the generated adapter.

<adapertype>

The type of adapter. Valid values: `http`, `castiron`, `sap`, `jco`, and `java`.

[--jsonstore|-j]

Your choice of JSONStore procedures. JSONStore procedures are not valid for JCo and Java adapters.

[--ussd|-u]

The option for the Unstructured Supplementary Service Data (USSD) communication technology.

[--package|-p]

The name of the package that contains the Java adapter classes. Package option is valid only for Java adapters.

add api

Generates a new native API into the `apps` folder of the current project.

Syntax

```
mfp add api [<name> --environment|-e
ios|android|javame|windowsphone8|windows8|windowsphoneuniversal]
```

Parameters

<name>

The name that you want for the generated native API.

--environment|-e

`ios`|`android`|`javame`|`windowsphone8`|`windows8`|`windowsphoneuniversal`

The environment or mobile platform.

Usage

Run this command in your current working directory.

add environment

Adds a platform-specific environment to a hybrid application, and adds an entry to the build-settings.xml file.

Syntax

```
mfp add environment [--app|-a <app>][<environments>]
```

Parameters

--app|-a <app>

The app to which you are adding the environment.

[<environments>]

Environment that you are adding to the app. Valid values are: iphone, ipad, android, blackberry, blackberry10, windowsphone8, windows8, air, mobilewebapp, and desktopbrowser.

Usage

- To add an environment when only one hybrid application exists, or when you work in the directory of a hybrid application: **\$ mfp add environment iphone,android**
- To add an environment that specifies the hybrid application: **\$ mfp add environment iphone,android --app myHybridApps**

add feature

Adds optional features to your app.

Syntax

```
mfp add feature [fips|jsonstore|tealeaf]
```

Parameters

fips

FIPS 140-2

jsonstore

JSONStore

tealeaf

IBM Tealeaf SDK

add hybrid

Generates a new hybrid application in the apps folder of the current project.

Syntax

```
mfp add hybrid [<name>]
```

Parameters

<name>

The name that you want for the hybrid application.

Usage

Run this command in your current working directory. If you do not specify a **<name>**, then the interactive mode prompt asks you for one.

add skin

Creates MobileFirst skins in your hybrid app.

Syntax

```
mfp add skin [--environment|-e <type> <name>]
```

Parameters

--environment|-e <type>

Your app environment. Valid values:

android|blackberry|blackberry10|iphone|ipad.

<name>

Name of the skin.

Usage

- Interactive: **\$ mfp add skin**. You are prompted for the environment type and the name of the skin.
- Direct: **\$ mfp add skin [-e android superSkins]**.

(deprecated) bd

Builds and deploys to the local test server the set of MobileFirst resources that are most local to the current working directory.

 **mfp bd** is deprecated, see Table 3-1 on page 3-20. Use **mfp push** instead.

Syntax

```
mfp bd
```

Important: If the certificate of the server is not recognized as a trusted certificate, the following error is displayed when you run this command: Failed to retrieve runtime information: CERT_UNTRUSTED. To add your certificate to the list of trusted certificates, see “Specifying a trusted SSL certificate” on page 6-199.

(deprecated) build

Builds the set of MobileFirst resources that are most local to the current working directory.

 **mfp build** is deprecated, see Table 3-1 on page 3-20. Use **mfp push** instead.

Syntax

```
mfp build [--minify|-m] [--concatenate|-c]
```

Parameters

--minify|-m

Enables minification. The default is to not minify resources during the build. For more information, see the “**build config**” command.

--concatenate|-c

Enables concatenation. The default is to not concatenate resources during the build. For more information, see the “**build config**” command.

Usage

- If you run the command from the root folder of your project, the command builds all the apps and adapters in the project.
- If you run the command from the apps folder, the command builds all the apps in the project.
- If you run the command from the folder of a specific adapter, the command builds that one adapter.

build config

Configures and application’s build settings.

Syntax

```
mfp build-config [update-env <env> --optimize|-o <level>]
```

Purpose

You can configure application environments to enable or disable the minification optimization.

Parameters

<env> The environment that is updated.

--optimize|-o <level>

The level of minification. The following values are valid for the **<level>** parameter.

- **none** - No minification is done to your code by the builder.
- **simple** - Removes comments from your code. Also removes line breaks, unnecessary spaces, and other white space.
- **whitespaces** - Removes the same white space and comments as whitespaces, but also optimizes expressions and functions. This optimization includes renaming variables to shorter names to make the code smaller.

For more information about minification, see “Minification of JS and CSS files” on page 8-371.

Usage

The current working directory must be under an existing hybrid application. If you use this command in any other folder, you receive an error message.

- Interactive mode: Run **\$ mfp build-config** and follow the prompts by using the arrow keys.
- Direct mode: Run **\$ mfp build-config update-env mobileWebApp --optimize simple**

config

Configure settings of your project.

You can configure global settings, that apply to all projects, and client app settings that are specific to individual projects. You can use the **config** command in interactive mode or direct mode. Using the **config** modifies settings that are defined in the `application-descriptor.xml` file, the `.mfp_cli_config.json` file (located in the same directory as the `application-descriptor.xml` file), and the `$HOME/.ibm/mobilefirst/config_cli.json` file. Using the **config** command modifies the values in these files.

Syntax

```
mfp config [<setting>[<value>]]
```

Parameters

<setting>

Name of the setting. For example: `app_author_email` is used to specify the email address of the application author.

<value>

Value to which you are changing the setting. For example: For the `app_author_email` setting, the value might be `"myname@company.com"`.

Usage

Interactive mode

```
$ mfp config
```

In interactive mode you have two options: **Global** or **Client App**. You are prompted for the options that you want to specify.

Global

You can configure the following global settings for your projects.

development_browser

The web browser that you use to preview your app.

default_preview_type

Set the default preview type of your app. You can choose from either the Browser or the Mobile Browser Simulator.

global_app_id_default_prefix

Value with which you can prefix all of your apps. Changing this will change the **application id** attribute of the `application-descriptor.xml` file.

Client App

You can configure settings, or *keys*, that apply to only a specific project. You must be in a MobileFirst project directory of the project that you want to modify when you change these settings.

Common Keys

Configure keys common to all apps.

Platform Keys

Keys that are specific to your target platform.

Direct mode

In direct mode you have two options: **Direct mode setting** or **Direct mode setting and value**:

Direct mode setting

Displays the current value of the entered setting.

Syntax

```
$ mfp config [<setting>]
```

Example

```
$ mfp config app_author_email  
Current value for app_author_email: myname@company.com
```

Direct mode setting and value

Specifies the setting to change and its value.

Syntax

```
$ mfp config [<setting> [<value>] ]
```

Example

```
$ mfp config app_author_email myname@company.com
```

console

Opens the MobileFirst Operations Console in your default browser for the default or specified server.

Syntax

```
mfp console [server]
```

Parameters

server

where *server* is the name of the MobileFirst server definition. If *server* is not specified, then the default server name is used.

Usage

You can run the **mfp console** command from any directory.

cordova create

Creates a Cordova project.

Syntax

```
mfp cordova create [  
  <name>  
  [--platform|-p <platform>]  
  [--id|-i <package>]  
  [--template|-t <template>]  
  [--appversion|-a <version>]  
]
```

Parameters

<name>

Name of your project.

[--platform|-p <platform>]

Space-separated list of platforms to add to the project. Valid values: ios and android.

Important: If you are creating an app for the Android platform, make sure that you set your *ANDROID_HOME* environment variable to your Android SDK.

[--id|-i <package>]

Package ID in reverse domain notation. Example: com.ibm.hellocordova.

[--template|-t <template>]

Template or archive to use as a base line. Example: templates/www.

Important:

- The template must contain a *config.xml* file. Otherwise, a *config.xml* file that is incompatible with IBM MobileFirst Platform Foundation is automatically generated, and an error will occur.
- The *config.xml* file in the template that you use must specify Cordova plug-ins that are compatible with the Cordova platforms that are supplied with IBM MobileFirst Platform Foundation; otherwise an error will occur. For a list of these platforms and other components, see “Product components” on page 2-7.

[--appversion|-a <version>]

Version of the app in the format of *number.number.number*. Example: 5.1.2

Usage

You must run this command outside of an existing project.

- Interactive mode: **\$ mfp cordova create**, then follow the prompts.
- Direct mode: **\$ mfp cordova create helloCordova --platform android**, and you can select your plug-ins.

cordova emulate

Deploys apps on the platform and emulators that you specify.

Prerequisites

Android

- Cordova for Android requires the Android SDK. See this Android web page.
- Before you run **cordova emulate**, make sure to add both Android Debug Bridge (ADB) and Android command-line tools to the system path.

iOS

The Apple tools that are required to build iOS applications run only on the OS X operating system on Intel based Macintosh computers. Xcode 4.5 (the minimum required version) runs only on OS X version 10.7 (Lion) or later, and includes the iOS 6 SDK (Software Development Kit). To submit apps to the Apple App Store[△], you must work with the latest versions of Apple tools.

Syntax

```
mfp cordova emulate [-p|--platform <platform> [-t|--target <target>]]
```

Parameters

-p|--platform <platform>

Platforms on which you run the project. Valid values: ios and android.

Important: Running this command against the ios platform is only applicable for Mac environments. You can add the iOS platform and build your Cordova app while you are working in another development environment such as Linux or Windows. However, the **cordova emulate** command, against ios, must be run from a Mac.

-t|--target <target>

Target platform ID to which you are deploying. Use the device ID for this value. To get the target:

- Android: Use the **adb** command: **\$ adb devices**.
- iOS: Use interactive mode and save the value. Or, you can run **ios-sim showdevicetypes**.

Usage

- Interactive mode: **\$ mfp cordova emulate**
- Direct mode with **<platform>** and **<target>**: **\$ mfp cordova emulate --platform android --target ANDROID_DEVICE_ID**
- Direct mode with **<platform>**: **\$ mfp cordova emulate --platform android**

cordova platform add

Adds a new platform to your Cordova app.

Syntax

```
mfp cordova platform add [<platforms>]
```

Parameters

[<platforms>]

The name of the platforms to add. You can use either a space or a comma to separate the list items. Valid values: ios and android.

Usage

- Interactive mode: **mfp cordova platform add**
- Direct mode: **mfp cordova platform add ios android**

cordova platform list

Lists the platforms that are available and contained in the Cordova app.

Syntax

```
mfp cordova platform list
```

```
mfp cordova platform ls
```

Usage

```
$ mfp cordova platform list
```

cordova platform remove

Removes a platform from your Cordova app.

Syntax

```
mfp cordova platform remove [<platform>]
```

```
mfp cordova platform rm [<platform>]
```

Parameters

<platform>

The platforms that you want to remove from the app. Valid values: ios and android.

Usage

- Direct mode: `$ mfp cordova platform remove`
- Interactive mode: `$ mfp cordova platform remove ios`

cordova platform update

Updates Cordova assets for each platform that you have installed in your app. A backup ZIP file is created for each platform folder before the Cordova assets are updated.

Syntax

```
mfp cordova platform update
```

Usage

```
$ mfp cordova platform update
```

cordova plugin add

Adds plug-ins to your Cordova app.

Syntax

```
mfp cordova plugin add [<plugins>]
```

Parameters

<plugins>

Comma- or space-separated list of plug-ins that you are adding to your app. If the plug-in matches completely or partially one of the known Cordova plug-ins, it is added from a local tools-based repository. Otherwise, the plug-in value is passed to the Cordova plug-in CLI command for processing. Valid types of plug-in patterns: Web URL, Git URL, or a local file path. For example, camera matches org.apache.cordova.camera, but cam does not match org.apache.cordova.camera.

Usage

You must be in a Cordova project to use this command.

- Interactive mode: **\$ mfp cordova plugin add**, then follow the command prompt.
- Direct mode: **\$ mfp cordova plugin add org.apache.cordova.camera** or **\$ mfp cordova plugin add camera**.

cordova plugin list

Lists plugins that are defined in the Cordova app.

Syntax

```
mfp cordova plugin list
```

Or

```
mfp cordova plugin ls
```

Usage

You must be in a Cordova project to use this command.

```
$ mfp cordova plugin list
```

This command results in an output similar to the following example:
org.apache.cordova.camera 0.3.4 "Camera". The plug-in ID in this example is Camera.

cordova plugin remove

Removes a plugin from a Cordova app.

Syntax

```
mfp cordova plugin remove <plugins>
```

or

```
mfp cordova plugin rm <plugins>
```

Parameters

<plugins>

The comma- or space-separated list of plug-ins that you are removing. To find the ID of your plug-in, run the **mfp cordova plugin list** command. The plug-in ID is the String that is represented in reverse domain notation.

Usage

You must be in a Cordova project to use this command.

```
$ mfp cordova plugin remove org.apache.cordova.camera
```

```
$ mfp cordova plugin remove camera
```

cordova plugin search

Searches for a new plugin to install.

Syntax

```
mfp cordova plugin search <key>
```

Parameters

<key>

Keys that you are searching for. The key can be a partial word. For example, `andr` matches `android`.

Usage

You must be in a Cordova project to use this command.

```
$ mfp cordova plugin search andr
```

cordova plugin update

Updates the Cordova assets for each plug-in that is installed in the app.

Syntax

```
mfp cordova plugin update
```

Usage

You must be in a Cordova project to use this command.

```
$ mfp cordova plugin update
```

cordova prepare

Copies all of the necessary files into the platform that you specify, then updates the related source files to build the project.

Syntax

```
mfp cordova prepare [<platforms>]
```

Parameters

<platforms>

Comma-separated or space-separated list of platforms to prepare. If you do not specify this parameter, all platforms in your project are prepared.

Usage

After you create and edit your Cordova project, run the following command to copy and update the necessary files of your project.

```
$ mfp cordova prepare android
```

cordova preview

Previews the current application.

Syntax

```
mfp cordova preview [--platform|-p <environments> --type|-t  
<browser>]7001_byocord
```

Parameters

--platform|-p <environments>

Environments with which you want to preview the application. Valid environments are only environments that exist in your app.

If your comma-separated list of environments contains at least one supported environment, then those environments are used. If the environments that are passed in do not exist in the application or are invalid environments, your app is previewed against the first valid environment in the application.

--type|-t <browser>

The type of browser with which you preview your app. Valid values:

- **mbs**: Mobile Browser Simulator.
- **browser**: Your default browser.

If you do not specify a type, the default browser is used. This default preview type is defined by the **mfp config** command.

Usage

To use this command, the `JAVA_HOME` environment variable must be set to a file path. This file path must be to a Java Development Kit (JDK) root directory.

You must run **mfp start** on a legacy project to use this command. You must have a project runtime that is deployed to push and preview Cordova applications.

- Interactive mode: **\$ mfp cordova preview**. You are prompted for the browser type and environments.
- Direct with the **environment** option: **\$ mfp cordova preview --platform android**.
- Direct with **browser** option: **\$ mfp cordova preview --type mbs**. If you run this command inside a Cordova app folder, the preview is opened for you to view each environment in the app.
- Direct with both environments: **\$ mfp preview --platform android --type mbs**.

cordova run

Deploys apps on the platform and devices that you specify.

Prerequisites

Android

- Cordova for Android requires the Android SDK. See this [Android web page](#).
- Before you run **cordova run**, make sure to add both Android Debug Bridge (ADB) and Android command-line tools to the system path.

iOS The Apple tools that are required to build iOS applications run only on the OS X operating system on Intel based Macintosh computers. Xcode 4.5 (the minimum required version) runs only on OS X version 10.7 (Lion) or later,

and includes the iOS 6 SDK (Software Development Kit). To submit apps to the Apple App Store, you must work with the latest versions of Apple tools.

Syntax

```
mfp cordova run [-p|--platform <platform> [-t|--target <target>]]
```

Parameters

-p|--platform <platform>

Platforms on which you run the project. Valid values: ios and android.

Important: Running this command against the ios platform is only applicable for Mac environments. You can add the iOS platform and build your Cordova app while you are working in another development environment such as Linux or Windows. However, the **cordova run** command, against ios, must be run from a Mac.

-t|--target <target>

Target platform ID to which you are deploying. Use the device ID for this value. To get the target:

- Android: Use the **adb** command: **\$ adb devices**.
- iOS: Try interactive mode, and save the value to use later in direct mode. You can also run **ios-deploy-c**.

Usage

- Interactive mode: **\$ mfp cordova run**
- Direct mode with **<platform>** and **<target>**: **\$ mfp cordova run --platform android --target ANDROID_DEVICE_ID**
- Direct mode with **<platform>**: **\$ mfp cordova run --platform ios**

create

Creates a new project in the current working directory.

Syntax

```
mfp create [<name>]
```

Parameters

<name>

The name of the project that you are creating.

Usage

- To create a project named MyProject: **\$ mfp create MyProject**

(deprecated) create-server

This command does not need to be run manually because the built-in development server is automatically created and started as needed. Creates a new WebSphere Application Server Liberty application server in your default folder.

 **mfp create-server** is deprecated, see Table 3-1 on page 3-20. Use **mfp server create** instead.

Syntax

mfp create-server

Usage

\$ mfp create-server

(deprecated) deploy

Deploys to the local test server the set of resources that are found in the current working directory.

 **mfp deploy** is deprecated, see Table 3-1 on page 3-20. Use **mfp push** instead.

Syntax

mfp deploy

Usage

- If you run the command from the root folder of a project, the command deploys all apps and adapters in the project.
- If you run the command from the apps folder, the command deploys all the apps in the project.
- If you run the command from the folder of a specific adapter, the command deploys that one adapter.
- If you run the command from the folder of a specific application, the command deploys that one application.

Important: If the certificate of the server is not recognized as a trusted certificate, the following error is displayed when you run this command: Failed to retrieve runtime information: CERT_UNTRUSTED. To add your certificate to the list of trusted certificates, see “Specifying a trusted SSL certificate” on page 6-199.

export

Creates a compressed file, which contains either the entire project or the hybrid assets for use in a native application.

Syntax

mfp export [**<path to zip file>**] [**--includeNativeLibs|-i**]

Usage

The current working directory must be under an existing hybrid application or in the root directory. Otherwise, the command returns an error message.

- If your current working directory is in a project root folder, the source files for the entire project are exported.
- If your current working directory is an environment folder inside a hybrid application, the hybrid web assets are exported for that environment.

help

Displays either information about the general use of the CLI, or detailed help for each command.

Syntax

mfp help [<command>]

Usage

- Information about the use of the CLI: **\$ mfp help**.
- Information about the **invoke** command: **\$ mfp help invoke**.
- Information about the IBM MobileFirst Platform Foundation development environment: **\$ mfp help intro**

info

Generates information about your environment. This information contains the operating system, the memory consumption on your machine, the node version, and the CLI version.

Syntax

mfp info

Usage

If your current directory is a project folder, it also displays information about your project.

invoke

This command is deprecated. You can use the **adapter call** command instead. The **invoke** command starts a procedure for a specified adapter on the MobileFirst Server.

Syntax

mfp invoke [<adapter>:<procedure>[\"<json array>\"|**--file**|-f <file path>]]

Parameters

<adapter>

The name of the adapter you are invoking.

<procedure>

The adapter's procedure that you are invoking.

<json array>

JSON array you are passing to the adapter's procedure.

--file|-f <file path>

File path to the JSON array file.

Usage

Pass the arguments as a comma-separated list. If you enter the command with no arguments, you are prompted for an adapter and procedure, based on what is available in the current working directory of your project.

- Interactive: **\$ mfp invoke**, then follow the prompts by using the arrow keys.
- Direct with no parameters: **\$ mfp invoke adapterName:function**.

- Direct with a JSON array parameter: `$ mfp invoke adapterName:function ["string", 2, true]`.
- Direct with a JSON file parameter: `$ mfp invoke adapterName:function --file ./myArts.json`.

logs

Displays the path to the local test server logs.

Syntax

`mfp logs`

Usage

You can run this command from any directory: `$ mfp logs`

preview

displays a preview of the current application or environment in your default browser by using the Mobile Browser Simulator (MBS). This command does not support the use of remote servers.

Syntax

`mfp preview [<environments>] [--noshell|-n]`

Parameters

<environments>

The environments that you are previewing in MBS. If the environments that are passed in do not exist in the application or are invalid environments, the application is previewed by using the first valid environment in the application. If there are no valid environments, the common preview is used to view the application. If the list of environments contains at least one supported environment, then the MBS is used to preview the application with the valid environment.

--noshell|-n

Opens the application's environments directly in your default browser. These environments are opened with the MBS. If this option is run inside an application folder, the common preview is opened to view each environment in the application. If this option is run inside an environment folder, the common preview is used to preview the application by using that environment.

Usage

Note: To use this command, the `JAVA_HOME` environment variable must be set to a file path. This file path must be to the root directory of a Java Development Kit (JDK).

- Preview in application folder: `$ mfp preview`.
- Preview in environment folder: `$ mfp preview`.
- Preview with environments: `$ mfp preview <environments>`.
- Preview with the `--noshell|-n` option: `$ mfp preview --noshell|-n`.
- Preview with Environments and `--noshell|-n` option: `$ mfp preview <environments> --noshell|-n`.

push

This command replaces the previous **mfp build**, **mfp deploy**, and **mfp bd** commands. Prepares and transfers the relevant assets to either a local or remote MobileFirst Server. These assets can either be native app registration, hybrid app registration, or Cordova app registration. These assets also include web content for either direct update or the deployment of adapters.

Syntax

```
mfp push [<server>] [<runtime>] [--password|-p <password>] [--minify|-m]
[--concatenate|-c] [--nosend|-n]
```

Parameters

<server>

Name of predefined server to push to. This parameter is optional, and the default server is used if you do not provide this parameter. For a list of defined servers, run **mfp server info**. Define new servers by running **mfp server add**.

<runtime>

Runtime of your back-end project running on the server.

- If this value is not specified and the **mfp push** command was previously run for this application, the command uses the runtime value from the last time **mfp push** was run.
- If this value is not specified and this is the first time **mfp push** is run for this application, the runtime value is obtained from the server:
 - if there is a single runtime on the server, it is used.
 - if there are multiple runtimes, you are prompted to select a runtime.
 - if there are no runtimes on the server, the command exits with an error.
- If the **mfp push** command is run from within a MobileFirst project folder, the runtime value must exactly match the project runtime name; otherwise the command exits with an error.

--password|-p <password>

The password for the admin login ID. If you do not supply this parameter and it is not in server configuration, you are prompted for the admin password on all server management tasks.

--minify|-m

Enables minification of web assets for hybrid apps. By default, no minification is performed during a hybrid app push.

--concatenate|-c

Enables concatenation of web assets for hybrid apps. By default, no concatenation is performed during a hybrid app push.

--nosend|-n

Prevents the deployment of artifacts to the target server. You can use this in automated build environments where the build and deployment steps are isolated.

The following actions are taken:

- MobileFirst Project:
 - WAR and .wladapter are created.

- If the target server is a local server and if the WAR file was not deployed to this server before: the WAR file is built and deployed to the server (no matter where you run the command from).
- If the target server is a local server and if the WAR file was deployed to this server before: the WAR is not deployed again, unless you run the **mfp push** command from the root directory of your project (in which case the WAR is redeployed).
- MobileFirst Native app: application-descriptor.xml and .wlap are created and updated.
- MobileFirst Hybrid app: application-descriptor.xml and .wlap are created and updated with optional minification and concatenation.
- Cordova app: Cordova app built, application-descriptor.xml and .wlap are created and updated.
- Android native app: wlClient.properties, application-descriptor.xml and .wlap are created and updated.
- iOS native app: worklight.plist, application-descriptor.xml and .wlap are created and updated.
- Standalone Windows Phone 8 native app: wlclient.properties, application-descriptor.xml and .wlap are created and updated.
- Standalone Windows Universal native app: Windows Universal consists of the platforms Windows 8 and Windows Phone Universal. wlclient.properties, application-descriptor.xml, and .wlap are created and updated for both platforms.

Usage

Run this command in the current working directory, which is a child of a project.

```
$ mfp push
```

Important: If the certificate of the server is not recognized as a trusted certificate, the following error is displayed when you run this command: Failed to retrieve runtime information: CERT_UNTRUSTED. To add your certificate to the list of trusted certificates, see “Specifying a trusted SSL certificate” on page 6-199.

remove feature

Removes optional features from your hybrid applications.

Syntax

```
mfp remove feature [fips|jsonstore|tealeaf]
```

Parameters

fips

FIPS 140-2

jsonstore

JSONStore

tealeaf

IBM Tealeaf SDK

Usage

The current working directory must be under an existing hybrid application.

- Interactive: **\$ mfp remove feature:** the [?] prompt shows what features you can remove. Use the arrow keys to select the feature and press Enter to remove it.
- Direct: **\$ mfp remove feature [fips|jsonstore|tealeaf].**

restart

Restarts the local test server.

Syntax

```
mfp restart
```

Usage

Run this command in the current working directory, which is a child of a project. On completion, a message indicates a successful start, and control is returned to the command line.

```
$ mfp restart
```

run

Starts the local test server.

Syntax

```
mfp run
```

Usage

Run this command in the current working directory, which is a child of a project. This command does not return control to the command line. It displays new status messages from the server until the server is stopped.

```
$ mfp run
```

server add

Adds a server definition.

Syntax

```
mfp server add  
  [<name> --url|-u <url> [--login|-l <login>]  
  [--password|-p <password>]  
  [--contextroot|-c <context root>]  
  [--setdefault|-s]  
  ]
```

Parameters

<name>

The name of the server to use as an alias.

--url|-u <url>

The fully qualified URL of the server. The syntax must include the full: protocol://name.domain:port. The IP address might also be used instead of name.domain. This value is required if the server name is supplied on the command line.

--login|-l <login>

The admin login ID that is used to manage the MobileFirst Server. If not set, defaults to admin.

--password|-p <password>

The password for the admin login ID. If you do not set this parameter, you are prompted for the admin password on all server management tasks. There is no default password.

--contextroot|-c <context root>

The context root of the MobileFirst administration services. If not set, defaults to worklightadmin.

--setdefault|-s

Providing this flag makes this new server the new default server profile. You can switch the default by using the **mfp server edit** command.

Usage

- Interactive mode: **\$ mfp server add**
- Direct mode: **\$ server add name --url http://acme.com:10080 --setdefault**

Important: If the certificate of the server is not recognized as a trusted certificate, the following error is displayed when you run this command: Failed to retrieve runtime information: CERT_UNTRUSTED. To add your certificate to the list of trusted certificates, see “Specifying a trusted SSL certificate” on page 6-199.

server create

Create or recreate a local development server. A server profile is automatically generated for this server. This command replaces the deprecated **mfp create-server** command.

Syntax

```
mfp server create
```

Usage

```
$ mfp server create.
```

Important: If the certificate of the server is not recognized as a trusted certificate, the following error is displayed when you run this command: Failed to retrieve runtime information: CERT_UNTRUSTED. To add your certificate to the list of trusted certificates, see “Specifying a trusted SSL certificate” on page 6-199.

server edit

Edits an existing server definition.

Syntax

mfp server edit

```
[<name> [--name|-n <newName>] [--url|-u <newUrl>]
[--login|-l <newLogin>] [--password|-p <newPassword>]
[--contextroot|-c <newContextRoot>] [--setdefault|-s]]
```

Parameters

<name>

The name of the server to modify.

--name|-n <newName>

The new name for this alias. Renames this entry.

--url|-u <newUrl>

The fully qualified URL of the server. The syntax must include the full: protocol://name.domain:port. The IP address can also be used instead of name.domain. This value is required if the server name is supplied on the command line.

--login|-l <newLogin>

The admin login ID used to manage the MobileFirst Server.

--password|-p <newPassword>

The password for the admin login ID. If not supplied, you are prompted for the admin password on all server management tasks.

--contextroot|-c <newContextRoot>

The context root of the MobileFirst administration services.

--setdefault|-s

Providing this flag makes this new server the new default server profile.

Usage

- Interactive mode: **\$ mfp server edit**.
- Direct mode: **\$ mfp server edit staging --name preprod --setdefault**

Important: If the certificate of the server is not recognized as a trusted certificate, the following error is displayed when you run this command: Failed to retrieve runtime information: CERT_UNTRUSTED. To add your certificate to the list of trusted certificates, see “Specifying a trusted SSL certificate” on page 6-199.

server info

Provides information for all servers or a specific server.

Syntax

```
mfp server info [<name> [--password|-p <password>]]
```

Parameters

<name>

The name of a specific server that you want information about.

--password|-p <password>

The password for the admin login ID. If not supplied, you are prompted for the admin password on all server management tasks. Not applicable if you don't provide a server.

Usage

There is no interactive mode for this command, other than the possible prompt for a server's password.

- **\$ mfp server info**
- **\$ mfp server info name**

Important: If the certificate of the server is not recognized as a trusted certificate, the following error is displayed when you run this command: Failed to retrieve runtime information: CERT_UNTRUSTED. To add your certificate to the list of trusted certificates, see "Specifying a trusted SSL certificate" on page 6-199.

server remove

Removes an existing server definition.

Syntax

mfp server remove [<name>]

Parameters

<name>

The name of the server to remove.

Usage

- Interactive mode: **\$ mfp server mode.**
- Direct mode: **\$ mfp server remove name**

start

Starts the local test server.

Syntax

mfp start

Usage

Run this command in the current working directory, which is a child of a project. On completion, a message indicates that a successful start and control is returned to the command line.

\$ mfp start

status

Displays the status of the local test server, which is either running or stopped.

Syntax

mfp status

Usage

Run the command in the current working directory, which is a child of a project.

```
$ mfp status
```

stop

Stops the local test server.

Syntax

```
mfp stop [--kill|-k]
```

Parameters

--kill|-k

If you are unable to stop your server, this flag causes your operating system to send signals to the running server process to request the process to end.

Usage

Run this command in the current working directory, which is a child of a project.

```
$ mfp stop
```

```
$ mfp stop --kill
```

Ant configuredatabase task reference

Reference information for the **configuredatabase** Ant task. This reference information is for relational databases only. It does not apply to Cloudant.

Overview

Note: In MobileFirst Server V7.1.0, the reports database (WLREPORT) is deprecated. Use “Operational analytics” on page 14-9 instead. Note that setting up the reports database is optional in this release and earlier releases.

The **configuredatabase** Ant task creates the relational databases that are used by MobileFirst Administration Services, the MobileFirst runtime, and the Application Center Services. This Ant task configures a relational database for a MobileFirst project, or the Application Center Services, through the following actions:

- Checks whether the MobileFirst tables exist and creates them if necessary.
- If the tables exist for an older version of IBM MobileFirst Platform Foundation, migrates them to the current version.
- If the tables exist for the current version of IBM MobileFirst Platform Foundation, does nothing.

In addition, if one of the following conditions is met:

- The DBMS type is Derby.
- An inner element <dba> is present.
- The DBMS type is DB2, and the specified user has the permissions to create databases.

Then, the task can have the following effects:

- Create the database if necessary (except for DB2, Oracle 12c, and Cloudant).
- Create a user, if necessary, and grants that user access rights to the database.

Note: The **configuredatabase** Ant task has not effect if you use it with Cloudant.

In IBM Worklight Foundation V6.2.0, a new database was introduced, which is referenced with kind **WorklightAdmin** for Administration Services. This database can support one MobileFirst runtime or more, and can handle the artifacts of those MobileFirst runtimes.

Important: If you upgrade from an IBM Worklight version earlier that V6.2.0, you must also migrate the data from the IBM Worklight runtime to the new database for MobileFirst Administration Services. IBM Worklight Foundation V6.2.0 introduced a new element, **admindatabase**, for this purpose, as shown in Table 2.

Attributes and elements for configuredatabase

The **configuredatabase** task has the following attributes:

Table 16-1. Attributes for the **configuredatabase** Ant task

Attribute	Description	Required	Default
kind	Type of database: In MobileFirst Server: Worklight , WorklightReports , or WorklightAdmin In Application Center: ApplicationCenter	Yes	None

IBM MobileFirst Platform Foundation V7.1.0 supports four kinds of database: MobileFirst runtimes use **Worklight** and **WorklightReports** databases. MobileFirst Administration Services use the **WorklightAdmin** database. Application Center uses the **ApplicationCenter** database.

The **configuredatabase** task supports the following elements:

Table 16-2. Inner elements for the **<configuredatabase>** Ant task

Element	Description	Count
derby	Parameters for Derby	0..1
db2	Parameters for DB2	0..1
mysql	Parameters for MySQL	0..1
oracle	Parameters for Oracle	0..1
driverclasspath	JDBC driver class path	0..1
admindatabase	Parameters for migrating data from IBM Worklight V6.1.x runtime to IBM MobileFirst Platform Foundation V7.1.0 Administration Services database	0..1

For each database type, you can use a **<property>** element to specify a JDBC connection property for access to the database. The **<property>** element has the following attributes:

Table 16-3. Attributes for the <property> element

Attribute	Description	Required	Default
name	Name of the property	Yes	None
value	Value for the property	Yes	None

Attributes and elements for admindatabase

Use the <admindatabase> element for migrating data from a MobileFirst runtime database to the MobileFirst Administration Services database. This element is mandatory when you migrate your IBM Worklight runtime projects from V6.1.x and the kind attribute of **configuredatabase** is **Worklight**.

The admindatabase element has the following attribute.

Table 16-4. Attribute for the <admindatabase> element

Attribute	Description	Required	Default
runtimeContextRoot	Context root of the MobileFirst runtime	Yes	None

Because the MobileFirst Administration Services can handle one or more MobileFirst runtimes, you must reference a specific context root for each runtime. Use the runtimeContextRoot attribute to specify this context root. After MobileFirst data is migrated, you cannot change the context root of the MobileFirst runtime, unless the MobileFirst Administration Services database is removed and a new database is created.

The <admindatabase> element supports the following elements.

Table 16-5. Inner elements for the <admindatabase> element

Element	Description	Count
derby	Parameters for Derby	0..1
db2	Parameters for DB2	0..1
driverclasspath	JDBC driver class path	0..1
mysql	Parameters for MySQL	0..1
oracle	Parameters for Oracle	0..1

Apache Derby

The <derby> element has the following attributes:

Table 16-6. Attributes for the <derby> element

Attribute	Description	Required	Default
database	Database name	No	WRKLGHT, WLREPORT, WLADMIN, or APPCNTR, depending on kind.
datadir	Directory that contains the databases	Yes	None

Table 16-6. Attributes for the <derby> element (continued)

Attribute	Description	Required	Default
schema	Schema name	No	WORKLIGHT, WORKLIGHT, WLADMINISTRATOR, or APPCENTER, depending on kind

The <derby> element supports the following elements:

Table 16-7. Inner elements for the <derby> element

Element	Description	Count
property	JDBC connection property	0..∞

For the available properties, see Setting attributes for the database connection URL.

DB2

The <db2> element has the following attributes:

Table 16-8. Attributes for the <db2> element

Attribute	Description	Required	Default
database	Database name	No	WRKLGHT, WLREPORT, WLADMIN, or APPCNTR, depending on kind
server	Host name of the database server	Yes	None
port	Port on the database server	No	50000
user	User name for accessing databases	Yes	None
password	Password for accessing databases	No	Queried interactively
instance	Name of the DB2 instance	No	Depends on the server
schema	Schema name	No	Depends on the user

For more information about DB2 user accounts, see DB2 security model overview.

The <db2> element supports the following elements:

Table 16-9. Inner elements for the <db2> element

Element	Description	Count
property	JDBC connection property	0..∞
dba	Database administrator credentials	0..1

For the available properties, see Properties for the IBM Data Server Driver for JDBC and SQLJ.

The inner element <dba> specifies credentials for database administrators. This element has the following attributes:

Table 16-10. Attributes for the <dba> element for DB2 databases

Attribute	Description	Required	Default
user	User name for accessing database	Yes	None
password	Password or accessing database	No	Queried interactively

The user that is specified in a <dba> element must have the SYSADM or SYSCTRL DB2 privilege. For more information, see Authorities overview.

The <driverclasspath> element must contain JAR files for the DB2 JDBC driver and for the associated license. You can retrieve those files in one of the following ways:

- Download DB2 JDBC drivers from the DB2 JDBC Driver Versions page
- Or fetch the db2jcc4.jar file and its associated db2jcc_license_*.jar files from the DB2_INSTALL_DIR/java directory on the DB2 server.

You cannot specify details of table allocations, such as the table space, by using the Ant task. To control the table space, you must use the manual instructions in section “Configuring the DB2 databases manually” on page 12-20.

MySQL

The element <mysql> has the following attributes:

Table 16-11. Attributes for the <mysql> element

Attribute	Description	Required	Default
database	Database name	No	WRKLGHT, WLREPORT, WLADMIN, or APPCNTR, depending on kind
server	Host name of the database server	Yes	None
port	Port on the database server	No	3306
user	User name for accessing databases	Yes	None
password	Password for accessing databases	No	Queried interactively

For more information about MySQL user accounts, see MySQL User Account Management.

The <mysql> element supports the following elements:

Table 16-12. Inner elements for the <mysql> element

Element	Description	Count
property	JDBC connection property	0..∞
dba	Database administrator credentials	0..1
client	The host that is allowed to access the database	0..∞

For the available properties, see Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J.

The inner element <dba> specifies database administrator credentials. This element has the following attributes:

Table 16-13. Attributes for the <dba> element for MySQL databases

Attribute	Description	Required	Default
user	User name for accessing databases	Yes	None
password	Password for accessing databases	No	Queried interactively

The user that is specified in a <dba> element must be a MySQL superuser account. For more information, see Securing the Initial MySQL Accounts.

Each <client> inner element specifies a client computer or a wildcard for client computers. These computers are allowed to connect to the database. This element has the following attributes:

Table 16-14. Attributes for the <client> element for MySQL databases

Attribute	Description	Required	Default
hostname	Symbolic host name, IP address, or template with % as a placeholder	Yes	None

For more information about the hostname syntax, see Specifying Account Names.

The <driverclasspath> element must contain a MySQL Connector/J JAR file. You can download that file from the Download Connector/J page.

Alternatively, you can use the <mysql> element with the following attributes:

Table 16-15. Alternative attributes for the <mysql> element

Attribute	Description	Required	Default
url	Database connection URL	Yes	None
user	User name for accessing databases	Yes	None
password	Password for accessing databases	No	Queried interactively

Note: If you specify the database with the alternative attributes, this database must exist, the user account must exist, and the database must already be accessible to the user. In this case, the **configuredatabase** task does not attempt to create the database or the user, nor does it attempt to grant access to the user. The **configuredatabase** task ensures only that the database has the required tables for the current MobileFirst Server version. You do not have to specify the inner elements <dba> or <client>.

Oracle

The element `<oracle>` has the following attributes:

Table 16-16. Attributes for the `<oracle>` element

Attribute	Description	Required	Default
database	Database name, or Oracle service name Note: You must always use a service name to connect to a PDB database.	No	ORCL
server	Host name of the database server	Yes	None
port	Port on the database server	No	1521
user	User name for accessing databases. See the note under this table.	Yes	None
password	Password for accessing databases	No	Queried interactively
sysPassword	Password for the user SYS	No	Queried interactively if the database does not yet exist
systemPassword	Password for the user SYSTEM	No	Queried interactively if the database or the user does not exist yet

Note: For the **user** attribute, use preferably a user name in uppercase letters. Oracle user names are generally in uppercase letters. Unlike other database tools, the **configuredatabase** Ant task does not convert lowercase letters to uppercase letters in the user name. If the **configuredatabase** Ant task fails to connect to your database, try to enter the value for the **user** attribute in uppercase letters.

For more information about Oracle user accounts, see Overview of Authentication Methods.

The `<oracle>` element supports the following elements:

Table 16-17. Inner elements for the `<oracle>` element

Element	Description	Count
property	JDBC connection property	0..∞
dba	Database administrator credentials	0..1

For information about the available connection properties, see Class OracleDriver.

The inner element `<dba>` specifies database administrator credentials. This element has the following attributes:

Table 16-18. Attributes for the `<dba>` element for Oracle databases

Attribute	Description	Required	Default
user	User name for accessing databases	Yes	None
password	Password for accessing databases	No	Queried interactively

The `<driverclasspath>` element must contain an Oracle JDBC driver JAR file. You can download Oracle JDBC drivers from JDBC, SQLJ, Oracle JPublisher and Universal Connection Pool (UCP).

You cannot specify details of table allocation, such as the table space, by using the Ant task. To control the table space, you can create the user account manually and assign it a default table space before running the Ant task. To control other details, you must use the manual instructions in section “Configuring the Oracle databases manually” on page 12-32.

Alternatively, you can use the <oracle> element with the following attributes:

Table 16-19. Alternative attributes for the <oracle> element

Attribute	Description	Required	Default
url	Database connection URL	Yes	None
user	User name for accessing databases	Yes	None
password	Password for accessing databases	No	Queried interactively

Note: If you specify the database with the alternative attributes, this database must exist, the user account must exist, and the database must already be accessible to the user. In this case, the task does not attempt to create the database or the user, nor does it attempt to grant access to the user. The **configuredatabase** task ensures only that the database has the required tables for the current MobileFirst Server version. You do not have to specify the inner element <dba>.

Customizing the database connection with JDBC properties

You can customize the database connection with JDBC properties. This can be used to define the security (SSL) of the connection to the database server, timeouts, or JDBC traces.

About this task

To customize the database connection, you must add <property> elements to the database elements for the tasks **configuredatabase**, **configureapplicationserver**, and **installworklightadmin**. The JDBC properties are used by the Ant tasks when connecting to the database, and by the application server data source installed by **configureapplicationserver** and **installworklightadmin**.

You can find in the following procedure an example that defines the properties to set the command timeout for DB2 for the connection to the administration database.

Note: The steps for customization that are described in this page do not apply if you are using a Cloudant database. For customizing Cloudant, see Property keys and values for Cloudant configuration and Table 6-29 on page 6-121.

Procedure

1. From the “Sample configuration files” on page 16-77, select the file `configure-liberty-db2.xml`, and copy it to your working directory.
2. Review the Properties for the IBM Data Server Driver for JDBC and SQLJ in the DB2 for Linux UNIX and Windows user documentation.
3. Edit the Ant file to add the relevant JDBC properties in **configuredatabase**, **configureapplicationserver**, and **installworklightadmin**.

```
<target name="admdatabases">
  <configuredatabase kind="WorklightAdmin">
    <db2 database="{database.db2.wladmin.dbname}"
      server="{database.db2.host}"
```

```

        instance="${database.db2.instance}"
        user="${database.db2.wladmin.username}"
        port= "${database.db2.port}"
        schema = "${database.db2.wladmin.schema}"
        password="${database.db2.wladmin.password}">

        <property name="commandTimeout" value="10"/>

    </db2>

    (...)

<target name="admininstall">
  <installworklightadmin>
    <console install="${wladmin.console.install}"/>
    <jmx/>
    <applicationserver>
      <websphereapplicationserver installdir="${appserver.was.installdir}"
        profile="${appserver.was.profile}">
        <server name="${appserver.was85liberty.serverInstance}"/>
      </websphereapplicationserver>
    </applicationserver>
    <user name="${wladmin.default.user}"
      role="worklightadmin"
      password="${wladmin.default.user.initialpassword}"/>
    <database kind="WorklightAdmin">
      <db2 database="${database.db2.wladmin.dbname}"
        server="${database.db2.host}"
        user="${database.db2.wladmin.username}"
        port= "${database.db2.port}"
        schema = "${database.db2.wladmin.schema}"
        password="${database.db2.wladmin.password}">

        <property name="commandTimeout" value="10"/>

      </db2>

    (...)

```

Encrypting database password with Ant tasks for Liberty

You can use Ant tasks to encrypt database passwords for the WebSphere Application Server Liberty server with the aes algorithm.

About this task

By default, Ant tasks encrypt passwords for the WebSphere Application Server Liberty server with the xor algorithm. You can encrypt them with the aes algorithm, but only with the default key.

You can use passwords that are already encrypted as input for the Ant tasks, for example if the Ant tasks are used by persons that should not have access to database production passwords.

Procedure

1. From the "Sample configuration files" on page 16-77 select the file `configure-liberty-<database>.xml`, and copy it to your working directory.
2. Add a **libertyEncoding** attribute with the value `none` in the `websphereapplicationserver` element of the **configureApplicationServer** and **installWorklightAdmin** Ant tasks. For more information, see table 6 of "Ant tasks for installation of MobileFirst runtime environments" on page 16-42.

- For each database element of **configureApplicationServer** and **installWorklightAdmin**, add an attribute **validate** with the value **false**.

```

<target name="admininstall">
  <installworklightadmin >
    [...]
    <applicationserver>
      <websphereapplicationserver installldir="${appserver.was.installldir}"
        profile="${appserver.was.profile}"
        libertyEncoding="none">
        <server name="${appserver.was85liberty.serverInstance}"/>
      </websphereapplicationserver>
    </applicationserver>
    <database kind="WorklightAdmin" validate="false">
    [...]

<target name="install">
  <configureapplicationserver contextroot="${worklight.contextroot}">
    <project warfile="${worklight.project.war.file}"/>
    <applicationserver>
      <websphereapplicationserver installldir="${appserver.was.installldir}"
        profile="${appserver.was.profile}"
        libertyEncoding="none">
        <server name="${appserver.was85liberty.serverInstance}"/>
      </websphereapplicationserver>
    </applicationserver>
    <database kind="Worklight" validate="false">
    [...]
  </database>
  <database kind="WorklightReports" validate="false">
  [...]

```

- Put the encrypted values in the properties for the database passwords.
For more information about the parameters of Ant tasks, see “Ant tasks for installation of MobileFirst runtime environments” on page 16-42 and “Ant tasks for installation of MobileFirst Operations Console and Administration Services.”

Note: You can use this `configure-liberty-<database>.xml` file only to deploy, update, or uninstall applications to an application server, with the targets `install`, `minimal-update`, `uninstall`, `adminstal`, `adm-minimalupdate`, or `admuninstall`. You cannot use this file to create or migrate a database, with the targets `databases` or `admdatabases`, because the Ant file must have valid unencrypted database credentials to perform the database operations.

What to do next

See also:

- “Deploying the MobileFirst Operations Console and Administration Services with Ant tasks” on page 6-75
- “Deploying a project WAR file and configuring the application server with Ant tasks” on page 12-16

Ant tasks for installation of MobileFirst Operations Console and Administration Services

The `<installworklightadmin>`, `<updateworklightadmin>`, and `<uninstallworklightadmin>` Ant tasks are provided for the installation of the MobileFirst Operations Console and Administration Services.

Task effects

<installworklightadmin>

The <installworklightadmin> task configures an application server to run an Administration Services WAR file as a web application and, optionally, to install the MobileFirst Operations Console. This task has the following effects:

- It declares the Administration Services web application in the specified context root, by default /worklightadmin.
- For the relational databases, it declares data sources and, on WebSphere Application Server Full Profile, JDBC providers for Administration Services.
- It deploys the Administration Services on the application server.
- Optionally, it declares the MobileFirst Operations Console as a web application in the specified context root, by default /worklightconsole. If the MobileFirst Operations Console instance is specified, the Ant task declares the appropriate JNDI environment entry to communicate with the corresponding management service. For example:

```
<target name="admininstall">  
  <installworklightadmin servicewar="${worklight.service.war.file}">  
    <console install="${wladmin.console.install}" warFile="${worklight.console.war.file}"/>  
  </installworklightadmin>  
</target>
```

- Optionally, it deploys the MobileFirst Operations Console WAR file on the application server.
- It configures configuration properties for the Administration Services by using JNDI environment entries. These JNDI environment entries also give some additional information about the application server topology, for example whether the topology is a stand-alone configuration, a cluster, or a server farm.
- Optionally, it configures users that it maps to roles used by the MobileFirst Operations Console and Administration Services web applications.
- It configures the application server for use of JMX.
- On WebSphere Application Server, it configures the necessary custom property for the web container.

<updateworklightadmin>

The <updateworklightadmin> task updates an already-configured MobileFirst web application on an application server. This task has the following effects:

- It updates the Administration Services WAR file. This file must have the same base name as the corresponding WAR file that was previously deployed.
- It updates the MobileFirst Operations Console WAR file. This file must have the same base name as the corresponding WAR file that was previously deployed.

The task does not change the application server configuration, that is, the web application configuration, data sources, JNDI environment entries, user-to-role mappings, and JMX configuration.

Note: On WebSphere Application Server Liberty profile, the task does not change the features, which leaves a potential non-minimal list of features in the server.xml file for the installed application.

<uninstallworklightadmin>

The <uninstallworklightadmin> Ant task undoes the effects of an earlier run of <installworklightadmin>. This task has the following effects:

- It removes the configuration of the Administration Services web application with the specified context root. As a consequence, the task also removes the settings that were added manually to that application.
- It removes the Administration Services WAR file and the MobileFirst Operations Console WAR file from the application server as an option.
- For the relational DBMS, it removes the data sources and – on WebSphere Application Server Full Profile – the JDBC providers for Administration Services.
- For the relational DBMS, it removes the database drivers that were used by Administration Services from the application server.
- It removes the associated JNDI environment entries.
- It removes the users configured by the installworklightadmin invocation.
- It removes the JMX configuration.

Attributes and elements

The <installworklightadmin>, <updateworklightadmin>, and <uninstallworklightadmin> tasks have the following attributes:

Table 16-20. Attributes for the <installworklightadmin>, <updateworklightadmin>, and <uninstallworklightadmin> Ant tasks

Attribute	Description	Required	Default
contextroot	Common prefix for URLs to admin services, to get information about MobileFirst runtime environments, applications, and adapters	No	/worklightadmin
id	Distinguishes different deployments	No	Empty
environmentId	Distinguishes different MobileFirst environments	No	Empty
servicewar	The WAR file for the Administration Services	No	The worklightadmin.war file is in the same directory as the worklight-ant-deployer.jar file.
shortcutsDir	Directory where to place shortcuts	No	None
wasStartingWeight	Start order for WebSphere Application Server. Lower values start first.	No	1

contextroot and id

The contextroot and id attributes distinguish different deployments of MobileFirst Operations Console and Administration Services.

In WebSphere Application Server Liberty profiles and in Tomcat environments, the contextroot parameter is sufficient for this purpose. In WebSphere Application Server Full profile environments, the id attribute is

used instead. Without this id attribute, two WAR files with the same context roots might conflict and these files would not be deployed.

environmentId

Use the environmentId attribute to distinguish several environments, consisting each of MobileFirst Server administration and MobileFirst runtime web applications, that must operate independently. For example, with this option you can host a test environment, a pre-production environment, and a production environment on the same server or in the same WebSphere Application Server Network Deployment cell. This environmentId attribute creates a suffix that is added to MBean names that the Administration Services and the MobileFirst runtime projects use when they communicate through Java Management Extensions (JMX).

servicewar

Use the servicewar attribute to specify a different directory for the Administration Services WAR file. You can specify the name of this WAR file with an absolute path or a relative path.

shortcutsDir

The shortcutsDir attribute specifies where to place shortcuts to the MobileFirst Operations Console. If you set this attribute, you can add the following files to that directory:

- mobilefirst-console.url: This file is a Windows shortcut. It opens the MobileFirst Operations Console in a browser.
- mobilefirst-console.sh: This file is a UNIX shell script and opens the MobileFirst Operations Console in a browser.
- worklight-admin-service.url: This file is a Windows shortcut. It opens in a browser and calls a REST service that returns a list of the MobileFirst projects that can be managed in JSON format. For each listed MobileFirst project, some details are also available about their artifacts, such as the number of applications, the number of adapters, the number of active devices, the number of decommissioned devices. The list also indicates whether the MobileFirst project runtime is running or idle.
- worklight-admin-service.sh: This file is a UNIX shell script that provides the same output as the worklight-admin-service.url file.

wasStartingWeight

Use the wasStartingWeight attribute to specify a value that is used in WebSphere Application Server as a weight to ensure that a start order is respected. As a result of the start order value, the Administration Services web application is deployed and started before any other MobileFirst runtime projects. If MobileFirst projects are deployed or started before the web application, the JMX communication is not established and the runtime cannot synchronize with the administration database and cannot handle server requests.

The <installworklightadmin>, <updateworklightadmin>, and <uninstallworklightadmin> tasks support the following elements:

Table 16-21. Inner elements for the <installworklightadmin>, <updateworklightadmin>, and <uninstallworklightadmin> Ant tasks

Element	Description	Count
applicationserver	Application server	1
console	Administration console	0..1
database	Databases	1

Table 16-21. Inner elements for the <installworklightadmin>, <updateworklightadmin>, and <uninstallworklightadmin> Ant tasks (continued)

Element	Description	Count
jmx	Enable Java Management Extensions	1
property	Properties	0..∞
user	User to be mapped to a security role	0..∞

To specify a MobileFirst Operations Console

The <console> element collects information to customize the installation of the MobileFirst Operations Console. This element has the following attributes:

Table 16-22. Attributes of the <console> element

Attribute	Description	Required	Default
contextroot	URI of the MobileFirst Operations Console	No	/worklightconsole
install	Indicates whether the MobileFirst Operations Console must be installed	No	Yes
warfile	Console WAR file	No	The worklightconsole.war file is in the same directory as the worklight-ant-deployer.jar file.

The <console> element supports the following element:

Table 16-23. Inner element for the <console> element

Element	Description	Count
property	Properties	0..∞

The <property> element specifies a deployment property to be defined in the application server. It has the following attributes:

Table 16-24. Attributes for the <property> element

Attribute	Description	Required	Default value
name	Name of the property	Yes	None
value	Value of the property	Yes	None

By using this element, you can define your own JNDI properties or override the default value of the JNDI properties that are provided by the Administration Services and the MobileFirst Operations Console WAR files.

For more information about the JNDI properties, see “List of JNDI properties for MobileFirst Server administration” on page 6-111.

To specify an application server

Use the `<applicationserver>` element to define the parameters that depend on the underlying application server. The `<applicationserver>` element supports the following elements. The attributes and inner elements of these elements are described in Table 16-36 on page 16-46 through Table 16-43 on page 16-48 of “Ant tasks for installation of MobileFirst runtime environments” on page 16-42.

Table 16-25. Inner elements of the `<applicationserver>` element

Attribute	Description	Count
<code>websphereapplicationserver</code> or <code>was</code>	The parameters for WebSphere Application Server.	0..1
<code>tomcat</code>	The parameters for Apache Tomcat.	0..1

To specify JMX communication between the MobileFirst Server administration and the MobileFirst projects

Use the `<jmx>` element to ensure that a JMX connection can be established between the MobileFirst Server administration and the MobileFirst runtime projects. The `<jmx>` element has the following attributes, which depend on the underlying application server.

Table 16-26. Attributes of the `<jmx>` element

Attribute	Description	Required	Default
<code>libertyAdminUser</code>	The administrator (for Liberty only)	No	None
<code>libertyAdminPassword</code>	The administrator password (for Liberty only).	No	None
<code>CreateLibertyAdmin</code>	Whether the <code>admin</code> user must be created in the basic registry, if it does not exist (for Liberty only).	No	true
<code>tomcatRMIPort</code>	The RMI port that Apache Tomcat uses to connect to MobileFirst projects (for Tomcat only)	No	8686
<code>tomcatSetEnvConfig</code>	Prevents automatic modification of <code>setenv.bat</code> and <code>setenv.sh</code> scripts. The valid values are <code>manual</code> and <code>auto</code> .	No	auto

Note: The `libertyAdminUser` and `libertyAdminPassword` attributes are not mandatory, but if you define one of these attributes, you must also define the other.

`libertyAdminUser`

`libertyAdminCreate`

`libertyAdminPassword`

You use these attributes to create an `admin` user in the `server.xml` file, which is the configuration file for Liberty, in the basic registry section.

`tomcatRMIPort`

If the default port 8686 is not available on the system, you use this

attribute to specify a different port for JMX communication between the MobileFirst Server administration and the managed MobileFirst projects. In this case, the port values range from 1 to 65535.

tomcatSetEnvConfig

You use this attribute to allow or prevent the <installworklightadmin> and <uninstallworklightadmin> Ant tasks from adding or removing contents to the setenv.sh or setenv.bat script, in the <TomcatRootInstallDir>/bin directory.

Important: Security warning. The default value auto does not secure the JMX communication. This setting is not suitable for production environments. In production environments, you must manually configure JMX with authentication, as described in the Enabling JMX Remote page of the Apache Tomcat user documentation.

Use the following values for this attribute:

- manual: The <installworklightadmin> and <uninstallworklightadmin> Ant tasks do not update the setenv.bat and setenv.sh script for JMX usage.

If you select the value manual, you must update the scripts manually to define the RMI port that is used for JMX communications internally between the Administration Services and the MobileFirst runtime environment, whether this connection must be secured or not with user or role authentication, or SSL. For more information, see the documentation of the JVM that you are using.

- auto: The <installworklightadmin> and <uninstallworklightadmin> Ant tasks update the setenv.bat and setenv.sh script automatically, for JMX usage. If these scripts do not exist, they are created before they are updated.

If you select the auto value, the following modifications are made to extend the CATALINA_OPTS environment variable:

- For setenv.bat:

```
REM Allow to inspect the MBeans through jconsole
set CATALINA_OPTS=%CATALINA_OPTS% -Dcom.sun.management.jmxremote
```

REM Configure JMX.

```
set CATALINA_OPTS=%CATALINA_OPTS% -Djava.rmi.server.hostname=localhost
set CATALINA_OPTS=%CATALINA_OPTS% -Dcom.sun.management.jmxremote.port=8686
set CATALINA_OPTS=%CATALINA_OPTS% -Dcom.sun.management.jmxremote.authenticate=false
set CATALINA_OPTS=%CATALINA_OPTS% -Dcom.sun.management.jmxremote.ssl=false
```

- For setenv.sh:

```
# Allow to inspect the MBeans through jconsole
CATALINA_OPTS="$CATALINA_OPTS -Dcom.sun.management.jmxremote"
```

Configure JMX.

```
CATALINA_OPTS="$CATALINA_OPTS -Djava.rmi.server.hostname=localhost"
CATALINA_OPTS="$CATALINA_OPTS -Dcom.sun.management.jmxremote.port=8686"
CATALINA_OPTS="$CATALINA_OPTS -Dcom.sun.management.jmxremote.authenticate=false"
CATALINA_OPTS="$CATALINA_OPTS -Dcom.sun.management.jmxremote.ssl=false"
```

To specify a connection to the administration database

The <database> element collects the parameters that specify a data source declaration in an application server to access the administration database.

You must declare a single database: `<database kind="WorklightAdmin">`. You specify the `<database>` element similarly to the `<configuredatabase>` Ant task, except that the `<database>` element does not have the `<dba>` and `<client>` elements. It might have `<property>` elements.

The `<database>` element has the following attributes:

Table 16-27. Attributes of the `<database>` element

Attribute	Description	Required	Default
kind	The kind of database (WorklightAdmin)	Yes	None
validate	To validate whether the database is accessible	No	True

The `<database>` element supports the following elements. For more information about the configuration of these database elements for relational DBMS, see Table 16-49 on page 16-51 through Table 16-59 on page 16-55 in “Ant tasks for installation of MobileFirst runtime environments” on page 16-42.

Note: The attributes of the Cloudant element are slightly different from the runtime. For more information, see the following table, *Inner elements for the <applicationserver> element*.

Table 16-28. Inner elements for the `<database>` element

Element	Description	Count
db2	Parameter for DB2 databases	0..1
derby	Parameter for Apache Derby databases	0..1
mysql	Parameter for MySQL databases	0..1
oracle	Parameter for Oracle databases	0..1
cloudant	Parameter for Cloudant databases	0..1
driverclasspath	Parameter for JDBC driver class path (relational DBMS only)	0..1

Table 16-29. Attributes of the `<cloudant>` element

Attribute	Description	Required	Default
url	The URL of the Cloudant account	No	<code>https://user.cloudant.com</code>
user	The user name of the Cloudant account	Yes	None
password	The password of the Cloudant account	No	Queried interactively

Table 16-29. Attributes of the <cloudant> element (continued)

Attribute	Description	Required	Default
dbName	The cloudant database name. Important: This database name must start with a lowercase letter and contain only lowercase characters (a-z), Digits (0-9), any of the characters <code>_</code> , <code>\$</code> , and <code>-</code>	No	mfp_admin_db

Note: The <driverclasspath> element is not relevant to Cloudant, and you do not have to specify it.

To specify a user and a security role

The <user> element collects the parameters about a user to include in a certain security role for an application.

Table 16-30. Attributes of the <user> element

Attribute	Description	Required	Default
role	A valid security role for the application	Yes	None
name	The user name	Yes	None
password	The password if the user needs to be created	No	None

After you defined users by using the <user> element, you can map them to any of the following roles for authentication in the MobileFirst Operations Console.

- worklightmonitor
- worklightoperator
- worklightdeployer
- worklightadmin

For information about which authorizations are implied by the specific roles, see the chapter about the “REST API Administration Services” on page 11-9.

Tip: If users exist in an external LDAP directory, set only the **role** and **name** attributes but do not define any passwords.

Ant tasks for installation of MobileFirst runtime environments

Reference information for the <configureapplicationserver>, <updateapplicationserver>, and <unconfigureapplicationserver> Ant tasks.

Task effects

<configureapplicationserver>

The `<configureapplicationserver>` Ant task configures an application server to run a MobileFirst project WAR file as a web application. This task has the following effects.

- It declares the MobileFirst web application in the specified context root, by default `/worklight`.
- It deploys the project WAR file on the application server.
- It declares data sources and – on WebSphere Application Server full profile – JDBC providers for runtime and reports.
- It deploys the MobileFirst Server runtime file `worklight-jee-library.jar` and the database drivers in the application server.
- It sets MobileFirst configuration properties through JNDI environment entries. These JNDI environment entries override the MobileFirst project default values that are contained in the `worklight.properties` file inside the WAR file.
- On WebSphere Application Server, it configures a web container custom property.

`<updateapplicationserver>`

The `<updateapplicationserver>` Ant task updates on an application server a MobileFirst web application that is already configured. This task has the following effects.

- It updates the project WAR file. The file must have the same base name as the project WAR file that was previously deployed.
- It updates the MobileFirst Server runtime `worklight-jee-library.jar` library file.
- It updates the application server configuration related to BIRT reports, which is a deprecated feature, or, if such reports are no longer used, it sets the value of the JNDI environment entry `reports.exportRawData` to “false”.

Other than that, the task does not change the application server configuration, that is, the web application configuration, data sources, and JNDI environment entries.

Note: On WebSphere Application Server Liberty profile, the task does not change the features, which leaves a potential non-minimal list of features in the `server.xml` file for the installed application.

`<unconfigureapplicationserver>`

The `<unconfigureapplicationserver>` Ant task undoes the effects of an earlier `<configureapplicationserver>` run. This task has the following effects.

- It removes the configuration of the MobileFirst web application with the specified context root. The task also removes the settings that have been added manually to that application.
- It removes the project WAR file from the application server.
- It removes the data sources and – on WebSphere Application Server full profile – the JDBC providers for runtime and reports.
- It removes the MobileFirst Server runtime `worklight-jee-library.jar` library file and the database drivers from the application server.
- It removes the associated JNDI environment entries.

Attributes and elements

The <configureapplicationserver>, <updateapplicationserver>, and <unconfigureapplicationserver> tasks have the following attributes:

Table 16-31. Attributes for the <configureapplicationserver>, <updateapplicationserver>, and <unconfigureapplicationserver> Ant tasks

Attribute	Description	Required	Default
contextroot	Common prefix in URLs to the application (context root)	No	/worklight
id	Distinguishes different deployments	No	Empty
environmentId	Distinguishes different MobileFirst environments	No	Empty
wasStartingWeight	Start order for WebSphere Application Server. Lower values start first.	No	2
shortcutsDir	Directory where to place shortcuts	No	None
useWorklightReports	Specifies whether you install the reports database or not. The possible values are true, false, or auto.	No	Auto

contextroot and id

The contextroot and id attributes distinguish different MobileFirst projects. By default, when a project is created in V6.0.0 of this product and higher, its context root is the name of the project. The default value of /worklight was chosen to facilitate compatibility with IBM Worklight V5.x applications.

In WebSphere Application Server Liberty profiles and in Tomcat environments, the contextroot parameter is sufficient for this purpose. In WebSphere Application Server full profile environments, the id attribute is used instead.

environmentId

Use the environmentId attribute to distinguish several environments, consisting each of MobileFirst Server administration and MobileFirst runtime web applications, that must operate independently. You must set this attribute to the same value for the runtime application as the one that was set in the <installworklightadmin> invocation, for the Administration Services application.

wasStartingWeight

Use the wasStartingWeight attribute to specify a value that is used in WebSphere Application Server as a weight to ensure that a start order is respected. As a result of the start order value, the MobileFirst Administration Services web application is deployed and started before any other MobileFirst runtime projects. If MobileFirst projects are deployed or started before the web application, the JMX communication is not established and you cannot manage your MobileFirst projects.

shortcutsDir

The shortcutsDir attribute for the <unconfigureApplicationServer> Ant task specifies where to expect the shortcuts to the MobileFirst Operations Console if it was installed by a version of the <configureApplicationServer> Ant task older than V6.2.0. If you set this

attribute, the Ant task might remove the following files from that directory: `worklight-console.url`, `worklight-console.sh`, and `worklight-console.html`.

useWorklightReports

If this parameter is set to `false`, the reports data source is not installed. If set to `true`, the reports data source is installed. If set to `auto`, the reports data source is installed only if the task contains a database element of kind `WorklightReports`. This attribute has no effect on the `<updateapplicationserver>` task when you upgrade, and the status of the reports remains untouched.

The `<configureapplicationserver>`, `<updateapplicationserver>`, and `<unconfigureapplicationserver>` tasks support the following elements:

Table 16-32. Inner elements for the `<configureapplicationserver>`, `<updateapplicationserver>`, and `<unconfigureapplicationserver>` Ant tasks

Element	Description	Count
project	Project	1
property	Properties	0..∞
applicationserver	Application server	1
reports	Reports Note: The predefined BIRT reports are deprecated in V7.1.0. Use “Operational analytics” on page 14-9 instead.	0..1
database	Databases	1..2
analytics	Analytics	0..1

The `<project>` element specifies details about the project to deploy to the application server. It has the following attributes:

Table 16-33. Attributes for the `<project>` element

Attribute	Description	Required	Default
warfile	Project WAR file	Yes	None
libraryfile	File name of <code>worklight-jee-library.jar</code>	No	In the same directory as <code>worklight-ant-deployer.jar</code>
migrate	Whether to automigrate the WAR file to the current MobileFirst Server version	No	True
migratedWarBackupFile	Where to store a backup of the migrated WAR file	No	None

To create the `warfile` attribute, run the `<war-builder>` Ant task. See “Building a project WAR file with Ant” on page 12-4.

By default, the WAR file is automatically migrated to the current MobileFirst Server version. In this case, you can request a backup of the migrated WAR file on disk before it is deployed in the application server. To do so, specify a value for the `migratedWarBackupFile` attribute. If you set the `migrate` attribute to `false`, the

WAR file is not migrated and, if the MobileFirst version that produced the WAR file is not suitable for the MobileFirst Server version, the deployment fails.

The <property> element specifies a deployment property to be defined in the application server. It has the following attributes:

Table 16-34. Attributes for the <property> element

Attribute	Description	Required	Default value
name	Name of the property	Yes	None
value	Value for the property	Yes	None

For general information about MobileFirst properties, or for a list of properties that you can set, see “Configuration of MobileFirst applications on the server” on page 12-50.

The <applicationserver> element describes the application server to which the MobileFirst application is deployed. It is a container for one of the following elements:

Table 16-35. Inner elements for the <applicationserver> element

Element	Description	Count
websphereapplicationserver or was	Parameters for WebSphere Application Server	0..1
tomcat	Parameters for Apache Tomcat	0..1

The <websphereapplicationserver> element (or <was> in its short form) denotes a WebSphere Application Server instance, version 7.0 or later. WebSphere Application Server full profile (Base, and Network Deployment) are supported, as is Liberty profile (Core). Liberty profile Network Deployment is not yet supported. The <websphereapplicationserver> element has the following attributes:

Table 16-36. Attributes for the <websphereapplicationserver> or <was> element

Attribute	Description	Required	Default
installdir	WebSphere Application Server installation directory.	Yes	None
profile	WebSphere Application Server profile, or Liberty	Yes	None
user	WebSphere Application Server administrator name	Yes, except for Liberty	None
password	WebSphere Application Server administrator password	No	Queried interactively

Table 16-36. Attributes for the <websphereapplicationserver> or <was> element (continued)

Attribute	Description	Required	Default
libertyEncoding	Algorithm to encode data source passwords for WebSphere Application Server Liberty. The possible values are none, xor, and aes. Note: aes is not supported for WebSphere Application Server Liberty V8.5.0.x. For the other versions, it is supported only with the default key. On WebSphere Application Server Liberty 8.5.5.x, if the aes encoding is requested, the clear password is passed as argument to the securityUtility program, which is called through an external process. You can see the password with a ps command, or in the /proc file system on UNIX operating systems.	No	xor
libertyAESKey	Do not set this property because the aes custom key is not supported.	No	

It supports the following elements for single-server deployment:

Table 16-37. Inner elements for the <was> element (single-server deployment)

Element	Description	Count
server	A single server	0..1

The <server> element, which is used in this context, has the following attributes:

Table 16-38. Inner elements for the <server> element (single-server deployment)

Attribute	Description	Required	Default
name	Server name	Yes	None

It supports the following elements for Network Deployment:

Table 16-39. Inner elements for the <was> element (network deployment)

Element	Description	Count
cell	The entire cell	0..1
cluster	All servers of a cluster	0..1
node	All servers in a node, clusters excluded	0..1
server	A single server	0..1

The <cell> element has no attributes.

The <cluster> element has the following attributes:

Table 16-40. Attributes for the <cluster> element (network deployment)

Attribute	Description	Required	Default
name	Cluster name	Yes	None

The <node> element has the following attributes:

Table 16-41. Attributes for the <node> element (network deployment)

Attribute	Description	Required	Default
name	Node name	Yes	None

The <server> element, which is used in a Network Deployment context, has the following attributes:

Table 16-42. Attributes for the <server> element (network deployment)

Attribute	Description	Required	Default
nodeName	Node name	Yes	None
serverName	Server name	Yes	None

The <tomcat> element denotes an Apache Tomcat server. It has the following attributes:

Table 16-43. Attributes of the <tomcat> element

Attribute	Description	Required	Default
installDir	Tomcat installation directory. For a Tomcat installation that is split between a CATALINA_HOME directory and a CATALINA_BASE directory, specify the value of the CATALINA_BASE environment variable.	Yes	None

The <reports> element specifies what set of BIRT *.rptdesign report files to instantiate for access to the database of reports.

The <reports> element has the following attribute:

Note: The predefined BIRT reports are deprecated in V7.1.0. Use “Operational analytics” on page 14-9 instead.

Table 16-44. Attributes of the <reports> element

Attribute	Description	Required	Default
toDir	Destination directory	Yes	None

The <reports> element supports the following element:

Table 16-45. Inner elements for the <reports> element

Element	Description	Count
fileset	Set of files to copy and process	0..∞

A <reports> element without any inner <fileset> element instantiates all the report templates that are provided in the WorklightServer/report-templates/ directory in the MobileFirst Server distribution.

The <database> element specifies what information is necessary to access a particular database. Two databases must be declared: <database kind="Worklight"> and <database kind="WorklightReports">. The <database> element is specified like the <configuredatabase> Ant task, except that it does not have the <dba> and <client> elements. It might, however, have <property> elements. The <database> element has the following attributes:

Note: The Reports database, referenced as **WorklightReports** and **WLREPORT** in the subsequent tables, is deprecated in V7.1.0. Use “Operational analytics” on page 14-9 instead. Note that setting up the Reports database is optional in this release and earlier releases.

Table 16-46. Attributes of the <database> element

Attribute	Description	Required	Default
kind	The kind of database: Worklight or WorklightReports	Yes	None
validate	To validate whether the database is accessible or not. The possible values are true or false.	No	true

The <database> element supports the following elements:

Table 16-47. Inner elements for the <database> element

Element	Description	Count
derby	Parameters for Derby	0..1
db2	Parameters for DB2	0..1
mysql	Parameters for MySQL	0..1
oracle	Parameters for Oracle	0..1
cloudant	Parameters for Cloudant	0..1
driverclasspath	JDBC driver class path Note: This element is not relevant to Cloudant	0..1

The <analytics> element indicates that you want to connect the MobileFirst runtime to an already installed MobileFirst Operational Analytics console and services. It has the following attributes:

Table 16-48. Attributes of the <analytics> element

Attribute	Description	Required	Default
install	Whether to connect the MobileFirst runtime to MobileFirst Operational Analytics	No	true
analyticsURL	MobileFirst Operational Analytics Services URL	Yes	None
consoleURL	MobileFirst Operational Analytics Console URL	Yes	None
username	The user name	Yes	None

Table 16-48. Attributes of the <analytics> element (continued)

Attribute	Description	Required	Default
password	The password	Yes	None
validate	To validate whether the MobileFirst Operational Analytics Console is accessible or not.	No	true
forwardLogs	Whether to send server logs to MobileFirst Operational Analytics	No	true
tenant	The tenant for indexing data that is collected from a MobileFirst runtime.	No	None

install

Use the `install` attribute to indicate that this MobileFirst runtime must be connected and send events to MobileFirst Operational Analytics. Valid values are true or false.

analyticsURL

Use the `analyticsURL` attribute to specify the URL that is exposed by MobileFirst Operational Analytics, which receives incoming analytics data.

For example: `http://<hostname>:<port>/analytics-service/data`

Note: Optionally, you might append a tenant to this URL. For more information, see “Multi-tenancy” on page 14-23.

consoleURL

Use the `consoleURL` attribute to the URL that is exposed by MobileFirst Operational Analytics, which links to the MobileFirst Operational Analytics console.

For example: `http://<hostname>:<port>/analytics/console`

Note: Optionally, you might append a tenant to this URL. For more information, see “Multi-tenancy” on page 14-23.

username

Use the `username` attribute to specify the user name that is used if the data entry point for the MobileFirst Operational Analytics is protected with basic authentication.

password

Use the `password` attribute to specify the password that is used if the data entry point for the MobileFirst Operational Analytics is protected with basic authentication.

validate

Use the `validate` attribute to validate whether the MobileFirst Operational Analytics Console is accessible or not, and to check the user name authentication with a password. The possible values are true, or false

forwardLogs

When the `forwardLogs` attribute is set to true, server logs that are recorded on the MobileFirst Server are captured and forwarded to the MobileFirst Operational Analytics.

tenant

For more information about this attribute, see “Multi-tenancy” on page 14-23.

To specify an Apache Derby database

The <derby> element has the following attributes:

Table 16-49. Attributes of the <derby> element

Attribute	Description	Required	Default
database	Database name	No	WRKLGHT or WLREPORT , depending on the kind
datadir	Directory that contains the databases	Yes	None
schema	Schema name	No	WORKLIGHT

The <derby> element supports the following element:

Table 16-50. Inner element for the <derby> element

Element	Description	Count
property	Data source property or JDBC connection property	0..∞

For more information about the available properties, see the documentation for Class `EmbeddedDataSource40`. See also the documentation for Class `EmbeddedConnectionPoolDataSource40`.

For more information about the available properties for a Liberty server, see the documentation for **properties.derby.embedded** at Liberty profile: Configuration elements in the server.xml file.

When the `worklight-ant-deployer.jar` file is used within the installation directory of IBM MobileFirst Platform Foundation, a `<driverclasspath>` element is not necessary.

To specify a DB2 database

The <db2> element has the following attributes:

Table 16-51. Attributes of the <db2> element

Attribute	Description	Required	Default
database	Database name	No	WRKLGHT or WLREPORT , depending on the kind
server	Host name of the database server	Yes	None
port	Port on the database server	No	50000

Table 16-51. Attributes of the <db2> element (continued)

Attribute	Description	Required	Default
user	User name for accessing databases. This user does not need extended privileges on the databases. If you implement restrictions on the database, you can set a user with the restricted privileges that are listed in “Restricting database user permissions for IBM MobileFirst Platform Server runtime operations” on page 6-31.	Yes	None
password	Password for accessing databases	No	Queried interactively
schema	Schema name	No	Depends on the user

For more information about DB2 user accounts, see DB2 security model overview.

The <db2> element supports the following element:

Table 16-52. Inner elements for the <db2> element

Element	Description	Count
property	Data source property or JDBC connection property	0..∞

For more information about the available properties, see Properties for the IBM Data Server Driver for JDBC and SQLJ.

For more information about the available properties for a Liberty server, see the **properties.db2.jcc** section at Liberty profile: Configuration elements in the server.xml file.

The <driverclasspath> element must contain JAR files for the DB2 JDBC driver and the associated license. You can download DB2 JDBC drivers from DB2 JDBC Driver Versions.

To specify a MySQL database

The <mysql> element has the following attributes:

Table 16-53. Attributes of the <mysql> element

Attribute	Description	Required	Default
database	Database name	No	WRKLGHT or WLREPORT, depending on kind
server	Host name of the database server	Yes	None
port	Port on the database server	No	3306

Table 16-53. Attributes of the <mysql> element (continued)

Attribute	Description	Required	Default
user	User name for accessing databases. This user does not need extended privileges on the databases. If you implement restrictions on the database, you can set a user with the restricted privileges that are listed in “Restricting database user permissions for IBM MobileFirst Platform Server runtime operations” on page 6-31.	Yes	None
password	Password for accessing databases	No	Queried interactively

Instead of database, server, and port, you can also specify a URL. In this case, use the following attributes:

Table 16-54. Alternative elements for the <mysql> element

Attribute	Description	Required	Default
url	URL for connection to the database	Yes	None
user	User name for accessing databases. This user does not need extended privileges on the databases. If you implement restrictions on the database, you can set a user with the restricted privileges that are listed in “Restricting database user permissions for IBM MobileFirst Platform Server runtime operations” on page 6-31.	Yes	None
password	Password for accessing databases	No	Queried interactively

For more information about MySQL user accounts, see MySQL User Account Management.

The <mysql> element supports the following element:

Table 16-55. Inner elements for the <mysql> element

Element	Description	Count
property	Data source property or JDBC connection property	0..∞

For more information about the available properties, see the documentation at Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J.

For more information about the available properties for a Liberty server, see the **properties** section at Liberty profile: Configuration elements in the server.xml file.

The <driverclasspath> element must contain a MySQL Connector/J JAR file. You can download it from Download Connector/J.

To specify an Oracle database

The <oracle> element has the following attributes:

Table 16-56. Attributes of the <oracle> element

Attribute	Description	Required	Default
database	Database name, or Oracle service name Note: You must always use a service name to connect to a PDB database.	No	ORCL
server	Host name of the database server	Yes	None
port	Port on the database server	No	1521
user	User name for accessing databases. This user does not need extended privileges on the databases. If you implement restrictions on the database, you can set a user with the restricted privileges that are listed in “Restricting database user permissions for IBM MobileFirst Platform Server runtime operations” on page 6-31. See the note under this table.	Yes	None
password	Password for accessing databases	No	Queried interactively

Note: For the **user** attribute, use preferably a user name in uppercase letters. Oracle user names are generally in uppercase letters. Unlike other database tools, the **configureapplicationserver** Ant task does not convert lowercase letters to uppercase letters in the user name. If the **configureapplicationserver** Ant task fails to connect to your database, try to enter the value for the **user** attribute in uppercase letters.

Instead of database, server, and port, you can also specify a URL. In this case, use the following attributes:

Table 16-57. Alternative attributes of the <oracle> element

Attribute	Description	Required	Default
url	URL for connection to the database	Yes	None
user	User name for accessing databases. This user does not need extended privileges on the databases. If you implement restrictions on the database, you can set a user with the restricted privileges that are listed in “Restricting database user permissions for IBM MobileFirst Platform Server runtime operations” on page 6-31. See the note under this table.	Yes	None
password	Password for accessing databases	No	Queried interactively

Note: For the **user** attribute, use preferably a user name in uppercase letters. Oracle user names are generally in uppercase letters. Unlike other database tools,

the **configureapplicationserver** Ant task does not convert lowercase letters to uppercase letters in the user name. If the **configureapplicationserver** Ant task fails to connect to your database, try to enter the value for the **user** attribute in uppercase letters.

For more information about Oracle user accounts, see Overview of Authentication Methods.

For more information about Oracle database connection URLs, see the **Database URLs and Database Specifiers** section at Data Sources and URLs.

It supports the following elements:

Table 16-58. Inner elements for the <oracle> element

Element	Description	Count
property	Data source property or JDBC connection property	0..∞

For more information about the available properties, see the **Data Sources and URLs** section at Data Sources and URLs.

For more information about the available properties for a Liberty server, see the **properties.oracle** section at Liberty profile: Configuration elements in the server.xml file.

The <driverclasspath> element must contain an Oracle JDBC driver JAR file. You can download Oracle JDBC drivers from JDBC, SQLJ, Oracle JPublisher and Universal Connection Pool (UCP).

The <property> element, which can be used inside <derby>, <db2>, <mysql>, or <oracle> elements, has the following attributes:

Table 16-59. Attributes for the <property> element in a database-specific element

Attribute	Description	Required	Default
name	Name of the property	Yes	None
type	Java type of the property values, usually java.lang.String/Integer/Boolean	No	java.lang.String
value	Value for the property	Yes	None

To specify a Cloudant database

The <cloudant> element has the following attributes:

Table 16-60. Attributes of the <cloudant> element

Attribute	Description	Required	Default
url	The URL of the Cloudant account	No	https:// user.cloudant.com
user	The user name of the Cloudant account	Yes	None
password	The password of the Cloudant account	No	Queried interactively

Table 16-60. Attributes of the <cloudant> element (continued)

Attribute	Description	Required	Default
dbNamePrefix	The prefix that is added to the database name of the MobileFirst runtime. For example, if the value department is assigned to this attribute, and the context root of your MobileFirst runtime is /mfp, the database name would be department_mfp_runtime_db. Important: This prefix must start with a lowercase letter, and can contain only lowercase characters (a-z), digits (0-9), and any of the following characters: _, \$, -.	No	Empty string
connectTimeout	The timeout to establish a connection, in milliseconds. A value of zero means an infinite timeout.	No	Undocumented default value
socketTimeout	The timeout to wait for a response, in milliseconds. A value of zero means an infinite timeout.	No	Undocumented default value
maxConnections	The maximum number of connections to the database.	No	Undocumented default value
proxyHost	The host name to connect through the proxy	No	Undocumented default value
proxyPort	The proxy port	No	Undocumented default value

Note: The <driverclasspath> element is not relevant to Cloudant, and you do not have to specify it.

Ant tasks for installation of Application Center

The <installApplicationCenter>, <updateApplicationCenter>, and <uninstallApplicationCenter> Ant tasks are provided for the installation of the Application Center Console and Services.

Task effects

<installApplicationCenter>

The <installApplicationCenter> task configures an application server to run the Application Center Services WAR file as a web application, and to install the Application Center Console. This task has the following effects:

- It declares the Application Center Services web application in the /applicationcenter context root.
- It declares data sources, and on WebSphere Application Server full profile, it declares also JDBC providers for Application Center Services.
- It deploys the Application Center Services web application on the application server.
- It declares the Application Center Console as a web application in the /appcenterconsole context root.
- It deploys the Application Center Console WAR file on the application server.

- It configures configuration properties for Application Center Services by using JNDI environment entries. The JNDI environment entries that are related to the endpoint and proxies are commented. You must uncomment them in some cases. For more information, see “Defining the endpoint of the MobileFirst Administration services” on page 6-102.
- It configures users that it maps to roles used by the Application Center Console and Services web applications.
- On WebSphere Application Server, it configures the necessary custom property for the web container.

<updateApplicationCenter>

The <updateApplicationCenter> task updates an already configured Application Center application on an application server. This task has the following effects:

- It updates the Application Center Services WAR file. This file must have the same base name as the corresponding WAR file that was previously deployed.
- It updates the Application Center Console WAR file. This file must have the same base name as the corresponding WAR file that was previously deployed.

The task does not change the application server configuration, that is, the web application configuration, data sources, JNDI environment entries, and user-to-role mappings. This task applies only to an installation that is performed by using the <installApplicationCenter> task that is described in this topic.

Note: On WebSphere Application Server Liberty profile, the task does not change the features, which leaves a potential non-minimal list of features in the server.xml file for the installed application.

<uninstallApplicationCenter>

The <uninstallApplicationCenter> Ant task undoes the effects of an earlier run of <installApplicationCenter>. This task has the following effects:

- It removes the configuration of the Application Center Services web application with the /applicationcenter context root. As a consequence, the task also removes the settings that were added manually to that application.
- It removes both the Application Center Services and Console WAR files from the application server.
- It removes the data sources and, on WebSphere Application Server full profile, it also removes the JDBC providers for the Application Center Services.
- It removes the database drivers that were used by Application Center Services from the application server.
- It removes the associated JNDI environment entries.
- It removes the users who are configured by the <installApplicationCenter> invocation.

Attributes and elements

The <installApplicationCenter>, <updateApplicationCenter>, and <uninstallApplicationCenter> tasks have the following attributes:

Table 16-61. Attributes for the <installApplicationCenter>, <updateApplicationCenter>, and <uninstallApplicationCenter> Ant tasks

Attribute	Description	Required	Default
id	It distinguishes different deployments in WebSphere Application Server full profile	No	Empty
servicewar	The WAR file for the Application Center Services	No	The applicationcenter.war file is in the application Center console directory: <i>product_install_dir/</i> ApplicationCenter/ <i>console</i> .
shortcutsDir	The directory where you place the shortcuts	No	None
aaptDir	The directory that contains the aapt program, from the Android SDK platform-tools package.	No	None

id

In WebSphere Application Server full profile environments, the `id` attribute is used to distinguish different deployments of Application Center Console and Services. Without this `id` attribute, two WAR files with the same context roots might conflict and these files would not be deployed.

servicewar

Use the `servicewar` attribute to specify a different directory for the Application Center Services WAR file. You can specify the name of this WAR file with an absolute path or a relative path.

shortcutsDir

The `shortcutsDir` attribute specifies where to place shortcuts to the Application Center Console. If you set this attribute, the following files are added to this directory:

- `appcenter-console.url`: This file is a Windows shortcut. It opens the Application Center Console in a browser.
- `appcenter-console.sh`: This file is a UNIX shell script. It opens the Application Center Console in a browser.

aaptDir

The `aapt` program is part of the IBM MobileFirst Platform Foundation distribution: *product_install_dir/*ApplicationCenter/*tools/*android-sdk.

If this attribute is not set, during the upload of an apk application, Application Center parses it by using its own code, which might have limitations.

The <installApplicationCenter>, <updateApplicationCenter>, and <uninstallApplicationCenter> tasks support the following elements:

Table 16-62. Inner elements for the <installApplicationCenter>, <updateApplicationCenter>, and <uninstallApplicationCenter> Ant tasks

Element	Description	Count
applicationserver	The application server	1
console	The Application Center console	1
database	The databases	1
user	The user to be mapped to a security role	0..∞

To specify an Application Center console

The <console> element collects information to customize the installation of the Application Center Console. This element has the following attributes:

Table 16-63. Attributes for the <console> element

Attribute	Description	Required	Default
warfile	The WAR file for the Application Center Console	No	The appcenterconsole.war file is in the Application Center console directory: <i>product_install_dir/</i> ApplicationCenter/console.

To specify an application server

Use the <applicationserver> element to define the parameters that depend on the underlying application server. The <applicationserver> element supports the following elements. The attributes and inner elements of these elements are described in tables Table 16-36 on page 16-46 to Table 16-43 on page 16-48 of the page “Ant tasks for installation of MobileFirst runtime environments” on page 16-42.

Table 16-64. Inner elements for the <applicationserver> element

Element	Description	Count
websphereapplicationserver or was	The parameters for WebSphere Application Server.	0..1
tomcat	The parameters for Apache Tomcat.	0..1

To specify a connection to the services database

The <database> element collects the parameters that specify a data source declaration in an application server to access the services database.

You must declare a single database: <database kind="ApplicationCenter">. You specify the <database> element similarly to the <configuredatabase> Ant task,

except that the <database> element does not have the <dba> and <client> elements. It might have <property> elements.

The <database> element has the following attributes:

Table 16-65. Attributes for the <database> element

Attribute	Description	Required	Default
kind	The kind of database (ApplicationCenter)	Yes	None
validate	To validate whether the database is accessible or not	No	True

The <database> element supports the following elements. For more information about the configuration of these database elements, see Table 16-49 on page 16-51 to Table 16-59 on page 16-55 in “Ant tasks for installation of MobileFirst runtime environments” on page 16-42

Table 16-66. Inner elements for the <database> element

Element	Description	Count
db2	The parameter for DB2 databases	0..1
derby	The parameter for Apache Derby databases	0..1
mysql	The parameter for MySQL databases	0..1
oracle	The parameter for Oracle databases	0..1
driverclasspath	The parameter for JDBC driver class path	0..1

To specify a user and a security role

The <user> element collects the parameters about a user to include in a certain security role for an application.

Table 16-67. Attributes for the <user> element

Attribute	Description	Required	Default
role	The user role appcenteradmin	Yes	None
name	The user name	Yes	None
password	The password, if you must create the user	No	None

This Ant task supports only the **appcenteradmin** role. Users that are defined by using the <user> element can be mapped only to the **appcenteradmin** role for authentication in the Application Center Console.

Ant tasks for installation of MobileFirst Data Proxy

Reference information for the <installdataprox>, <updatedataprox>, and <uninstalldataprox> Ant tasks.

About the Ant tasks for installing MobileFirst Data Proxy

The purpose of these Ant Tasks is to configure the MobileFirst Data Proxy on an application server so that it can communicate with the following components:

- a Cloudant database (either Cloudant Managed or Cloudant Local)
- an Authorization Server that is embedded in a MobileFirst runtime environment.

For a Liberty server, and a stand-alone WebSphere Application Server, these Ant tasks install a Trust Association Interceptor (TAI), which acts as the front end for performing OAuth authentication of incoming requests to the MobileFirst Data Proxy.

Note: None of these Ant tasks install, update, or uninstall a MobileFirst runtime environment.

For more information about how to use these Ant tasks, see “Installing the MobileFirst Data Proxy with Ant tasks” on page 6-226.

For more information about installing a MobileFirst runtime environment, see “Installing the MobileFirst runtime environment” on page 6-125.

Important:

- The MobileFirst Data Proxy is not supported on Apache Tomcat, or on versions of WebSphere Application Server Liberty profile earlier than V8.5.5.0.
- You must install the TAI manually on WebSphere Application Server Network Deployment.

Task effects

<installdataprox>

The <installdataprox> Ant task configures an application server to run a MobileFirst Data Proxy. This task has the following effects:

- It deploys the MobileFirst Data Proxy WAR file on the application server.
- It configures a TAI on WebSphere Application Server Liberty and WebSphere Application Server standalone, and copies the requested files in the application server in the appropriate locations. On WebSphere Application Server standalone, it creates a configuration file for this TAI if that is required.
- It declares the MobileFirst web application in the specified context root, by default /imf-data-proxy.
- It sets MobileFirst Data Proxy configuration properties through JNDI environment entries.
- On WebSphere Application Server Liberty, it configures the web container.

<updatedataprox>

The <updatedataprox> Ant task updates the MobileFirst Data Proxy web application, which is already configured, on an application server. This task has the following effects.

- It updates the project WAR file. The file must have the same base name as the project WAR file that was previously deployed.

- It updates the TAI files on WebSphere Application Server Liberty and WebSphere Application Server stand-alone.

The task does not change the application server configuration, which includes the web application configuration, data sources, and JNDI environment entries.

<uninstalldataprox>

The <uninstalldataprox> Ant task undoes the effects of an earlier <installdataprox> run. This task has the following effects.

- It removes the configuration of the MobileFirst Data Proxy web application with the specified context root.
- It removes the MobileFirst Data Proxy WAR file from the application server.
- It removes the associated JNDI environment entries.

Note: It does not remove the TAI JAR and feature manifest files from the application server.

Attributes and elements

The <installdataprox>, <updatedataprox>, and <uninstalldataprox> tasks have the following attributes:

Table 16-68. Attributes for the <installdataprox>, <updatedataprox>, and <uninstalldataprox> Ant tasks

Attribute	Description	Required	Default
contextroot	Common prefix in URLs to the application (context root)	No	/imf-data-proxy
id	Distinguishes different deployments	No	Empty
serviceWar	The WAR file for the MobileFirst Data Proxy.	No	The imf-data-proxy WAR file is in the directory Datastore, at the same level than the WorklightServer directory.
DBAccount	Cloudant database account, or host name of the MobileFirst Cloudant Local server.	Yes	None
DBAccountUser	User name for accessing the database.	Yes	None
DBAccountPassword	Password for accessing the database.	Yes	Queried interactively
validate	To validate whether the Cloudant database is accessible or not. The possible values are true or false.	No	true
cloudantPort	Port to access Cloudant.	No	443 or 80
useHttps	To indicate whether the access to Cloudant must use https. The possible values are true or false.	No	true

contextroot and id

The contextroot and id attributes distinguish different MobileFirst projects.

In WebSphere Application Server Liberty profiles, the contextroot parameter is sufficient for this purpose. In WebSphere Application Server full profile environments, the id attribute is used instead.

serviceWar

Use the `serviceWar` attribute to specify a different directory for the MobileFirst Data Proxy WAR file. You can specify the name of this WAR file with an absolute path or a relative path.

DBAccount

The `DBAccount` attribute identifies either an Cloudant Managed account name or a user name defined in the configuration of a MobileFirst Cloudant Local database.

DBAccountUser

Use the `DBAccountUser` attribute to specify the name of a user to connect to Cloudant.

This user name can be an administrator or a non-administrator user. In all cases, the user name you provide must exist in Cloudant as the Ant task does not create it.

DBAccountPassword

Use the `DBAccountPassword` attribute to specify the password associated to the user specified with attribute `DBAccountUser`.

validate

When set to true, the `validate` attribute enables you to check that the Cloudant database identified by attribute `DBAccount` is on a reachable system and can be accessed using the credentials provided with attributes `DBAccountUser` and `DBAccountPassword`. By default, this validation is enabled.

cloudantPort

With the `cloudantPort` attribute, you can specify a port to access a Cloudant database directly, or a Load Balancer port if a Cloudant haproxy service is used to access the Cloudant database. If this attribute is not specified, the default port is set to 443, unless the `useHttps` attribute is set to false. In this case, the default port is set to 80.

useHttps

With the `useHttps` attribute, you can indicate which of the http or https protocol the MobileFirst Data Proxy must use to connect to the Cloudant database. The default protocol used is https.

The `<installdataprox>`, `<updatedataprox>`, and `<uninstalldataprox>` tasks support the following elements:

Table 16-69. Inner elements for the `<installdataprox>`, `<updatedataprox>`, and `<uninstalldataprox>` Ant tasks

Element	Description	Count
<code>authenticate</code>	TAI	0 for WebSphere Application Server Network Deployment 1 for WebSphere Application Server Liberty profile and WebSphere Application Server full profile
<code>applicationserver</code>	application server	1

Important: You cannot specify an **authenticate** element for WebSphere Application Server Network Deployment environments.

To install a TAI

Use the <authentication> element to define the TAI and, optionally, the location of the files that implement it. The attributes of this element are described in Table 3.

Table 16-70. Attributes for the <authentication> element

Attribute	Description	Count	Required	Default
serverURL	The Authorization Server URL	1	Yes	None
taiJAR	The TAI JAR file	0..1	No	File com.ibm.worklight.oauth.tai_1.0.0.jar located in a subdirectory external-server-libraries of the directory where you find worklight-ant-deployer.jar
libertyFeatureManifest	The TAI feature manifest (for Liberty only)	0..1	No	File 0authTai-1.0.mf located in a subdirectory external-server-libraries of the worklight-ant-deployer.jar location

Note: The taiJAR and libertyFeatureManifest attributes are not mandatory. For WebSphere Application Server full profile environments, you might want to specify a taiJAR attribute. For Liberty profile environments, if you specify one of these attributes, you must also specify the other.

serverURL

Use the serverURL attribute to specify the URL of a MobileFirst project in the form *http[s]://hostname:port/context-root*, where <context-root> is the context root of a MobileFirst project.

taiJAR

Use the taiJAR attribute to specify a different directory for the MobileFirst Data Proxy TAI JAR file. You can specify the name of this JAR file with an absolute path or a relative path. By default, the Ant task uses the file com.ibm.worklight.oauth.tai_1.0.0.jar that is in a subdirectory external-server-libraries of the directory where worklight-ant-deployer.jar is.

libertyFeatureManifest

Use the libertyFeatureManifest attribute to specify a different directory for the Liberty feature manifest file. You can specify the name of this file with an absolute path or a relative path. By default, the Ant task uses the file 0authTai-1.0.mf that is in a subdirectory external-server-libraries of the worklight-ant-deployer.jar location.

To specify an application server

Use the <applicationserver> element to define the parameters that depend on the underlying application server. The <applicationserver> element supports the

following element. The attributes and inner elements of this element are described in tables 6 through 12 of “Ant tasks for installation of MobileFirst runtime environments” on page 16-42.

Note: You cannot specify Apache Tomcat, as this application server is not supported by MobileFirst Data Proxy.

Table 16-71. Inner elements for the <applicationserver> element.

Element	Description	Count
websphereapplicationserver or was	The parameters for WebSphere Application Server.	1

Ant tasks for installation of MobileFirst Operational Analytics

The <installanalytics>, <updateanalytics>, and <uninstallanalytics> Ant tasks are provided for the installation of MobileFirst Operational Analytics.

About these Ant tasks

The purpose of these Ant Tasks is to configure the MobileFirst Operational Analytics console and the MobileFirst Operational Analytics service with the appropriate storage for the data on an application server.

The task installs MobileFirst Operational Analytics nodes that act as a master and data. For more information, see “Setting up a production cluster” on page 14-90.

Task effects

<installanalytics>

The <installanalytics> Ant task configures an application server to run IBM MobileFirst Platform Operational Analytics. This task has the following effects:

- It deploys the MobileFirst Operational Analytics Service and the MobileFirst Operational Analytics Console WAR files on the application server.
- It declares the MobileFirst Operational Analytics Service web application in the specified context root /analytics-service.
- It declares the MobileFirst Operational Analytics Console web application in the specified context root /analytics.
- It sets MobileFirst Operational Analytics Console and MobileFirst Operational Analytics Services configuration properties through JNDI environment entries.
- On WebSphere Application Server Liberty profile, it configures the web container.
- Optionally, it creates users to use the MobileFirst Operational Analytics Console.

<updateanalytics>

The <updateanalytics> Ant task updates the already configured MobileFirst Operational Analytics Service and MobileFirst Operational Analytics Console web applications WAR files on an application server. These files must have the same base names as the project WAR files that were previously deployed.

The task does not change the application server configuration, that is, the web application configuration and JNDI environment entries.

<uninstallanalytics>

The <uninstallanalytics> Ant task undoes the effects of an earlier <installanalytics> run. This task has the following effects:

- It removes the configuration of both the MobileFirst Operational Analytics Service and the MobileFirst Operational Analytics Console web applications with their respective context roots.
- It removes the MobileFirst Operational Analytics Service and the MobileFirst Operational Analytics Console WAR files from the application server.
- It removes the associated JNDI environment entries.

Attributes and elements

The <installanalytics>, <updateanalytics>, and <uninstallanalytics> tasks have the following attributes:

Table 16-72. Attributes for the <installanalytics>, <updateanalytics>, and <uninstallanalytics> Ant tasks

Attribute	Description	Required	Default
serviceWar	The WAR file for the MobileFirst Operational Analytics Service	No	The analytics-service.war file is in the directory Analytics.

serviceWar

Use the serviceWar attribute to specify a different directory for the MobileFirst Operational Analytics Services WAR file. You can specify the name of this WAR file with an absolute path or a relative path.

The <installanalytics>, <updateanalytics>, and <uninstallanalytics> tasks support the following elements:

Table 16-73. Inner elements for the <installanalytics>, <updateanalytics>, and <uninstallanalytics> Ant tasks

Attribute	Description	Required	Default
console	MobileFirst Operational Analytics	Yes	1
user	The user to be mapped to a security role.	No	0..∞
storage	The type of storage.	Yes	1
applicationserver	The application server.	Yes	1
property	Properties.	No	0..∞

To specify a MobileFirst Operational Analytics Console

The <console> element collects information to customize the installation of the MobileFirst Operational Analytics Console. This element has the following attributes:

Table 16-74. Attributes of the <console> element

Attribute	Description	Required	Default
warfile	The console WAR file	No	The analytics-ui.war file is in the Analytics directory.
shortcutsdir	The directory where you place the shortcuts.	No	None

warFile

Use the warFile attribute to specify a different directory for the MobileFirst Operational Analytics Console WAR file. You can specify the name of this WAR file with an absolute path or a relative path.

shortcutsDir

The shortcutsDir attribute specifies where to place shortcuts to the MobileFirst Operational Analytics Console. If you set this attribute, you can add the following files to that directory:

- analytics-console.url: This file is a Windows shortcut. It opens the MobileFirst Operational Analytics Console in a browser.
- analytics-console.sh: This file is a UNIX shell script. It opens the MobileFirst Operational Analytics Console in a browser.

Note: These shortcuts do not include the ElasticSearch tenant parameter.

The <console> element supports the following nested element:

Table 16-75. Inner element of the <console> element

Element	Description	Count
property	Properties	0..∞

With this element, you can define your own JNDI properties.

The <property> element has the following attributes:

Table 16-76. Attributes of the <property> element

Attribute	Description	Required	Default
name	The name of the property.	Yes	None
value	The value of the property.	Yes	None

To specify a user and a security role

The <user> element collects the parameters about a user to include in a certain security role for an application.

Table 16-77. Attributes of the <user> element

Attribute	Description	Required	Default
role	A valid security role for the application.	Yes	None
name	The user name.	Yes	None
password	The password, if the user must be created.	No	None

After you defined users by using the <user> element, you can map them to any of the following roles for authentication in the MobileFirst Operations Console:

- worklightmonitor
- worklightoperator
- worklightdeployer
- worklightadmin

To specify a type of storage for MobileFirst Operational Analytics

The <storage> element indicates which underlying type of storage MobileFirst Operational Analytics uses to store the information and data it collects.

It supports the following element:

Table 16-78. Inner element of the <storage> element

Element	Description	Count
elasticsearch	ElasticSearch cluster	1

The <elasticsearch> element collects the parameters about an ElasticSearch cluster.

Table 16-79. Attributes of the <elasticsearch> element

Attribute	Description	Required	Default
clusterName	The ElasticSearch cluster name.	No	worklight
nodeName	The ElasticSearch node name. This name must be unique in an ElasticSearch cluster.	No	worklightNode_<random number>
mastersList	A comma-delimited string that contains the host name and ports of the ElasticSearch master nodes in the ElasticSearch cluster (For example: hostname1:transport-port1,hostname2:transport-port2)	No	Depends on the topology
dataPath	The ElasticSearch cluster location.	No	Depends on the application server
shards	The number of shards that the ElasticSearch cluster creates. This value can be set only by the master nodes that are created in the ElasticSearch cluster.	No	5
replicasPerShard	The number of replicas for each shard in the ElasticSearch cluster. This value can be set only by the master nodes that are created in the ElasticSearch cluster.	No	1
transportPort	The port used for node-to-node communication in the ElasticSearch cluster.	No	9600

clusterName

Use the clusterName attribute to specify a name of your choice for the ElasticSearch cluster.

An ElasticSearch cluster consists of one or more nodes that share the same cluster name so you might specify the same value for the `clusterName` attribute if you configure several nodes.

nodeName

Use the `nodeName` attribute to specify a name of your choice for the node to configure in the ElasticSearch cluster. Each node name must be unique in the ElasticSearch cluster even if nodes span on several machines.

mastersList

Use the `mastersList` attribute to provide a comma-separated list of the master nodes in your ElasticSearch cluster. Each master node in this list must be identified by its host name, and the ElasticSearch node-to-node communication port. This port is 9600 by default, or it is the port number that you specified with the attribute `transportPort` when you configured that master node.

For example: `hostname1:transport-port1, hostname2:transport-port2`.

Note:

- If you specify a `transportPort` that is different than the default value 9600, you must also set this value with the attribute `transportPort`. By default, when the attribute `mastersList` is omitted, an attempt is made to detect the host name and the ElasticSearch transport port on all supported application servers.
- If the target application server is WebSphere Application Server Network Deployment cluster, and if you add or remove a server from this cluster at a later point in time, you must edit this list manually to keep in sync with the ElasticSearch cluster.

dataPath

Use the `dataPath` attribute to specify a different directory to store ElasticSearch data. You can specify an absolute path or a relative path.

If the attribute `dataPath` is not specified, then ElasticSearch cluster data is stored in a default directory that is called `analyticsData`, whose location depends on the application server:

- For WebSphere Application Server Liberty profile, the location is `${wlp.user.dir}/servers/serverName/analyticsData`.
- For Apache Tomcat, the location is `${CATALINA_HOME}/bin/analyticsData`.
- For WebSphere Application Server and WebSphere Application Server Network Deployment, the location is `${was.install.root}/profiles/<profileName>/analyticsData`.

The directory `analyticsData` and the hierarchy of sub-directories and files that it contains are automatically created at run time, if they do not already exist when the MobileFirst Operational Analytics Service component receives events.

shards

Use the `shards` attribute to specify the number of shards to create in the ElasticSearch cluster.

replicasPerShard

Use the `replicasPerShard` attribute to specify the number of replicas to create for each shard in the ElasticSearch cluster.

Each shard can have zero or more replicas. By default, each shard has one replica, but the number of replicas can be changed dynamically on an existing index in the MobileFirst Operational Analytics. A replica shard can never be started on the same node as its shard.

transportPort

Use the `transportPort` attribute to specify a port that other nodes in the ElasticSearch cluster must use when communicating with this node. You must ensure that this port is available and accessible if this node is behind a proxy or firewall.

To specify an application server

Use the `<applicationserver>` element to define the parameters that depend on the underlying application server. The `<applicationserver>` element supports the following elements.

Note: The attributes and inner elements of this element are described in tables 6 through 12 of “Ant tasks for installation of MobileFirst runtime environments” on page 16-42.

Table 16-80. Inner elements of the <applicationserver> element

Element	Description	Count
<code>websphereapplicationserver</code> or <code>was</code>	The parameters for WebSphere Application Server.	0..1
<code>tomcat</code>	The parameters for Apache Tomcat.	0..1

To specify custom JNDI properties

The `<installanalytics>`, `<updateanalytics>`, and `<uninstallanalytics>` elements support the following element:

Table 16-81. Inner element of the <property> element

Element	Description	Count
<code>property</code>	Properties	0..∞

By using this element, you can define your own JNDI properties.

This element has the following attributes:

Table 16-82. Attributes of the <property> element

Attribute	Description	Required	Default
<code>name</code>	The name of the property.	Yes	None
<code>value</code>	The value of the property.	Yes	None

Internal runtime databases

You can access common runtime tables in both relational databases and the Cloudant database. In relational databases, the entities are organized in database tables; in a Cloudant database, they are organized as document entities.

The following table provides a list of common runtime database tables and entities, their descriptions, and how they are used in relational databases and the Cloudant database.

Entity name	Description	Relational database table name	Cloudant database mfpEntityType	Order of magnitude (rows for relational databases and documents for Cloudant)
AttributeStoreEntity	Stores the attribute store in the authorization server that is used for storing the authentication context of the client.	ATTRIBUTE_STORE	AttributeStoreEntity	One row or document per application.
ClientInstance	Stores instances of client applications that have registered with the OAuth server.	CLIENT_INSTANCES	ClientInstance	One row or document per device or application pair.
ClusterSingletonDetails	Details of cluster synchronization tasks.	CLUSTER_SYNC	ClusterSingletonDetails	Details of rows or documents.
Device	Tracks Client Devices that access the platform. The Client Devices are recorded as active or inactive, based on the configured decommissioning policy, and other information might be stored for them.	DEVICES	Device	One row or document per device that accessed the platform in the last n days, where n is the sum of the values for the <code>wl.device.decommission.when</code> and <code>wl.device.archiveDecommissioned</code> parameters.
GadgetDeviceAssociation	Stores relationships between a device and the applications that the device uses.	GADGET_DEVICE_ASSOC	GadgetDeviceAssociation	One row or document per device or application pair.

Entity name	Description	Relational database table name	Cloudant database mfpEntityType	Order of magnitude (rows for relational databases and documents for Cloudant)
UserPref	User preferences according to unique user identifier. No user preferences are ready for immediate use. The App developer can add preferences.	GADGET_USER_PREF	UserPref	If used, this table can contain one row or document per preference per user.
LicenseTerms	Stores the various license metrics captured every time the device decommissioning task is run.	LICENSE_TERMS	LicenseTerms	Tens of rows or documents. This value does not exceed the value set by the <code>wl.device.decommission.when</code> property.
PushDevice	Push notification table. Stores a record per device.	PUSH_DEVICES	PushDevice	One row or document per device.
PushSubscription	Push notification table. Stores a record per tag subscription or user subscription to event sources.	PUSH_SUBSCRIPTIONS	PushSubscription	One row or document per device subscription.
SsoEntity	Stores the active sessions that use the SSO feature.	SSO_LOGIN_CONTEXTS	SsoEntity	If SSO enabled, there is one row or document per session.
LicenseTermsAddressableDevice	Stores the addressable device metrics daily. An entry is also added each time that a cluster is started.	ADDRESSABLE_DEVICES	LicenseTermsAddressableDevice	Up to 400 rows. Entries older than 13 months are deleted daily.
Version	The product version.	WORKLIGHT_VERSION	-	One row.

The following table provides a list of common reports database tables and their usage.

Note:

- The Reports database and all the tables in the following list are deprecated in IBM MobileFirst Platform Foundation V7.1.0. Use “Operational analytics” on page 14-9 instead.
- Setting up the Reports database is optional in this release and earlier releases.
- The Reports database is not supported in Cloudant.

Name	Description	Order of Magnitude
ACTIVITIES_CUBE	<p>A materialized table of the 4-dimensional data cube.</p> <p>Populated every night, based on the last 30 days of data. Can be used by BIRT or other reporting tools.</p>	<p>Size depends on app and device usage, but is limited to the last 30 days for faster access to the last 30 days of activities.</p>
APP_ACTIVITY_REPORT	<p>The reports row data. Data is aggregated by either the product aggregation task or by the customer aggregation task.</p> <p>For more information about using the row data, see “Using raw data reports” on page 14-103.</p>	<p>The size depends on application. The customer is responsible for purging older entries after aggregating to Data Warehouse.</p>
FACT_ACTIVITIES	<p>Summarization of activities that are used for device analytics.</p> <p>Updated by MobileFirst Server every 24 hours with data from the APP_ACTIVITY_REPORT table. Primarily used by BIRT reports and by other reporting tools. The update interval can be configured with the <code>wl.db.factProcessingInterval</code> property. The processing and update can also be disabled by setting the <code>wl.db.factProcessingInterval</code> to a negative value if only the raw data from the APP_ACTIVITY_REPORT table is of interest. For more information about the property, see “Device usage reports” on page 14-107.</p>	<p>Size depends on app/device usage.</p> <p>property</p>

Name	Description	Order of Magnitude
NOTIFICATION_ACTIVITIES	Summarization of activities that are used for notification analytics. Updated with data from the NOTIFICATION_REPORT table. Primarily used by BIRT reports and by other reporting tools.	Size depends on app/notification usage.
NOTIFICATION_PROC_REPORT	Internal table to store raw notification data. The data is aggregated by an aggregation task.	One row per notification.
NOTIFICATION_REPORT	Each time the data processing is done, a time stamp is added to the PROC_REPORT table with the processing result (time stamp and number of processed entries).	About 72 rows per day.
OPENJPA_SEQUENCE_TABLE	Internal table created for JPA. Not used, and will be removed in the future.	n/a
PROC_REPORT	Internal table that is used for housekeeping and maintaining the state of the scheduler tasks.	About 72 rows per day.

You can access common administration database tables in both relational databases and the Cloudant database. In relational databases, the entities are organized in database tables; in Cloudant, they are organized as document entities. The following table provides a list of common administration database tables and entities, their descriptions, and how they are used in relational databases and the Cloudant database. Entity names in brackets such as "(Version)", are database tables that occur internally and do not correspond to any Java Entity or Cloudant document entity.

Entity name	Description	Relational database table name	Cloudant database mfpEntityType	Order of Magnitude (rows for relational databases and documents for Cloudant)
AdapterEntity	Stores the adapter deployable elements. This table is used to synchronize the adapter deployable elements between cluster nodes; many-to-many relationships with ProjectEntity.	ADAPTERS	Adapter	Tens of rows or documents.
AdminNodeEntity	Stores information about the servers that run the administration services. In a stand-alone topology with only one server, this entity is not used.	ADMIN_NODE	AdminNode	One row or document per server; empty if a stand-alone server is used.
ApplicationEntity	Stores the application deployable elements. This table is used to synchronize the application deployable elements between cluster nodes; many-to-many relationships with ProjectEntity.	APPLICATIONS	Application	Tens of rows or documents.
ApplicationEnvironmentEntity	Stores information about application environments, for example, iPhone or Android, of deployed applications. Many-to-one relationships with ApplicationEntity.	APPLICATIONS_ENVIRONMENTS	ApplicationEnvironment	Tens of rows or documents.

Entity name	Description	Relational database table name	Cloudant database mfpEntityType	Order of Magnitude (rows for relational databases and documents for Cloudant)
ApplicationVersionAccessDataEntity	Stores the applications that have the remote disable mode to block or notify. References ApplicationEnvironmentEntity.	APP_VERSION_ACCESS_DATA	ApplicationVersionAccessData	Tens of rows or documents.
AuditEntity	Stores an audit trail of all administrative actions performed on the administration server.	AUDIT_TRAIL	Audit	Thousands of rows or documents.
BeaconEntity	Stores information about registered beacons.	BEACONS	Beacon	One row or document per registered beacon.
BeaconTriggerEntity	Stores information about the action that is triggered when the user's mobile device comes into the vicinity of an associated beacon.	BEACON_TRIGGERS	BeaconTrigger	Tens of rows or documents.
BeaconTriggerAssociationEntity	Stores the association between beacons and triggers; many-to-many relationship between beacons and beacon triggers.	BEACON_TRIGGER_ASSOCIATION	BeaconTriggerAssociation	One row or document for each association between a registered beacon and a beacon trigger.
ClientConfigProfileEntity	Stores custom logging configuration profiles that have been created by the server administrator.	CONFIG_PROFILES	ClientConfigProfile	One row or document per configuration profile. Usually no more than 5-10 rows in total.
DifferentialDirectUpdateEntity	Stores Entity information on differential direct updates and their binaries.	DIFFERENTIAL_DIRECT_UPDATE	DifferentialDirectUpdate	One row or document per environment per deployment.

Entity name	Description	Relational database table name	Cloudant database mfpEntityType	Order of Magnitude (rows for relational databases and documents for Cloudant)
FarmConfigEntity	Stores the configuration of farm nodes when a server farm is used.	FARM_CONFIG	FarmConfig	Tens of rows or documents; empty if no server farm is used.
ProjectEntity	Stores the names of the deployed projects.	PROJECT	Project	Tens of rows or documents.
(Project-Adapter-Association)	Bidirectional association between projects and adapters.	PROJECT_ADAPTERS		Tens of rows.
(Project-Application-Association)	Bidirectional association between projects and applications.	PROJECT_APPLICATIONS		Tens of rows.
ProjectLockEntity	Internal cluster synchronization tasks.	PROJECT_LOCK		Tens of rows.
PushEnvironmentEntity	Push notification table; stores details of push environments.	PUSH_ENVIRONMENTS	PushEnvironment	Tens of rows or documents.
PushTagEntity	Push notification table; stores details of defined tags.	PUSH_TAGS	PushTag	Tens of rows or documents.
TransactionEntity	Internal cluster synchronization table; stores the state of all current administrative actions.	TRANSACTIONS	Transaction	Tens of rows or documents.
(Version)	The product version.	WORKLIGHTMGT_VERSION		One row.

Sample configuration files

IBM MobileFirst Platform Foundation includes a number of sample configuration files to help you get started with the Ant tasks to install the MobileFirst Server administration and the MobileFirst runtime environment.

The easiest way to get started with the <configuredatabase>, <installworklightadmin> and <configureapplicationserver> Ant tasks is by working with the sample configuration files provided in the WorklightServer/configuration-samples/ directory of the MobileFirst Server distribution.

Step 1

Pick the appropriate sample configuration file. The following files are provided

Table 16-83. Sample configuration files provided with IBM MobileFirst Platform Foundation

Task	Derby	DB2	MySQL	Oracle	Cloudant
Create databases with database administrator credentials	create-database-derby.xml	create-database-db2.xml	create-database-mysql.xml	create-database-oracle.xml	Not relevant for this database
Install MobileFirst Server administration and MobileFirst runtime environment on Liberty	configure-liberty-derby.xml	configure-liberty-db2.xml	configure-liberty-mysql.xml (See Note on MySQL)	configure-liberty-oracle.xml	configure-liberty-cloudant.xml
Install MobileFirst Server administration and MobileFirst runtime environment on WebSphere Application Server full profile, single server	configure-was-derby.xml	configure-was-db2.xml	configure-was-mysql.xml (See Note on MySQL)	configure-was-oracle.xml	configure-was-cloudant.xml
Install MobileFirst Server administration and MobileFirst runtime environment on WebSphere Application Server Network Deployment (See Note on configuration files)	configure-wasnd-cluster-derby.xml configure-wasnd-server-derby.xml configure-wasnd-node-derby.xml configure-wasnd-cell-derby.xml	configure-wasnd-cluster-db2.xml configure-wasnd-server-db2.xml configure-wasnd-node-db2.xml configure-wasnd-cell-db2.xml	configure-wasnd-cluster-mysql.xml (See Note on MySQL) configure-wasnd-server-mysql.xml (See Note on MySQL) configure-wasnd-node-mysql.xml (See Note on MySQL) configure-wasnd-cell-mysql.xml	configure-wasnd-cluster-oracle.xml configure-wasnd-server-oracle.xml configure-wasnd-node-oracle.xml configure-wasnd-cell-oracle.xml	configure-wasnd-cluster-cloudant.xml configure-wasnd-server-cloudant.xml configure-wasnd-node-cloudant.xml configure-wasnd-cell-cloudant.xml

Table 16-83. Sample configuration files provided with IBM MobileFirst Platform Foundation (continued)

Task	Derby	DB2	MySQL	Oracle	Cloudant
Install MobileFirst Server administration and MobileFirst runtime environment on Apache Tomcat	configure-tomcat-derby.xml	configure-tomcat-db2.xml	configure-tomcat-mysql.xml	configure-tomcat-oracle.xml	configure-tomcat-cloudant.xml
Install or upgrade IBM Worklight V5.0.6 on Liberty	redeploy506-liberty-derby.xml	redeploy506-liberty-db2.xml	redeploy506-liberty-mysql.xml (See Note on MySQL)	redeploy506-liberty-oracle.xml	None
Install or upgrade IBM Worklight V5.0.6 on WebSphere Application Server full profile, single server	redeploy506-was-derby.xml	redeploy506-was-db2.xml	redeploy506-was-mysql.xml (See Note on MySQL)	redeploy506-was-oracle.xml	None
Install or upgrade IBM Worklight V5.0.6 on WebSphere Application Server Network Deployment (See Note on configuration files)	redeploy506-wasnd-cluster-derby.xml redeploy506-wasnd-server-derby.xml redeploy506-wasnd-node-derby.xml redeploy506-wasnd-cell-derby.xml	redeploy506-wasnd-cluster-db2.xml redeploy506-wasnd-server-db2.xml redeploy506-wasnd-node-db2.xml redeploy506-wasnd-cell-db2.xml	redeploy506-wasnd-cluster-mysql.xml (See Note on MySQL) redeploy506-wasnd-server-mysql.xml (See Note on MySQL) redeploy506-wasnd-node-mysql.xml (See Note on MySQL) redeploy506-wasnd-cell-mysql.xml	redeploy506-wasnd-cluster-oracle.xml redeploy506-wasnd-server-oracle.xml redeploy506-wasnd-node-oracle.xml redeploy506-wasnd-cell-oracle.xml	None
Install or upgrade IBM Worklight V5.0.6 on Apache Tomcat	redeploy506-tomcat-derby.xml	redeploy506-tomcat-db2.xml	redeploy506-tomcat-mysql.xml	redeploy506-tomcat-oracle.xml	None

Note on MySQL: : MySQL in combination with WebSphere Application Server Liberty profile or WebSphere Application Server full profile is not classified as a supported configuration. For more information, see WebSphere Application Server Support Statement. Consider using IBM DB2 or another database that is supported by WebSphere Application Server to benefit from a configuration that is fully supported by IBM Support.

Note on configuration files for WebSphere Application Server Network

Deployment: The configuration files for wasnd contain a scope that can be set to **cluster**, **node**, **server**, or **cell**. For example, for `configure-wasnd-cluster-derby.xml`, the scope is **cluster**. These scope types define the deployment target as follows:

- **cluster:** To deploy to a cluster.
- **server:** To deploy to a single server that is managed by the deployment manager.
- **node:** To deploy to all the servers that are running on a node, but that do not belong to a cluster.
- **cell:** To deploy to all the servers on a cell.

Step 2

Change the file access rights of the sample file to be as restrictive as possible. Step 3 requires that you supply some passwords. If you must prevent other users on the same computer from learning these passwords, you must remove the read permissions of the file for users other than yourself. You can use a command, such as the following examples:

- On UNIX:
`chmod 600 configure-file.xml`
- On Windows:
`cacls configure-file.xml /P Administrators:F %USERDOMAIN%\%USERNAME%:F`

Step 3

Similarly, if the server is a WebSphere Application Server Liberty profile or Apache Tomcat server, and the server is meant to be started only from your user account, you must also remove the read permissions for users other than yourself from the following file:

- For WebSphere Application Server Liberty profile: `wlp/usr/servers/<server>/server.xml`
- For Apache Tomcat: `conf/server.xml`

Step 4

Replace the placeholder values for the properties at the beginning of the file.

Note: The following special characters need to be escaped when used in values in Ant XML scripts:

- The dollar sign (\$) must be written as \$\$, unless you explicitly want to reference an Ant variable through the syntax `${variable}`, as described in Properties in the *Apache Ant Manual*.
- The ampersand character (&) must be written as `&`, unless you explicitly want to reference an XML entity.

- Double quotation marks (") must be written as ", except when inside a string that is enclosed in single quotation marks.

Step 5

In the <configureapplicationserver> and <unconfigureapplicationserver> invocations (in target install and uninstall), define MobileFirst properties. For a list of properties that can be set, see “Configuration of MobileFirst applications on the server” on page 12-50. In production, you must often define the following specific properties:

- publicWorkLightHostname
- publicWorkLightProtocol
- publicWorkLightPort

Step 6

Note: You must run the following commands only if you are using a relational database. If you are using Cloudant, you must not run them.

Run the commands:

```
ant -f configure-file.xml admddatabases
ant -f configure-file.xml databases
```

These commands ensure that the designated databases exist and contain the required tables for IBM MobileFirst Platform Foundation. The target admddatabases must be run before the target databases. This is especially important in the case of an upgrade where management data is migrated from the runtime database to the administration database, which must be initialized first by the target admddatabases.

For an initial installation, and if a DBA did not create the databases manually, use the file in row “Create databases with database administrator credentials” of Table 16-83 on page 16-78. These files add special parameters to the configuredatabase Ant task (the DBA credentials). The parameters enable the Ant task to create a database and a user if required.

Step 7

Run the command:

```
ant -f configure-file.xml admininstall
```

This command installs your Administration Services and MobileFirst Operations Console components onto the application server.

To install updated Administration Services and MobileFirst Operations Console components (for example, to apply a MobileFirst Server fix pack), run the command:

```
ant -f configure-file.xml minimal-admupdate
```

To reverse the installation step, run the command:

```
ant -f configure-file.xml admininstall
```

This command uninstalls the Administration Services and MobileFirst Operations Console components.

Step 8

Run the command:

```
ant -f configure-file.xml install
```

This command installs your MobileFirst runtime environment as a .war file onto the application server.

To install an updated MobileFirst runtime environment onto the application server, run the command:

```
ant -f configure-file.xml minimal-update
```

To reverse the installation step, run the command:

```
ant -f configure-file.xml uninstall
```

This command uninstalls the MobileFirst runtime environment.

At least for WebSphere Application Server, it is a good idea to keep the modified `configure-file.xml` for later use when you install updates of the MobileFirst project's .war file. This file makes it possible to redeploy an updated .war file with the same MobileFirst properties. If you use the WebSphere Application Server administrative console to update the .war file, all properties that are configured for this web application are lost.

Sample configuration files for MobileFirst Operational Analytics

IBM MobileFirst Platform Foundation includes a number of sample configuration files to help you get started with the Ant tasks to install the MobileFirst Operational Analytics Services, and the MobileFirst Operational Analytics Console.

The easiest way to get started with the `<installanalytics>`, `<updateanalytics>`, and `<uninstallanalytics>` Ant tasks is by working with the sample configuration files provided in the `Analytics/configuration-samples/` directory of the MobileFirst Server distribution.

Step 1

Pick the appropriate sample configuration file. The following XML files are provided. They are referred to as `configure-file.xml` in the next steps.

Table 16-84. Sample configuration files provided with IBM MobileFirst Platform Foundation

Task	Application server
Install MobileFirst Operational Analytics Services and Console on WebSphere Application Server Liberty profile	<code>configure-liberty-analytics.xml</code>
Install MobileFirst Operational Analytics Services and Console on Apache Tomcat	<code>configure-tomcat-analytics.xml</code>
Install MobileFirst Operational Analytics Services and Console on WebSphere Application Server full profile	<code>configure-was-analytics.xml</code>
Install MobileFirst Operational Analytics Services and Console on WebSphere Application Server Network Deployment, single server	<code>configure-wasnd-server-analytics.xml</code>

Table 16-84. Sample configuration files provided with IBM MobileFirst Platform Foundation (continued)

Task	Application server
Install MobileFirst Operational Analytics Services and Console on WebSphere Application Server Network Deployment, cell	configure-wasnd-cell-analytics.xml
Install MobileFirst Operational Analytics Services and Console on WebSphere Application Server Network Deployment, node	configure-wasnd-node.xml
Install MobileFirst Operational Analytics Services and Console on WebSphere Application Server Network Deployment, cluster	configure-wasnd-cluster-analytics.xml

Note on configuration files for WebSphere Application Server Network Deployment:

The configuration files for wasnd contain a scope that can be set to **cluster**, **node**, **server**, or **cell**. For example, for `configure-wasnd-cluster-analytics.xml`, the scope is **cluster**. These scope types define the deployment target as follows:

- **cluster**: To deploy to a cluster.
- **server**: To deploy to a single server that is managed by the deployment manager.
- **node**: To deploy to all the servers that are running on a node, but that do not belong to a cluster.
- **cell**: To deploy to all the servers on a cell.

Step 2

Change the file access rights of the sample file to be as restrictive as possible. *Step 3* requires that you supply some passwords. If you must prevent other users on the same computer from learning these passwords, you must remove the read permissions of the file for users other than yourself. You can use a command, such as the following examples:

- On UNIX:

```
chmod 600 configure-file.xml
```
- On Windows:

```
cacls configure-file.xml /P Administrators:F %USERDOMAIN%\%USERNAME%:F
```

Step 3

Similarly, if your application server is WebSphere Application Server Liberty profile, or Apache Tomcat, and the server is meant to be started only from your user account, you must also remove the read permissions for users other than yourself from the following files:

- For WebSphere Application Server Liberty profile: `wlp/usr/servers/<server>/server.xml`
- For Apache Tomcat: `conf/server.xml`

Step 4

Replace the placeholder values for the properties at the top of the file.

Note: The following special characters must be escaped when they are used in the values of the Ant XML scripts:

- The dollar sign (\$) must be written as \$\$, unless you explicitly want to reference an Ant variable through the syntax `${variable}`, as described in Properties section of the Apache Ant Manual.
- The ampersand character (&) must be written as `&`, unless you explicitly want to reference an XML entity.
- Double quotation marks (") must be written as `"`, except when it is inside a string that is enclosed in single quotation marks.

Step 5

Run the command:

```
ant -f configure-file.xml install
```

This command installs your MobileFirst Operational Analytics Services and MobileFirst Operational Analytics Console components in the application server.

To install updated MobileFirst Operational Analytics Services and MobileFirst Operational Analytics Console components, for example if you apply a MobileFirst Server fix pack, run the following command:

```
ant -f configure-file.xml minimal-update
```

To reverse the installation step, run the command:

```
ant -f configure-file.xml uninstall
```

This command uninstalls the MobileFirst Operational Analytics Services and MobileFirst Operational Analytics Console components.

Glossary

This glossary provides terms and definitions for IBM MobileFirst Platform Foundation software and products.

The following cross-references are used in this glossary:

- *See* refers you from a nonpreferred term to the preferred term or from an abbreviation to the spelled-out form.
- *See also* refers you to a related or contrasting term.

For other terms and definitions, see the IBM Terminology website (opens in new window).

"A" "B" on page 17-2 "C" on page 17-2 "D" on page 17-4 "E" on page 17-4 "F" on page 17-4 "G" on page 17-5 "H" on page 17-5 "I" on page 17-5 "J" on page 17-5 "K" on page 17-6 "L" on page 17-6 "M" on page 17-7 "N" on page 17-7 "O" on page 17-8 "P" on page 17-8 "R" on page 17-9 "S" on page 17-9 "T" on page 17-10 "U" on page 17-11 "V" on page 17-11 "W" on page 17-11 "X" on page 17-11

A

acquisition policy

A policy that controls how data is collected from a sensor of a mobile device. The policy is defined by application code.

adapter

The server-side code of a MobileFirst application. Adapters connect to enterprise applications, deliver data to and from mobile applications, and perform any necessary server-side logic on sent data.

administration database

The database of the MobileFirst Operations Console and of the Administration Services. The database tables define elements such as applications, adapters, projects with their descriptions and orders of magnitude.

Administration Services

An application that hosts the REST services and administration tasks. The Administration Services application is packaged in its own WAR file.

alias An assumed or actual association between two data entities, or between a data entity and a pointer.

Android

A mobile operating system created by Google, most of which is released under the Apache 2.0 and GPLv2 open source licenses. See also mobile device.

API See application programming interface.

app A web or mobile device application. See also web application.

Application Center

A MobileFirst component that can be used to share applications and facilitate collaboration between team members in a single repository of mobile applications. See also Company Hub.

Application Center installer

An application that lists the catalog of available applications in the Application Center. The Application Center Installer must be present on a device so that one can install applications from your private application repository.

application descriptor file

A metadata file that defines various aspects of an application.

application programming interface (API)

An interface that allows an application program that is written in a high-level language to use specific data or functions of the operating system or another program.

authentication

A security service that provides proof that a user of a computer system is genuinely who that person claims to be. Common mechanisms for implementing this service are passwords and digital signatures.

authentication realm

A combination of one authenticator and one login module. Each authentication realm defines its authentication flow. An authentication realm must have a corresponding challenge handler.

authenticator

1. A server-side component that issues a sequence of challenges on the server side and responds on the client side. See also challenge handler.
2. In the Kerberos protocol, a string of data that is generated by the client and sent with a ticket that is used by the server to certify the identity of the client.

B**Base64**

A plain-text format that is used to encode binary data. Base64 encoding is commonly used in User Certificate Authentication to encode X.509 certificates, X.509 CSRs, and X.509 CRLs. See also DER encoded, PEM encoded.

binary Pertaining to something that is compiled, or is executable.

BlackBerry OS

A closed source, proprietary mobile operating system created by Research in Motion. See also mobile device.

block A collection of several properties (such as adapter, procedure, or parameter).

broadcast notification

A notification that is targeted to all of the users of a specific MobileFirst application. See also tag-based notification.

build definition

An object that defines a build, such as a weekly project-wide integration build.

C

CA See certificate authority.

callback function

Executable code that allows a lower-level software layer to call a function defined in a higher-level layer.

catalog

A collection of apps.

certificate

In computer security, a digital document that binds a public key to the identity of the certificate owner, thereby enabling the certificate owner to be authenticated. A certificate is issued by a certificate authority and is digitally signed by that authority. See also certificate authority.

certificate authority (CA)

A trusted third-party organization or company that issues the digital certificates. The certificate authority typically verifies the identity of the individuals who are granted the unique certificate. See also certificate.

certificate authority enterprise application

A company application that provides certificates and private keys for its client applications.

certificate revocation list (CRL)

A list of certificates that have been revoked before their scheduled expiration date. Certificate revocation lists are maintained by the certificate authority and used, during a Secure Sockets Layer (SSL) handshake to ensure that the certificates involved have not been revoked.

challenge

A request for certain information to a system. The information, which is sent back to the server in response to this request, is necessary for client authentication.

challenge handler

A client-side component that issues a sequence of challenges on the server side and responds on the client side. See also authenticator.

client A software program or computer that requests services from a server.

client-side authentication component

A component that collects client information, then uses login modules to verify this information.

clone An identical copy of the latest approved version of a component, with a new unique component ID.

cluster

A collection of complete systems that work together to provide a single, unified computing capability.

company application

An application that is designed for internal use inside a company.

Company Hub

An application that can distribute other specified applications to be installed on a mobile device. For example, Application Center is a Company Hub. See also Application Center.

component

A reusable object or program that performs a specific function and works with other components and applications.

credential

A set of information that grants a user or process certain access rights.

CRL See certificate revocation list.

D**data source**

The means by which an application accesses data from a database.

deployment

The process of installing and configuring a software application and all its components.

DER encoded

Pertaining to a binary form of an ASCII PEM formatted certificate. See also Base64, PEM encoded.

device See mobile device.

device context

Data that is used to identify the location of a device. This data can include geographical coordinates, WiFi access points, and timestamp details. See also trigger.

device enrollment

The process of a device owner registering their device as trusted.

documentify

A JSONStore command used to create a document.

E**emulator**

An application that can be used to run an application meant for a platform other than the current platform.

encryption

In computer security, the process of transforming data into an unintelligible form in such a way that the original data either cannot be obtained or can be obtained only by using a decryption process.

enterprise application

See company application.

entity A user, group, or resource that is defined to a security service.

environment

A specific instance of a configuration of hardware and software.

event An occurrence of significance to a task or system. Events can include completion or failure of an operation, a user action, or the change in state of a process.

event source

An object that supports an asynchronous notification server within a single Java virtual machine. Using an event source, the event listener object can be registered and used to implement any interface.

F

facet An XML entity that restricts XML data types.

farm node

A networked server that is housed in a server farm.

fire In object-oriented programming, to cause a state transition.

fragment

A file that contains HTML tags that can be appended to a parent element.

G**gateway**

A device or program used to connect networks or systems with different network architectures.

geocoding

The process of identifying geocodes from more traditional geographic markers (addresses, postal codes, and so on). For example, a landmark can be located at the intersection of two streets, but the geocode of that landmark consists of a number sequence. See also geolocation.

geofence

A circle or a polygon that defines a geographical area.

geolocation

The process of pinpointing a location based on the assessment of various types of signals. In mobile computing, often WLAN access points and cell towers are used to approximate a location. See also geocoding, location services.

H**homogeneous server farm**

A server farm in which all application servers are of the same type, level, and version.

hybrid application

An application that is primarily written in web-oriented languages (HTML5, CSS, and JS), but is wrapped in a native shell so that the app behaves like, and provides the user with all the capabilities of, a native app.

I**in-house application**

See company application.

inner application

An application that contains the HTML, CSS, and JavaScript parts that run within a shell component. Inner applications must be packaged within a shell component to create a full hybrid application.

J**Java Management Extensions (JMX)**

A means of doing management of and through Java technology. JMX is a universal, open extension of the Java programming language for management that can be deployed across all industries, wherever management is needed.

JMX See Java Management Extensions.

K

key

1. A cryptographic mathematical value that is used to digitally sign, verify, encrypt, or decrypt a message. See also private key, public key.
2. One or more characters within an item of data that are used to uniquely identify a record and establish its order with respect to other records.

keychain

A password management system for Apple software. A keychain acts as a secure storage container for passwords that are used by multiple applications and services.

key pair

In computer security, a public key and a private key. When the key pair is used for encryption, the sender uses the receiver's public key to encrypt the message, and the recipient uses their private key to decrypt the message. When the key pair is used for signing, the signer uses their private key to encrypt a representation of the message, and the recipient uses the sender's public key to decrypt the representation of the message for signature verification.

L

library

1. A system object that serves as a directory to other objects. A library groups related objects, and allows users to find objects by name.
2. A collection of model elements, including business items, processes, tasks, resources, and organizations.

load balancing

A computer networking method for distributing workloads across multiple computers or a computer cluster, network links, central processing units, disk drives, or other resources. Successful load balancing optimizes resource use, maximizes throughput, minimizes response time, and avoids overload.

local store

An area on a device where applications can locally store and retrieve data without the need for a network connection.

location services

A feature that can be used to create differentiated services that are based on a user location. Location services involve collecting geolocation and WiFi data and transmitting this data to a server, where it can be used for executing business logic and analytics. Changes in the location data result in triggers being activated, which cause application logic to execute. See also geolocation.

login module

A server-side entity that is responsible for verifying the user credentials and for creating a user identity object that holds the user properties for the remainder of the session.

M

Managed Bean (MBean)

In the Java Management Extensions (JMX) specification, the Java objects that implement resources and their instrumentation.

MBean

See Managed Bean.

mobile

See mobile device.

mobile client

See Application Center installer.

mobile device (mobile)

A telephone, tablet, or personal digital assistant that operates on a radio network. See also Android, BlackBerry OS.

MobileFirst adapter

See adapter.

MobileFirst Data Proxy

A server-side component to the IMFData SDK that can be used to secure mobile application calls to Cloudant by using MobileFirst Platform OAuth security capabilities. The MobileFirst Data Proxy requires an authentication through the trust association interceptor.

MobileFirst Operations Console

A web-based interface that is used to control and manage MobileFirst runtime environments that are deployed in MobileFirst Server, and to collect and analyze user statistics.

MobileFirst runtime environment

A mobile-optimized server-side component that runs the server side of your mobile applications (back-end integration, version management, security, unified push notification). Each runtime environment is packaged as a web application (WAR file).

MobileFirst Server

A MobileFirst component that handles security, back-end connections, push notifications, mobile application management, and analytics. The MobileFirst Server is a collection of apps that run on an application server and acts as a runtime container for MobileFirst runtime environments.

MobileFirst Studio

A MobileFirst component that is an integrated development environment (IDE) that can be used to develop and test mobile applications.

N

native app

An app that is compiled into binary code for use on the mobile operating system on the device.

node A logical group of managed servers.

notification

An occurrence within a process that can trigger an action. Notifications can be used to model conditions of interest to be transmitted from a sender to a (typically unknown) set of interested parties (the receivers).

O

OAuth

An HTTP-based authorization protocol that gives applications scoped access to a protected resource on behalf of the resource owner, by creating an approval interaction between the resource owner, client, and resource server.

P

page navigation

A browser feature that enables users to navigate backwards and forwards in a browser.

PEM encoded

Pertaining to a Base64 encoded certificate. See also Base64, DER encoded.

PKI See public key infrastructure.

PKI bridge

A MobileFirst Server concept that enables the User Certificate Authentication framework to communicate with a PKI.

poll To repeatedly request data from a server.

private key

In secure communication, an algorithmic pattern used to encrypt messages that only the corresponding public key can decrypt. The private key is also used to decrypt messages that were encrypted by the corresponding public key. The private key is kept on the user system and is protected by a password. See also key, public key.

project

The development environment for various components, such as applications, adapters, configuration files, custom Java code, and libraries.

project WAR file

A web archive (WAR) file that contains the configurations for the MobileFirst runtime environment and is deployed on an application server.

provision

To provide, deploy, and track a service, component, application, or resource.

proxy An application gateway from one network to another for a specific network application such as Telnet or FTP, for example, where a firewall proxy Telnet server performs authentication of the user and then lets the traffic flow through the proxy as if it were not there. Function is performed in the firewall and not in the client workstation, causing more load in the firewall.

public key

In secure communication, an algorithmic pattern used to decrypt messages that were encrypted by the corresponding private key. A public key is also used to encrypt messages that can be decrypted only by the corresponding private key. Users broadcast their public keys to everyone with whom they must exchange encrypted messages. See also key, private key.

public key infrastructure (PKI)

A system of digital certificates, certification authorities, and other

registration authorities that verify and authenticate the validity of each party involved in a network transaction.

push To send information from a server to a client. When a server pushes content, it is the server that initiates the transaction, not a request from the client.

push notification

An alert indicating a change or update that appears on a mobile app icon.

R

realm A collection of resource managers that honor a common set of user credentials and authorizations.

reverse proxy

An IP-forwarding topology where the proxy is on behalf of the back-end HTTP server. It is an application proxy for servers using HTTP.

root The directory that contains all other directories in a system.

S

salt Randomly generated data that is inserted into a password or passphrase hash, making those passwords uncommon (and more difficult to hack).

SDK See software development kit.

security test

An ordered set of authentication realms that is used to protect a resource such as an adapter procedure, an application, or a static URL.

server farm

A group of networked servers.

server-side authentication component

See authenticator.

service

A program that performs a primary function within a server or related software.

session

A logical or virtual connection between two stations, software programs, or devices on a network that allows the two elements to communicate and exchange data for the duration of the session.

shell A component that provides custom native capabilities and security features for applications.

sideloading

On Windows 8 environments, the process of loading a file of type appx on a mobile device without using the Windows Store.

sign To attach a unique electronic signature, derived from the sender's user ID, to a document or field when a document is mailed. Signing mail ensures that if an unauthorized user creates a new copy of a user's ID, the unauthorized user cannot forge signatures with it. In addition, the signature verifies that no one has tampered with the data while the message was in transit.

simulator

An environment for staging code that is written for a different platform.

Simulators are used to develop and test code in the same IDE, but then deploy that code to its specific platform. For example, one can develop code for an Android device on a computer, then test it using a simulator on that computer.

skin An element of a graphical user interface that can be changed to alter the appearance of the interface without affecting its functionality.

slide To move a slider interface item horizontally on a touchscreen. Typically, apps use slide gestures to lock and unlock phones, or toggle options.

software development kit (SDK)

A set of tools, APIs, and documentation to assist with the development of software in a specific computer language or for a particular operating environment.

subelement

In UN/EDIFACT EDI standards, an EDI data element that is part of an EDI composite data element. For example, an EDI data element and its qualifier are subelements of an EDI composite data element.

subscription

A record that contains the information that a subscriber passes to a local broker or server to describe the publications that it wants to receive.

syntax The rules for the construction of a command or statement.

system message

An automated message on a mobile device that provides operational status or alerts, for example if connections are successful or not.

T

tag-based notification

A notification that is targeted to devices that are subscribed for a specific tag. Tags are used to represent topics that are of interest to a user. See also broadcast notification.

TAI See trust association interceptor.

tap To briefly touch a touchscreen. Typically, apps use tap gestures to select items (similar to a left mouse button click).

template

A group of elements that share common properties. These properties can be defined only once, at the template level, and are inherited by all elements that use the template.

trigger

A mechanism that detects an occurrence, and can cause additional processing in response. Triggers can be activated when changes occur in the device context. See also device context.

trust association interceptor (TAI)

The mechanism by which trust is validated in the product environment for every request received by the proxy server. The method of validation is agreed upon by the proxy server and the interceptor.

U

Unstructured Supplementary Service Data (USSD)

A communication technology that is used by GSM cellular telephones to send text messages between a mobile phone and an application program in the network. USSD establishes a real-time session between the mobile phone and the application that handles the service.

USSD See Unstructured Supplementary Service Data.

V

view A pane that is outside of the editor area that can be used to look at or work with the resources in the workbench.

W

web app

See web application.

web application (web app)

An application that is accessible by a web browser and that provides some function beyond static display of information, for instance by allowing the user to query a database. Common components of a web application include HTML pages, JSP pages, and servlets. See also app.

web application server

The runtime environment for dynamic web applications. A Java EE web application server implements the services of the Java EE standard.

web resource

Any one of the resources that are created during the development of a web application for example web projects, HTML pages, JavaServer Pages (JSP) files, servlets, custom tag libraries, and archive files.

widget

A portable, reusable application or piece of dynamic content that can be placed into a web page, receive input, and communicate with an application or with another widget.

wrapper

A section of code that contains code that could otherwise not be interpreted by the compiler. The wrapper acts as an interface between the compiler and the wrapped code.

X

X.509 certificate

A certificate that contains information that is defined by the X.509 standard.

Support and comments

For the entire IBM MobileFirst Platform documentation set, training material and online forums where you can post questions, see the IBM website at:

<http://www.ibm.com/mobile-docs>

Support

Software Subscription and Support (also referred to as Software Maintenance) is included with licenses purchased through Passport Advantage and Passport Advantage Express. For additional information about the International Passport Advantage Agreement and the IBM International Passport Advantage Express Agreement, visit the Passport Advantage website at:

<http://www.ibm.com/software/passportadvantage>

If you have a Software Subscription and Support in effect, IBM provides you assistance for your routine, short duration installation and usage (how-to) questions, and code-related questions. For additional details, consult your IBM Software Support Handbook at:

<http://www.ibm.com/support/handbook>

Comments

We appreciate your comments about this publication. Please comment on specific errors or omissions, accuracy, organization, subject matter, or completeness of this document. The comments you send should pertain to only the information in this manual or product and the way in which the information is presented.

For technical questions and information about products and prices, please contact your IBM branch office, your IBM business partner, or your authorized remarketer.

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate without incurring any obligation to you. IBM or any other organizations will only use the personal information that you supply to contact you about the issues that you state.

Thank you for your support.

If you would like a response from IBM, please provide the following information:

- Name
- Address
- Company or Organization
- Phone No.
- Email address

Notices

This information was developed for products and services offered in the US. This material might be available from IBM in other languages. However, you may be required to own a copy of the product or product version in that language in order to access it.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

*IBM Director of Licensing
IBM Corporation
North Castle Drive, MD-NC119
Armonk, NY 10504-1785
US*

For license inquiries regarding double-byte character set (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

*Intellectual Property Licensing
Legal and Intellectual Property Law
IBM Japan Ltd.
19-21, Nihonbashi-Hakozakicho, Chuo-ku
Tokyo 103-8510, Japan*

INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some jurisdictions do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM websites are provided for convenience only and do not in any manner serve as an endorsement of those

websites. The materials at those websites are not part of the materials for this IBM product and use of those websites is at your own risk.

IBM may use or distribute any of the information you provide in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

*IBM Director of Licensing
IBM Corporation
North Castle Drive, MD-NC119
Armonk, NY 10504-1785
US*

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

The performance data and client examples cited are presented for illustrative purposes only. Actual performance results may vary depending on specific configurations and operating conditions.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to actual people or business enterprises is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Each copy or any portion of these sample programs or any derivative work must include a © (your company name) (year).
Portions of this code are derived from IBM Corp. Sample Programs.

Trademarks

IBM, the IBM logo, and ibm.com are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the web at "Copyright and trademark information" at www.ibm.com/legal/copytrade.shtml.

Adobe, the Adobe logo, PostScript, and the PostScript logo are either registered trademarks or trademarks of Adobe Systems Incorporated in the United States, and/or other countries.

Intel, Intel logo, Intel Inside, Intel Inside logo, Intel Centrino, Intel Centrino logo, Celeron, Intel Xeon, Intel SpeedStep, Itanium, and Pentium are trademarks or registered trademarks of Intel Corporation or its subsidiaries in the United States and other countries.

Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

Java and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Node.js is a trademark of Joyent, Inc. and is used with its permission. This documentation is not formally endorsed by or affiliated with Joyent.

Other company products or service names may be trademarks or service marks of others.

This document may not be reproduced in whole or in part without the prior written permission of IBM.

Terms and conditions for product documentation

Permissions for the use of these publications are granted subject to the following terms and conditions.

Applicability

These terms and conditions are in addition to any terms of use for the IBM website.

Personal use

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

Commercial use

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

Rights

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the above instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

IBM Online Privacy Statement

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth below.

Depending upon the configurations deployed, this Software Offering may use session cookies that collect session information (generated by the application server). These cookies contain no personally identifiable information and are required for session management. Additionally, persistent cookies may be randomly generated to recognize and manage anonymous users. These cookies also contain no personally identifiable information and are required.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws

applicable to such data collection, including any requirements for notice and consent. For more information about the use of various technologies, including cookies, for these purposes, see IBM's Privacy Policy at <http://www.ibm.com/privacy> and IBM's Online Privacy Statement at <http://www.ibm.com/privacy/details> the section entitled "Cookies, Web Beacons and Other Technologies" and the "IBM Software Products and Software-as-a-Service Privacy Statement" at <http://www.ibm.com/software/info/product-privacy>.
