About This Document

The products IBM[®] WebSphere[®] Business Server Express and IBM[®] WebSphere[®] Business Server Express Plus are made up of the following components: InterChange Server Express, the associated Toolset Express, CollaborationFoundation, and a set of software integration adapters. The tools in the Toolset help you to create, modify, and manage business processes. You can choose from among the prepackaged adapters for your business processes that span applications. The standard processes template - CollaborationFoundation - allows you to quickly create customized processes.

This document describes the installation, configuration, and business object development for the adapter for web services.

Except where noted, all the information in this guide applies to both IBM WebSphere Business Integration Server Express and IBM WebSphere Business Integration Server Express Plus. The term WebSphere Business Integration Server Express and its variants refer to both products.

Audience

This document is for IBM WebSphere customers, consultants, developers, and anyone who is implementing the WebSphere Business Integration Adapter for web services.

Prerequisites for This Document

A variety of prerequisites are cited throughout this book. Many of these consist of references to Web sites that contain information about, or resources for, web services. You should also be familiar with implementing the WebSphere business integration system. A good place to start is the *System Implementation Guide*, which contains cross-references to more detailed documentation.

Related Documents

The complete set of documentation available with this product describes the features and components common to all WebSphere Business Integration Server Express installations, and includes reference material on specific components.

You can download, install, and view the documentation at the following site:
<http://www.ibm.com/websphere/wbiserverexpress/infocenter>

Note: Important information about this product may be available in Technical Support Technotes and Flashes issued after this document was published. These can be found on the WebSphere Business Integration Support Web site, <http://www.ibm.com/software/integration/websphere/support/>. Select the component area of interest and browse the Technotes and Flashes sections.

Typographic Conventions

This document uses the following conventions :

<code>courier font</code>	Indicates a literal value, such as a command name, filename, information that you type, or information that the system prints on the screen.
bold	Indicates a new term the first time that it appears.
<i>italic, italic</i>	Indicates a variable name or a cross-reference.
blue outline	A blue outline, which is visible only when you view the manual online, indicates a cross-reference hyperlink. Click inside the outline to jump to the object of the reference.
{ }	In a syntax line, curly braces surround a set of options from which you must choose one and only one.
[]	In a syntax line, square brackets surround an optional parameter.
...	In a syntax line, ellipses indicate a repetition of the previous parameter. For example, <code>option[,...]</code> means that you can enter multiple, comma-separated options.
< >	In a naming convention, angle brackets surround individual elements of a name to distinguish them from each other, as in <code><server_name><connector_name>tmp.log</code> .
/, \	In this document, backslashes (\) are used as the convention for directory paths. All IBM product pathnames are relative to the directory where the product is installed on your system.
<code>%text%</code> and <code>\$text</code>	Text within percent (%) signs indicates the value of the Windows text system variable or user variable.
<i>ProductDir</i>	Represents the directory where the IBM WebSphere Business Integration Adapters product is installed. The CROSSWORLDS environment variable contains the <i>ProductDir</i> directory path, which is <code>IBM\WebSphereAdapters</code> by default.
"	Indicates a choice from a menu such as: Choose File " Update " SGML References

New in this release

Release 4.3

This is the initial release.

Chapter 1. Overview of the adapter

- “Adapter for Web Services environment”
- “Terminology” on page 3
- “Components of connector for web services” on page 4
- “Architecture of connector for web services” on page 8
- “Install, configure, and design checklist” on page 9
- “Limitations” on page 10

The connector is a runtime component of the WebSphere Business Integration Server Express and Express Plus for Web Services. The connector allows businesses to aggregate, publish, and consume web services for use either within their organization or by trading partners. The connector and other components described in this document provide the functionality needed to exchange business object information in the body of a Simple Object Access Protocol (SOAP) message.

This chapter describes the Adapter for Web Services component of the IBM WebSphere Business Integration Server Express and Express Plus. This chapter includes a description of the scope, components, design tools, and architecture used to implement the WebSphere Business Integration Server Express and Express Plus for Web Services. It also provides an overview of tasks you must complete to install and configure the web services components described in this document. For information about installing and configuring the components, see “Install, configure, and design checklist” on page 9.

Note: The adapter for Web Services implements the standard Adapter Framework API. For this reason, the adapter can operate with any integration broker that the Framework supports. However, the functionality provided by the adapter has been designed specifically to support the IBM WebSphere InterChange Server Express integration broker. Accordingly, when you select the Expose as Web Service option in System Manager, this refers to InterChange Server Express, and not to any other integration broker.

Adapter for Web Services environment

Before installing, configuring, and using the adapter, you must understand its environmental requirements:

- “Software prerequisites”
- “Adapter platforms” on page 2
- “Standards and APIs” on page 2

Software prerequisites

Review the following assumptions and software requirements before you install the connector for web services:

- The design of the connector and other components is based on the specifications published for SOAP 1.1.
- If you are using SOAP/JMS web services, you must install your own- JMS and JNDI implementation.
- If you are using HTTPS/SSL, you need your own third-party software for creating keystore and truststore.

Adapter platforms

The adapter runs on the following platforms (operating systems):

- Microsoft Windows 2000

Standards and APIs

A variety of standards and technologies give web services access to their functionality over a network.

The standards used by the adapter are as follows:

- SOAP version 1.1 See the SOAP specification version 1.1
- WSDL 1.1 SOAP bindings
- HTTP 1.0
- JMS 1.0.2

The APIs used by the adapter are as follows:

- Apache SOAP 2.3.1 APIs: The connector incorporates the SOAP APIs from Apache Foundation. Apache SOAP APIs are an open source implementation of the SOAP version 1.1. Apache SOAP APIs have the following requirements:
 - Java Activation Framework 1.0.1 (activation.jar)
 - JavaMail(TM) API 1.2 (mail.jar)
- Xerces Java parser 1.4.3 and higher Xerces2 is a fully conforming XML schema processor
- JMS API version 1.0.2
- WSDL4J 1.2.1 - The Web Service Description Language for Java API (WSDL4J) provides an object model for WSDL documents
- UDDI4J-WSDL 2.1.0 - The UDDI4J-WSDL API encapsulate classes present in the UDDI4J API, as well as some defined by the WSDL4J API
- JNDI 1.2.1
- WSDL4J 1.0
- IBM JSSE 1.0.2

Depending on your configuration, you may need to install additional software. The sections below discuss these contingencies.

JMS protocol

If you are using JMS protocol, you must install a JMS provider and create queues. The queue creation really depends on your requirements. You may use JMS Protocol for both exposing a collaboration as a web service and also for invoking external web services. For further information, see “Connector and JMS” on page 78.

JNDI: You must configure the JNDI and then enter appropriate parameters in the JNDI configuration properties for the connector. You also must ensure that the Connection factory and JMS destination (queue) object are made available in the JNDI. If you want to use JNDI and do not have JNDI implementation, you can download the reference implementation of File System JNDI from Sun Microsystems. For further information, see “Connector and JMS” on page 78.

SSL

If you plan to use SSL, you must use third-party software for managing your keystores, certificates, and key generation. No tooling is provided to set up

keystores, certificates, or for key generation. You may choose to use keytool (shipped with IBM JRE) to create self-signed certificates and to manage keystores. For further information, see “SSL” on page 80.

Terminology

The following terms are used in this Guide:

- **ASI (Application-Specific Information)** is code tailored to a particular application or technology. ASI exists at both the attribute level and business object level of a business object definition.
- **ASBO (Application-Specific Business Object)** A business object that can have ASI.
- **BO (Business Object)** A set of attributes that represent a business entity (such as Customer) and an action on the data (such as a create or update operation). Components of the IBM WebSphere system use business objects to exchange information and trigger actions.
- **Content-Type** The HTTP protocol header that includes the *type/subtype* and optional parameters. For example, in the Content-Type value `text/xml; charset=ISO-8859-1`, `text/xml` is the *type/subtype* and `charset=ISO-8859-1` is the optional *Charset* parameter.
- **ContentType** refers to the *type/subtype* portion of the Content-Type header value only. For example, in the Content-Type value `text/xml; charset=ISO-8859-1`, `text/xml` is referred to in this document as the *ContentType*.
- **MO_DataHandler_DefaultSOAPConfig** Child data handler meta-object specifically for the SOAP data handler.
- **GBO (Generic Business Object)** A business object with no ASI and not tied to any application.
- **MO_DataHandler_Default** Data handler meta-object used by the connector agent to determine which data handler to instantiate. This is specified in the *DataHandlerMetaObjectName* configuration property of the connector.
- **Non-Top Level Business Object (Non-TLO)** A non-TLO is any business object that does not adhere to the web services TLO structure.
- **Protocol Config MO** During request processing, the SOAP/JMS, SOAP/HTTP-HTTPS protocol handlers use a Protocol Config MO to determine the destination of the target web service. If during event processing you are exposing collaborations as SOAP/JMS web services, the connector uses the Protocol Config MO to convey the JMS message header information from the SOAP/JMS protocol listener to the collaboration.
- **SOAP (Simple Object Access Protocol)** defines a model of using simple request and response messages, written in XML, as the basic protocol for electronic communication. SOAP messaging is a platform-neutral remote procedure call (RPC) mechanism, but it can be used for the exchange of any kind of XML information (document exchange).
- **SOAP Business Object** A SOAP business object is a child of a TLO and can be a SOAP Request, a SOAP Response or a SOAP Fault business object. SOAP business objects contain information necessary for processing by the SOAP data handler, including SOAP ConfigMOs, which are children of SOAP business objects, and also contain SOAP header container business objects.
- **SOAP Config MO (Configuration Meta Object)** The data handler requires an object that contains configuration information about a single transformation, for example, from a SOAP message to a SOAP business object. This information is stored as meta-data in the child of a SOAP business object. This child object is the SOAP Config MO

- **SOAP Header Child Business Object** A business object that represents a single header element in a SOAP message. The header element is an immediate child of the SOAP-Env:Header element of the SOAP message. All attributes of a header container business object must be of this type. These business objects may have an actor and a mustUnderstand attribute. These attributes correspond to the actor and mustUnderstand attributes of the SOAP header element.
- **SOAP Header Container Business Object** A business object that contains information about the headers in a SOAP message. This business object contains one or more child business objects. Each child business object represents a header entry in the SOAP message. The SOAP data handler business object may have an attribute, which is of type SOAP header container business object. This attribute is also referred to as the SOAP header attribute. Such an attribute has special application-specific information requirements as described in Chapter 5, “SOAP data handler,” on page 105. This attribute must be an immediate child of a SOAP business object.
- **Top-Level Business Object** A web services top-level business object contains a SOAP Request, a SOAP Response (optional) and one or more SOAP Fault (optional) business objects. A TLO is used by the connector for both event processing and request processing.
- **Web services** are self-contained, modular, distributed, dynamic applications that can be described, published, located, or invoked over the network to create products, processes, and supply chains. They can be local, distributed, or Web-based. Web services are built on top of open standards such as TCP/IP, HTTP, Java, HTML, and XML. Web services use new standard technologies such as SOAP (Simple Object Access Protocol) for messaging, and UDDI (Universal Description, Discovery and Integration) and WSDL (Web Service Description Language) for publishing.
- **UDDI (Universal Description, Discovery and Integration)** is a specification that defines a way to publish and discover information about web services. UDDI specification provides for XML-based interfaces (APIs) that allow programmatic access to the UDDI registry information. SOAP is the underlying RPC mechanism for these APIs.
- **WSDL (Web Services Description Language)** is an XML vocabulary that defines the software interfaces for web services. It organizes all of the web service technical details required for automatic integration at the programming level, and is used to publish IBM WebSphere collaborations as web services. WSDL is to web services as IDL is to CORBA objects.

For more information on WSDL, go to:

<http://www.w3.org/TR/wsdl>

Components of connector for web services

Figure 1 illustrates the connector for web services, including its protocol handler and listener frameworks and the SOAP data handler.

Note: The Web Services Adapter comes with a limited use license of the XML data handler. The adapter, however, does not require the XML data handler to function.

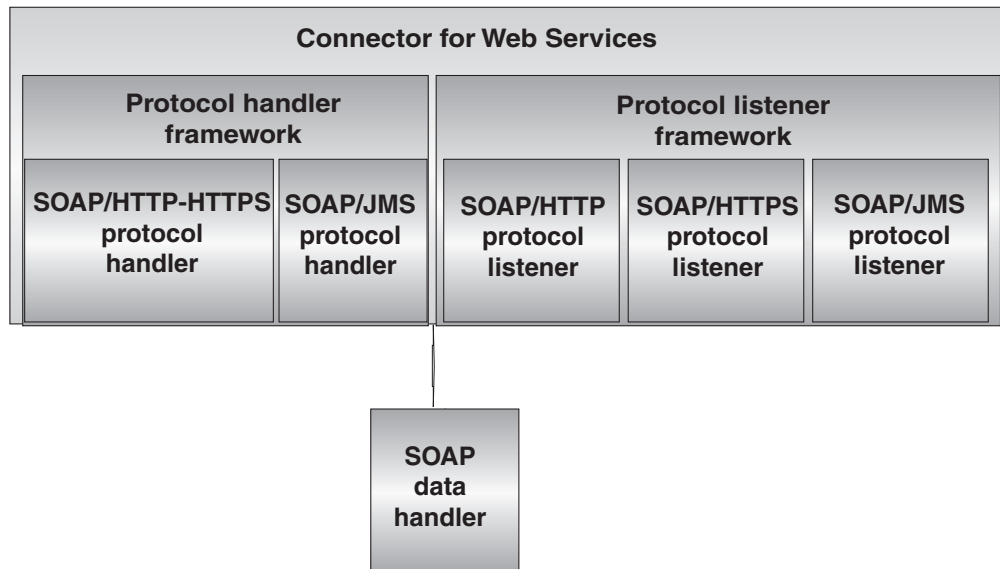

Figure 1. The connector for web services

The following components interact to enable data exchanges across the Internet:

- Web services connector, including the SOAP data handler and protocol listeners and handlers
- Web services-enabled collaborations
- Business objects and SOAP messages
- WebSphere Business Integration Server Express and Express Plus

Web services connector

During request processing, the web services connector responds to collaboration service calls by converting business objects to SOAP request messages and conveying them to destination web services. Optionally (for synchronous request processing) the connector converts SOAP response messages to SOAP Response business objects and returns these to the collaboration.

During event processing, the connector processes SOAP request messages from client web services by converting them into SOAP Request business objects and passing them on to collaborations (that have been exposed as web services) for processing. The connector optionally receives SOAP Response business objects from the collaboration, which are converted to SOAP response messages and then returned to client web services.

For further information, see Chapter 4, “Web services connector,” on page 55

Note: In this document, any mention of a connector is a reference to the web services connector, unless specified otherwise.

Protocol listeners and handlers

The connector includes the following protocol listeners and handlers:

- SOAP/HTTP protocol listener
- SOAP/HTTPS protocol listener
- SOAP/JMS protocol listener
- SOAP/HTTP-HTTPS protocol handler

- SOAP/JMS protocol handler

Protocol listeners detect events from internal or external web service clients in SOAP/HTTP, SOAP/HTTPS, or SOAP/JMS formats. They notify the connector of events that require processing by a collaboration that has been exposed as a web service. Protocol listeners then read the business-object-level and attribute-level ASI, connector properties, and transformation rules embedded in protocol configuration objects to determine the collaboration, data handler, processing mode (synchronous/asynchronous) and transport-specific aspects of the web services transaction. For a detailed account of protocol listener processing, see “Protocol listeners” on page 59.

Protocol handlers invoke web services in SOAP/HTTP, SOAP/HTTPS, or SOAP/JMS formats on behalf of a collaboration. Protocol handlers read TLO ASI and transformation rules embedded in protocol configuration objects to determine how to process the request (synchronously or asynchronously), which data handler to use to convert SOAP messages to SOAP business objects and vice versa, and to determine the target address of the web service (from the Destination attribute of the SOAP Request business object Protocol Config MO). For synchronous transactions, the protocol handler processes SOAP response messages, converting them into SOAP Response business objects and passing them back to the collaboration.

For further information on protocol handlers, see “Protocol handlers” on page 71.

SOAP data handler

The SOAP data handler converts SOAP business objects to SOAP messages and vice versa. For further information on the SOAP data handler, see Chapter 5, “SOAP data handler,” on page 105.

For further details, see Chapter 5, “SOAP data handler,” on page 105.

Web services configuration tools

You can deploy web service solutions with collaborations that invoke, or are exposed as, web services.

When you enable a collaboration for request processing, you use the WSDL Object Discovery Agent (ODA) to generate web service TLOs. For further information on request processing and the WSDL ODA, see Chapter 6, “Enabling collaborations for request processing,” on page 137.

When you expose a collaboration as a web service, you use the WSDL Configuration Wizard, which helps you generate a WSDL document for the collaboration that you then publish, for example, via a UDDI registry. The connector provides no tools for publishing this information. For information on exposing collaborations as web services, see Chapter 7, “Exposing collaborations as web services,” on page 139.

Deploying the connector

There are two ways to deploy the web services connector:

- Behind the firewall as an intranet-based solution (see Figure 2) within an enterprise whose business processes communicate in SOAP/HTTP, SOAP/HTTPS, or SOAP/JMS web service formats.

Figure 2. Web services adapter as an intranet solution

- Behind the firewall with a front-end or gateway server to process, filter, and otherwise manage communications with web services that are external to the enterprise.

Note: The web services connector does not include a gateway or front-end for managing incoming or outgoing messages from or to external web services. You must configure and deploy your own gateway. *The connector must be deployed within the enterprise only, not in the DMZ or outside of the firewall.*

Architecture of connector for web services

To illustrate the architecture of the components at a high level, this section describes two data flows. Figure 3 illustrates the two scenarios. These two scenarios are described below.

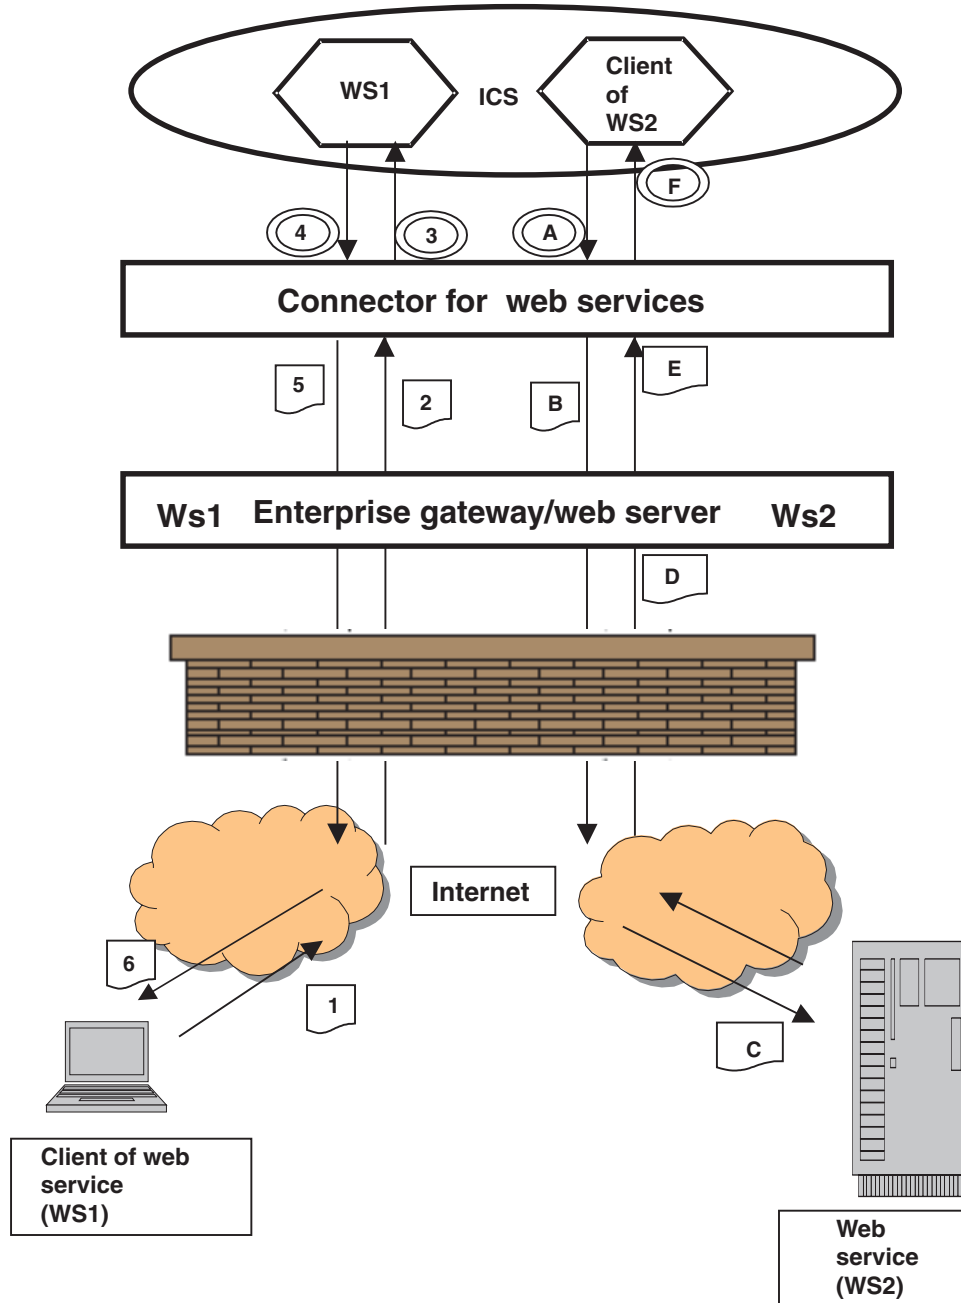

Figure 3. Flow of a web services message

Request processing illustrates the sequence of events that occurs when a collaboration makes a service call request to the connector to invoke a web service. In this scenario, the collaboration plays the role of a client, sending a request to a server.

- A The collaboration sends a service call request to the connector, which calls the SOAP data handler to convert the business object to a SOAP request message.
- B The connector invokes the web service WS2 by sending the SOAP message. If the destination is an external web service, the connector sends the SOAP message to a gateway. The gateway sends the SOAP message to the endpoint corresponding to the destination web service. This invokes the web service.
- C The invoked web service receives the SOAP request message and performs the requested processing.
- D The invoked web service sends a SOAP response (or fault) message. If the web service is external to the enterprise, a gateway receives and routes the SOAP response message.
- E The SOAP response (or fault) message is routed back to the connector, which calls the data handler to convert it to a response or fault business object.
- F The connector returns the SOAP response or fault business object to the collaboration.

Event processing illustrates the sequence of events that occurs when a collaboration is called as a web service. In this scenario, the collaboration, which is exposed as a web service, plays the role of the server, accepting a request from a client, external or internal, and responding as required.

- 1 The client web service (WS1) sends a SOAP request message to the destination specified in the WSDL document generated for the collaboration.
- 2 If the client web service is external, the gateway receives and routes the message to the connector.
- 3 The connector sends the SOAP message to the SOAP data handler to convert the SOAP message to a business object. The connector invokes the collaboration exposed as a web service.
- 4 The collaboration returns a SOAP Response (or Fault) business object.
- 5 The connector calls the SOAP data handler to convert the SOAP Response (or Fault) business object to a SOAP response message. The connector returns the response to the gateway.
- 6 If the client web service is external, the gateway routes the SOAP response message to the client web service (WS1).

Install, configure, and design checklist

This section summarizes the tasks you must perform to install, configure, and design your web services solution. Each section briefly describes the tasks and then provides links to sections in this document (and cross references to related documents) that describe how to perform the task or provide background information.

Installing the adapter

See Chapter 2, “Installation and startup,” on page 13 for a description of what and where you must install.

Configuring connector properties

Connectors have two types of configuration properties: standard configuration properties and connector-specific configuration properties. Some of these properties have default values that you do not need to change. You may need to set the values of some of these properties before running the connector. For more information, see Chapter 4, “Web services connector,” on page 55.

Configuring protocol handlers and listeners

You configure protocol handlers and listeners when you assign values to connector configuration properties that govern the behavior of these components. For more information, see Chapter 4, “Web services connector,” on page 55.

Enabling collaborations for web services

When you enable collaborations for web services, you create collaborations that can invoke, or be exposed as, web services. You also create or adapt business objects. For an overview of the tasks involved, see “Web services configuration tools” on page 6.

Exposing collaborations as web services

For a step-by-step description see Chapter 7, “Exposing collaborations as web services,” on page 139.

Enabling collaborations to invoke web services

For a step-by-step description, see Chapter 6, “Enabling collaborations for request processing,” on page 137.

Configuring the SOAP data handler

You configure information in data handler meta-objects after you install the product files, but before startup. Unless you are adding a custom name handler, you can use the default SOAP data handler configuration to save time. You must, however, configure specific meta-object information for each data handler transformation. This information is contained in SOAP Config MOs. You specify SOAP Config MOs when you create business objects. Much of this work is automated when you are developing collaborations that invoke web services (request processing): when you use the WSDL ODA to generate business objects for SOAP messages, the SOAP Config MOs are automatically generated for you.

For further information on configuring the data handler, see Chapter 5, “SOAP data handler,” on page 105.

Limitations

- The WSDL ODA automatically generates business objects. If the results do not meet your requirements, you must manually create business objects using Business Object Designer Express.
See describes WSDL ODA support for various combinations of attributes style, use, and part definitions using type and element.
- For XML limitations on style (rpc, document) use (literal, encoded), and how parts are defined, see Chapter 5, “SOAP data handler,” on page 105 and Chapter 6, “Enabling collaborations for request processing,” on page 137.
- The connector supports SOAP/HTTP and SOAP/JMS bindings only.
- The connector’s SOAP/JMS protocol listener supports queue destinations only; topics are not supported. JMS text and byte messages are supported.

- HTTP POST Request and Response are supported. No other HTTP method is supported. HTTP 1.1 persistent connection is not supported.

Chapter 2. Installation and startup

- “Overview of Installation Tasks”
- “Installing the connector and related files”
- “Overview of configuration tasks” on page 14
- “Running multiple instances of the adapter” on page 15
- “Starting and stopping the connector” on page 17

This chapter describes how to install components for implementing the connector for web services. For information regarding installation of an Business Integration Server Express and Express Plus system generally, see the *Installation Guide for WebSphere Business Integration Server Express* appropriate for your platform.

Overview of Installation Tasks

For information on broker compatibility, adapter framework, software prerequisites, dependencies, and standards and APIs, see “Adapter for Web Services environment” on page 1.

To install the connector for web services, you must perform the following tasks:

Install Business Integration Server Express and Express Plus

This task, which includes installing the system and starting Business Integration Server Express and Express Plus, is described in the *Installation Guide for WebSphere Business Integration Server Express*. You must install Business Integration Server Express and Express Plus, version 4.2.

To load files into the repository, consult the *Implementation Guide for WebSphere Business Integration Server Express and Express Plus*.

Install the connector and related files

This task includes installing the files for the connector (and related components) from the software package onto your system. See “Installing the connector and related files.”

Installing the connector and related files

For information on installing the adapter, refer to the *Installation Guide for WebSphere Business Integration Server Express*, located in the WebSphere Business Integration Server Express Infocenter at the following site:

<http://www.ibm.com/websphere/wbiserverexpress/infocenter>

Installed file structure

The tables in this section show the installed file structure.

Windows connector file structure

The Installer copies the standard files associated with the connector into your system.

The utility installs the connector and adds a shortcut for the connector agent to the Start menu.

Table 1 describes the Windows file structure used by the connector, and shows the files that are automatically installed when you choose to install the connector through Installer.

Table 1. Installed Windows file structure for the adapter

connectors\WebServices\samples\WebSphereICS\CLIENT_ASYNC_TLO_Order.bo	Sample (asynchronous) business object for test connector
connectors\messages\WebServicesConnector.txt	Connector message file
ODA\messages\WSDLODAAgent.txt	Message file for WSDL ODA

Note: All product pathnames are relative to the directory where the product is installed on your system.

For more information on installing the connector component, refer to

- *Installation Guide for WebSphere Business Integration Server Express*

Overview of configuration tasks

After installation and before startup, you must configure components as follows:

Configure the connector

This task includes setting up and configuring the connector. See “Configuring the connector” on page 82.

Configure business objects

The steps for configuring business objects depend on how you elect to implement the product suite:

- **Request Processing** You must create the business objects that correspond to:
 - The request messages to be sent to each web service
 - Each possible response, including faults

For further information, review Chapter 3, “Business object requirements,” on page 19 and then see Chapter 6, “Enabling collaborations for request processing,” on page 137.

- **Event Processing** You can use TLO or non-TLO business objects. For further information, review Chapter 3, “Business object requirements,” on page 19 and then see Chapter 7, “Exposing collaborations as web services,” on page 139.

Configure the data handler

The SOAP data handler meta-object must be configured after installation. In addition, SOAP Config MOs must be configured for each SOAP business object. To configure the data handler, see Chapter 5, “SOAP data handler,” on page 105

Configure collaborations

- **Request processing** For collaborations that invoke web services as part of their processing, you generate business objects using the WSDL ODA and then bind collaboration object ports to the connector. For further information including a step-by-step procedure, see Chapter 6, “Enabling collaborations for request processing,” on page 137.
- **Event processing** For a collaboration that is exposed as a web service, you must generate a WSDL document using the WSDL Configuration Wizard, make the document available to potential clients, and then configure the ports of the collaboration object so that clients can invoke the collaboration. For further information including a step-by-step procedure, see Chapter 7, “Exposing collaborations as web services,” on page 139.

Running multiple instances of the adapter

Creating multiple instances of a connector is in many ways the same as creating a custom connector.

Note: Each additional instance of any adapter supplied with WebSphere Business Integration Server Express will be treated as a separate adapter by the function that limits the total number of adapters that can be deployed.

You can set your system up to create and run multiple instances of a connector by following the steps below. You must:

- Create a new directory for the connector instance
- Make sure you have the requisite business object definitions
- Create a new connector definition file
- Create a new start-up script

Create a new directory

You must create a connector directory for each connector instance. This connector directory should be named:

```
ProductDir\connectors\connectorInstance
```

where `connectorInstance` uniquely identifies the connector instance.

If the connector has any connector-specific meta-objects, you must create a meta-object for the connector instance. If you save the meta-object as a file, create this directory and store the file here:

```
ProductDir\repository\connectorInstance
```

Create business object definitions

If the business object definitions for each connector instance do not already exist within the project, you must create them.

1. If you need to modify business object definitions that are associated with the initial connector, copy the appropriate files and use Business Object Designer Express to import them. You can copy any of the files for the initial connector. Just rename them if you make changes to them.
2. Files for the initial connector should reside in the following directory:

```
ProductDir\repository\initialConnectorInstance
```

Any additional files you create should be in the appropriate `connectorInstance` subdirectory of `ProductDir\repository`.

Create a connector definition

You create a configuration file (connector definition) for the connector instance in Connector Configurator Express. To do so:

1. Copy the initial connector's configuration file (connector definition) and rename it.
2. Make sure each connector instance correctly lists its supported business objects (and any associated meta-objects).
3. Customize any connector properties as appropriate.

Create a start-up script

To create a startup script:

1. Copy the initial connector's startup script and name it to include the name of the connector directory:
`dirname`
2. Put this startup script in the connector directory you created in "Create a new directory."
3. Create a startup script shortcut.
4. Copy the initial connector's shortcut text and change the name of the initial connector (in the command line) to match the name of the new connector instance.

You can now run both instances of the connector on your integration server at the same time.

Starting and stopping the connector

Important: As noted earlier in this chapter, the connector, business objects, the SOAP data handler meta-objects, and collaborations must be configured after installation and before starting the connector to assure proper operation. For a summary of these tasks, see “Overview of configuration tasks” on page 14. In addition, connector polling should not be disabled (connector polling is enabled by default).

A connector must be explicitly started using its **connector start-up script**. The startup script should reside in the connector’s runtime directory:

ProductDir\connectors\connName

where *connName* identifies the connector. The name of the startup script depends on the operating-system platform, as Table 2 shows.

Table 2. Startup scripts for a connector

Operating system	Startup script
Windows	start_ <i>connName</i> .bat

You can invoke the connector startup script in any of the following ways:

- On Windows systems, from the **Start** menu
Select **Programs>IBM WebSphere Business Integration Express>Adapters>Connectors>your_connector_name**.
By default, the program name is “IBM WebSphere Business Integration Express”. However, it can be customized. Alternatively, you can create a desktop shortcut to your connector.
- From the command line
 - On Windows systems:

```
start_connName connName ICS [-cconfigFile ]
```

where *connName* is the name of the connector.
- From System Monitor
You can load, activate, deactivate, pause, shutdown or delete a connector using this tool.
- On Windows systems, you can configure the connector to start as a Windows service. In this case, the connector starts when the Windows system boots (for an Auto service) or when you start the service through the Windows Services window (for a Manual service).

For more information on how to start a connector, including the command-line startup options, refer to the *System Administration Guide*.

Chapter 3. Business object requirements

- “Business object meta-data”
- “Connector business object structure”
- “Synchronous event processing TLOs” on page 20
- “Asynchronous event processing TLOs” on page 34
- “Event processing non-TLOs” on page 37
- “Synchronous request processing TLOs” on page 38
- “Synchronous request processing TLOs” on page 38
- “Asynchronous request processing TLOs” on page 49
- “Developing business objects” on page 53

This chapter describes the structure, requirements, and attributes of connector business objects.

Business object meta-data

The connector for web services is a meta-data-driven connector. In business objects, meta-data is data about the application, which is stored in a business object definition and which helps the connector interact with an application. A meta-data-driven connector handles each business object that it supports based on meta-data encoded in the business object definition rather than on instructions hard-coded in the connector.

Business object meta-data includes the structure of a business object, the settings of its attribute properties, and the content of its application-specific information. Because the connector is meta-data-driven, it can handle new or modified business objects without requiring modifications to the connector code. However, the connector’s configured data handler makes assumptions about the structure of its business objects, object cardinality, the format of the application-specific text, and the database representation of the business object. Therefore, when you create or modify a business object for web services, your modifications must conform to the rules the connector is designed to follow, or the connector cannot process new or modified business objects correctly.

For more information on meta-data, meta-objects, and their configuration and interaction with business objects and SOAP messages, see Chapter 5, “SOAP data handler,” on page 105.

Connector business object structure

The connector processes two kinds of business objects:

- **TLOs** A web services top-level business object (TLO) contains a Request business object and, optionally, Response and Fault business objects. These child objects contain content data as well as SOAP Config MOs, and, optionally, Protocol Config MOs. The TLO, Request, Response, and Fault objects as well as application-specific information, attributes, and requirements with regard to request versus event processing are described and illustrated in the sections below.

Note: *TLOs are used for request processing and event processing.*

- **Non-TLOs** These are generic business objects (GBOs) and application-specific business objects (ASBOs) that are not TLOs, but which have been used by the WSDL Configuration Wizard in WSDL generation. The connector can process non-TLOs during event processing. These objects are discussed below in “Event processing non-TLOs” on page 37. For further information, see “WSDL Configuration Wizard” on page 142.

Note: *Non-TLOs are used for event processing only.*

Note: SOAP header container and header business objects, which are included in Request, Response, and Fault business objects, are not discussed in this chapter. For information on SOAP header container and header business objects, see Chapter 5, “SOAP data handler,” on page 105.

Synchronous event processing TLOs

For event processing the connector allows two kinds of TLOs—synchronous and asynchronous. This section discusses synchronous event processing TLOs.

Figure 4 on page 21 shows the business object hierarchy for synchronous event processing. Request and Response objects are required, Fault objects are optional.

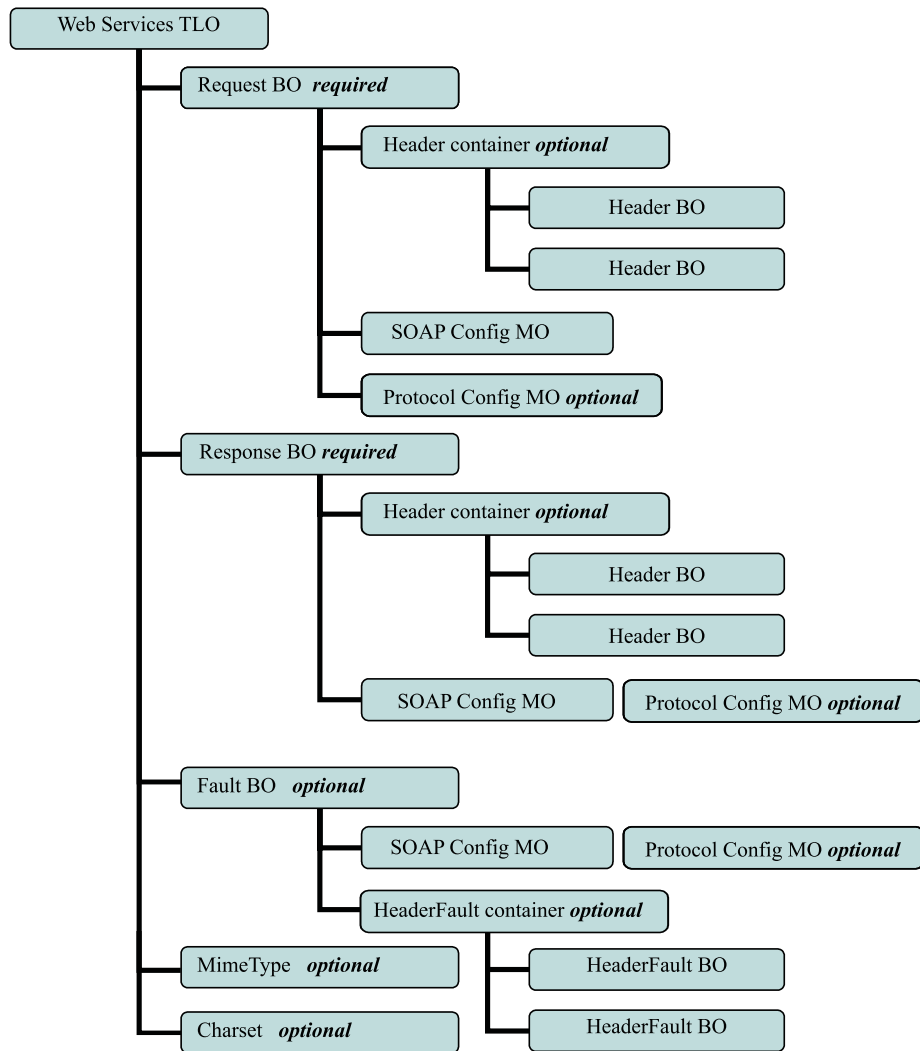

Figure 4. Business object hierarchy for synchronous event processing

The TLO contains object-level ASI as well as attributes with attribute-level ASI. Both kinds of ASI are discussed below.

Object-level ASI for synchronous event processing TLOs

Object-level ASI provides fundamental information about the nature of a TLO and the objects it contains. Figure 5 shows the object-level ASI for SERVICE_SYNCH_OrderStatus, a sample TLO for synchronous event processing.

Figure 5. Top-level business object for synchronous event processing

Table 3 below describes the object-level ASI for a synchronous event processing TLO.

Table 3. Synchronous event processing TLO object ASI

Object-level ASI	Description
<code>ws_eventtlo=true</code>	If this ASI property is set to true, the connector treats this object as a TLO for event processing only. Note that the WSDL Configuration Wizard uses this ASI to determine whether a business object is a TLO. For more on this see “WSDL Configuration Wizard” on page 142.
<code>ws_collab=collabname</code>	This ASI tells the connector which collaboration to invoke. Its value is the name of the collaboration. (This ASI is also used during WSDL generation to determine the TLO for a collaboration. For more on this see “WSDL Configuration Wizard” on page 142.) In the sample shown in Figure 5, the collaboration name is SERVICE_SYNCH_OrderStatus_Collab)
<code>ws_verb=verb</code>	Before delivering the TLO to the collaboration, the connector uses this ASI to set the verb on the TLO. In the sample shown in Figure 5, the verb is Retrieve.
<code>ws_mode=synch</code>	During event notification, the connector uses this ASI property to determine whether to invoke the collaboration synchronously (<code>synch</code>) or asynchronously (<code>asynch</code>). For synchronous processing, this ASI must be set to <code>synch</code> . The default is <code>asynch</code> .

Attribute-level ASI for synchronous event processing TLOs

Each synchronous event processing TLO has attributes and attribute-level ASI. Figure 6 shows the attributes of SERVICE_SYNCH_OrderStatus, a sample TLO. It also shows the attribute-level ASI in the App Spec Info column.

	Pos	Name	Type	Key	Foreign	Required	Card	App Spec Info
1	1	Request	SERVICE_SYNCH_OrderStatus_Request	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1	ws_botype=request
2	2	Response	SERVICE_SYNCH_OrderStatus_Response	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1	ws_botype=response
3	3	Fault	SERVICE_SYNCH_OrderStatus_Fault	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1	ws_botype=fault
4	4	ObjectEventId	String					
5	5			<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		

Figure 6. TLO attributes for synchronous event processing

Table 4 summarizes the attribute-level ASI for the Request, Response, Fault, MimeType, and Charset attributes of an synchronous event processing TLO.

Table 4. Synchronous event processing TLO attribute ASI

TLO attribute	Attribute-level ASI	Description
MimeType		Optional attribute; if specified, its value is used as the mime type of the data handler to invoke for the synchronous response. The type is String and the default is xml/soap.
Charset		This optional parameter of type String specifies the charset to be set on the data handler when transforming an outgoing business object to the message. NOTE: the charset value specified in this attribute will not be propagated in the Content-Type protocol header of the response message.
Request	ws_botype=request	This attribute corresponds to a web service request. The connector uses its ASI to determine whether this TLO attribute is of type SOAP Request BO. This ASI, not the attribute name, determines the attribute type. If there is more than one request attribute, the connector uses the ASI of the first one. This attribute is required for synchronous event processing TLOs.

Table 4. Synchronous event processing TLO attribute ASI (continued)

TLO attribute	Attribute-level ASI	Description
Response	ws_botype=response	<p>This attribute corresponds to the response returned by a web service. The connector uses this ASI to determine whether this TLO attribute is of type SOAP Response BO. This ASI, not the attribute name, determines the attribute type. If there is more than one response attribute, the connector uses the ASI of the first one.</p> <p>This attribute is required for synchronous event processing TLOs.</p>
Fault	ws_botype=fault ws_botype=defaultfault	<p>This attribute, optional for synchronous event processing, corresponds to a fault message returned by a collaboration when it cannot successfully populate a response. The connector uses this ASI, not the attribute name, to determine if the attribute is of type SOAP Fault BO. If ws_botype=defaultfault, then the WSDL Configuration Wizard uses this Fault business object for header processing. For further information, see "Header fault processing" on page 116.</p>

Request business object for synchronous event processing

A Request business object is a child of a TLO and is required for synchronous event processing. A Request business object has object-level ASI. For example, if you open SERVICE_SYNCH_OrderStatus_Request in Business Object Designer Express and click the General tab, the object level ASI is displayed as shown in Figure 7 on page 25.

Figure 7. Object-level ASI for synchronous event processing request object

The object-level ASI for a Request business object for synchronous event processing is described in Table 5. As shown in Figure 7, you can specify a default verb for the Request business object. You do so by specifying:

`DefaultVerb=true;`

in the ASI field for the verb in the Supported Verbs list at the top-level of the Request business object. If `DefaultVerb` ASI is not specified and the data handler processes a business object with no verb set, the business object is returned without a verb.

Table 5. Synchronous event processing: object-level ASI for Request business objects

Object-level ASI	Description
<code>cw_mo_soap=SOAPCfgMO</code>	The value of this ASI must match the name of the attribute that corresponds to the SOAP Config MO. This is the meta-object that defines the data handler transformation for the Request business object. For further information, see “SOAP Config MO” on page 26.
<code>cw_mo_jms=SOAPJMSCfgMO</code> or <code>cw_mo_http=SOAPHHTPCfgMO</code>	The value of this ASI must match the name of the attribute that corresponds to the Protocol Config MO. The first ASI designates the SOAP/JMS protocol listener; the second designates the SOAP/HTTP or SOAP/HTTPS protocol listener. Both the ASI and the Protocol Config MO are optional. For further information, see “Protocol Config MO” on page 27.
<code>ws_tlname=tloname</code>	This ASI specifies the name of the web services TLO that this object belongs to. During event processing, the connector uses this ASI to determine whether the Request business object delivered by the data handler is a child of the TLO. If so, the connector creates the specified TLO, sets the Request business object as its child, and uses the TLOs object-level ASI to deliver it to the subscribing collaboration.

Response business object for synchronous event processing

A Response business object is a child of a TLO and is required for synchronous event processing. The object-level ASI for a Response business object for synchronous event processing is described in Table 6.

Table 6. Synchronous event processing: object-level ASI for Response business objects

Object-level ASI	Description
<code>cw_mo_soap=SOAPCfgMO</code>	The value of this ASI must match the name of the attribute that corresponds to the SOAP Config MO. This is the SOAP Config MO that defines the data handler transformation for the Response business object. For further information, see “SOAP Config MO.”

Note: You can optionally include a Protocol Config MO object-level ASI for the Response BO.

Fault business object for synchronous event processing

A Fault business object is a child of a TLO and is optional for synchronous event processing. The object-level ASI for a Fault business object for synchronous event processing is described in Table 7.

Table 7. Synchronous event processing: object-level ASI for Fault business objects

Object-level ASI	Description
<code>cw_mo_soap=SOAPCfgMO</code>	The value of this ASI must match the name of the attribute that corresponds to the SOAP Config MO. This is the SOAP Config MO that defines the data handler transformation for the Fault business object. For further information, see “SOAP Config MO.”

Note: You can optionally include a Protocol Config MO object-level ASI for the Fault BO.

SOAP Config MO

Figure 8 shows a sample SOAP Config MO, expanded in Business Object Designer Express.

Pos	Name	Type	Key	Foreign	Required	Card	Maximum Length	Default	
1	1	OrderId	String	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>		255	
2	4	SOAPJMSCfgMO	SERVICE_SYNCH_SOAP_JMS_OrderStatus_Req	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1		
3	5	ObjectEventId	String						
4	2	OrderHeader	SERVICE_SYNCH_OrderStatus_Request_Header	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1		
5	3	SOAPCfgMO	SERVICE_SYNCH_OrderStatus_Request_CfgMO	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1		
5.1	3.6	BodyName	String	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255	getOrderStatus
5.2	3.3	Style	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255	rpc
5.3	3.4	TypeInfo	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255	true
5.4	3.5	TypeCheck	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255	none
5.5	3.2	BOVerb	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255	Retrieve
5.6	3.7	ObjectEventId	String						
5.7	3.1	BodyNS	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255	http://www.mycompany.com/samples/orderstatus

Figure 8. SOAP Config MO attributes for synchronous event processing

The SOAP Config MO defines the formatting behavior for one data handler transformation — either a SOAP-message-to-business-object or business-object-to-SOAP-message transformation. Each Request, Response, and Fault attribute has a SOAP Config MO. Its attributes, BodyName, BodyNS, Style, Use, TypeInfo, TypeCheck and BOVerb, are always of type String. They correspond to SOAP message elements and their values determine how messages and objects are read and validated by the SOAP data handler. For more information on SOAP Config MOs and attributes, see “SOAP configuration meta-object: child of every SOAP business object” on page 107.. All SOAP Config MOs, whether for a request, response, or fault object, must have unique entries for default values of BodyName and BodyNS.

Protocol Config MO

Figure 9 shows a JMS Protocol Config MO, whose attributes correspond to headers in the inbound SOAP message.

	Pos	Name	Type	Key	Foreign	Required	Card
1	1	Request	SERVICE_SYNCH_OrderStatus_Request	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1
1.1	1.1	OrderId	String	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	
1.2	1.5	ObjectEventId	String				
1.3	1.3	SOAPCfgMO	SERVICE_SYNCH_OrderStatus_Request_CfgMO	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1
1.4	1.4	SOAPJMScfgMO	SERVICE_SYNCH_SOAP_JMS_OrderStatus_Request_CfgMO	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1
1.4.1	1.4.1	MessageId	String	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	
1.4.2	1.4.2	Priority	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	
1.4.3	1.4.3	Expiration	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	
1.4.4	1.4.4	DeliveryMode	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	
1.4.5	1.4.5	ReplyTo	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	
1.4.6	1.4.6	ObjectEventId	String				

Figure 9. JMS Protocol Config MO attributes for synchronous event processing

This MO is optionally included as a child of the request, response, or fault business objects for event processing. Typically you specify it when you need to read (from request messages) or propagate (to response or fault messages) the protocol headers and custom properties. As noted above, the request business object optionally declares the name of the Protocol Config MO as business-object-level ASI:

- `cw_mo_jms=JMSProtocolListenerConfigMOAttribute`
- `cw_mo_http=HTTPProtocolListenerConfigMOAttribute`

During event processing, the connector uses protocol listeners (SOAP/HTTP, SOAP/HTTPS or SOAP/JMS) to retrieve events from the transport. These events are messages from internal or external web service clients requesting service from collaborations that have been exposed as web services. Each transport has its own header requirements. The connector uses the Protocol Config MO to convey the protocol-specific header information from the protocol listener to the collaboration. The Protocol Config MO attributes correspond to headers in the inbound SOAP/JMS message. The connector sets the value of these attributes in the business object using inbound SOAP message content. For SOAP/JMS protocol, the Protocol Config MO attributes for event and request processing are as follows:

Table 8. SOAP JMS Protocol Config MO attributes: event and request processing

SOAP/JMS Protocol Config MO attribute	JMSHeaderName	Description
CorrelationID	JMSCorrelationID	Inbound messages: this attribute will be populated with the value from JMSCorrelationID header. Outbound messages: : the value from this attribute will be set as the JMSCorrelationID header of outgoing message.

Table 8. SOAP JMS Protocol Config MO attributes:event and request processing (continued)

SOAP/JMS Protocol Config MO attribute	JMSHeaderName	Description
MessageId	JMSMessageId	Inbound messages: this attribute will be populated with the value from the JMSMessageId header. Outbound messages: this attribute is not used for outbound messages.
Priority	JMSPriority	Inbound messages: this attribute will be populated with the value from the JMSPriority header. Outbound messages: the value from this attribute will be set in the JMSPriority header of outgoing message.
Expiration	JMSExpiration	Inbound messages: this attribute will be populated with the value from the JMSExpiration header. Outbound messages: the value from this attribute will be set in the JMSExpiration header of outgoing message.
DeliveryMode	JMSDeliveryMode	Inbound messages: : this attribute will be populated with the value from the JMSDeliveryMode header. Outbound messages: the value from this attribute will be set in the JMSDeliveryMode header of outgoing message.
Destination	JMSDestination	Inbound messages: this attribute will be populated with the value from the JMSDestination header. Outbound messages: Request processing the value from this attribute will be used as the destination queue name and will indirectly be set in the JMSDestination header of outgoing messages to the derived destination path. Synchronous response in event notification: this attribute is not used.

Table 8. SOAP JMS Protocol Config MO attributes:event and request processing (continued)

SOAP/JMS Protocol Config MO attribute	JMSHeaderName	Description
Redelivered	JMSRedelivered	Inbound messages: this attribute will be populated with the value from the JMSRedelivered header. Outbound messages: the value from this attribute will be set in the JMSRedelivered header of outgoing message..
ReplyTo	JMSReplyTo	Inbound messages: this attribute will be populated with the value from the JMSReplyTo header. Outbound messages: the value from this attribute will be set in the JMSReplyTo header of outgoing message
TimeStamp	JMSTimeStamp	Inbound messages: this attribute will be populated with the value from the JMSTimeStamp header. Outbound messages: the value from this attribute will be set in the JMSTimeStamp header of outgoing message..
Type	JMSType	Inbound messages: this attribute will be populated with the value from the JMSType header. Outbound messages: the value from this attribute will be set in the JMSType header of outgoing message.
UserDefinedProperties	See "User-defined properties for event processing" on page 31.	This optional read/write attribute will hold the user-defined protocol properties business object. For further information, see "User-defined properties for event processing" on page 31.

Note: It is the responsibility of the collaboration to ensure that the header values passed to the JMS Protocol Config MO are logically correct in the context of a request-response event.

For SOAP/HTTP(S) protocol, the Protocol Config MO attributes are as follows:

Table 9. HTTP/HTTPS Protocol Config MO Attributes for Event Processing

Attribute	Required	Type	Description
Content-Type	No	String	The value of this attribute defines the Content-Type header of the outgoing message (which includes message ContentType and 0 or more parameters --the charset-- for the outgoing message). The syntax is the same as that for the Content-Type header in the HTTP Protocol, for example: text/html ; charset=ISO-8859-4. If there is no Content-Type attribute defined, the connector uses the ContentType of the request as the ContentType of the response/fault message.
UserDefinedProperties	No	Business object	This attribute holds the user-defined protocol properties business object.
One or more HTTP headers	No	String	This attribute allows the handler to pass or retrieve the value for the specified HTTP header.
Authorization_UserID	No	String	This attribute corresponds to the userID of the HTTP basic authentication.
Authorization_Password	No	String	This attribute corresponds to the password of the HTTP basic authentication

These attributes are described in:

- “User-defined properties for event processing”
- “HTTP credential propagation for event processing” on page 32

For further information on protocol listeners, see “Protocol listeners” on page 59.(For information describing the Protocol Config MO for request processing, see “Synchronous request processing TLOs” on page 38).

User-defined properties for event processing: You can optionally specify custom properties in the HTTP(S) Protocol Config MO. You do so by including the UserDefinedProperties attribute. This attribute corresponds to a business object that has one or more child attributes with property values. Every attribute in this business object must define a single property to be read (or, for synchronous responses, written) in the variable portion of the message header as follows:

- The type of the attribute should always be String regardless of the protocol property type. The application-specific information of the attribute can contain two name-value pairs defining the name and format of the protocol message property to which the attribute maps.

Table 10 summarizes the application-specific information for these attributes.

Table 10. Application-specific information for user-defined protocol property attributes: name=value pair content

Name	Value	Description
ws_prop_name (case-insensitive; if not specified the attribute name will be used as the property name)	Any valid protocol property name	This is the name of the protocol property. Some vendors reserve certain properties to provide extended functionality. In general, you should not define custom properties that begin with JMS (for JMS protocol) unless you are seeking access to these vendor-specific features.
ws_prop_type (case insensitive, optional for JMS - if not specified String is assumed; irrelevant for HTTP(S) since only String types make sense)	String, Integer, Boolean, Float, Double, Long, Short	The type of the protocol property. For JMS protocol, the JMS API provides a number of methods for setting property values in the JMS Message: setIntProperty, setLongProperty, setStringProperty, etc. The type of the JMS property specified here dictates which of these methods will be used for setting the property value in the message.

If the given custom property ASI (either the ws_prop_name or ws_prop_type) is invalid and there is no logical way to process this header (such as ignoring the property type for HTTP processing), the connector logs a warning and ignores this property. If the value of the custom property can neither be set nor retrieved after the necessary check against ws_prop_name or ws_prop_type has been performed, the connector logs the error and fails the event.

If the UserDefinedProperties attribute is specified, the connector will create an instance of a UserDefinedProperties business object. The connector then attempts to extract property values from the message and store them in the business object. If at least one property value is successfully retrieved, the connector will set a modified UserDefinedProperties attribute in the Protocol Config MO.

For synchronous event processing, if a UserDefinedProperties attribute is specified and its business object is instantiated, the connector will process each attribute of this child business object and set the message property value accordingly.

HTTP credential propagation for event processing: For the purpose of credential propagation, the connector supports the Authorization_UserID and Authorization_Password attributes in the HTTP Protocol Config MO. The support is limited to the propagation of these credentials as part of the HTTP Basic authentication scheme.

If a SOAP/HTTP or SOAP/HTTPS protocol listener processes a SOAP/HTTP web service request that includes an authorization header, the listener will parse the header to determine whether it conforms to HTTP Basic authentication. If so, the

listener extracts and decodes (using Base64) the username and password. This decoded string consists of a username and password separated by a colon. If the protocol listener finds the Authorization_UserID and Authorization_Password attributes in the Protocol Config MO, the listener sets these values with those extracted from the event authorization header.

Header container business objects

Figure 10 shows the expanded header container attribute, OrderHeader.

	Pos	Name	Type	Key	Required	Card	App Spec Info
	1	Request	SERVICE_SYNCH_OrderStatus_	<input checked="" type="checkbox"/>	<input type="checkbox"/>	1	ws_botype=request

3	3	Fault	SERVICE_SYNCH_OrderStatus_	<input type="checkbox"/>	<input type="checkbox"/>	1	ws_botype=fault

Figure 10. Header container and child business objects

The header container attribute, also known as the SOAP header attribute, corresponds to a business object that contains only child business objects. Each child represents a header entry in the SOAP message. In the example shown in Figure 10, the request header container is OrderHeader. SOAP header attributes have application-specific information (ASI) required by the SOAP data handler. For example, a header container business object is identified by its ASI: soap_location=SOAPHeader. For information on header processing, see “SOAP data handler processing” on page 111.

All SOAP business objects, whether a Request, Response, or Fault object, have one and only one header container.

Header child business objects

In the example shown Figure 10, the two child attributes of the request header container (OrderHeader) are 1) transaction of type SERVICE_SYNCH_OrderStatus_TransactionHeaderChild and 2) affiliate of type

SERVICE_SYNCH_OrderStatus_TradingPartnerHeaderChild. These attributes correspond to header child business objects. Each represents a single header element in a SOAP message. The header element is an immediate child of the SOAP-Env:Header element of the SOAP message. As shown Figure 10, the header child business objects may have an actor and a mustUnderstand attribute. These attributes correspond to the actor and mustUnderstand attributes of the SOAP header element. For information on header processing, see “SOAP data handler processing” on page 111.

There may be as many header child objects as are needed to represent the SOAP header message elements.

Asynchronous event processing TLOs

Figure 11 shows the business object hierarchy for asynchronous event processing. A request object only is required.

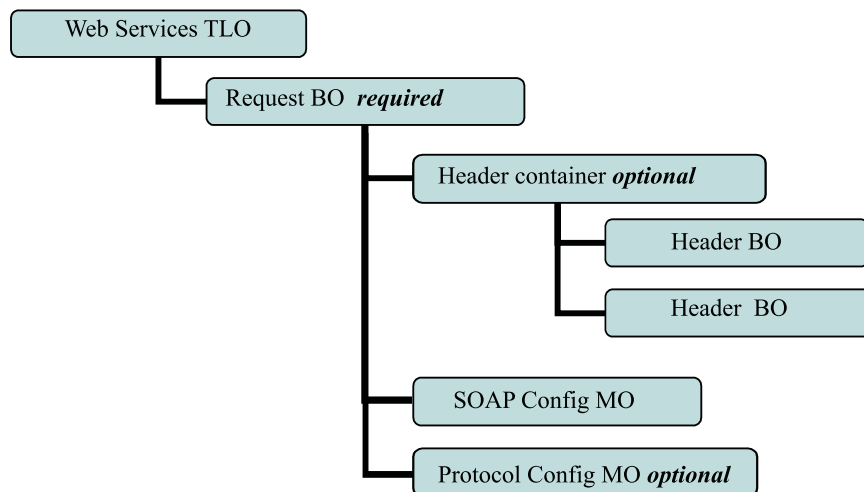

Figure 11. Business object hierarchy for asynchronous event processing

The TLO contains object-level ASI as well as attributes with attribute-level ASI. Both kinds of ASI are discussed below. For information on the header container and header child business objects, see “Header container business objects” on page 33.

Object-level ASI for asynchronous event processing TLOs

Object-level ASI provides fundamental information about the nature of a TLO and the objects it contains. Figure 12 shows the object-level ASI for SERVICE_ASYNCH_TLO_Order, a sample TLO for asynchronous event processing.

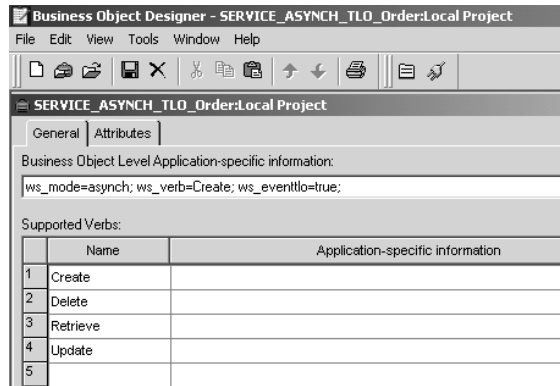

Figure 12. Top-level business object for asynchronous event processing

Table 3 below describes the object-level ASI for an asynchronous event processing TLO.

Table 11. Asynchronous event processing TLO object ASI

Object-level ASI	Description
ws_eventtlo=true	If this ASI property is set to true, the connector treats this object as a TLO for event processing. Note that the WSDL Configuration Wizard uses this ASI to determine whether a business object is a TLO. For more on this see “WSDL Configuration Wizard” on page 142.
ws_verb=verb	Before delivering the TLO to the collaboration, the connector uses this ASI to set the verb on the TLO. In the sample shown in Figure 12, the verb is Create.
ws_mode=asynch	During event notification, the connector uses this ASI property to determine whether to invoke the collaboration synchronously (synch) or asynchronously (asynch). For asynchronous processing, this ASI must be set to asynch. The default is asynch.

Note: Unlike synchronous event processing, no collaboration name ASI is required at the TLO level for asynchronous event processing. Instead the integration broker assures that application events reach all subscribing collaborations.

Attribute-level ASI for asynchronous event processing TLOs

Each asynchronous event processing TLO has a single attribute that corresponds to a Request business object. Figure 13 shows the request attribute of SERVICE_ASYNC_TLO_Order, a sample TLO, and the attribute’s ASI.

Figure 13. TLO attribute for asynchronous event processing

Table 12 summarizes the attribute-level ASI for the request attribute of an asynchronous event processing TLO.

Table 12. Asynchronous event processing TLO attribute ASI

TLO attribute	Attribute-level ASI	Description
Request	ws_botype=request	This attribute corresponds to a web service request. The connector uses its ASI to determine whether this TLO attribute is of type SOAP Request BO. This ASI, not the attribute name, determines the attribute type. If there is more than one request attribute, the connector uses the ASI of the first one. This attribute is required for synchronous event processing TLOs.

Request business object for asynchronous event processing

A Request business object is a child of a TLO and is required for asynchronous event processing. You can specify a default verb for the Request business object. You do so by specifying:

`DefaultVerb=true;`

in the ASI field for the verb in the Supported Verbs list at the top-level of the Request business object. If `DefaultVerb` ASI is not specified and the data handler processes a business object with no verb set, the business object is returned without a verb. The object-level ASI for a Request business object for asynchronous event processing is described in Table 13.

Table 13. Asynchronous event processing: object-level ASI for Request business objects

Object-level ASI	Description
<code>cw_mo_soap=SOAPCfgMO</code>	The value of this ASI must match the name of the attribute that corresponds to the SOAP Config MO. This is the SOAP Config MO that defines the data handler transformation for the Request business object. For further information, see “SOAP Config MO” on page 26.

Table 13. Asynchronous event processing: object-level ASI for Request business objects (continued)

Object-level ASI	Description
cw_mo_jms=SOAPJMScfgMO or cw_mo_http=SOAPHTTpcfgMO	The value of this ASI must match the name of the attribute that corresponds to the Protocol Config MO. The first ASI designates the SOAP/JMS protocol listener; the second designates the SOAP/HTTP or SOAP/HTTPS protocol listener. Both the ASI and the Protocol Config MO are optional. For further information, see “Protocol Config MO” on page 27.
ws_tloname=tloname	This ASI specifies the name of the web services TLO that this object belongs to. During event processing, the connector uses this ASI to determine whether the Request business object delivered by the data handler is a child of the TLO. If so, the connector creates the specified TLO, sets the Request business object as its child, and uses the TLOs object-level ASI to deliver it to the subscribing collaboration.

In the sample shown in Figure 14, the Request attribute contains a SOAP Config MO and header container (OrderHeader), as well as a content-related attribute (OrderLineItems). The requirements and characteristics of the SOAP Config MO, Protocol Config MO, SOAP header container, and header child business objects are the same for asynchronous event processing as they are for synchronous event processing. For further information, see these topics above in “Synchronous event processing TLOs” on page 20.

	Pos	Name	Type	Key	Required	Card	Maximum	App Spec Info
1	1	Request	SERVICE_ASYNC_Order	<input checked="" type="checkbox"/>	<input type="checkbox"/>	1		ws_botype=request
1.1	1.1	OrderId	String	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>		255	
1.2	1.2	OrderDate	Date	<input type="checkbox"/>	<input type="checkbox"/>			
1.3	1.3	CustomerId	String	<input type="checkbox"/>	<input type="checkbox"/>		255	
1.4	1.4	OrderLineItems	SERVICE_ASYNC_Order_LineItem	<input type="checkbox"/>	<input type="checkbox"/>	N		type_name=Order_LineItem
1.5	1.5	OrderHeader	SERVICE_ASYNC_Order_Header	<input type="checkbox"/>	<input type="checkbox"/>	1		soap_location=SOAPHeader
1.6	1.6	SOAPCfgMO	SERVICE_ASYNC_Order_CfgMO	<input type="checkbox"/>	<input type="checkbox"/>	1		
1.7	1.7	SOAPJMScfgMO	SERVICE_ASYNC_SOAP_JMS_Order_CfgMO	<input type="checkbox"/>	<input type="checkbox"/>	1		
1.8	1.8	ObjectEventId	String					
2	2	ObjectEventId	String					
3	3			<input type="checkbox"/>	<input type="checkbox"/>		255	

Figure 14. Request attributes for asynchronous event processing

Event processing non-TLOs

If the object-level ASI `ws_eventtlo=true` is not present in a business object, the connector concludes that the object is not a TLO. During event processing, the connector can process non-TLOs—generic business objects and application specific business objects. With non-TLOs, the same business object represents the Request and Response business object.

Non-TLOs do not have SOAP Config MOs. When you expose a collaboration as a web service, the WSDL Configuration Wizard configures the WSCollaborations property of the connector. The connector uses the WSCollaborations property to determine the BodyName and BodyNS of the request message. Note that for non-TLOs, the WSCollaborations property is used for business object resolution.

The advantage to using non-TLOs is that you need not develop new, TLO-structured business objects for use with your web services solution. TLOs, however, allow a more precise and economical exposure of data—customer, company, or otherwise. TLO business objects also lend themselves to more customization than do non-TLOs.

For further information on requirements when using non-TLOs as input to the WSDL Configuration Wizard, see “Identifying or Developing Business Objects” on page 140.

Synchronous request processing TLOs

For request processing the connector allows two kinds of TLOs—synchronous and asynchronous. This section discusses synchronous request processing TLOs.

Figure 15 shows the TLO business object hierarchy for synchronous request processing. Request and Response objects are required, Fault objects are optional. Unlike event processing, a Protocol Config MO is required for the Request objects, and optional for the Response and Fault objects. For information on the header container and header child business objects, see “Header container business objects” on page 33.

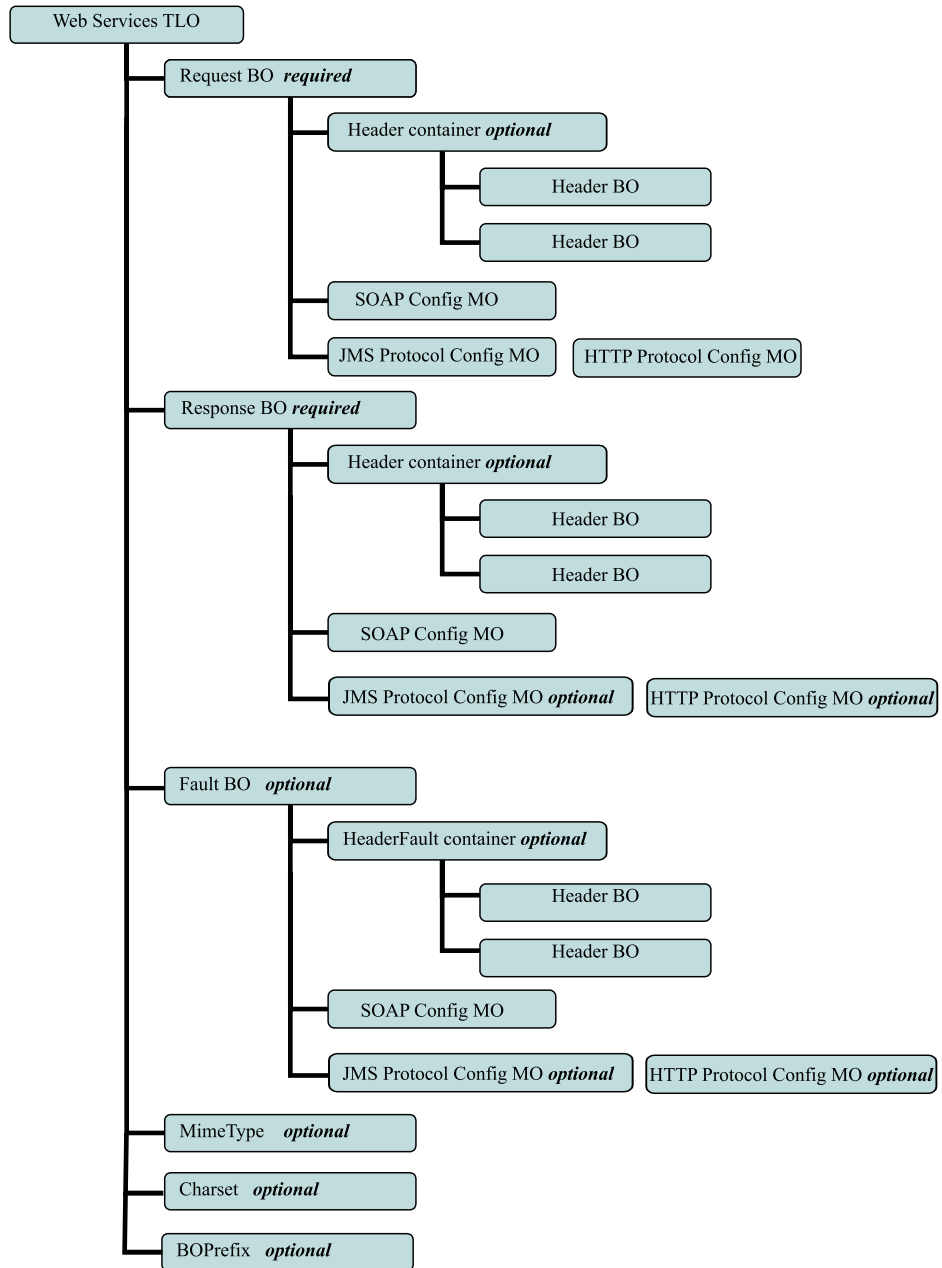

Figure 15. Business object hierarchy for synchronous request processing

Object-level ASI for synchronous request processing TLOs

Object-level ASI provides important information about the nature of a TLO and the objects it contains. Figure 16 shows CLIENT_SYNCH_TLO_OrderStatus, a sample TLO for synchronous request processing.

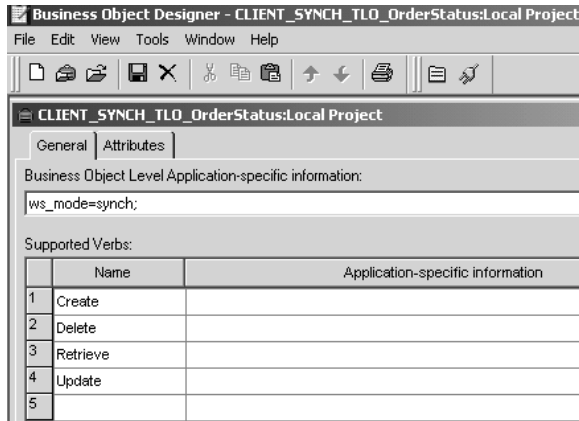

Figure 16. Top-level business object for synchronous request processing

Table 14 describes the object-level ASI for a synchronous request processing TLO. Unlike the ASI for synchronous event processing TLOs, no `ws_collab`, `ws_verb` or `ws_eventtlo` ASI is required at this level for request processing.

Table 14. Synchronous request processing TLO object ASI

Object-level ASI	Description
<code>ws_mode=synch</code>	<p>During request processing, the connector uses this ASI property to determine whether to invoke the web service synchronously (<code>synch</code>) or asynchronously (<code>asynch</code>). If <code>synch</code> is indicated, then the connector expects a response, and the TLO must include request and response business objects and, optionally, one or more fault objects.</p> <p>The default is <code>asynch</code>.</p>

Attribute-level ASI for synchronous request processing TLOs

Figure 17 shows the attributes of the `CLIENT_SYNCH_TLO_OrderStatus` TLO as well as attribute-level ASI.

The screenshot shows the 'Business Object Designer' interface for the project 'CLIENT_SYNCH_TLO_OrderStatus:Local Project'. The 'Attributes' tab is selected, displaying a table of attributes with the following data:

	Pos	Name	Type	Key	Card	Maximum Length	Default	App Spec Info
1	7	ObjectEventId	String					
2	2	MimeType	String	<input type="checkbox"/>		255	xml/soap	
3	3	BOPrefix	String	<input type="checkbox"/>		255		
4	1	Handler	String	<input type="checkbox"/>		255	soap/http	
5	6	<input type="checkbox"/> Fault	CLIENT_SYNCH_OrderStatus_Fault	<input type="checkbox"/>	1			ws_botype=fault
6	4	<input type="checkbox"/> Request	CLIENT_SYNCH_OrderStatus_Request	<input checked="" type="checkbox"/>	1			ws_botype=request
7	5	<input type="checkbox"/> Response	CLIENT_SYNCH_OrderStatus_Response	<input type="checkbox"/>	1			ws_botype=response

Figure 17. TLO attributes for synchronous request processing

Table 15 describes the attributes and ASI shown in Figure 17.

Table 15. Request processing TLO attributes

TLO attribute	Attribute-level ASI	Description
MimeType	None	This attribute specifies the mime type of the data handler that the connector invokes for transforming a Request business object into a request message. This value may be used for transforming synchronous response/fault messages into business objects, depending on the Message Transformation Rules configuration.
BOPrefix	None	This attribute of type String is passed to the data handler.
Handler	None	This attribute specifies the protocol handler to use to process the web service request and is for request processing only. It takes one of the following values: <ul style="list-style-type: none"> • soap/jms The connector uses the SOAP/JMS protocol handler to process the request • soap/http The connector uses the SOAP/HTTP, SOAP/HTTPS protocol handler to process this web service request. The default is soap/http
Charset		This optional parameter of type String specifies the charset to be set on the data handler when transforming the Request business object to a message. NOTE: the charset value specified in this attribute will not be propagated in the Content-Type protocol header of the request message.
Request	ws_botype=request	This attribute corresponds to a web service request business object. The connector uses this attribute ASI to determine whether this TLO attribute is of type SOAP Request BO. This ASI, not the attribute name, determines the attribute type. If there is more than one request attribute, the connector uses the ASI of the first populated attribute.
Response	ws_botype=response	This attribute corresponds to the response returned to a collaboration and is required for synchronous request processing. The connector uses this attribute ASI to determine whether this TLO attribute is of type SOAP Response BO. This ASI, not the attribute name, determines the attribute type.

Table 15. Request processing TLO attributes (continued)

TLO attribute	Attribute-level ASI	Description
Fault	ws_botype=fault or ws_botype=defaultfault	<p>This attribute, optional for synchronous request processing, corresponds to a fault message returned by a web service when it cannot successfully populate a response.</p> <p>The connector uses this ASI to determine if the attribute of TLO is of type SOAP Fault BO. This ASI, not the attribute name, determines the attribute type. A defaultfault business object is returned if the fault message is a detail element. defaultfault is used in default business object resolution. For further information, see Chapter 5, "SOAP data handler," on page 105.</p>

Request business object for synchronous request processing

A Request business object is a child of a TLO and is required for synchronous request processing. A Request business object has object-level ASI.

For example, if you open CLIENT_SYNCH_OrderStatus_Request and click the General tab, the object-level ASI is displayed as shown in Figure 18.

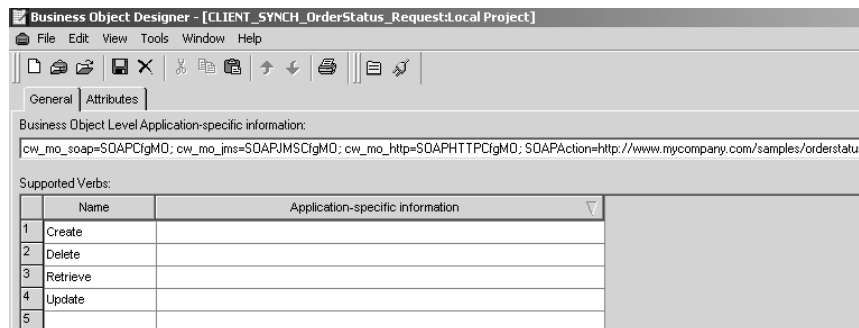

Figure 18. Request object ASI for synchronous request processing

Table 16 describes the object-level ASI for a Request business object for synchronous request processing.

Table 16. Synchronous request processing: object-level ASI for Request business objects

Object-level ASI	Description
cw_mo_soap=SOAPCfgMO	The value of this ASI must match the name of the attribute that corresponds to the SOAP Config MO. This is the SOAP Config MO that defines the data handler transformation for the Request business object. For further information, see "SOAP Config MO" on page 26.

Table 16. Synchronous request processing: object-level ASI for Request business objects (continued)

Object-level ASI	Description
<code>cw_mo_jms=SOAPJMSCfgMO</code>	The value of this ASI must match the name of the attribute that corresponds to the Protocol Config MO. This is the Protocol Config MO that specifies the destination web service for the JMS protocol handler. For further information, see “JMS Protocol Config MO of request business object for request processing” on page 44.
<code>cw_mo_http=SOAPHTTPCfgMO</code>	The value of this optional ASI must match the name of the attribute that corresponds to the Protocol Config MO. This is a separate Protocol Config MO that specifies the destination for the SOAP/HTTP-HTTPS protocol handler. This ASI is used by the SOAP/HTTP and SOAP/HTTPS Protocol Handler. Note that the TLO request attribute must have either a JMS or an HTTP Protocol Config MO for request processing, depending on the type of web service protocol you are using. For further information, see “HTTP Protocol Config MO for request processing” on page 45.
<code>SOAPAction=SOAPActionURI</code>	The connector uses this ASI to determine whether to set a SOAPAction header on the request message. Specify this ASI only if the target web service requires a SOAPAction header. Note that this ASI is used for request processing but not for event notification.

Response business object for synchronous request processing

A Response business object is a child of a TLO and is required for synchronous request processing. The object-level ASI for a Response business object for synchronous request processing is described in Table 17.

Table 17. Synchronous request processing: object-level ASI for response business objects

Object-level ASI	Description
<code>cw_mo_soap=SOAPCfgMO</code>	The value of this ASI must match the name of the attribute that corresponds to the SOAP Protocol Config MO. This is the SOAP Config MO that defines the data handler transformation for the Response business object. For further information, see “SOAP Config MO” on page 26.
<code>cw_mo_jms=SOAPJMSCfg MO</code> or <code>cw_mo_http=SOAPHTTPCfgMO</code>	The value of this ASI must match the name of the attribute that corresponds to the Protocol Config MO. This is the Protocol Config MO, optional for a Response business object, that specifies the headers in the response SOAP message for the JMS or HTTP(s) protocol handler. For further information, see “Protocol Config MO” on page 27

You can specify a default verb for the Response business object. You do so by specifying:

```
DefaultVerb=true;
```

in the ASI field for the verb in the Supported Verbs list at the top-level of the Response business object. If DefaultVerb ASI is not specified and the data handler processes a business object with no verb set, the Response business object is returned without a verb.

Fault business object for synchronous request processing

A Fault business object is a child of a TLO and is optional for synchronous request processing. The object-level ASI for a Fault business object for synchronous request processing is described in Table 7.

Table 18. Synchronous request processing: object-level ASI for Fault business objects

Object-level ASI	Description
<code>cw_mo_soap=SOAPCfgMO</code>	The value of this ASI must match the name of the attribute that corresponds to the SOAP Protocol Config MO. This is the SOAP Config MO that defines the data handler transformation for the Fault business object. For further information, see “SOAP Config MO” on page 26.
<code>cw_mo_jms=SOAPJMScfg MO</code> or <code>cw_mo_http=SOAPHTTPCfgMO</code>	The value of this ASI must match the name of the attribute that corresponds to the Protocol Config MO. This is the Protocol Config MO, optional for a Fault business object, that specifies the headers in the response SOAP message for the JMS protocol handler. For further information, see “Protocol Config MO” on page 27

SOAP Config MO

The SOAP Config MO (SOAPCfgMO) has the same attributes as those for the event processing SOAP Config MO. For further information, see “SOAP Config MO” on page 26, as well as “SOAP configuration meta-object: child of every SOAP business object” on page 107.

JMS Protocol Config MO of request business object for request processing

The JMS Protocol Config MO is required in a Request business object when you are using JMS web services, and optional for Response and Fault objects. Table 19 on page 45 describes the request processing JMS Protocol Config MO—Destination is the most important and only required attribute. The JMS protocol handler uses this attribute to locate the requested web service. In addition, all the attributes described for the JMS Config MO in “Protocol Config MO” on page 27 are optional.

Table 19. JMS Protocol Config MO Attributes for Request Processing

Attribute	Required	Type	Description
Destination	Yes	String	The destination queue name of the target web service. The JMS Protocol Handler uses this attribute to determine the destination of the web service. If the connector-specific JNDI property <code>LookupQueuesUsingJNDI</code> is set to true, the JMS Protocol Handler looks up this queue using JNDI. Make sure that this attribute gives the JNDI name of the destination queue.

HTTP Protocol Config MO for request processing

During request processing, the SOAP/HTTP-HTTPS protocol handlers use the HTTP Protocol Config MO to determine the destination of the target web service. This Protocol Config MO is required for a Request business object. The SOAP/HTTP-HTTPS protocol handlers support HTTP 1.0 POST request only. As shown in Table 20 the sole required attribute (Destination) is the full URL of the target web service. The optional authorization attributes are described in the sections below.

Table 20. HTTP Protocol Config MO Attributes for Request Processing

Attribute	Required	Type	Description
Destination	Yes	String	The destination URL of the target web service. The SOAP/HTTP-HTTPS protocol handler uses this attribute to determine the destination of the web service.
Content-Type	Required for the Request business object, otherwise optional.	String	The value of this attribute defines the Content-Type header of the outgoing message (which includes message ContentType and optionally charset for the outgoing message). The syntax is the same as that for the Content-Type header in the HTTP Protocol, for example: <code>text/html; charset=ISO-8859-4</code> . If there is no Content-Type attribute defined, the connector uses <code>text/xml</code> as the ContentType of the message.
Authorization_UserID	No	String	This attribute corresponds to the userID of the HTTP basic authentication. For further information, see "HTTP credential propagation for request processing" on page 48
Authorization_Password	No	String	This attribute corresponds to the password of the HTTP basic authentication. For further information, see "HTTP credential propagation for request processing" on page 48
One or more HTTP headers	No	String	This attribute allows the handler to pass or retrieve the value for the specified HTTP header.

Table 20. HTTP Protocol Config MO Attributes for Request Processing (continued)

Attribute	Required	Type	Description
UserDefinedProperties	No	Business object	This attribute holds the user-defined protocol properties business object. For further information, see “User-defined properties for request processing.”
MessageTransformationMap	No	Single cardinality business object	This is the attribute that points to business object holding 0 or more message transformation rules. The rules hold information regarding the mime type and charset to apply to the incoming message that is specified in the rule. For further information, see “Message transformation maps” on page 47.

Figure 19 shows some of the HTTP Protocol Config MO attributes in Business Object Designer Express.

General		Attributes								
	Pos	Name	Type	Key	Foreign	Required	Card	Maximum	Default	App Spec Info
	1	OrderId	String	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>		255		
	2	OrderHeader	CLIENT_SYNCH_OrderStatus_Request_Header	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1			
	3	HTTPCfgMO	CLIENT_SYNCH_OrderStatus_HTTPCfgMO	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1			
3.1	3.1	Date	String	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255		
3.2	3.2	Content-Type	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255		
3.3	3.3	MessageTransformationMap	HTTP_CfgMo_MsgTrnsfMap	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1			
3.3.1	3.3.1	TransformationRule	HTTP_CfgMo_MsgTrnsfRule	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	N			
3.3.1.1	3.3.1.1	Content-Type	String	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>		255	*/*	
3.3.1.2	3.3.1.2	MimeType	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255		
3.3.1.3	3.3.1.3	Charset	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255		
3.3.1.4	3.3.1.4	ObjectEventId	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>				
3.3.1.5	3.3.1.5	ObjectEventId	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>				
3.4	3.4	UserDefinedProperties	HTTP_CfgMo_CustomProperties	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1			
3.4.1	3.4.1	CustomProperty1	String	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255		
3.4.2	3.4.2	CustomProperty2	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255		ws_prop_type=Integer
3.4.3	3.4.3	CustomPropertyN	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255		ws_prop_type=Boolean
3.4.4	3.4.4	ObjectEventId	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>				
3.5	3.5	ObjectEventId	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>				
4	4	ObjectEventId	String	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>				
5	5			<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>		255		

Figure 19. HTTP Protocol Config MO attributes for request processing

The HTTP Protocol Config MO attributes are described in:

- “User-defined properties for request processing”
- “Message transformation maps” on page 47
- “HTTP credential propagation for request processing” on page 48

User-defined properties for request processing: You can optionally specify custom properties in the HTTP Protocol Config MO. You do so by including the UserDefinedProperties attribute. This attribute corresponds to a business object that has one or more child attributes with property values. Every attribute in this business object must define a single property to be read (or, for synchronous responses, written) in the variable portion of the message header as follows:

- The type of the attribute should always be String regardless of the protocol property type. The application-specific information of the attribute can contain two name-value pairs defining the name and format of the protocol message property to which the attribute maps.

Table 21 summarizes the application-specific information for these attributes.

Table 21. Application-specific information for user-defined protocol property attributes: name=value pair content

Name	Value	Description
ws_prop_name (case-insensitive; if not specified the attribute name will be used as the property name)	Any valid protocol property name	This is the name of the protocol property. Some vendors reserve certain properties to provide extended functionality. In general, you should not define custom properties that begin with JMS (for JMS protocol) unless you are seeking access to these vendor-specific features.
ws_prop_type (case insensitive, optional for JMS - if not specified String is assumed; irrelevant for HTTP(S) since only String types make sense)	String, Integer, Boolean, Float, Double, Long, Short	The type of the protocol property. For JMS protocol, the JMS API provides a number of methods for setting property values in the JMS Message: setIntProperty, setLongProperty, setStringProperty, etc. The type of the JMS property specified here dictates which of these methods will be used for setting the property value in the message.

If the given custom property ASI (either the ws_prop_name or ws_prop_type) is invalid and there is no logical way to process this header (such as ignoring the property type for HTTP processing), the connector logs a warning and ignores this property. If the value of the custom property can neither be set nor retrieved after the necessary check against ws_prop_name or ws_prop_type has been performed, the connector logs the error and fails the event.

If the UserDefinedProperties attribute is specified and its business object is instantiated, the connector processes each attribute of this child business object and sets the message properties values accordingly.

For synchronous request processing, upon receipt of a response message from the web service/url, if the UserDefinedProperties attribute is specified, the connector creates an instance of a UserDefinedProperties business object and attempts to extract property values from the message and then stores them in the new business object. If at least one property value was successfully retrieved, the connector will set modified UserDefinedProperties business object in the Protocol Config MO.

Message transformation maps: The Message Transformation Map (MTM) feature is supported for request processing HTTP(S) protocol handlers only. MessageTransformationMap is an optional attribute in the Protocol Config MO that points to a business object. The business object contains rules for transforming messages with mime types and charsets that are specified in the rules. If it finds the (case-sensitive) attribute name MessageTransformationMap and this attribute is of the business object type (see Figure 19), the connector uses the rules in that object to transform a message.

As shown in Figure 19, the MTM attribute must have one cardinality N child business object attribute that is named TransformationRule. When trying to find TransformationRule for a message, the SOAP/HTTP(s) Protocol Handler first attempts to match the message exactly by the ContentType specified in all TransformationRules. If unsuccessful, the connector attempts to find the rule that applies to multiple types of messages. For further information on protocol handler processing, see “SOAP/HTTP-HTTPS protocol handler processing” on page 71.

Each instance of a TransformationRule business object must have attributes specified as shown in Table 22.

Table 22. TransformationRule attributes for MessageTransformationMaps in HTTP Protocol Config MO

Attribute name	Required	Type	Default value	Description
TransformationRule	No	Business object, cardinality N		This is the attribute that holds 1 rule for message transformation. There can be 0 or more instances of this attribute under the MessageTransformationMap attribute.
+ContentType	Yes	String	*/*	The value of this property specifies the HTTP ContentType of the message for which this transformation rule applies. The default value */* for this attribute enables the connector to apply this rule to any ContentType. For further information on protocol handler processing, see “SOAP/HTTP-HTTPS protocol handler processing” on page 71. Note that if Protocol Handler finds more than one rule that has the same ContentType as the other rule, Protocol Handler will log the warning and ignore all duplicate rules, but will use unique rules
+MimeType	No			The mime type to use when calling a data handler while processing messages of the ContentType specified in this business object.
+Charset	No			The charset to use when transforming a request of the ContentType specified in this business object.

HTTP credential propagation for request processing: For the purpose of credential propagation, the connector supports the Authorization_UserID and Authorization_Password attributes in the HTTP Protocol Config MO. The support is limited to the propagation of these credentials as part of the HTTP Basic authentication scheme.

If credential propagation is desired during request processing, you must manually add the Authorization_UserID and Authorization_Password attributes to the Protocol Config MO generated by the WSDL ODA. You do this in Business Object Designer Express after generating the business object and meta-object definitions.

(For further information on the WSDL ODA, see Chapter 6, “Enabling collaborations for request processing,” on page 137.)

The collaboration sets the values of the `Authorization_UserID` and `Authorization_Password` attributes in the Protocol Config MO. If these attributes are neither null nor empty, the connector creates an authorization header on the request its sends to the target web service. The SOAP HTTP/HTTPS protocol handler follows *HTTP Authentication: Basic and Digest Access Authentication (RFC 2617)* when creating the authorization header.

Note: The digest authentication scheme is not supported, nor is the optional challenge-response mechanism for HTTP authentication defined in Rfc2617. If the HTTP(s) protocol handler is invoking a server that requires a credential, the connector does not wait for the challenge response from the server. Instead, it sends the credentials continuously.

Asynchronous request processing TLOs

Figure 20 shows the business object hierarchy for asynchronous request processing. A request object only is required, and this object contains a SOAP Config MO for the SOAP data handler as well as two Protocol Config MOs, one each for the SOAP/JMS and SOAP/HTTP/HTTPS protocol handlers. These are described in the sections below.

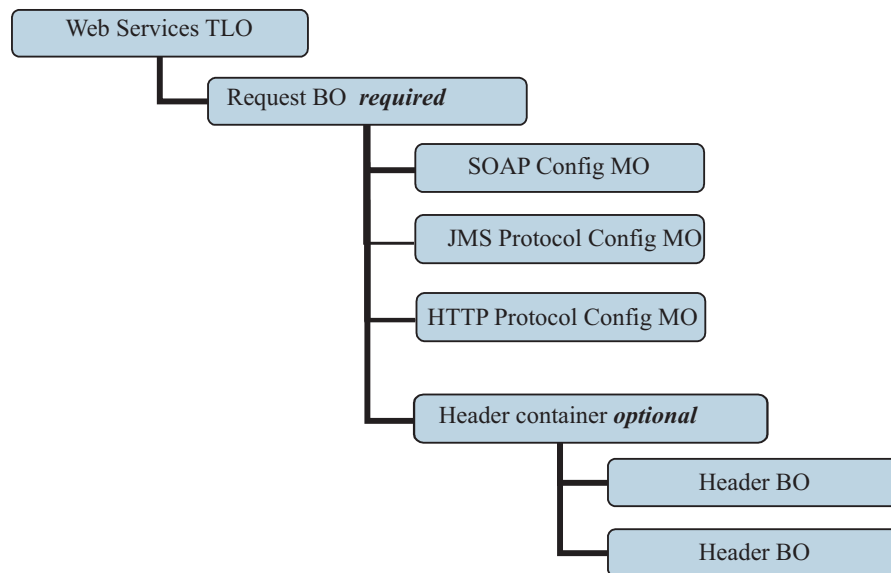

Figure 20. Business object hierarchy for asynchronous request processing

The TLO contains object-level ASI as well as attributes with attribute-level ASI. Both kinds of ASI are discussed below. For information on the header container and header child business objects, see “Header container business objects” on page 33.

Object-level ASI for asynchronous event processing TLOs

Figure 21 shows `CLIENT_ASYNC_Order_TLO`, a sample TLO for asynchronous request processing.

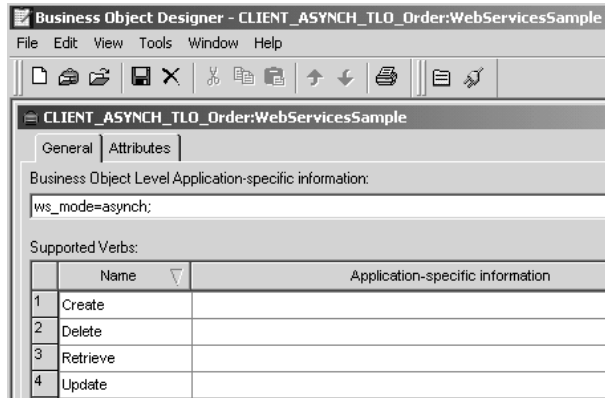

Figure 21. Top-level business object for asynchronous request processing

Table 23 below describes the object-level ASI for an asynchronous request processing TLO.

Table 23. Asynchronous request processing TLO object ASI

Object-level ASI	Description
ws_mode=asynch	<p>During request processing, the connector uses this ASI property to determine whether to invoke the collaboration synchronously (synch) or asynchronously (asynch). For asynchronous request processing, this ASI must be set to asynch.</p> <p>The default is asynch.</p>

Attribute-level ASI for asynchronous request processing TLOs

Figure 22 shows the attributes of the CLIENT_ASYNC_TLO_Order, a sample request processing TLO.

	Pos	Name	Type	Key	Required	Card	Maximum Length	Default	App Spec Info
1	1	Handler	String	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>		255		soap/http
2	2	MimeType	String	<input type="checkbox"/>	<input type="checkbox"/>		255		xml/soap
3	3	BOPrefix	String	<input type="checkbox"/>	<input type="checkbox"/>		255		
4	4	Request	CLIENT_ASYNC_Order	<input type="checkbox"/>	<input type="checkbox"/>	1			ws_botype=request
5	5	ObjectEventId	String						

Figure 22. TLO attributes for asynchronous request processing

Table 24 summarizes the attribute-level ASI for the request attribute of an asynchronous request processing TLO.

Table 24. Asynchronous request processing TLO attributes

TLO attribute	Attribute-level ASI	Description
MimeType	None	This attribute specifies the mime type of the data handler that the connector invokes. Note that this attribute is used only for Request Processing. (For event processing, protocol listeners use the SOAPDHMimeType connector-specific configuration property.) The default is xml/soap.
BOPrefix	None	This attribute of type String is reserved for future development and not required.
Handler	None	This attribute specifies the protocol handler to use to process the web service request and is for request processing only. It takes one of the following values: <ul style="list-style-type: none"> • soap/jms The connector uses the SOAP/JMS protocol handler to process the request • soap/http The connector uses the SOAP/HTTP-HTTPS protocol handler to process this web service request. The default is soap/http
Request	ws_botype=request	This attribute corresponds to a web service request business object. The connector uses this attribute ASI to determine whether this TLO attribute is of type SOAP Request BO. This ASI, not the attribute name, determines the attribute type. If there is more than one request attribute, the connector uses the ASI of the first one.

Request business object for asynchronous request processing

A Request business object is a child of a TLO and is required for asynchronous request processing. The object-level ASI for a Request business object for asynchronous request processing is described in Table 25.

Table 25. Asynchronous request processing: object-level ASI for Request business objects

Object-level ASI	Description
cw_mo_soap=SOAPCfgMO	The value of this ASI must match the name of the attribute that corresponds to the SOAP Config MO. This is the SOAP Config MO that defines the data handler transformation for the Request business object. For further information, see “SOAP Config MO” on page 26.

Table 25. Asynchronous request processing: object-level ASI for Request business objects (continued)

Object-level ASI	Description
<code>cw_mo_jms=SOAPJMScfgMO</code>	The value of this ASI must match the name of the attribute that corresponds to the Protocol Config MO. This is the Protocol Config MO that specifies the destination web service for the JMS protocol handler. For further information, see “JMS Protocol Config MO of request business object for request processing” on page 44.
<code>cw_mo_http=SOAPHTTPCfgMO</code>	The value of this ASI must match the name of the attribute that corresponds to the Protocol Config MO. This is a separate Protocol Config MO that specifies the destination for the SOAP/HTTP-HTTPS protocol handler. This ASI is used by the SOAP/HTTP-HTTPS Protocol Handler. Note that the TLO request attribute must have both JMS and HTTP Protocol Config MOs for request processing. For further information, see “HTTP Protocol Config MO for request processing” on page 45.
<code>SOAPAction=SOAPActionURI</code>	The connector uses this ASI to determine whether to set a SOAPAction header on the request message. Specify this ASI only if the target web service requires a SOAPAction header. Note that this ASI is used for request processing but not for event notification.

In the sample shown in Figure 14, the Request attribute contains a SOAP Config MO and header container (OrderHeader), as well as a content-related attribute (OrderLineItems). The requirements and characteristics of the SOAP Config MO, Protocol Config MO, SOAP header container, and header child business objects are the same for asynchronous request processing as they are for synchronous request processing. For further information, see these topics above in “Synchronous request processing TLOs” on page 38..

Pos	Name	Type	Key	Requ red	Card	Maximu m	App Spec Info
1	Request	SERVICE_ASYNC_Order	<input checked="" type="checkbox"/>	<input type="checkbox"/>	1		ws_botype=request
1.1	OrderId	String	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>		255

Figure 23. Request attributes for asynchronous event processing

Config MOs for asynchronous request processing

The SOAP Config MO (SOAPCfgMO) has the same attributes as those for the event processing SOAP Config MO. For further information, see “SOAP Config MO” on page 26, as well as “SOAP configuration meta-object: child of every SOAP business object” on page 107.

The JMS Protocol Config MO is required in a Request business object when you are using JMS web services. For further information, see “JMS Protocol Config MO of request business object for request processing” on page 44.

During request processing, the SOAP/HTTP-HTTPS protocol handlers use the HTTP Protocol Config MO to determine the destination of the target web service. This Protocol Config MO is required for a Request business object. For further information, see “HTTP Protocol Config MO for request processing” on page 45.

Developing business objects

You use Business Object Designer Express to create business objects and Connector Configurator Express to configure the connector to support them. For more information on the Business Object Designer Express tool, see the *Business Object Development Guide* and Chapter 7, “Exposing collaborations as web services,” on page 139. For further information on Connector Configurator Express, see Appendix B, “Connector Configurator Express,” on page 177.

Chapter 4. Web services connector

- “Connector processing”
- “SOAP/HTTP(S) web services” on page 58
- “SOAP/JMS web services” on page 58
- “Event processing” on page 59
- “Request processing” on page 70
- “SSL” on page 80
- “Connector and JMS” on page 78
- “Configuring the connector” on page 82
- “Connector at startup” on page 101
- “Logging” on page 102
- “Tracing” on page 102

This chapter describes the web services connector and how to configure it.

All WebSphere business integration connectors operate with an integration broker. The web services connector operates with the IBM WebSphere InterChange Server Express integration broker, which is described in the *System Implementation Guide*.

A connector is a runtime component of an adapter. Connectors consist of an application-specific component and the connector framework. The application-specific component contains code tailored to a particular application. The connector framework, whose code is common to all connectors, acts as an intermediary between the integration broker and the application-specific component. The connector framework provides the following services between the integration broker and the application-specific component:

- Receives and sends business objects
- Manages the exchange of startup and administrative messages

This document contains information about the application-specific component and connector framework. It refers to both of these components as the connector.

For more information about the relationship of the integration broker to the connector, see the *System Administration Guide*.

Connector processing

The connector includes a protocol listener framework for event processing and a protocol handler framework for request processing. This bi-directional functionality enables the connector framework to:

- Expose collaborations as web services and then process calls from web service clients
- Process a request by a collaboration that invokes a web service

For further information on the SOAP data handler, see Chapter 5, “SOAP data handler,” on page 105.

Note: The connector supports SOAP/HTTP and SOAP/JMS bindings only.

Event processing overview

Connector event processing (or event notification) is used to handle requests from web service clients. This event processing capability encompasses a protocol listener framework, including the following components, which are discussed in greater detail later in this chapter:

- SOAP/HTTP protocol listener
- SOAP/HTTPS protocol listener
- SOAP/JMS protocol listener

The connector uses the listeners to expose collaborations as web services, and to listen on the transport for calls from web services clients to exposed collaborations.

The SOAP/HTTP and SOAP/HTTPS protocol listeners expose a collaboration as a SOAP/HTTP web service. The SOAP/JMS protocol listener exposes a collaboration as a SOAP/JMS web service.

When requests from web service clients arrive, the listener converts the SOAP request message into a business object and invokes the collaboration. If it is a synchronous request, the connector receives a Response business object of the same type as the Request business object. The listener converts the Response business object into a SOAP response message. The listener then transports the SOAP response message to the web service client. Note that event sequencing is not a requirement for this connector; the connector may deliver the events in any order.

The web services connector utilizes the SOAP data handler to convert incoming SOAP request messages into business objects. To aid the data handler in determining which business object to resolve for the incoming SOAP request message, the connector provides meta information regarding its supported business objects to the data handler. From its supported business objects, the connector first makes a list of all business objects that are potential candidates for the conversion. This list may be comprised of both TLOs and non-TLOs. Supported TLO business objects are those that have object-level ASI `ws_eventtlo=true`.

If TLOs are used, the protocol listener reads the object-level ASI of the TLO as follows:

- `ws_collab=` This determines which collaboration to invoke
- `ws_mode=` This determines how to invoke the collaboration, synchronously (`synch`) or asynchronously (`asynch`)

If non-TLOs, are used, then the protocol listener reads the collaboration and processing mode from the `WSCollaborations` configuration property values generated by the WSDL Configuration Wizard.

The connector compares and attempts to match the `BodyName` and `BodyNamespace` in the SOAP request to the names of potential business objects. In the case of TLOs, this `BodyName/BodyNamespace` pair is found using the SOAP Config MO properties of the SOAP Request business object. For non-TLOs, the `BodyName/BodyNamespace` pair is found using the `WSCollaborations` connector configuration property. (Note that the connector considers only those non-TLOs that have an entry in the `WSCollaborations` property.) The data handler uses the `BodyName/BodyNamespace` pair to determine the business object to use for the SOAP request to business object conversion.

The connector inspects the Request business object returned by the SOAP data handler. If this business object has `ws_tloname ASI`, the connector sets the Request business object in this TLO. This TLO is used to invoke the collaboration. However, if this ASI is not set, the connector invokes the collaboration using the Request business object returned by the SOAP data handler.

For synchronous collaboration execution, the connector utilizes the SOAP data handler to create a SOAP response or fault message to send back to the client. In this case, the connector simply passes either a SOAP business object (child of TLO), or a non-TLO to the data handler. The SOAP data handler returns a SOAP message based on the business object that it is passed to it.

Request processing overview

On behalf of a collaboration, the connector can invoke web services over SOAP/HTTP(S) and SOAP/JMS. This request processing functionality is supported by a WSDL Object Discovery Agent (ODA) and by a protocol handler framework. The WSDL ODA is a design-time tool you use to generate SOAP business objects that include information about the target web services. For further information, see Chapter 6, “Enabling collaborations for request processing,” on page 137. The protocol handler framework is a configurable run-time module that consists of the following components, which are discussed in detail later in this chapter:

- SOAP/HTTP-HTTPS protocol handler
- SOAP/JMS protocol handler

Upon receipt of a collaboration Request business object, which is always (via the WSDL ODA) set in a TLO, the protocol handler framework loads the appropriate protocol handler. The protocol handlers manage transport-level details required for invoking the web service and (optionally) securing a response, performing three main tasks: converting a collaboration Request business object into a SOAP request message, invoking the endpoint web service with the request message, and, if in Request/Response (synchronous) mode, converting the SOAP response message into a business object and returning that object to the collaboration. The connector uses the SOAP/HTTP-HTTPS protocol handler to invoke SOAP/HTTP(S) web services, and the SOAP/JMS protocol handler to invoke SOAP/JMS web services.

The web services connector is always called from a collaboration using TLOs. The connector determines the SOAP Request business object from the TLO, and invokes the SOAP data handler with this business object. The data handler returns a request message which is sent on by the connector to the web service.

For synchronous web service execution, the connector utilizes the SOAP data handler to convert SOAP response and fault messages into SOAP Response and Fault business objects. To aid the data handler in determining which business object to resolve for these SOAP response/faults to business object conversions, the connector provides the data handler with specific meta information. Specifically, the connector makes a list of all Response and Fault business objects that are children of the invoking TLO. There should be only one response business object and, optionally, many Fault business objects. There may also be one and only one defaultfault business object. The connector attempts to match, and then map, the SOAP BodyName and BodyNamespace to a business object name that appears in the list of all Response business objects. In the case of SOAP Response business objects, this pair is found using the SOAP Config MO properties of the SOAP Response business object. In the case of SOAP Fault business objects, this pair is found using the `elem_name` and `elem_ns` attribute-level ASI properties for the first child of the detail element. For the defaultfault business object, the connector

simply notifies the data handler of the name of the default business object. The default business object should be resolved by the data handler as a last resort if no other fault business objects are resolved for this transformation.

SOAP/HTTP(S) web services

Web services support the HTTP transport protocol. HTTP embodies a client-server model in which an HTTP client opens a connection and sends a request message to an HTTP server. The client request message is to invoke a web service. The HTTP server dispatches the message containing the invocation and closes the connection.

The connector's SOAP/HTTP and SOAP/HTTPS protocol listeners make use of the HTTP client-server and the Request/Response models when handling client requests to a collaboration exposed as a web service. However, the SOAP/HTTP listener is not intended to function as an HTTP server— proxy, intermediary, or otherwise. Rather the SOAP/HTTP listener functions as an endpoint for use within an enterprise and behind a firewall. Accordingly, a separate web server or gateway must be deployed in the firewall to route client requests to the listener. For further information, see Chapter 1, “Overview of the adapter,” on page 1.

The SOAP/HTTP and SOAP/HTTPS protocol listeners expose a collaboration as a SOAP/HTTP(S) web service. The connector uses the SOAP/HTTP-HTTPS protocol handler to invoke SOAP/HTTP(S) web services.

Synchronous SOAP/HTTP(S) web service

From the perspective of connector processing, a synchronous HTTP web service is one that follows a Request/Response path. If the SOAP/HTTP or SOAP/HTTPS protocol listener successfully processes an HTTP request message, the body will contain the web service response and an HTTP status code of 200 OK. If a fault is returned, then the body contains the fault message and a status code of 500.

Asynchronous SOAP/HTTP(S) web service

From the perspective of connector processing, an asynchronous HTTP web service is one that follows a request-only path. If the SOAP/HTTP or SOAP/HTTPS protocol listener successfully receives and processes a request-only web service operation, an HTTP status code of 202 Accepted is generated. You can also configure the connector to generate an HTTP status code of 200 OK—for further information see the `HTTPAsyncResponseCode` property in Table 39. If a fault occurs, an HTTP status code of 500 is generated. There is no response, although a fault body may be returned.

SOAP/JMS web services

JMS is a transport level API that enterprises can combine with web service solutions for messaging, data persistence, and access to Java-based applications. A SOAP/JMS web service is a web service that implements a JMS queue-based transport.

A web service solution may implement a JMS destination for a queue or a topic. The connector's SOAP/JMS protocol listener supports queue destinations only; topics are not supported. JMS text messages only are supported.

During event processing, a SOAP/JMS web service client wraps a request message with a JMS message and publishes it to the queue whose JMS destination is a connector. The JMS destination retrieves the JMS message containing the web

service request and extracts the SOAP request message from the JMS message. It then processes the SOAP request message.

Synchronous SOAP/JMS web service

For synchronous connector processing (Request/Response), a response message is wrapped with a JMS message (like that of the request message). The JMS message containing the web service response is then sent to the JMSReplyTo queue from the incoming request. JMS headers in the response message are set to the values of the headers in the JMS request message as follows:

- The JMSCorrelationID of the response message must be set to the value of JMSMessageID from the JMS request message
- The JMS DeliveryMode of the response message is set to the JMSDeliveryMode of the request.
- The JMSPriority of the response message is set to the JMSPriority of the request.
- JMSExpiration of the request message is set to the JMSExpiration of the request

This processing is discussed in detail in “SOAP/JMS protocol listener processing” on page 64.

Asynchronous SOAP/JMS web service

From the perspective of connector processing, an asynchronous SOAP/JMS web service is one that follows a request-only path. If the SOAP/JMS protocol listener successfully receives and processes a request-only web service message, no JMS message containing a response is returned to the client. If a ReplyToQueue is configured and a fault occurs upon receipt of a JMS message, a fault message is returned to the web service client. In addition, if an ErrorQueue is specified in the SOAP/JMS listener, the fault message is archived there.

Event processing

The first step in implementing an event processing capability is exposing a business process -- a collaboration -- as a web service. You then publish this web service, in a UDDI registry, for example, and configure the connector to respond to web service clients that invoke the collaboration.

During event processing, the connector uses protocol listeners and the SOAP data handler to convert SOAP request messages from web service clients to business objects that can be manipulated by collaborations that have been exposed as web services. Protocol listeners play a crucial role in event processing.

Protocol listeners

Web Service requests may come over variety of transports, including HTTP, HTTPS, and JMS. The Web Services protocol listener monitors the arrival of such requests on its transport channel. There are three protocol listeners and corresponding channels:

- SOAP/HTTP protocol listener
- SOAP/HTTPS protocol listener
- SOAP/JMS protocol listener

Each of these consists of a thread that listens on its transport. When it receives a SOAP request message from a client, the listener registers the event with the protocol listener framework.

The protocol listener framework manages the protocol listeners, scheduling requests as resources are available. You configure the listeners and aspects of the protocol listener framework when you set values to connector-specific properties. Among the protocol listener framework properties you can configure are the following:

- **WorkerThreadCount** Total number of threads available to the protocol listener framework, which is the number of requests that it can process in parallel.
- **RequestPoolSize** Maximum number of requests that can be registered with the protocol listener framework. If it receives more than this maximum requests, it will no longer register new requests.

These two connector-specific properties control memory allocation in a way that prevents protocol listeners from clogging the connector with infinite web service events. The allocation algorithm is as follows: At any time, the connector can receive a total number of events equal to `WorkerThreadCount + RequestPoolSize`. It can process `WorkerThreadCount` number of requests in parallel.

You can plug additional protocol listeners into the protocol listener framework. For further information, see “Creating multiple protocol listeners” on page 100 and “Connector-specific configuration properties” on page 83.

SOAP/HTTP and SOAP/HTTPS protocol listener processing

The SOAP/HTTP(S) protocol listener consists of a thread that continuously listens for HTTP(S) requests from web service clients. The listener thread binds the host and port that are specified in the Host and Port connector-specific configuration (listener) properties. Another configuration property—`RequestWaitTimeout`—defines the interval during which the listener waits for a request before checking whether the connector has shut down.

Figure 24 illustrates SOAP/HTTP protocol listener processing for a synchronous operation.

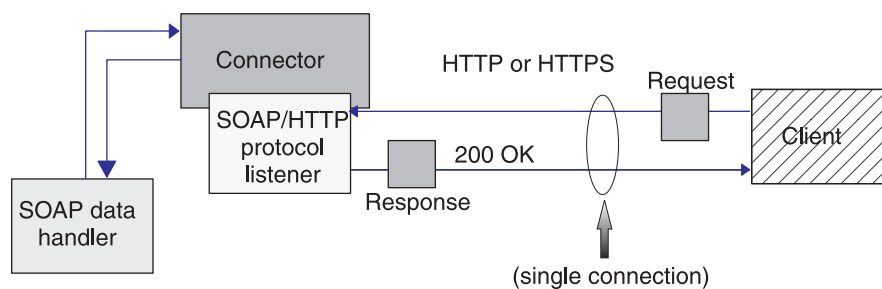

Figure 24. SOAP/HTTP protocol listener: synchronous event processing

Figure 25 shows SOAP/HTTP protocol listener processing for an asynchronous operation.

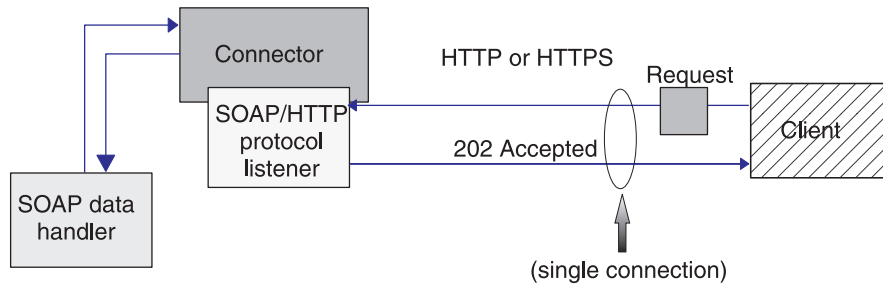

Figure 25. SOAP/HTTP protocol listener: asynchronous event processing

When a web services client initiates a SOAP/HTTP or SOAP/HTTPS request, it posts a SOAP request message to the URL of the SOAP/HTTP or SOAP/HTTPS listener. The client should use the HTTP POST method to invoke the protocol listener URL.

When an HTTP(S) request arrives, the listener registers the request with protocol listener framework, which schedules the event for processing as resources become available. The listener then extracts the protocol headers and the payload from the request.

Table 26 summarizes the order of precedence of rules used by the listener to determine the Charset, MimeType, ContentType and Content-Type header for inbound messages.

Table 26. SOAP/HTTP(s) protocol listener processing rules for inbound message

Order of Precedence	Charset	MimeType	ContentType	Content-Type header
1	Charset parameter value from the incoming HTTP message Content-Type header value	URLsConfiguration connector property value for this listener	Incoming HTTP message type/subtype value from the Content-Type header value	Incoming HTTP message Content-Type header
2	URLsConfiguration property value for this listener	SOAPDHMimeType connector property value		
3	If the type of the request message ContentType is text with any subtype (for example, text/xml, text/plain, etc.), default to ISO-8859-1. Otherwise, charset will not be used.	Default to ContentType		

As shown in Table 26:

- The protocol listener determines the Charset of the inbound message according to the following rules:
 1. The listener attempts to extract the Charset from the charset parameter of HTTP message Content-Type header value.

2. If no Charset value is obtained from the Content-Type header, then the protocol listener attempts to read the URLsConfiguration property value for this listener.
 3. If a Charset value is not obtained using methods described in the previous steps, and if type of the message ContentType is text with any subtype (for example, text/xml, text/plain, etc.), the listener uses a default Charset value of ISO-8859-1. Otherwise, Charset value is not used.
- The listener determines the MimeType for the response message according to these rules:
 1. If you have configured the TransformationRules for the URL used by the incoming request message, and if the request ContentType matches the ContentType of a TransformationRule, then the listener uses the TransformationRule to extract the MimeType for conversion of the request message into a SOAP Request business object. The listener attempts to find the exact TransformationRule match based on the ContentType value (for example, text/xml) in the URLsConfiguration property for the requested URL.
 2. If that fails, the listener attempts to find a TransformationRule that applies to more than one ContentType under the request URL (for example */*).
 3. If there is no TransformationRule match for the MimeType, then the listener uses the SOAPDHMMimeType connector configuration property as the MimeType value.
 4. If all previous steps fail to determine the MimeType, the value of ContentType will be used as the MimeType to invoke the SOAP data handler and convert the request message into a SOAP Request business object.
 - The listener determines the ContentType by extracting type/subtype from the incoming HTTP message Content-Type header.
 - The listener determines the Content-Type header from that of the incoming HTTP message Content-Type header.

If the collaboration is invoked asynchronously, the listener delivers the request business object to the integration broker and responds to the web services client with the HTTP status code 202 Accepted. This concludes listener processing.

If it is a synchronous invocation, the listener invokes the collaboration synchronously. The collaboration responds with a SOAP Response business object.

Table 27 summarizes the order of precedence for rules used by the listener when determining the Charset, MimeType, ContentType, and Content-Type header for response messages.

Table 27. SOAP/HTTP(s) protocol listener processing rules for outbound synchronous response message

Order of Precedence	Charset	MimeType	ContentType	Content-Type header
1	Protocol ConfigMO Content-Type Header	MimeType property in the TLO	Protocol ConfigMO Content-Type header	Protocol ConfigMO Content-Type header
2	The Charset property value in the TLO	The request message MimeType, but only if the request and response ContentType match.	Request message ContentType	Construct Content-Type Header using ContentType and Charset

Table 27. SOAP/HTTP(s) protocol listener processing rules for outbound synchronous response message (continued)

3	The request message Charset, but only if the request and response ContentType match.	SOAPDHMimeType connector property value		
4	If the ContentType is text/*, default to ISO-8859-1. Otherwise, charset will not be used.	Use ContentType value as the MimeType		

As shown in Table 27:

- The listener determines the Charset for the response message according to these rules:
 1. If Charset is specified in the Response business object Protocol Config MO, its value is used.
 2. If there is no Charset value specified in the Response business object Protocol Config MO header and if the Request and Response business object are children of TLOs, the listener checks if Charset is specified in the TLO.
 3. If there is no Charset specified in the TLO, or if the Response business object is not a TLO, then if the response has the same ContentType as the request, the Charset of the request will be used for the response.
 4. If the previous steps fail to determine the response Charset value, and if the type portion of the message ContentType is text with a subtype of anything (for example, text/xml, text/plain, etc.), the listener uses a default Charset value of ISO-8859-1. Otherwise, the Charset value is not used.
- The listener determines the MimeType for the response message according to these rules:
 1. The TLO's MimeType attribute
 2. If the TLO MimeType attribute is missing, and if the request and response ContentType match, the listener uses the request MimeType for the response message.
 3. If the previous steps fail, then the listener uses the value of the SOAPDHMimeType connector property.
 4. Otherwise the listener uses the ContentType value as the MimeType.
- The listener determines the ContentType for the response message according to these rules:
 1. If the Content-Type header is specified in the Response business object Protocol Config MO, the type/subtype portion of the Content-Type header will be used as the ContentType.
 2. If the Content-Type header is not specified in the Response business object Protocol Config MO, the listener constructs a Content-Type header using the determined ContentType and Charset (if the Charset was determined for the response message).

The listener processes the HTTP Protocol Config MO. It is the responsibility of collaboration to ensure that the header values passed in the HTTP Protocol Config MO are correct in the context of the request-response event. The listener populates standard headers and custom properties according to the following rules:

1. The listener will investigate each item of the HTTP Protocol Config MO in order to ignore special attributes (such as ObjectEventId).
2. Each non-empty header will be put on the outgoing message and additional processing (for example, the Content-Type header) may take place.

3. Please note that with the above approach, the listener may set non-standard headers on the message, but will not check that the message is logically or semantically correct.
4. If there are one or more custom properties in the HTTP Protocol Config MO UserDefinedProperties attribute, the listener will add them in the Entity Headers Section (the last headers section). For more on custom properties, see “User-defined properties for event processing” on page 31.

Note: Specifying any of the following headers in the HTTP Protocol Config MO is very likely to result in an incorrect HTTP message: Connection, Trailer, Transfer-Encoding, Content-Encoding, Content-Length, Content-MD5, Content-Range.

The listener then invokes the SOAP data handler to convert the Response business object returned by the Collaboration into a SOAP response message.

The listener delivers the response message to the web service client and includes a 200 OK HTTP status code. If the collaboration returns a SOAP Fault business object, it is converted to a Fault message. This fault message is delivered to the web service client with a 500 Internal Server Error HTTP code.

The listener then closes the connection and the thread that processed the event becomes available.

Unsupported SOAP/HTTP protocol listener processing features

The SOAP/HTTP protocol listener does not support the following:

- Caching: The protocol listener does not perform any caching functions as defined in HTTP specifications (RFC2616)
- Proxy: The protocol listener does not perform any proxy functions as defined in HTTP specifications (RFC2616).
- Persistent Connection: The protocol listener does not support persistent connections as defined in HTTP specifications (RFC2616). Instead, the protocol listener assumes that the scope of each HTTP connection is a single client request. and closes the connection when the service request is completed. The protocol listener does not attempt to reuse the connection across the service invocations.
- Redirections: The protocol listener does not support redirections.
- Large file transfer: The protocol listener cannot be used for large file transfers. Alternatively, you may consider passing large files by reference instead.
- State management: The protocol listener does not support the HTTP state management mechanism described by RFC2965.
- Cookies: The protocol listener does not support cookies.

SOAP/HTTPS listener processing using secure sockets

SOAP/HTTPS protocol listener processing is the same as that described in the SOAP/HTTP protocol listener processing section except that HTTPS uses secure sockets. For further information, see “SSL” on page 80.

SOAP/JMS protocol listener processing

The SOAP/JMS protocol listener consists of a thread that continuously listens on the InputQueue, which is the JMS destination for requests from web service clients.

The RequestWaitTimeout connector configuration property defines how long the listener will wait for a request before checking whether the connector has shut down.

Figure 26 shows SOAP/JMS protocol listener processing for a synchronous operation. The figure does not show JMS provider information.

Figure 26. SOAP/JMS protocol listener: synchronous event processing

Figure 27 shows SOAP/JMS protocol listener processing for an asynchronous operation.

Figure 27. SOAP/JMS protocol listener: asynchronous event processing

Note: If the LookupQueueUsingJNDI configuration property is set to true, the SOAP/JMS protocol listener uses the JNDI to look up the queue. The JNDI properties are specified in connector properties. For further information, see “Connector and JMS” on page 78 and the JNDI-related properties in “Connector-specific configuration properties” on page 83.

When a web service client initiates a SOAP/JMS request, it sends a SOAP request message to the InputQueue on which the SOAP/JMS listener is listening. When it receives the SOAP request message from the InputQueue, the SOAP/JMS protocol listener registers the request with the protocol listener framework. The protocol listener framework schedules the request as and when resources are available.

Note: If the connector configuration property `InDoubtEvents` is set to `Reprocess`, the protocol listener framework will schedule JMS messages from the `InProgressQueue` before scheduling messages from the `InputQueue`.

The listener then dispatches this message—the body as well as the required JMS headers (`JMSCorrelationID`, `JMSMessageID`, `JMSPriority`, `JMSExpiration`, `JMSDeliveryMode`, `JMSReplyTo`, `JMSTimeStamp`, `JMSType`)— to the `InProgressQueue`. The protocol listener framework then registers the event.

The listener then reads the JMS message from the `InProgressQueue`, extracting the body of the message and the following headers:

- `JMSDestination`
- `JMSRedelivered`
- `JMSCorrelationID`
- `JMSMessageID`
- `JMSPriority`
- `JMSExpiration`
- `JMSDeliveryMode`
- `JMSReplyTo`
- `JMSTimeStamp`
- `JMSType`

The `JMSType` can be in `TextMessage` or `BytesMessage` format. In `TextMessage` format, the listener invokes the data handler through String APIs with the Web Service Request message extracted as String. In the case of `BytesMessage`, the listener invokes the data handler via Bytes Data Handler APIs with the Web Service Request message extracted as a bytes array.

Using the `SOAPDHMimeType` connector configuration property, the listener invokes the SOAP data handler to convert the request message into a SOAP Request business object. If errors occur during conversion and the `JMSReplyTo` JMS header is specified, the listener responds with a SOAP fault message, setting the faultcode to `Client` and the faultstring to `Cannot Parse`. The fault message provides no other detail.

The listener uses the object-level `cw_mo_jms` ASI of the SOAP Request business object returned by the data handler to determine the Protocol Config MO. Note that both the ASI and the Protocol Config MO are optional for event processing. If it finds a Protocol Config MO, the listener populates it with the JMS message headers extracted earlier. Table 41 shows the mapping between the attributes in the Protocol Config MO and the JMS message headers.

Table 28. JMS header-Protocol Config MO attribute mapping

Protocol Config MO attribute	JMS header name	Description
CorrelationID	JMSCorrelationID	The JMSCorrelationID header from the request message
MessageId	JMSMessageId	The JMSMessageID header from the request message
Priority	JMSPriority	The JMSPriority header from the request message

Table 28. JMS header-Protocol Config MO attribute mapping (continued)

Expiration	JMSExpiration	The JMSExpiration header from the request message
DeliveryMode	JMSDeliveryMode	The JMSDeliveryMode header from the request message
ReplyTo	JMSReplyTo	The JMSReplyTo header from the request message. The JMS API returns this header as JMSDestination, but the SOAP/JMS protocol listener returns the queue name.
Timestamp	JMSTimestamp	The JMSTimestamp header from the request message
Redelivered	JMSRedelivered	The JMSRedelivered header from the request message
Type	JMSType	The JMSType header from the request message
Destination	JMSDestination	The JMSDestination header from the request message

If there are one or more custom properties in the SOAP/JMS Protocol Config MO UserDefinedProperties attribute, the listener will try to extract their values from the message and populate the UserDefinedProperties business object. For more on custom properties, see “User-defined properties for event processing” on page 31.

If the TLO (in the case of a non-TLO SOAP Request business object) is not subscribed by the integration broker, the listener logs an error. If the JMSReplyTo header is specified in the request message, the listener creates a SOAP fault message and places it on the JMSReplyTo queue. The faultcode is set to Client and the faultString is set to Not subscribed to this message. No other detail is provided in the fault message. If configured to do so, the listener also archives the original JMS request message including its JMS headers to the UnsubscribedQueue.

If the collaboration is invoked asynchronously, the listener delivers the Request business object to the integration broker. The listener then removes the message from the InProgressQueue. If configured to do so, the listener also archives the original JMS request message including its JMS headers to the ArchiveQueue.

If errors occur during asynchronous processing and JMSReplyTo is specified, the listener responds with a fault message. Its faultcode is set to Server and its faultstring is set to Internal Error. If configured to do so, the listener also archives the original JMS request message, including its JMS headers, to ErrorQueue.

If it is a synchronous invocation, the listener invokes the collaboration synchronously. The collaboration responds with a SOAP Response business object. The listener invokes the SOAP data handler to convert the Response business object returned by the Collaboration into a SOAP/JMS response message. The listener delivers the response message to the ReplyTo queue (this is provided by the JMSReplyTo header on the original request message). The listener then sets the response message returned by the data handler as a TextMessage, setting the headers shown in Table 29.

Table 29. Header values set by SOAP/JMS protocol listener in response message

JMS header name	Value
JMSCorrelationId	The JMSMessageId of the request message
JMSDeliveryMode	The JMSDeliveryMode of the request message
JMSPriority	The JMSPriority of the request message
JMSExpiration	The JMSExpiration of the request message
JMSRedelivered	The JMSRedelivered of the request message
JMSReplyTo	The JMSReplyTo of the request message
JMSTimestamp	The JMSTimestamp of the request message
JMSType	The JMSType of the request message

The listener will set JMS Custom Properties in the response message if they are present in the Response or Fault business objects' JMS Protocol Config MO UserDefinedProperties attribute.

If configured to do so, the listener then moves the original JMS message (request from the web service client), including its headers, from the InProgressQueue to the ArchiveQueue.

If errors occur and JMSReplyTo is specified, the listener responds with a fault message, and, if configured to do so, also archives the original JMS request message to the ErrorQueue.

Event persistence and delivery

Event persistence is protocol contingent:

- **SOAP/HTTP protocol listener** no persistence and therefore no guaranteed delivery
- **SOAP/HTTPS protocol listener** no persistence and therefore no guaranteed delivery
- **SOAP/JMS protocol listener** JMS queue event persistence and at-least-once guaranteed delivery. For more on the JMS queues, see "Connector-specific configuration properties" on page 83.

Event sequencing

The connector may deliver events in any sequence.

Event triggering

The event triggering mechanism depends on how the protocol listener is configured.

- **SOAP/HTTP protocol listener** Listening occurs over a ServerSocket for HTTP connection requests
- **SOAP/HTTPS protocol listener** Listening occurs over a secure ServerSocket layer for HTTPS connection requests
- **SOAP/JMS protocol listener** Listening occurs over the input queue for incoming JMS messages carrying web service requests. For more on the JMS queues, see "Connector-specific configuration properties" on page 83.

Note: Connector does not distinguish between Create or Update or Retrieve or Delete. All such events follow the same approach.

Event detection

Event detection is performed by each protocol listener. The event detection mechanism depends utterly on the transport and how you configure the connector-specific properties for each listener. For more on these properties, see “Connector-specific configuration properties” on page 83.

Event status

Event status is managed by the protocol listener and depends on the transport and also on how you configure the listener.

- **SOAP/HTTP protocol listener** HTTP is inherently non-persistent and synchronous in nature. Accordingly, event status is not maintained.
- **SOAP/HTTPS protocol listener** HTTP is inherently non-persistent and synchronous in nature. Accordingly, event status is not maintained.
- **SOAP/JMS protocol listener** JMS is a persistent transport. Event status is maintained using queues. For more on the JMS queues, see “Connector-specific configuration properties” on page 83.

Event retrieval

Event retrieval is managed by the protocol listener and depends on the transport and also on how you configure the listener.

- **SOAP/HTTP protocol listener** Events are retrieved by extracting HTTP requests from the socket.
- **SOAP/HTTPS protocol listener** Events are retrieved by extracting HTTP requests from the socket.
- **SOAP/JMS protocol listener** Events are retrieved using the JMS API. The JMS protocol listener retrieves events from the JMS input queue and moves them to the in-progress queue. For more on the JMS queues, see “Connector-specific configuration properties” on page 83.

Event archiving

Event archiving is managed by the protocol listener and depends on the transport and also on how you configure the listener.

- **SOAP/HTTP protocol listener** Because of the non-persistent and synchronous nature of the transport, archiving is not performed.
- **SOAP/HTTPS protocol listener** Because of the non-persistent and synchronous nature of the transport, archiving is not performed.
- **SOAP/JMS protocol listener** You can configure the connector to archive events into a JMS queues including those for unsubscribed events, successful events, and failed events. For more on the JMS queues, see “Connector-specific configuration properties” on page 83.

Event recovery

Event recovery is managed by the protocol listener and depends on the transport and also on how you configure the listener.

- **SOAP/HTTP protocol listener** Because of the non-persistent nature of the transport, event recovery is not performed.
- **SOAP/HTTPS protocol listener** Because of the non-persistent nature of the transport, event recovery is not performed.
- **SOAP/JMS protocol listener** JMS is a persistent transport. If the connector shuts down while events are being processed, they remain available in the

InProgressQueue. You can configure the connector to process these events at startup, thereby enabling event recovery. The InDoubtEvents connector configuration property determines the event recovery mechanism.

Note: The SOAP/JMS listener assures at-least once delivery to the integration broker. The listener cannot assure once and only once delivery. Also, events received by the listener may be delivered in any order to the integration broker.

At startup, the JMS protocol listener first attempts to retrieve events from the InProgressQueue. What happens next is determined by the value you assign to the InDoubtEvents configuration property. The recovery scenarios are illustrated in table. For more on the JMS queues, see “Connector-specific configuration properties” on page 83.

Table 30. Header values set by SOAP/JMS protocol listener in response message

InDoubtEvents value	Event recovery processing
FailOnStartup	If it finds events in the InProgressQueue, the listener logs a fatal error and immediately shuts down.
Reprocess	If it finds events in the InProgressQueue, the listener processes those events first. The listener can trace the number of messages found in the InProgressQueue.
Ignore	Events in the InProgressQueue are ignored. The listener can trace the events found in the InProgressQueue and the ignoring of those events by the listener.
LogError	If it finds events in the InProgressQueue, the listener logs error and continues processing.

Request processing

You use the request processing capability of the connector to enable a collaboration to invoke a web service. The development tasks include using the WSDL ODA to generate a web services top-level object (TLO) and configuring a collaboration to deploy it. For further information, see Chapter 6, “Enabling collaborations for request processing,” on page 137. You must also configure the connector and its request processing components: the protocol handler framework and protocol handlers.

At run time, the connector receives requests from the collaboration in the form of business objects. The business objects— SOAP Request, and optionally SOAP Response and SOAP Fault business objects— are contained by the TLO generated by the WSDL ODA and issued by a collaboration that is configured to use web services. The TLO and its child business objects contain attributes and ASI that specify the processing mode (synchronous or asynchronous), the data handler mime type, which protocol handler to use, as well as the address of the target web service. The protocol handler uses this information to invoke an instance of the SOAP data handler, convert the Request business object to a SOAP request message, and invoke the target web service. If the mode is synchronous, the protocol handler again invokes the data handler to convert the response message into a SOAP Response business object and returns this to the collaboration.

In response to a SOAP request message, the connector can receive any of the following from the remote trading partner:

- A SOAP response message that contains data
- A SOAP response message that contains fault information

Protocol handlers play a key role in request processing.

Protocol handlers

A collaboration can invoke a web service over HTTP, HTTPS, or JMS transports. The connector has two protocol handlers and corresponding channels:

- A SOAP/HTTP-HTTPS protocol handler for invoking SOAP/HTTP and SOAP/HTTPS web services
- A SOAP/JMS protocol handler for invoking SOAP/JMS web services

The protocol handler framework manages the protocol handlers, loading them at startup time. When the connector receives a Request business object, the request thread (note that each collaboration request comes in a thread of its own) invokes the protocol handler framework to process the request.

The protocol handler framework reads the TLOs Handler attribute ASI to determine which protocol handler to use. Applying a series of rules (see “SOAP/HTTP-HTTPS protocol handler processing” and “SOAP/JMS protocol handler processing” on page 75), the protocol handler invokes a data handler to convert the Request business object into a SOAP request message. The protocol handler packages the request message into the transport—HTTP(S) or JMS—message. If it finds SOAPAction ASI in the Request business object, the protocol handler adds this to the request message header.

The protocol handler then reads the Destination attribute of the Request business object Protocol Config MO to determine the target address. The protocol handler then invokes the target web service with the request message.

Reading the ws_mode TLO ASI, the protocol handler determines whether the processing mode is synchronous or asynchronous. If this ASI is set to asynch, the protocol handler processing is completed. Otherwise the protocol handler waits for a response message. If a response message arrives, the protocol handler extracts the protocol headers and the payload. It then invokes the data handler (indicated by the MIMEType TLO attribute) to convert the message into a Response or Fault business object. Again using the Protocol Config MO, the protocol handler sets the protocol headers in the business object. The protocol handler then returns the Response or Fault business object to the collaboration.

Depending on connector configuration, there may be one or more protocol handlers plugged into the connector. Connector-specific properties allow you to configure protocol handlers.

SOAP/HTTP-HTTPS protocol handler processing

The SOAP/HTTP(S) protocol handler performs as described in “Protocol handlers” with exceptions noted in this section. Figure 28 shows the SOAP/HTTP-HTTPS protocol handler for a synchronous operation.

Figure 28. SOAP/HTTP-HTTPS protocol handler: synchronous request processing

Figure 29 shows the SOAP/HTTP-HTTPS protocol handler for an asynchronous request process

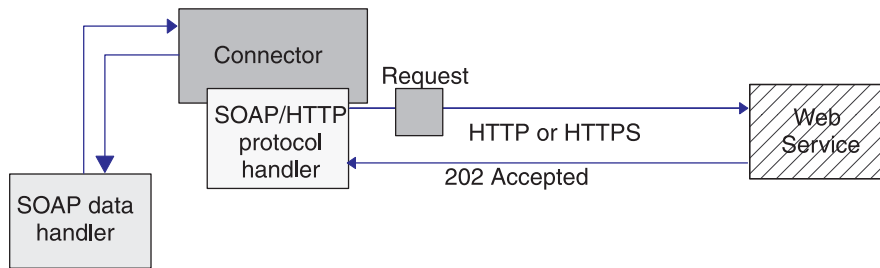

Figure 29. SOAP/HTTP-HTTPS protocol handler: asynchronous request processing

Note: This section describes SOAP/HTTP protocol handling only.

The SOAP/HTTP-HTTPS protocol handler uses the object-level ASI (`cw_mo_http`) of the SOAP Request business object to determine the Protocol Config MO. The SOAP/HTTP-HTTPS protocol handler determines the URL of the target web service by reading the Destination attribute in the HTTP Protocol Config MO. If the URL is missing or is incomplete, the protocol handler fails the service call. For further information on the HTTP Protocol Config MO and its attributes, see “HTTP Protocol Config MO for request processing” on page 45.

The SOAP/HTTP-HTTPS protocol handler invokes the web service using the SOAP request message returned by the SOAP data handler. If HTTP Proxy connector configuration properties are specified, the SOAP/HTTP(S) protocol handler behaves accordingly. If a response is returned, the SOAP/HTTP(S) protocol handler reads it.

Table 31 summarizes the order of precedence of rules used by the SOAP/HTTP-HTTPS protocol handler to determine the Charset, MimeType, ContentType, and ContentType header for outgoing request messages.

Table 31. SOAP/HTTP-HTTPS protocol handler processing rules for outbound messages

Order of Precedence	Charset	MimeType	ContentType	ContentType header
---------------------	---------	----------	-------------	--------------------

Table 31. SOAP/HTTP-HTTPS protocol handler processing rules for outbound messages (continued)

1	Protocol Config MO's Content-Type Header	MimeType property in TLO attribute	Protocol Config MO's Content-Type Header	Protocol Config MO's Content-Type Header
2	Charset property in TLO attribute	Default to ContentType	Default to text/xml	Construct Content-Type header using ContentType and Charset
3	If the ContentType is text/*, default to ISO-8859-1. Otherwise, charset will not be used.			

As shown in Table 31:

- The SOAP/HTTP-HTTPS protocol handler determines the Charset for the response message according to these rules:
 1. If specified in the Request business object Protocol Config MO headers, the Charset value is used.
 2. If Charset is not determined by the previous step, the protocol handler attempts to extract the Charset from the TLO attribute.
 3. If the operation described in the previous step is unsuccessful, the table is used to determine the Charset:

Table 32. Default request processing Charsets

ContentType	Default Charset
text/*	ISO-8859-1 For further information, see RFC2616,
application/*	No default
All others	No default

4. If Charset was determined by the previous step, the Charset is set on the data handler.
 5. The data Handler is invoked with Stream or Byte array APIs, depending on the data structure needed for writing out the request.
- The SOAP/HTTP-HTTPS protocol handler determines the MimeType for the request according to these rules:
 1. The TLO MimeType attribute.
 2. If the TLO MimeType attribute is missing, the protocol handler uses the ContentType to determine the MimeType.
 - The SOAP/HTTP-HTTPS protocol handler determines the ContentType for the request message according to these rules:
 1. If the Content-Type header is specified in the Request business object Protocol Config MO, the type/subtype of the header will be used as ContentType.
 2. Otherwise, the handler uses the default ContentType: text/xml.
 - The SOAP/HTTP-HTTPS protocol handler determines the Content-Type header for the request message according to these rules:
 1. If the Content-Type header is specified in the Request business object Protocol Config MO, its value is set on the outgoing message.

2. If the Content-Type header is not specified in the Request business object Protocol Config MO, the listener constructs a Content-Type header using the ContentType and Charset parameter (if the Charset was determined for the request message).

Table 33 summarizes the order of precedence for rules used by the handler when determining the Charset, MimeType, ContentType, and ContentType header for response messages.

Table 33. SOAP/HTTP(s) protocol handler processing rules for inbound synchronous response message

Order of Precedence	Charset	MimeType	ContentType	ContentType header
1	Charset parameter value from the incoming HTTP message Content-Type header value	Message TransformationMap child business object in the Request business object's Protocol Config MO	Incoming HTTP message type/subtype value from the Content-Type header value	Incoming HTTP message Content-Type header
2	Message TransformationMap child business object in the Request business object's Protocol Config MO	The request message MimeType, but only if the request and response ContentType match.		
3	The request message Charset, but only if the request and response ContentType match.	MimeType property in TLO		
4	Charset property in TLO.	Default to ContentType		
5	If the Content-Type is text/*, default to ISO-8859-1. Otherwise, Charset is not used.			

As shown in Table 33:

- The protocol handler determines the Charset of the synchronous response message according to the following rules:
 1. If the Charset parameter is set in the Content-Type header of the incoming response message, the protocol handler uses the Charset value to set on the data handler.
 2. If there is no Charset value in the response message header, then the protocol handler attempts to read the collaboration-defined Charset from the TLO Request Protocol Config MO MessageTransformationMap.
 3. If there is no Charset value specified in the TLO, or if there is no TLO, then if the response has the same ContentType as the request, the Charset of the request will be used for the response.
 4. If the previous step fails to yield a Charset value, then the protocol handler attempts to read the TLO Charset attribute.
 5. If a Charset value is not obtained using methods described in the previous steps, and if type of the message ContentType is text with any subtype (for example, text/xml, text/plain, etc.), default ISO-8859-1. Otherwise, charset value is not used.
- The protocol handler determines the MimeType of the synchronous response message according to the following rules:

1. The protocol handler first attempts to extract the `MimeType` from the TLO Request Protocol Config MO's `MessageTransformationMap`. Specifically, the protocol handler tries to find an exact `ContentType` match in the MTM to extract `MessageTransformationRule` and then use the `MimeType` property value from it. Otherwise, the protocol handler looks for a `MessageTransformationRule` that applies to more than one `ContentType` (`ContentType` is `*/*`).
 2. If the `MimeType` is not determined by using a `MessageTransformationMap`, the protocol handler uses the request `MimeType` for that of the response if and only if the request and response `ContentTypes` match.
 3. If the `MimeType` cannot be extracted using the previous steps, the protocol handler uses the `MimeType` attribute of the TLO. or the default `MimeType`, if available to the protocol handler.
 4. If all previous steps fail, the protocol handler uses the `ContentType` to set the `MimeType`.
- The handler determines the `ContentType` by extracting type/subtype from the incoming HTTP message `Content-Type` header.

The handler processes the HTTP Protocol Config MO. It is the responsibility of the collaboration to ensure that the header values passed in the HTTP Protocol Config MO are correct in the context of the request-response event. The handler populates standard headers and custom properties according to the following rules:

1. The handler will investigate each item of the HTTP Protocol Config MO in order to ignore special attributes (such as `ObjectEventId`).
2. Each non-empty header will be put on the outgoing message and additional processing (for example, the `Content-Type` header) may take place.
3. Please note that with the above approach, the handler may set non-standard headers on the message, but will not guarantee that the message is logically or semantically correct.
4. If there are one or more custom properties in the HTTP Protocol Config MO `UserDefinedProperties` attribute, the handler will add them in the Entity Headers Section (the last headers section). For more on custom properties, see "User-defined properties for request processing" on page 46.

Note: Specifying any of the following headers in the HTTP Protocol Config MO is very likely to result in incorrect HTTP messages: `Connection`, `Trailer`, `Transfer-Encoding`, `Content-Encoding`, `Content-Length`, `Content-MD5`, `Content-Range`.

SOAP/JMS protocol handler processing

The SOAP/JMS protocol handler performs as described in "Protocol handlers" on page 71 with exceptions noted in this section.

Note: If the `LookupQueueUsingJNDI` configuration property is set to `true`, the SOAP/JMS protocol handler uses the JNDI to look up the destination queue. The JNDI properties are specified in connector properties. For further information, see "Connector and JMS" on page 78 and the JNDI-related properties in "Connector-specific configuration properties" on page 83.

The SOAP/JMS protocol handler creates a JMS transport message using the body of the web service request message returned by the SOAP data handler and with JMS headers set as shown in Table 34..

Table 34. Header values set by SOAP/JMS protocol handler in request message

JMS header name	Default value if not set in SOAP/JMS Protocol Config MO
JMSPriority	4
JMSExpiration	0
JMSDeliveryMode	PERSISTENT
JMSReply	
JMSCorrelationId	
JMSRedelivered	
JMSTimestamp	
JMSType	

If the target web service is invoked asynchronously, the JMSReplyTo header is not set. Otherwise (for synchronous processing), the SOAP/JMS protocol handler sets the JMSReplyTo header. Using the ReplyToQueue configuration property, the SOAP/JMS protocol handler obtains the JMSDestination—the return destination for a response or fault from the target web service—and sets it on the JMSReplyTo header on the JMS transport message.

Figure 30 shows SOAP/JMS protocol handler processing for a synchronous request operation.

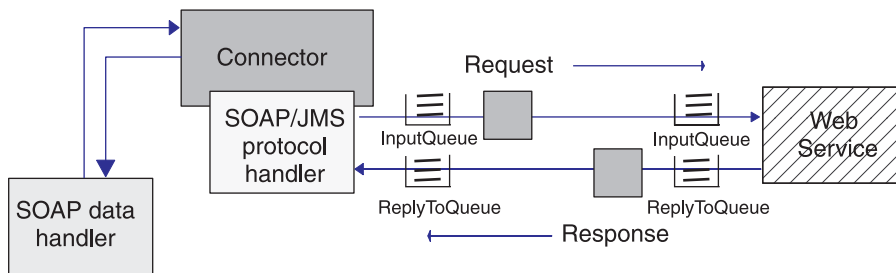

Figure 30. SOAP/JMS protocol handler: synchronous request processing

Figure 31 shows SOAP/JMS protocol handler processing for an asynchronous request operation.

Figure 31. SOAP/JMS protocol handler: asynchronous request processing

The SOAP/JMS protocol handler uses object-level ASI (`cw_mo_jms`) of the SOAP Request business object to determine the Protocol Config MO. The Destination attribute of the Protocol Config MO gives the queue name of the target web service. If JNDI is enabled, the SOAP/JMS protocol handler obtains the JMSDestination for the SOAP request message by looking up the JNDI object. Otherwise it uses the Destination attribute in the SOAP Protocol Config MO.

If the response does not arrive in the interval specified in the ResponseWaitTimeout property, the SOAP/JMS protocol handler fails the collaboration request. On arrival of the SOAP response (or fault) message, the SOAP/JMS protocol handler extracts the JMS headers and payload for conversion by the SOAP data handler. The SOAP/JMS protocol handler then sets the SOAP Response (or Fault) business object in the TLO, using the Protocol Config MO in the Response (or Fault) business object to map the JMS headers. Table 35 shows this mapping.

Table 35. Protocol Config MO—JMS header attribute mapping for response during synchronous request processing

Protocol Config MO attribute	JMS header name	Description
Destination	JMSDestination	The JMSDestination header from the response message.
MessageId	JMSMessageId	The JMSMessageId header from the response message
Priority	JMSPriority	The JMSPriority header from the response message
Expiration	JMSExpiration	The JMSExpiration header from the response message
DeliveryMode	JMSDeliveryMode	The JMSDeliveryMode header from the response message
ReplyTo	JMSReplyTo	The JMSReplyTo header from the response message. The JMS API returns this header as JMSDestination, but the SOAP/JMS protocol listener returns the queue name.
CorrelationId	JMSCorrelationId	The JMSCorrelationId header from the response message
Redelivered	JMSRedelivered	The JMSRedelivered header from the response message

Table 35. Protocol Config MO—JMS header attribute mapping for response during synchronous request processing (continued)

TimeStamp	JMSTimeStamp	The JMSTimeStamp header from the response message
Type	JMSType	The JMSType header from the response message

The SOAP/JMS protocol handler then returns the TLO to the collaboration.

Connector and JMS

Note: This section assumes that you are familiar with JMS and JNDI, especially how JMS works. For further information, refer to your JMS and JNDI source documentation.

The connector can expose collaborations as SOAP/JMS web services as well as enable collaborations to invoke SOAP/JMS web services. The requirements for using SOAP/JMS with the web services connector are as follows:

1. You have installed and configured your JMS service provider.
2. You have installed and configured your JNDI.
3. Your JMS provider supports JMS API version 1.0.2.
4. All required jar files are in the classpath of the connector. (See your JMS provider documentation to determine all required jar files.)
5. All required libraries are in the path of the connector. (See your JMS provider documentation to determine all required libraries.)

JNDI

For SOAP/JMS, the connector uses JNDI to lookup the connection factory using JNDI context. During initialization, the connector reads the JNDI connector-specific property to connect to JNDI. If you do not configure this property, you will be unable to use SOAP/JMS. You can specify following JNDI connector specific properties:

- JNDIProviderURL
- InitialContextFactory
- JNDIConnectionFactoryName
- CTX_ObjectFactories
- CTX_ObjectFactories
- CTX_StateFactories
- CTX_URLPackagePrefixes
- CTX_DNS_URL
- CTX_Authoritative
- CTX_Batchsize
- CTX_Referral
- CTX_SecurityProtocol
- CTX_SecurityAuthentication
- CTX_SecurityPrincipal
- CTX_SecurityCredentials
- CTX_Language

- `LookupQueuesUsingJNDI`

Refer to your JNDI documentation for guidance in specifying these properties. To use SOAP/JMS with the connector, the following JNDI connector-specific properties are required:

- **JNDIProviderURL** Set this property to the URL of the JNDI Service provider. For the value of this property, refer to your JNDI provider documentation.
- **InitialContextFactory** Set this property to the fully qualified class name of the factory class that will create the JNDI initial context. For the value of this property, refer to your JNDI provider documentation. Make sure that this class and its dependencies are in the classpath of the connector.
- **JNDIConnectionFactoryName** Set this property to the JNDI name of the Connection factory to lookup (using JNDI context). Make sure that this name can be looked up using the JNDI.

If you set `LookupQueuesUsingJNDI` to `true`, make sure all the queues used by the connector can be looked up using JNDI.

Exposing collaborations as SOAP/JMS web services

To expose collaborations as SOAP/JMS web services, you must use the SOAP/JMS protocol listener. Using the SOAP/JMS protocol listener requires that you specify JNDI connector properties.

Your JMS provider configuration should reflect the requirements of the SOAP/JMS protocol listener. Make sure all the queues required by the SOAP/JMS protocol listener are defined by your JMS service provider. Be sure to check your JMS provider documentation—the task of defining queues varies by provider. You must define six queues for the SOAP/JMS protocol listener. You must set the queue names in SOAP/JMS listener configuration properties and, if you have set JNDI “ `LookupQueuesUsingJNDI` to `true`, you also must specify the JNDI names of the queues in the SOAP/JMS listener configuration properties.

You should specify the queues names as the values of the following SOAP/JMS Listener configuration properties:

- `InputQueue`
- `InProgressQueue`
- `ArchiveQueue`
- `UnsubscribedQueue`
- `ErrorQueue`
- `ReplyToQueue`

`InputQueue` and `InProgressQueue` are required properties. Make sure that you have correctly configured these queues.

`ArchiveQueue`, `UnsubscribedQueue` and `ErrorQueue` are optional properties. These queues are used to archive web service requests. If you plan to use any of these properties, make sure you have configured the corresponding JMS queues correctly. When defining these queues with your JMS provider, you should carefully specify the capacity of these queues.

Collaborations invoking SOAP/JMS web services

To enable collaborations to invoke SOAP/JMS web services, you use the SOAP/JMS protocol handler. The SOAP/JMS protocol handler requires that you

specify JNDI connector properties. Work with your web service provider to determine the JMS and JNDI requirements.

To invoke SOAP/JMS web services, the connector requires that the value of the Destination attribute in the SOAP/JMS Protocol Config MO be set to the input queue of the target web service. If you have set JNDI " LookupQueuesUsingJNDI to true, you must specify the JNDI name of the input queue.

If you are invoking request-reply web services, you must work with your web service provider to determine the requirements for the ReplyTo queue. Make sure that the ReplyTo queue is defined. Also make sure that you have specified the name of the ReplyTo queue in the ReplyToQueue configuration property of the SOAP/JMS protocol handler. If JNDI " LookupQueuesUsingJNDI is set to true, the value of the ReplyToQueue configuration property should give the JNDI name of this queue.

It is important to note that, unlike protocol listeners, protocol handlers are not pluggable to the web services connector. As a result, the connector uses the same ReplyTo queue for all the request-reply web services that the connector invokes.

SSL

This section discusses the how the connector implements an SSL capability. For background information, see your SSL documentation. This section assumes a familiarity with SSL technology.

JSSE

The connector can expose collaborations as SOAP/HTTPS web services and enable collaborations to invoke SOAP/HTTPS web services. The connector uses JSSE to provide support for HTTPS and SSL. IBM JSSE is shipped with the connector. To enable this capability, make sure you have the following entry in the `java.security` file that is among the files installed with the connector:

```
security.provider.5=com.ibm.jsse.IBMJSSEProvider
```

Note that `java.security` is located in the `$ProductDir\lib\security` directory of your connector installation. The connector uses the value of the `JavaProtocolHandlerPackages` connector property to set the system property `java.protocol.handler.pkgs`. Note that for the IBM JSSE that is shipped with the connector, the value of this property should be set to `com.ibm.net.ssl.internal.www.protocol`.

The `JavaProtocolHandlerPackages` configuration property defaults to this value.

During initialization, the connector disables all anonymous cipher suites supported by JSSE.

KeyStore and TrustStore

To use SSL with the connector, you must set up keystores and truststores. No tool is provided to set up keystores, certificates, and key generation. You must use third party software tools to complete these tasks.

SSL Properties

You can specify the following SSL connector-specific properties:

- `SSLVersion`

- SSLDebug
- KeyStore
- KeyStoreAlias
- KeyStorePassword
- TrustStore
- TrustStorePassword

Note that these properties apply to a connector instance. The same set of SSL property values are used by all of the SOAP/HTTPS protocol listeners plugged into the connector and by the SOAP/HTTP-HTTPS protocol handler for each connector instance. For further information on HTTPS/SSL setup, see Appendix E, “Configuring HTTPS/SSL,” on page 209.

Exposing collaborations as SOAP/HTTPS web services

When you expose collaborations as SOAP/HTTPS web services, you use the SOAP/HTTPS protocol listener. To use the SOAP/HTTPS protocol listener, you must specify SSL connector-specific properties. The values you assign to these properties should reflect your SSL requirements:

- **SSLVersion** Make sure that the SSLVersion you want to use is supported by JSSE.
- **KeyStore** Because the SOAP/HTTPS protocol listener acts as a server in SSL communications, you must specify the keystore. The listener uses the keystore specified in the SSL “ KeyStore configuration property. The value of this property must be the complete path to your keystore file. Make sure that the keystore has key pair (private key and public key) for the connector. The alias of the private key should be specified as the SSL “ KeyStoreAlias property. You must specify the password required to access the keystore as the SSL “ KeyStorePassword property. Also make sure that the password required to access keystore and the private key (in the keystore) are same. Finally, you must distribute the digital certificate of the connector to your web service clients so that they can authenticate the connector.
- **TrustStore** If you want the SOAP/HTTPS protocol listener to authenticate web service clients, you must activate client authentication. You do this by setting the SSL “ UseClientAuth property to true. You must also specify:
 - the location of your truststore as the value of the SSL “ TrustStore configuration property
 - the password required to access the truststore as the value of the SSL “ TrustStorePassword property

Make sure that your truststore contains the digital certificate of your web service clients. Digital certificates used by your Web Service clients may be self-signed or issued by CA. Note that if your truststore trusts the root certificate of the CA, JSSE will authenticate all the digital certificates issued by that CA.

For further information on HTTPS/SSL setup, see Appendix E, “Configuring HTTPS/SSL,” on page 209.

Collaborations invoking SOAP/HTTPS web services

To enable collaborations to invoke SOAP/HTTPS web services, you use the SOAP/HTTP-HTTPS protocol handler. If you are using SSL with the SOAP/HTTP-HTTPS protocol handler, you must specify SSL connector-specific properties. The values you assign to these properties should reflect the HTTPS/SSL requirements of your web services provider:

- **SSLVersion** Make sure that the SSLVersion you want to use is supported by your web service provider and by JSSE.
- **TrustStore** Because the SOAP/HTTP-HTTPS protocol handler acts as a client in SSL communications, you must set up a truststore. The handler uses the truststore specified in the SSL -> Truststore configuration property. The value of this property must be the complete path to your truststore file. You must specify the password required to access the truststore in the SSL -> TrustStorePassword property. Make sure that your truststore contains the digital certificate of your web service provider. Digital certificates used by your web service provider may be self-signed or they may be issued by CA. Note that if your truststore trusts the root certificate of the CA, JSSE will authenticate all the digital certificates issued by that CA.
- **KeyStore** If your web service provider requires client authentication, you must set up a keystore. The SOAP/HTTP-HTTPS protocol handler uses the keystore specified in the SSL " KeyStore configuration property. This value must be the complete path to your keystore file. Make sure that keystore has a key pair (private key and public key) configured for the connector. The alias of the private key must be specified in the SSL " KeyStoreAlias property. The password required to access the keystore must be specified in the SSL " KeyStorePassword property. Finally, make sure that the password required to access the keystore and the private key (in the keystore) are the same. You must distribute the connector's digital certificate to your web service provider for authentication.

For further information on HTTPS/SSL setup, see Appendix E, "Configuring HTTPS/SSL," on page 209.

Configuring the connector

After using the Installer to install the connector files to your system, you must set the standard and application-specific connector configuration properties.

Setting configuration properties

Connectors have two types of configuration properties: standard configuration properties and connector-specific configuration properties. You must set the values of these properties using System Manager (SM) before running the connector.

Standard configuration properties

Standard configuration properties provide information that all connectors use. See Appendix A, "Standard configuration properties for connectors," on page 163 for documentation of these properties. The table below provides information specific to this connector about configuration properties in the appendix.

Property	Description
CharacterEncoding	This connector does not use this property.
Locale	Because this connector has not been internationalized, you cannot change the value of this property. See release notes for the connector to determine currently supported locales.

Because this connector supports only InterChange Server Express as the integration broker, the only configuration properties relevant to it are for InterChange Server Express.

You must set at least the following standard connector configuration properties:

- AgentTraceLevel

- ApplicationName
- ControllerTraceLevel
- DeliveryTransport

Connector-specific configuration properties

Connector-specific configuration properties provide information needed by the connector agent at runtime. Connector-specific properties also provide a way of changing static information or logic within the connector agent without having to recode and rebuild the agent.

Table 36 lists the connector-specific configuration properties. See the sections that follow for explanations of the properties. Note that some of the properties contain other properties. The + character indicates the entry's position in the property hierarchy.

Note: If you do not intend to use the SOAP/JMS protocol listener or SOAP/JMS protocol handler with the connector, be sure to delete SOAP/JMS-related connector-specific properties or to leave them blank.

Table 36. Connector-specific configuration properties

Name	Possible values	Default value	Required
ConnectorType	<i>Any valid connector type</i>	WebService	Yes
DataHandlerMetaObjectName	<i>Data handler meta-object name</i>	MO_DataHandler_Default	Yes
JavaProtocolHandlerPackages	<i>Valid Java protocol handler packages</i>	com.ibm.net.ssl. internal.www.protocol	No
ProtocolHandlerFramework	<i>This is a hierarchical property and has no value</i>	None	No
+ProtocolHandlers	<i>This is a hierarchical property and has no value</i>		No
++SOAPHTTPHTTTPSHandler	<i>This is a hierarchical property. For information on its sub-properties, see "SOAPHTTPHTTTPSHandler" on page 85.</i>		Yes
++SOAPJMSHandler	<i>This is a hierarchical property. For information on its sub-properties, see "SOAPJMSHandler" on page 86.</i>		
ProtocolListenerFramework	<i>This is a hierarchical property and has no value.</i>		No
+WorkerThreadCount	<i>An integer greater than 1 that gives the number of available listener threads.</i>	10	No
+RequestPoolSize	<i>Integer greater than WorkerThreadCount that gives the resource pool size.</i>	20	No
+ProtocolListeners	<i>This is a hierarchical property and has no value</i>		
++Listener1	<i>Uniquely named protocol listener</i>		Yes
+++Protocol	<i>soap/http, soap/https, soap/jms</i>		Yes
+++SOAPDHMMimeType	<i>Any valid mime type of a SOAP data handler</i>	xml/soap	
+++ListenerSpecific	<i>Properties unique to or required by the listener See "ListenerSpecific" on page 88.</i>		
ProxyServer	<i>This is a hierarchical property and has no value</i>		No
+HttpProxyHost	<i>Host name for the HTTP proxy server</i>		No

Table 36. Connector-specific configuration properties (continued)

Name	Possible values	Default value	Required
+HttpProxyPort	Port number for the HTTP proxy server	80	No
+HttpNonProxyHosts	HTTP host(s) requiring direct connection		No
+HttpsProxyHost	Host name for the HTTPS proxy server		No
+HttpsProxyPort	Port number for the HTTPS proxy server	443	No
+HttpsNonProxyHosts	HTTPS host(s) requiring direct connection		No
+SocksProxyHost	Socks proxy server name		No
+SocksProxyPort	Socks proxy server port		No
+HttpProxyUsername	Http proxy server username		No
+HttpProxyPassword	Http proxy server password		No
+HttpsProxyUsername	Https proxy server username		No
+HttpsProxyPassword	Https proxy server password		No
SSL	This is a hierarchical property and has no value		No
+SSLVersion	SSL, SSLv2, SSLv3, TLS, TLSv1	SSL	No
+SSLDebug	true, false	false	No
+KeyStoreType	Any valid keystore type	JKS	No
+KeyStore	Path to KeyStore file.		No
+KeyStorePassword	Password for private key in KeyStore		No
+KeyStoreAlias	Alias for key pair in KeyStore		No
+TrustStore	Path to TrustStore file		No
+TrustStorePassword	Password for TrustStore		No
+UseClientAuth	true false	false	No
WSCollaborations	This is a hierarchical property creating by the WSDL Configuration Wizard and has no value See "WSCollaborations" on page 97.		
+Collaboration1	This is a hierarchical property and has no value		
++CollaborationPort1	Name of the collaboration port		Yes
+++WebServiceOperation1	This is a hierarchical property and has no value		Yes
++++BodyName	Name of web service method; must be valid XML element name		Yes
++++BodyNS	Namespace of web service method; must be valid XML namespace		Yes
++++BOName	Name of Request business object for operation		Yes
++++Mode	synch asynch	asynch	No
JNDI	This is a JMS-related hierarchical property and has no value		No
+LookupQueuesUsingJNDI	true false	false	No
+JNDIProviderURL	Valid JNDI URL		No
+InitialContextFactory	Name of factory class for initial context		No
+JNDIConnectionFactoryName	Name of connection factory to look up using JNDI context.		No
+CTX_ObjectFactories	Properties specifying additional information about security and object lookup in the JNDI context		N
+CTX_properties			

ConnectorType: If this property is set to `WebService`, when binding the collaboration port, System Manager displays the connector as a web services connector. Otherwise it is displayed as a normal connector.

Default = `WebService`.

DataHandlerMetaObjectName: This is the name of the meta-object that the data handler uses to set configuration properties.

Default = `M0_DataHandler_Default`.

JavaProtocolHandlerPackages: The value of this property gives the Java Protocol Handler packages. The connector uses the value of this property to set the system property `java.protocol.handler.pkgs`.

Default = `com.ibm.net.ssl.internal.www.protocol`.

ProtocolHandlerFramework: The Protocol Handler Framework uses this property to load and configure its protocol handlers. This is a hierarchical property and has no value.

Default = `none`.

ProtocolHandlers: This hierarchical property has no value. Its first-level children represent discrete protocol handlers.

Default = `none`.

SOAPHTTPHTTPSHandler: The name of a SOAP/HTTP-HTTPS protocol handler. Note that this is a hierarchical property. Unlike listeners, protocol handlers may not be duplicated, and there can be only one handler for each protocol. Table 37 below shows the sub-properties for the SOAP/HTTP-HTTPS protocol handler. The + character indicates the entry's position in the property hierarchy.

Table 37. SOAP/HTTP-HTTPS protocol handler configuration properties

Name	Possible values	Default value	Required
++SOAPHTTPHTTPSHandler	This is a hierarchical property and has no value.		Yes
+++Protocol	The kind of protocol the handler is implementing. For SOAP/HTTP and SOAP/HTTPS, the value is <code>soap/http</code> . Note: If you do not specify a value for this property, the connector will not initialize this protocol handler.		Yes
+++HTTPReadTimeout	A SOAP/HTTP-specific property that specifies the timeout interval (in milliseconds) while reading from the remote host (web service). If this property is not specified or if set to 0, the SOAP/HTTP protocol handler blocks indefinitely while reading from the remote host.	0	No

Figure 32 shows the properties as displayed in Connector Configurator Express.

	Standard Properties	Application Config Properties	Supported Business Objects	Trace
	Property	Value	Update Method	Encrypt
1	DataHandlerMetaObjectName	MO_DataHandler_Default	agent restart	<input type="checkbox"/>
2	ConnectorType	WebService	agent restart	<input type="checkbox"/>
3	<input type="checkbox"/> ProxyServer		agent restart	<input type="checkbox"/>
4	<input type="checkbox"/> SSL		agent restart	<input type="checkbox"/>
5	<input type="checkbox"/> ProtocolListenerFramework		agent restart	<input type="checkbox"/>
6	<input type="checkbox"/> ProtocolHandlerFramework		agent restart	<input type="checkbox"/>
7	<input type="checkbox"/> ProtocolHandlers		agent restart	<input type="checkbox"/>
8	<input type="checkbox"/> SOAPHTTPHTTPSHandler		agent restart	<input type="checkbox"/>
9	Protocol	soap/http	agent restart	<input type="checkbox"/>

11	<input type="checkbox"/> SOAPJMSHandler		agent restart	<input type="checkbox"/>
12	<input type="checkbox"/> JNDI		agent restart	<input type="checkbox"/>
13	<input type="checkbox"/> WSCollaborations		agent restart	<input type="checkbox"/>

Figure 32. SOAP/HTTP-HTTPS protocol handler properties

SOAPJMSHandler: The name of a SOAP/JMS protocol handler. Note that this is a hierarchical property. Unlike listeners, protocol handlers may not be duplicated, and there can be only one handler for each protocol. Table 38 below shows the sub-properties for the SOAP/JMS protocol handler. The + character indicates the entry's position in the property hierarchy.

Table 38. SOAP/JMS protocol handler configuration properties

Name	Possible values	Default value	Required
++SOAPJMSHandler	This is a hierarchical property and has no value.		Yes
+++Protocol	The kind of protocol the handler is implementing. For SOAP/JMS, the value is soap/jms. Note: If you do not specify a value for this property, the connector will not initialize this protocol handler.		Yes
+++ResponseWaitTimeout	This is a JMS protocol handler-specific property that specifies the timeout interval (in milliseconds) that the protocol handler waits on ReplyToQueue for synchronous request processing. If the response does not arrive during this interval, the handler fails the collaboration request. If this property is not specified or if set to 0, the protocol handler waits on ReplyToQueue indefinitely.	0	No
+++ReplyToQueue	This is a required JMS protocol handler-specific property that names the ReplyTo queue. For synchronous request processing, the handler sets the JMSReplyTo field to this JMS destination. If <code>LookupQueuesUsingJNDI = true</code> , the SOAP/JMS protocol handler looks up this queue using JNDI.	none	Yes

Figure 33 shows the properties as displayed in Connector Configurator Express.

Standard Properties		Application Config Properties		Supported Business Objects		Trace/Log Files		D...

14	<input type="checkbox"/> WSCollaborations		agent restart	<input type="checkbox"/>					

Figure 33. SOAP/JMS protocol handler properties

ProtocolListenerFramework: The protocol listener framework uses this property to load protocol listeners. This is a hierarchical property and has no value.

WorkerThreadCount: This property, which must be an integer greater than 1, establishes the number of protocol listener worker threads available to the protocol listener framework. For further information, see “Protocol listeners” on page 59. Default = 10.

RequestPoolSize: This property, which must be an integer greater than WorkerThreadCount, sets the resource pool size of the protocol listener framework. The framework can process a maximum of WorkerThreadCount + RequestPoolSize requests concurrently.

Default = 20.

ProtocolListeners: This is a hierarchical property and has no value. Each first-level child of this property represents a discrete protocol listener.

Listener1: The name of a protocol listener. There may be multiple protocol listeners. Note that this is a hierarchical property. You can create multiple instances of this property and create additional, uniquely named listeners. When doing so, you can change the listener-specific properties but not the protocol property. The names of multiple listeners must be unique. Possible names (not values): SOAPHTTPListener1, SOAPHTTPListener1, SOAPJMSListener1

Protocol: This property specifies the protocol this listener is implementing. Possible values: soap/http, soap/https, soap/jms.

Note: If you do not specify a value for this property, the connector will not initialize this protocol listener.

SOAPDHMimeType: The SOAP data handler mime type to use for the requests received by this listener.

Default = xml/soap

ListenerSpecific: Listener specific properties are unique to, or required by, the specified protocol listener. For example, the HTTP listener has a listener-specific property Port, which represents the Port number on which Listener monitors requests. Table 39 summarizes the HTTP-HTTPS listener specific properties. The + character indicates the entry's position in the property hierarchy.

Table 39. SOAP/HTTP and SOAP/HTTPS protocol listener-specific configuration properties

Name	Possible values	Default value	Required
+++SOAPHTTPListener1	<i>Unique name of an HTTP protocol listener. This is a child of the ProtocolListenerFramework -> ProtocolListeners hierarchical property. There can be multiple listeners: you may plug-in additional HTTP listeners by creating another instance of this property and its hierarchy.</i>		Yes
++++Protocol	soap/http if SOAP/HTTP protocol listener soap/https if SOAP/HTTPS protocol listener Note: If you do not specify a value for this property, the connector will not initialize this protocol listener.		Yes
++++SOAPDHMMimeType	xml/soap	xml/soap	No
++++BOPrefix	<i>The value of this property is passed to the data handler.</i>		No
++++Host	<i>The listener will listen at the IP address specified by value of this property. If Host is not specified, it defaults to localhost. Note that you may either specify a host name (DNS name) or an IP address for the machine on which the listener is running. A machine may have multiple IP addresses or multiple names.</i>	localhost	No
++++Port	<i>The port on which the listener listens for requests. If unspecified, the port defaults to 80 for SOAP/HTTP and 443 for SOAP/HTTPS. If you clone the listener within a connector, then the combination of Host and Port properties is unique or the listener may be unable to bind to the port to accept requests.</i>	80 for SOAP/HTTP listener 443 for SOAP/HTTPS listener	No
++++SocketQueueLength	<i>Length of the queue (socket queue) for incoming connection requests. Specifies how many incoming connections can be stored at one time before the host refuses connections. The maximum queue length is operating system dependent.</i>	5	No
++++RequestWaitTimeout	<i>The time interval in milli-seconds that the listener thread will block on the host and port while waiting for web service requests to arrive. If it receives a web service request before this interval, the listener will process it. Otherwise the listener thread checks whether the connector shutdown flag is set. If it is set, the connector will terminate. Otherwise it will continue to block for RequestWaitTimeout interval. If this property is set to 0, it will block for ever. If unspecified, it defaults to 60000ms.</i>	60000 (ms)	No
++++HTTPReadTimeout	<i>The time interval in milli-seconds that the listener will be blocked while reading a web service request from a client. If this parameter is set to 0, the listener indefinitely blocks until it receives the entire request message.</i>	0	No
++++HttpAsyncResponseCode	<i>The HTTP response code for asynchronous requests to the listener:</i> 200 (OK) 202 (ACCEPTED)	202 (ACCEPTED)	No

Table 39. SOAP/HTTP and SOAP/HTTPS protocol listener-specific configuration properties (continued)

Name	Possible values	Default value	Required
++++URLsConfiguration	<i>This is a hierarchical property and has no value. It contains 1 or more configurations for URLs supported by this listener and, optionally, mime type and charset values. Note that this is child property of ProtocolListenerFramework->ProtocolListeners->SOAPHTTPListener1 hierarchical property. If this property is not specified, the listener assumes default values.</i>	ContextPath: / Enabled: true Data handler MimeType: equal to the ContentType of the request Charset: NONE. For further information, see "SOAP/HTTP and SOAP/HTTPS protocol listener processing" on page 60.	No
+++++URL1	<i>This is a hierarchical property and has no value. Its children provide the name of the URL supported by this listener. There can be multiple supported URLs. Note that you can plug in additional URLs by cloning this property and its hierarchy.</i>		No
++++++ContextPath	<i>The URI for the HTTP requests received by the listener. This value must be unique among ContextPath values under the URLsConfiguration property. Otherwise the connector will log an error and fail to start. ContextPath is case sensitive. However it may contain protocol, host name and port which are case-insensitive. If protocol is specified in ContextPath, it should be http. If host is specified, it should be equal to the value of the Host listener property. If port is specified, it should be equal to the value of Port listener property.</i>		No
++++++Enabled	<i>The value of this property determines if the parent URL hierarchical property is enabled for the connector.</i>	True	No
++++++TransformationRules	<i>This is a hierarchical property and has no value. It holds one or more transformation rules.</i>		No
++++++TransformationRule1	<i>This is a hierarchical property and has no value. It holds the transformation rule.</i>		No
+++++++ContentType	<i>The value of this property specifies the ContentType of the incoming request for which special handling (data handler mime type or charset) should be applied. If ContentType is not specified by the TransformationRuleN hierarchical property, the connector logs a warning message and ignores the TransformationRuleN property. Specifying the special value */* for this property enables the protocol listeners to apply this rule to any ContentType. Note that if a listener finds more than one rule for the same context path that shares a ContentType, the listener logs an error and fails to initialize.</i>		No
+++++++MimeType	<i>The mime type to use when calling a data handler to process requests of the specified ContentType.</i>		No
+++++++Charset	<i>Charset to use when transforming the request of the specified ContentType into a business object.</i>		No

Figure 34 shows the properties as displayed in Connector Configurator Express.

Figure 34. SOAP/HTTP protocol listener properties

Table 40 summarizes the SOAP/JMS protocol listener-specific properties. The + character indicates the entry's position in the property hierarchy.

Table 40. SOAP/JMS protocol listener-specific configuration properties

Name	Possible values	Default value	Required
+++SOAPJMSListener1	Unique name of a JMS protocol listener. This is a child of the ProtocolListenerFramework -> ProtocolListeners hierarchical property. There can be multiple listeners: you may plug-in additional JMS listeners by creating another instance of this property and its hierarchy.		Yes
++++Protocol	soap/jms		Yes
++++SOAPDHMimeType	xml/soap	xml/soap	No
++++BOPrefix	The value of this property is passed to the data handler specified by SOAPDHMimeType property.		No

Table 40. SOAP/JMS protocol listener-specific configuration properties (continued)

Name	Possible values	Default value	Required
++++RequestWaitTimeout	<i>This property sets the time interval that the SOAP/JMS listener thread blocks the InputQueue while waiting for a web service request. If it receives a web service request within this interval, the listener processes it. If it does not receive the request within this interval, the listener thread first checks if the connector shutdown flag is set. If the connector shutdown flag is set, the connector will terminate. Otherwise it will continue to block for RequestWaitTimeout interval. If this property is set to 0, it will block indefinitely.</i>	60000 milliseconds	No
++++SessionPoolSize	<i>Maximum number of sessions that can be allocated for a given listener and its worker threads. The minimum number of sessions (and default) is 2. For larger session pool sizes, the connector requires more memory.</i>	2	No
++++InputQueue	<i>This property gives the name of the input queue that the listener polls for inbound messages from web services. If LookupQueuesUsingJNDI = true, the listener looks up this queue using JNDI and the value of the InputQueue property is set to the jndiDestinationName attribute of the jms:address element of the SOAP/JMS binding. The jms:address element is specified in the wsdl:port section of the WSDL document. If during WSDL generation you select the SOAP/JMS listener, System Manager automatically creates the jndiDestinationName attribute using the value of this property. If LookupQueueUsingJNDI = false, then System Manager creates the jmsProviderDestinationName attribute instead.</i>		Yes
++++InProgressQueue	<i>This property gives the name of the in-progress queue. The listener sends copies of inbound messages from the InputQueue to InProgressQueue. If LookupQueuesUsingJNDI = true, the listener looks up this queue using JNDI.</i>		Yes
++++ArchiveQueue	<i>This property gives the name of the archival queue. The listener sends copies of successfully processed messages from the InProgressQueue to ArchiveQueue. If LookupQueuesUsingJNDI = true, the listener looks up this queue using JNDI.</i>		No
++++UnsubscribedQueue	<i>This property gives the name of the unsubscribed queue. The listener sends copies of unsubscribed messages from the InProgressQueue to UnsubscribedQueue. If LookupQueueUsingJNDI = true, the listener looks up this queue using JNDI.</i>		No
++++ErrorQueue	<i>This property gives the name of the error queue. The listener sends copies of failed messages to the ErrorQueue. If LookupQueueUsingJNDI = true, the listener looks up this queue using JNDI.</i>		No

Table 40. SOAP/JMS protocol listener-specific configuration properties (continued)

Name	Possible values	Default value	Required
++++InDoubtEvents	<p><i>This property specifies how to handle messages in the InProgressQueue that are not fully processed due to unexpected connector termination. It can take one of the following values:</i></p> <ul style="list-style-type: none"> • <i>FailOnStartup</i> Log an error and immediately shutdown • <i>Reprocess</i> Process the remaining messages in the InProgressQueue • <i>Ignore</i> Disregard any messages in the in-progress queue • <i>LogError</i> Log an error but do not shutdown 	Ignore	No
++++ReplyToQueue	<p><i>This property gives the name of the ReplyTo queue. The WSDL Configuration Wizard reads this property and writes it to the WSDL document. If this property is not specified, the utility does not create a ReplyTo JMS header in the SOAP/JMS binding in the WSDL document. (The listener does not use this property.) If JNDI properties are specified and LookupQueueUsingJNDI = false, the WSDL Generation Utility still create JNDI specific attributes in the WSDL document. Note that these JNDI-specific attributes are required because the SOAP/JMS binding does not provide any way to specify a ReplyTo attribute without JNDI. Though JNDI lookup for the InputQueue is not required, JNDI-specific properties are required for the ReplyTo queue. If the WSDL utility does not find JNDI-specific properties, the utility cannot create a ReplyTo attribute in the SOAP/JMS binding.</i></p>		
++++ JMSVendorURI	<p><i>A string that uniquely identifies the JMS implementation and that corresponds to the jmsVendorURI attribute of the jms:address element of the SOAP/JMS binding. The jms:address element is specified in wsdl:port section of the WSDL document. The listener does not use this property.</i></p>		No

Figure 35 shows the properties as displayed in Connector Configurator Express.

Figure 35. SOAP/JMS protocol listener properties

Note: Make sure that queue names specified in following properties are unique:

- InputQueue
- InProgressQueue
- ArchiveQueue
- UnsubscribedQueue
- ErrorQueue

ProxyServer: Configure the values under this property when the network uses a proxy server. This is a hierarchical property and has no value. The values specified under this property are used by the SOAP/HTTP/HTTPS protocol handlers.

Figure 36 shows the ProxyServer properties as displayed in Connector Configurator Express and discussed below.

Figure 36. ProxyServer properties

HttpProxyHost: The host name for the HTTP proxy server. Specify this property if the network uses a proxy server for HTTP protocol.

Default = none

HttpProxyPort: The port number that the connector uses to connect to the HTTP proxy server.

Default = 80

HttpNonProxyHosts: The value of this property gives one or more hosts (for HTTP) that must be connected not through the proxy server but directly. The value can be a list of hosts, each separated by a "|".

Default = none

HttpsProxyHost: The host name for the HTTPS proxy server.

Default = none

HttpsProxyPort: The port number that the connector uses to connect to the HTTPS proxy server.

Default = 443

HttpsNonProxyHosts: The value of this property gives one or more hosts (for HTTPS) that must be connected not through the proxy server but directly. The value can be a list of hosts, each separated by a "|".

Default = none

SocksProxyHost: The host name for the Socks Proxy server. Specify this property when the network uses a socks proxy.

Note: The underlying JDK must support socks.

Default = none

SocksProxyPort: The port number to connect to the Socks Proxy server. Specify this property when the network uses a socks proxy.

Default = none

HttpProxyUsername: The username for the HTTP proxy server. If the destination for the web service request is an HTTP URL and you specify ProxyServer ->HttpProxyUsername, the SOAP HTTP/HTTPS protocol handler creates a Proxy-Authorization header when authenticating with the proxy. The handler uses the CONNECT method for authentication.

The proxy-authentication header is base64 encoded and has the following structure:

Proxy-Authorization: Basic
Base64EncodedString

The handler concatenates the username and the password property values, separated by a colon (:), to create the base64 encoded string.

Default = none

HttpProxyPassword: The password for the HTTP proxy server. For more on how this value is used, see "HttpProxyUsername."

Default = none

HttpsProxyUsername: The username for the HTTPS proxy server. If the destination for the web service request is an HTTPS URL and you specify ProxyServer ->HttpsProxyUsername, the SOAP HTTP/HTTPS protocol handler creates a Proxy-Authorization header for authentication with the proxy. The handler concatenates the HttpsProxyUsername and HttpsProxyPassword configuration property values, separated by colon (:), to create the base64 encoded string.

Default = none

HttpsProxyPassword: The password for the HTTPS proxy server. For more on how this value is used, see "HttpsProxyUsername."

Default = none

SSL: Specify values under this property to configure SSL for the connector. This is a hierarchical property and has no value.

Figure 37 shows the SSL properties as displayed in Connector Configurator Express and discussed below.

Standard Properties		Application Config Properties		Supported Business Objects		Trace/Log Files		D:
	Property	Value	Update Method	Encrypt	Description			
1	DataHandlerMetaObjectName	MO_DataHandler_Default	agent restart	<input type="checkbox"/>				
2	ConnectorType	WebService	agent restart	<input type="checkbox"/>				
3	ProxyServer		agent restart	<input type="checkbox"/>				
4	SSL		agent restart	<input type="checkbox"/>				
5	SSLVersion	SSL	agent restart	<input type="checkbox"/>				
6	SSLDebug	False	agent restart	<input type="checkbox"/>				
7	KeyStoreType	JKS	agent restart	<input type="checkbox"/>				
8	KeyStore		agent restart	<input type="checkbox"/>				
9	KeyStorePassword		agent restart	<input type="checkbox"/>				
10	KeyStoreAlias		agent restart	<input type="checkbox"/>				
11	TrustStore		agent restart	<input type="checkbox"/>				
12	TrustStorePassword		agent restart	<input type="checkbox"/>				
13	UseClientAuth	False	agent restart	<input type="checkbox"/>				
14	ProtocolListenerFramework		agent restart	<input type="checkbox"/>				
15	ProtocolHandlerFramework		agent restart	<input type="checkbox"/>				
16	JNDI		agent restart	<input type="checkbox"/>				
17	WSCollaborations		agent restart	<input type="checkbox"/>				

Figure 37. SSL properties

SSLVersion: The SSL version to be used by the connector. For further information, see IBM JSSE documentation for the supported SSL versions.

Default = SSL

SSLDebug: If value of this property is set to true, the connector sets the value of the `javax.net.debug` system property to true. IBM JSSE uses this property to turn on the trace facility. For further information, refer to IBM JSSE documentation.

Default = false

KeyStoreType: The value of this property gives the type of the KeyStore and TrustStore. For further information, see IBM JSSE documentation for valid keystore types.

Default = JKS

KeyStore: This property gives the complete path to keystore file. If KeyStore and/or KeyStoreAlias properties are not specified, KeyStorePassword, KeyStoreAlias, TrustStore, TrustStorePassword properties are ignored. The connector will fail to startup if it cannot load the keystore using the path specified in this property. The path must be the complete path to the keystore file.

Default = None

KeyStorePassword: This property gives the password for the private key in the Keystore.

Default = None

KeyStoreAlias: This property gives the alias for the key pair in the KeyStore. SOAP/HTTPS listeners use this private key from the KeyStore. Also, the SOAP/HTTP-HTTPS protocol handler uses this alias from the KeyStore when invoking web services that require client authentication. The property must be set to a valid JSSE alias.

Default = None

TrustStore: This property gives the complete path to the TrustStore. TrustStore is used for storing the certificates that are trusted by the connector. TrustStore must be of the same type as KeyStore. You must specify the complete path to the TrustStore file.

Default = None

TrustStorePassword: This property gives the password for the Truststore.

Default = None

UseClientAuth: This property specifies whether SSL client authentication is used. When it is set to true, SOAP/HTTPS listeners use client authentication.

Default = false

WSCollaborations: This property is created automatically when you expose a collaboration object as a web services and is used for non-TLOs. This is a hierarchical property and has no value. Each first-level child of this property represents a collaboration exposed as a web service. For information on the tools used to automatically create these properties, see Chapter 7, "Exposing collaborations as web services," on page 139.

Note: If you delete a collaboration or its port in System Manager, the connector will not automatically delete the properties representing the collaboration. You must delete these properties using Connector Configurator Express.

Figure 38 shows WSCollaborations properties as displayed in Connector Configurator Express and discussed below.

Standard Properties		Application Config Properties	Supported Business Objects	Trace/Log Files	D
	Property	Value	Update	Encrypt	Description
1	DataHandlerMetaObjectName	MO_DataHandler_Default	agent restart	<input type="checkbox"/>	
2	ConnectorType	WebService	agent restart	<input type="checkbox"/>	
3	ProxyServer		agent restart	<input type="checkbox"/>	
4	SSL		agent restart	<input type="checkbox"/>	
5	ProtocolListenerFramework		agent restart	<input type="checkbox"/>	
6	ProtocolHandlerFramework		agent restart	<input type="checkbox"/>	
7	JNDI		agent restart	<input type="checkbox"/>	
8	WSCollaborations		agent restart	<input type="checkbox"/>	
9	Collaboration1		agent restart	<input type="checkbox"/>	
10	CollaborationPort1		agent restart	<input type="checkbox"/>	
11	WebServiceOperation1		agent restart	<input type="checkbox"/>	
12	BodyName		agent restart	<input type="checkbox"/>	
13	BodyNS		agent restart	<input type="checkbox"/>	
14	BOName		agent restart	<input type="checkbox"/>	
15	BOVerb		agent restart	<input type="checkbox"/>	
16	Synchronous		agent restart	<input type="checkbox"/>	

Figure 38. WSCollaborations properties

Collaboration1: This property names the collaboration object that is exposed as web service via this connector. This is a hierarchical property and has no value. There can be multiple such properties, one for each of collaboration object that is exposed as a web service. Each first-level child of this property represents a port of this collaboration object.

CollaborationPort1: This property names the collaboration port. This is a hierarchical property and has no value. There can be multiple such properties, one for each of the ports of this collaboration that are bound to the connector. Each first-level child of this property represents a web services operation.

WebServiceOperation1: This property represents a web services operation for the collaboration object. This is a hierarchical property and has no value. There may be one or more such properties, one for each of the web services operation defined by the user at the time of WSDL document generation.

BodyName: This property gives the name of the web service method and must be a valid XML element name.

Default = none

BodyNS: This property gives the namespace of the web service method and must be a valid XML namespace.

Default = none

BOName: This property gives the name of the Request business object for this operation.

Default = none

Mode: This property specifies the processing mode for the operation. If it is set to synch, the connector synchronously invokes the collaboration. Otherwise and by default, the connector asynchronously invokes the collaboration as a request only operation.

Default = asynch

JNDI: The connector maintains one set of JNDI (Java Naming and Directory Interface) provider properties that are used by the SOAP/JMS protocol handler and JMS protocol listener when connecting to JNDI. This is a hierarchical property and has no value. The connector uses JNDI to lookup the JMS connection factory object. Note that the WSDL Configuration Wizard uses this property when generating SOAP/JMS bindings.

Figure 39 shows JNDI properties as displayed in Connector Configurator Express and discussed below.

Standard Properties Application Config Properties Supported Business Objects Trace/Log Files D:					
	Property	Value	Update Method	Encrypt	Description
1	DataHandlerMetaObjectName	MO_DataHandler_Default	agent restart	<input type="checkbox"/>	
2	ConnectorType	WebService	agent restart	<input type="checkbox"/>	
3	ProxyServer		agent restart	<input type="checkbox"/>	
4	SSL		agent restart	<input type="checkbox"/>	
5	ProtocolListenerFramework		agent restart	<input type="checkbox"/>	
6	ProtocolHandlerFramework		agent restart	<input type="checkbox"/>	
7	JNDI		agent restart	<input type="checkbox"/>	
8	LookupQueuesUsingJNDI	False	agent restart	<input type="checkbox"/>	
9	InitialContextFactory		agent restart	<input type="checkbox"/>	
10	JNDIConnectionFactoryName		agent restart	<input type="checkbox"/>	
11	CTX_ObjectFactories		agent restart	<input type="checkbox"/>	
12	CTX_StateFactories		agent restart	<input type="checkbox"/>	
13	CTX_URLPackagePrefixes		agent restart	<input type="checkbox"/>	
14	CTX_DNS_URL		agent restart	<input type="checkbox"/>	
15	CTX_Authoritative		agent restart	<input type="checkbox"/>	
16	CTX_Batchsize		agent restart	<input type="checkbox"/>	
17	CTX_Referral		agent restart	<input type="checkbox"/>	
18	CTX_SecurityProtocol		agent restart	<input type="checkbox"/>	
19	CTX_SecurityAuthentication		agent restart	<input type="checkbox"/>	
20	CTX_SecurityPrincipal		agent restart	<input type="checkbox"/>	
21	CTX_SecurityCredentials		agent restart	<input type="checkbox"/>	
22	CTX_Language		agent restart	<input type="checkbox"/>	
23	WSCollaborations		agent restart	<input type="checkbox"/>	

Figure 39. JNDI properties

LookupQueuesUsingJNDI: If the value of this property is set to true, the connector's SOAP/JMS listeners and SOAP/JMS protocol handler will look up queues using JNDI.

Default = false

JNDIProviderURL: This property gives the URL of the JNDI service provider, which corresponds to jndiProviderURL attribute of the jms:address element of the SOAP/JMS binding. The jms:address element is specified in the wsdl:port section. This is used as the default JNDI provider and must be a valid JNDI URL. For further information, see JNDI specifications.

Default = none

InitialContextFactory: This property gives the fully qualified class name of the factory class (for example, com.ibm.NamingFactory) that creates an initial context. Note that this corresponds to the initialContextFactory attribute of the jms:address element of the SOAP/JMS binding. The jms:address element is specified in the wsdl:port section.

Default = none

JNDIConnectionFactoryName: This property gives the name of the connection factory to look up using JNDI context. Note that this corresponds to the jndiConnectionFactoryName attribute of the jms:address element of the SOAP/JMS binding. The jms:address element is specified in the wsdl:port section.

Default = none

CTX_ObjectFactories: Properties specifying additional information about security and object lookup in the JNDI context. Table 41 summarizes these properties. The + character indicates the entry's position in the property hierarchy.

Table 41. Java Naming and Directory Interface (JNDI) provider properties

Property Name	Description
+CTX_StateFactories +CTX_URLPackagePrefixes +CTX_DNS_URL +CTX_Authoritative +CTX_Batchsize +CTX_Referral +CTX_SecurityProtocol +CTX_SecurityAuthentication +CTX_SecurityPrincipal +CTX_SecurityCredentials +CTX_Language	Properties specifying additional information about security and object lookup in the JNDI context. See J2EE documentation for more information. These properties reflect those used by the Adapter for JMS.

Creating multiple protocol listeners

You can create multiple instances of protocol listeners. Protocol listeners are configured as child properties of the ProtocolListenerFramework -> ProtocolListeners connector property. Each child (of ProtocolListenerFramework -> ProtocolListeners) identifies a distinct protocol listener for the connector. Accordingly, you can create additional protocol listeners by configuring new child properties under the ProtocolListeners property. Make sure that you specify all of the child properties of the newly created listener property. Each listener must be uniquely named. However, you do not change the listener Protocol property (soap/http, soap/https, or soap/jms), which remains the same for multiple instances of a listener.

Note: The Protocol property is very important because it serves as a switch. If you do not want to use a listener or a handler, leave this property empty.

If you are creating multiple instances of a SOAP/HTTP or SOAP/HTTPS listener, be sure to specify different Port and Host properties for each instance. If you are specifying multiple SOAP/JMS listeners, be sure to use a different set of queues for each instance.

You cannot create multiple instances of a handler. There can be only one handler for each protocol.

Connector at startup

When you start the connector, the `init()` method reads the configuration properties that were set using System Manager's Connector Configurator Express. For proper functioning, be sure not to disable connector polling (connector polling is enabled by default). The sections below describe what occurs.

Proxy setup

If you specify the `ProxyServer` connector-specific property, the connector sets up the proxy system properties. A proxy server is used with the SOAP/HTTP-HTTPS protocol handler for request processing only. The connector also traces each of the system properties it sets up. For more on the `ProxyServer` property, see "Connector-specific configuration properties" on page 83.

JNDI initialization

The connector-specific property `JNDI` specifies the JNDI to be used by the connector. The connector uses JNDI to lookup the JMS Connection Factory object. If `JNDI "LookupQueuesUsingJNDI"` is set to true, the connector looks up JMS queue objects using JNDI.

If you do not want to use SOAP/JMS (the SOAP/JMS protocol listener and SOAP/JMS protocol handler), you need not specify JNDI properties. If you specify JNDI properties and the connector cannot initialize JNDI, the connector terminates. Note that the connector will not initialize JNDI unless all of the following connector-specific JNDI properties are specified:

- `JNDIProviderURL`
- `InitialContextFactory`
- `JNDIConnectionFactoryName`

Note: JNDI implementation is not provided with the connector

Protocol listener framework initialization

During startup the connector instantiates the protocol listener framework and initializes it. This framework reads the connector-specific property `ProtocolListenerFramework`. The connector then reads the value of `WorkerThreads` and `RequestPoolSize` connector properties. If the `ProtocolListenerFramework` property is unspecified or missing, the connector cannot receive requests from web service clients and logs a warning.

The connector next reads the `ProtocolListenerFramework -> ProtocolListeners` property. All the first-level properties of the `ProtocolListeners` property represent protocol listeners. The protocol listener framework attempts to load and initialize each of the listeners and traces them. If persistent event capable, the listener attempts an event recovery.

Protocol handler framework initialization

The connector reads the connector-specific property `ProtocolHandlerFramework` and instantiates and initializes the protocol handler framework. If this property is missing or not set properly, the connector cannot perform request processing and logs a warning. Next the connector reads all the `ProtocolHandlerFramework "ProtocolHandlers"` properties, which correspond to protocol handlers, and attempts to load, initialize, and trace them. Note that the protocol handlers are loaded

during connector initialization and are not instantiated when a collaboration makes a service request. The protocol handlers are multi-thread safe.

Logging

The connector logs a warning when:

- the `ProtocolListenerFramework` property is not specified. The connector warns that it cannot perform event notification. (Collaborations exposed as web services cannot be invoked by the connector.)
 - the `ProtocolHandlerFramework` property is not specified. The connector warns that it cannot perform (collaboration) request processing.
-

Tracing

Tracing is an optional debugging feature you can turn on to closely follow connector behavior. Trace messages, by default, are written to STDOUT. See the connector configuration properties for more on configuring trace messages.

Connector trace levels are as follows:

- | | |
|---------|---|
| Level 0 | This level is used for trace messages that identify the connector version. |
| Level 1 | Trace each time the <code>pollForEvents</code> method is called. Trace the TLO name created by listeners for delivery to InterChange Server Express. Trace the Request business object name and the corresponding attribute name in the TLO. |
| Level 2 | Use this level for trace messages that log each time a business object is posted to InterChange Server Express, either from <code>gotAppEvent()</code> or <code>executeCollaboration()</code> . Also, trace which protocol handler is processing the request. |
| Level 3 | Trace the ASI of the business object being processed. Trace attributes of the business object being processed. Trace the TLO of the SOAP Request business object during event notification. Trace the business object returned by the data handler. |
| Level 4 | Trace the transport headers associated with: <ul style="list-style-type: none">• a SOAP request message retrieved by the protocol listener from the transport• a response message sent to the client by the protocol listener. Trace the spawning of threads, all ASI that is processed, and all entries and exits of important functions. |
| Level 5 | Trace the following: <ul style="list-style-type: none">• the entries and exits for each important method• all of the configuration-specific properties• the loading of each of the protocol listeners• the request message retrieved by the protocol listener from the transport• the response message sent on the transport to the client by the protocol listener• the loading of each protocol handler• the messages returned by the SOAP data handler |

- business object dumps of the TLO sent to the collaboration
- dumps of the business objects returned by the data handler.

Chapter 5. SOAP data handler

- “Configuring the SOAP data handler”
- “SOAP data handler processing” on page 111
- “SOAP style and use guidelines” on page 134
- “XML limitations” on page 136

The SOAP data handler is a data-conversion module whose primary roles are to convert business objects into SOAP messages and SOAP messages into business objects. The SOAP data handler performs the following functions:

- Request Processing
 - SOAP request business object to SOAP request message
 - SOAP response message to SOAP response business object
 - SOAP fault message to SOAP fault business object
- Event Processing
 - SOAP request message to SOAP request business object
 - SOAP response business object to SOAP response message
 - SOAP fault business object to SOAP fault message

This chapter describes how to configure the SOAP data handler, how the SOAP data handler processes messages and objects, and how to customize the data handler.

Configuring the SOAP data handler

The SOAP data handler is a pivotal component in the connector for web services. The connector calls the SOAP data handler to transform business objects into web services-compliant SOAP messages.

When collaborations are exposed as web services, the connector also calls the SOAP data handler. The data handler then transforms SOAP messages sent from a remote trading partner (or internal client) into business objects. The connector passes the business objects to collaborations that have been configured for web services.

The information in data handler meta-objects plays a crucial role in these transformations. You configure this information after you install the product files, but before startup. Unless you are adding a custom name handler, you can use the default SOAP data handler configuration to save time. You must, however, configure specific meta-object information for each data handler transformation. Data handler meta-objects are discussed in the sections below.

Meta-object requirements

Meta-objects are business objects that contain configuration information. The connector uses meta-objects at runtime to configure the data handler and create instances of it. The SOAP data handler also uses meta-objects to locate the body of a SOAP message, to determine the business object and verb that the body corresponds to, to encode a business object in a SOAP message, and to perform a number of other tasks discussed in this chapter. This section describes requirements for these meta-objects.

Meta-object hierarchy and terminology

Figure 28 shows the meta-object structure for the adapter for web services product. The meta-objects are named in bold in the illustration and discussed below.

Figure 40. Meta-object structure

The following terminology is used throughout this document when discussing meta-objects:

- **MO_DataHandler_Default** Data handler meta-object used by the connector agent to determine which data handler to instantiate. This is specified in the `DataHandlerMetaObjectName` property of the connector.
- **MO_DataHandler_DefaultSOAPConfig** Child data handler meta-object specifically for the SOAP data handler.
- **SOAP Configuration Meta-Object (SOAP Config MO)** A meta-object specified as child of each SOAP business object and that contains the configuration information for a single transformation from business object to SOAP message or vice-versa.

MO_DataHandler_Default

The **MO_DataHandler_Default** is the top-level meta-object for all data handlers that are called from connectors. The MIME type contained in these meta-objects determines which data handler to use. The connector agent uses this meta-object to create instances of the SOAP data handler. Accordingly, the **MO_DataHandler_Default** object must include an attribute named `xml_soap` that is of type **MO_DataHandler_DefaultSOAPConfig**.

You can configure the **MO_DataHandler_Default** object after installing it. You must add `xml_soap` of type **MO_DataHandler_DefaultSOAPConfig**.

MO_DataHandler_DefaultSOAPConfig

The connector agent uses this meta-object to create and configure the SOAP data handler at runtime. The **MO_DataHandler_DefaultSOAPConfig** has two attributes of type string that designate:

- The class name for the SOAP data handler
- The SOAP name handler

These attributes are shown in Table 42.

Unless you wish to implement a custom name handler, which is discussed later in this chapter, you can use the **MO_DataHandler_DefaultSOAPConfig** as delivered and installed. No configuration is needed.

Table 42. Meta-object attributes for *MO_DataHandler_DefaultSOAPConfig*

Name	Type	Default value	Description
ClassName	String	com.ibm.adapters .dataHandlers.xml . soap	Standard attribute used by the data handler base class to find the class name based on a MIME type passed into the createHandler method.
SOAPName Handler	String		Name of the SOAP name handler to use.

SOAP configuration meta-object: child of every SOAP business object

A SOAP Config MO defines the data formatting behavior for one data handler transformation — either a SOAP-message-to-business-object or business-object-to-SOAP-message transformation. A SOAP Config MO is a child of a SOAP business object. These child SOAP Config MOs are critical for default business object resolution. When using default business object resolution, all child SOAP Config MOs, whether for a request, response, or fault object, must have unique entries for default values of BodyName and BodyNS. Table 43 shows these and other attributes of a SOAP Config MO.

Table 43. Attributes for *SOAP Config MOs*

Name	Required	Description
BodyNS	Yes	Namespace to be used for SOAP body.
BodyName	Yes	Name of the body of the SOAP message. For SOAP fault, set the default value to soap: fault.
BOVerb	Yes	Verb of the business object that contains the SOAP Config MO.
TypeInfo	No	True or false attribute that dictates whether type information (xsi:type) is written to and read from a SOAP element. Default = false
TypeCheck	No	This property is read only if TypeInfo is set to true. Possible values are none and strict. If none, type validation is skipped when reading SOAP messages into this business object. If strict, the data handler will strictly validate all SOAP type names and namespaces against the business object's application-specific information. Default = none
Style	No	This property dictates the SOAP message style and has implications for other attributes such as BodyName and BodyNS. The possible values for this attribute are rpc and document. Default = rpc
Use	No	This property dictates the SOAP message's use and affects how the SOAP body is constructed from a business object. The possible values are literal and encoded. The default is literal.

Figure 41 shows the relationship between a SOAP business object and a SOAP Config MO.

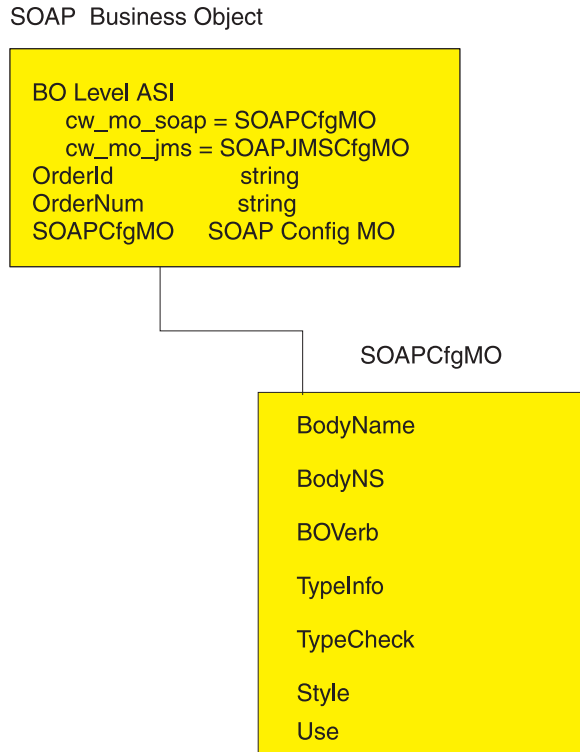

Figure 41. SOAP configuration meta-object

Figure 41 shows a SOAP response business object and its child business object. The child business object, SOAPCfgMO, is a SOAP Config MO that specifies the behavior for the SOAP data handler for a transformation from a business object response to a SOAP response message. The attribute indicating the child SOAP Config MO must use the name-value pair beginning cw_mo_soap.

By convention, when reading business object level application-specific information beginning with cw_mo_, the data handler recognizes that the child object specified in the name-value pair contains transformation meta-object information and therefore does not include this child as content in the body of the message it is transforming. In the example, the child objects indicated by the name-value pairs cw_mo_jms and cw_mo_soap are recognized as meta-objects and not written into the SOAP response message. In addition, the SOAP data handler ignores all business object level application-specific information beginning with cw_mo_ except for cw_mo_soap. Accordingly, the SOAP data handler ignores the application-specific information such as cw_mo_tpi. But the SOAP data handler reads and uses the SOAP Config MO specified in cw_mo_soap to execute the SOAP response transformation from business object to SOAP message.

All SOAP business objects must have child SOAP Config MOs and these must be specified as application-specific information at the business object level. Much of this is automated: when you use the WSDL ODA to generate business objects for SOAP messages, the SOAP Config MOs are automatically generated for you.

Style and Use impact on SOAP messages

The SOAP Config MO optional properties, Style and Use, affect the way that SOAP messages are created. The possible values for Style are rpc and document, and for

Use are literal and encoded. The sections below discuss how the Style and Use combinations impact SOAP message creation.

rpc/literal: When the Style property is set to rpc and the Use property to literal, the Body Name and Body Namespace for a SOAP Message are read from the SOAP ConfigMO's BodyName and BodyNS properties, respectively.

The following is an example of an rpc/literal style message where the Body Name and Body Namespace have been resolved to getOrderStatus and OrderStatusNS respectively:

```
<?xml version='1.0' encoding='UTF-8'?>
<SOAP-ENV:Envelope xmlns:SOAP-ENV='http://schemas.xmlsoap.org/soap/envelope/'
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <SOAP-ENV:Body>
    <ns1:getOrderStatus xmlns:ns1="http://www.ibm.com/">
      <Part1>
        <ns2:Elem1 xmlns:ns2="http://www.ibm.com/elem1">
          <Child1>1</Child1>
          <Child2>2</Child2>
        </ns2:Elem1>
        <ns3:Elem1 xmlns:ns3="http://www.ibm.com/elem1">
          <Child1>3</Child1>
          <Child2>4</Child2>
        </ns3:Elem1>
        <Elem2>10</Elem2>
      </Part1>
    </ns1:getOrderStatus>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

Figure 42 shows the corresponding business object for this rpc/literal message.

Name	Type	Key	Card	Default	App Spec Info
Part1	SOAP_Part1Type	<input checked="" type="checkbox"/>	1		
Elem1	SOAP_MaxType	<input checked="" type="checkbox"/>	N		maxoccurs=5;elem_ns=http://www.ibm.com/elem1
Child1	String	<input checked="" type="checkbox"/>			
Child2	String	<input type="checkbox"/>			
ObjectEventId	String				
Elem2	String	<input type="checkbox"/>			
ObjectEventId	String				
SOAPConfigMO	SOAP_Req_Cfg_MO	<input type="checkbox"/>	1		
BodyName	String	<input checked="" type="checkbox"/>		getOrderStatus	
BodyNS	String	<input type="checkbox"/>		http://www.ibm.com	
BOVerb	String	<input type="checkbox"/>		Retrieve	
TypeInfo	String	<input type="checkbox"/>		false	
TypeCheck	String	<input type="checkbox"/>		none	
Style	String	<input type="checkbox"/>		rpc	
Use	String	<input type="checkbox"/>		literal	

Figure 42. rpc/literal SOAP Config MO

Note: You must configure these properties and business object attributes appropriately so that a corresponding SOAP message is created.

rpc/encoded: When the Style property is set to rpc and Use is set to encoded, the Body Name and Body Namespace for a SOAP Message are read from the Child

ConfigMO's BodyName and BodyNS properties respectively. Also, the SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/" attribute is added to the Body tag.

The following is an example of an rpc/encoded message where the Body Name and Body Namespace have been resolved to getOrderStatus and OrderStatusNS respectively.

```
<?xml version='1.0' encoding='UTF-8'?>
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"

Figure 44. document/literal SOAP Config MO

Note that the encodingStyle attribute in the XML code fragment has not been set.

document/encoded: This Style/Use combination is not supported. The data handler fails if it encounters a SOAP ConfigMO with Style set to document and Use set to encoded.

SOAP data handler processing

The SOAP data handler performs transformations between SOAP messages and business objects in the following ways:

- **SOAP message to business object processing**

- Request-message-to-SOAP-request-business-object data handling occurs at that stage in event processing when web service clients make calls to collaborations exposed as web services
- Response-message-to-SOAP-response-business-object data handling occurs during request processing when a web service returns a SOAP response message to a collaboration that had invoked it. Alternatively, fault-message-to-SOAP-business-object data handling may occur at this phase.

For a detailed description of this processing, see “SOAP-body-message-to-business-object processing” on page 112 later in this section.

- **Business object to SOAP message processing**

- Business-object-to-SOAP-response-message data handling occurs during event processing when a response business object is returned by the collaboration

that is exposed as a web service. Alternatively, fault business object-to-SOAP-fault-message data handling may occur at this phase.

- Business-object-to-SOAP-request-message data handling occurs at that phase of request processing when a collaboration makes a service call to the connector to convert a business object to a SOAP request message.

For a detailed description of this processing, see “Business-object-to-SOAP-message-body processing” on page 114 later in this section.

SOAP-body-message-to-business-object processing

This section provides a step-by-step description of the SOAP-body-message-to-business-object transformation.

1. The SOAP data handler receives a SOAP message.
2. Using Apache SOAP APIs, the data handler parses the SOAP message.
3. The data handler extracts the components of the SOAP message: envelope, header, and body.
4. **Header processing** For more, see “SOAP-header-message-to-business-object processing” on page 113.
5. **Body processing** The data handler reads the first element of the SOAP body to determine if it carries a fault or data. If the body content is not a fault, the data handler does the following:
 - a. Performs business object resolution to determine which business object will be used in the transformation. If you have configured a custom name handler, the default business object resolution discussed below may not apply. For more on specifying a pluggable name handler, see “Specifying a pluggable name handler” on page 133.
 - b. The data handler also resolves the SOAP Config MO (a child of the SOAP business object that the data handler is creating) that will be used for the transformation. If an instance of the SOAP Config MO does not exist, the data handler creates an instance and reads its default values. From the ConfigMO attribute values, the data handler reads the business object verb. The data handler instantiates the SOAP business object and sets the verb accordingly. This is the business object into which the data handler will attempt to write the SOAP message.
 - c. The data handler continues parsing the SOAP message one element at a time. For `rpc`, the data handler expects the first element to be the parent.
 - d. The data handler expects that the attributes of the business object (or its application-specific information: for further information, see “ASI in business-object-to-SOAP-message transformations” on page 119) should have the same name as the child elements. If the attribute is not found in the business object, the data handler throws an exception. Child elements may be of simple type or they may be of complex type. Complex elements are those which have child elements.
 - e. **Simple element** If a child element is a simple element, by default, the data handler expects a business object attribute with the same name (or ASI) as that of a simple element. The data handler reads the value of the simple element and sets it in the business object.
 - f. **Complex element** If a child element is of complex type, the data handler expects the business object to have an attribute with the same name (or ASI) and of type child business object. This attribute may be of single cardinality or of multiple-cardinality depending on if there will be a complex SOAP element or SOAP array. Next the data handler instantiates the child business object (by default, the type of the attribute gives the name of the child

business object) and reads all the child elements of this complex element, setting their values in the child business object. The data handler sets this child business object into the parent business object attribute after verifying the cardinality of this attribute. If the attribute is cardinality n, the data handler appends this business object to the container. The complex element can have either simple or complex child elements. These are also handled in the same way: if it is simple element, the data handler sets the value in the child BO; if it is a complex element, the data handler instantiates a child business object.

6. **Fault processing** The data handler reads the name of the first element of the SOAP body to determine if it is a fault. If the name of the first element is `Fault`, the data handler concludes that this is a fault message. Fault business object resolution occurs to determine into which business object this fault message should be transformed. The data handler then follows the same processing as that for body processing. The data handler expects that the business object specified in the child business object should have the following attributes:
 - a. `faultcode`: Required. String attribute
 - b. `faultstring`: Required. String attribute
 - c. `faultactor`: Not required String attribute
 - d. `detail`: Not required. Child BO
7. If fault processing fails for any reason, the exception thrown will contain the text from the `faultcode`, `faultstring` and `faultactor` elements in the SOAP fault message

Note: According to SOAP specifications for fault messages, `faultcode`, `faultstring`, and `faultactor` are simple elements whereas `detail` is a complex element (an element with child elements). In addition, `faultcode`, `faultstring`, `faultactor`, and `detail` belong to the SOAP envelope namespace, whereas `detail` child elements may belong to user-defined namespaces.

SOAP-header-message-to-business-object processing

This section describes how the data handler converts the header of a SOAP message into a business object.

1. The SOAP data handler processes the body of a SOAP message. Body processing creates a SOAP business object.
2. If the SOAP message has a SOAP header element, the SOAP data handler expects a SOAP header attribute in the business object obtained from body processing. The `SOAPHeader` attribute is the child attribute of a business object and has `soap_location=SOAPHeader` as its application-specific information. If there is no such attribute, the SOAP data handler throws an error. The `SOAPHeader` attribute must be of type `SOAP Header Container` business object. The SOAP data handler creates an instance of this attribute in the SOAP business object obtained in step 1.
3. For each immediate child of the `SOAP-Env:Header` element:
 - a. The data handler expects a child attribute in the `SOAP Header Container Business Object`. The name of this attribute must be the same as that of the header element and conform to the `SOAP Header Child` business object. If the data handler cannot find such an attribute, it throws an error. Additionally, the namespace of this element should be the same as specified in the `elem_ns` application-specific information of this attribute. If it is not the same, the data handler throws an error.

- b. The data handler creates an instance of the SOAP Header Child business object and places it in the instance of SOAP Header Container business object created in step 2.
- c. If this header element has an actor attribute, the data handler expects an actor attribute to exist in the child business object created above. If it cannot find an actor attribute, the data handler throws an error.

Note: If you want to add an actor attribute, see “Specifying SOAP attributes” on page 122.

- d. If this header element has a mustUnderstand attribute, the data handler expects a mustUnderstand attribute to exist in the child business object created above. If it cannot find a mustUnderstand attribute, the data handler throws an error.

Note: If you want to add a mustUnderstand attribute, see “Specifying SOAP attributes” on page 122.

- e. For each child element of this header element, the data handler expects an attribute in the child business object with the same name. These elements will be processed in same way as the child elements of SOAP-Env:Body element.

Business-object-to-SOAP-message-body processing

The following is a step-by-step description of the business-object-to-SOAP-body-message transformation. For special cases involving application-specific-information, see “ASI in business-object-to-SOAP-message transformations” on page 119

1. The SOAP data handler looks for a SOAP ConfigMO that corresponds to the SOAP business object it is transforming.
2. The data handler composes the envelope and header of the SOAP message.
3. The data handler resolves the SOAP ConfigMO. If an instance of the SOAP ConfigMO does not exist, the data handler will create an instance and read from the default values. By default, the data handler reads the value of the BodyName attribute in the SOAP ConfigMO to determine whether it is processing a fault business object. If it is set to soap:faul t the business object is considered a SOAP fault business object. If it is not a fault business object, the data handler performs the processing described under composing body below, else that described under composing fault.
4. **Composing body** The following steps detail the processing performed by the data handler to compose the body of the SOAP message from a business object:
 - The data handler obtains the BodyName and BodyNS from the SOAP ConfigMO attributes and then composes the first (parent) element of the body of the SOAP message. The name of first element is, by default, the value for the BodyName. In this document, it is also referred to as the body element. The namespace of the body element is, by default, the value determined for BodyNS. If the Style attribute of the SOAP ConfigMO is set to document, this step (creating the first body element) is skipped.
 - The data handler then reads the attributes of the business object and processes them by type. The processing for each type of attribute is described below.
 - **Simple attributes** If the attribute is of type simple, the data handler creates a child element from the body element, with the same name as the

attribute (unless otherwise specified by special application-specific information). The data handler sets the value of this element to the value of the attribute in the business object.

– **Cardinality 1 child business object attributes**

If the attribute is a single cardinality child business object, the data handler creates a child element of the body element. This is referred to as a child business object element. The name of the child element created is the same as that of the attribute (unless otherwise specified by special ASI properties). The data handler then traverses the attributes of the child business object, creating the child elements for the attributes in the same way it processes the attributes of the incoming business object. However, the child elements are made children not of the body element but of the child business object element

– **Cardinality n child business object attributes** If an attribute is a cardinality n child business object, the data handler creates a SOAP array. Each attribute is handled the same way that a single cardinality child business object is handled.

5. **Composing fault** The following section walks through the process by which the data handler composes a fault message.

- The data handler expects the following attributes in the business object:
 - faultcode: Required, String attribute
 - faultstring: Required, String attribute
 - faultactor: Not required. String attribute
 - detail: Not required. Child BO attribute.

If any required attributes are missing, the data handler errors out.

- The data handler creates an element for faultcode. It sets the value given by the faultcode attribute of the business object.
 - The data handler creates an element for faultstring. It sets the value given by the faultstring attribute of the business object.
 - The data handler creates the faultactor. It sets the value given by the faultactor attribute of the business object.
 - If the detail attribute is present in the business object, the attribute should be of child business object type. Otherwise the data handler errors out. It handles the attributes of each detail business object as highlighted in the section on **Composing body** above.
6. **CxIgnore processing** If the data handler finds out that the value of an attribute is set to CxIgnore, the data handler does not create an element for this attribute.
7. **CxBlank processing** If the data handler determines that the value of an attribute is set to CxBlank, the data handler creates an element for this attribute but does not set its value.

Business-object-to-SOAP-message-header processing

This section describes the processing of the SOAP header attribute only. All other attributes are processed as described in “Business-object-to-SOAP-message-body processing” on page 114.

1. From the business object, the SOAP data handler obtains the SOAPHeader attribute. This attribute has soap_location=SOAPHeader as its application-specific information. The SOAP data handler creates a SOAP-Env:Header element if and

only if the value of this attribute is not null. If a business object contains more than one SOAPHeader attribute, the first one is processed and the rest are treated as part of the body.

2. The SOAP data handler expects that the SOAPHeader attribute is a single cardinality child representing a SOAP Header Container business object. The data handler processes the child attributes of the SOAP Header Container business object that are of type SOAP Header Child business object.
3. For each attribute of the SOAP Header Container business object, the data handler does the following:
 - a. Checks the cardinality: if this attribute is NOT a 1 or n cardinality child object, it is ignored.
 - b. Checks the value: if the value of this attribute is NULL, it will be ignored.
 - c. If the attribute is a 1 or n cardinality child object, the SOAP data handler creates a header element that is the immediate child of the SOAP-Env:Header element created in step 1. The name of this header element is same as that of the attribute. The namespace of this element is given by the elem_ns application-specific information of this attribute.
 - d. If the attribute is a SOAP Header Child business object, all of the attributes of this business object are processed. This attribute may have an actor and a mustUnderstand attribute.

Note: If you want to add a mustUnderstand or actor attribute, see “Specifying SOAP attributes” on page 122.

- e. If a SOAP Header Child business object has a non-null actor attribute, the data handler creates an actor attribute in the header element that was created in step c.
- f. If a SOAP Header Child business object has a non-null mustUnderstand attribute, the data handler will create a mustUnderstand attribute in the header element created in step c.
- g. All other non-null attributes of the SOAP Header Child business object become child elements of this header element. They are composed in the same manner as the child elements of the SOAP-Env:Body element.

Header fault processing

The SOAP specification states that errors pertaining to headers must be returned in headers. These headers are returned in the SOAP fault message. Just as message headers are specified in the SOAPHeader attribute of request and response business objects, fault headers are specified in the SOAPHeader attribute of fault business objects.

Each of the possible headers of request or response business objects may cause an error. Such errors are reported in the headers of the fault message.

WSDL documents have a SOAP binding header fault element that allows you to specify the fault header. For more information, see the SOAP and WSDL specifications listed in Chapter 1.

The application-specific information of headerfault allows you to specify header faults for each of your headers. You may specify headerfault application-specific information for each of the attributes of the SOAP Header Container business object. The list of attributes in the SOAP Header Container business object for the fault business object is as follows:

headerfault=attr1, attr2, attr3...

If the WSDL Configuration Wizard finds headerfault application-specific information in the SOAP Header Child business objects of request or response objects, the utility creates headerfault elements in the WSDL generated for these headers. Note that WSDL allows you to specify multiple header faults for each of your request (input) and response (output) headers. Therefore the value of this application-specific information is a comma-delimited list of attributes.

Using application-specific information functionality

You can specify object- and attribute-level application-specific information (ASI) to extend and enhance SOAP data handler functionality. Table 44 shows these attributes, which are discussed in the sections below. All of the entries in the table are attribute-level ASI unless otherwise noted.

Table 44. SOAP object ASI summary

ASI	Possible values	Description
soap_location	SOAPHeader	Specifies this business object attribute as the header attribute
headerfault	String	Identifies the BO attribute name of the corresponding SOAP header in the fault BO
elem_name	String	Specifies the name for the SOAP element corresponding to this BO attribute
elem_ns	String	Specifies the namespace for the SOAP element corresponding to this BO attribute
type_name	String	Specifies the type for the SOAP element corresponding to this BO attribute
type_ns	String	Specifies the type namespace for the element corresponding to this BO attribute
xsdtype	true	Specifies xsd as the namespace for the element corresponding to this BO attribute, overriding older xsd versions (such as 1999, 2000, etc.) with the latest version of xsd (for example, 2001).
attr_name	String	Specifies the name for the SOAP attribute corresponding to this BO attribute
attr_ns	String	Specifies the namespace for the SOAP attribute corresponding to this BO attribute

Table 44. SOAP object ASI summary (continued)

ASI	Possible values	Description
arrayof	String	Specifies the name of the n cardinality child business object attribute that must be used to create the array for this element
dh_mimetype	String	Specifies the mimeType of the data handler that will be used to transform this attribute of complex type
cw_mo_*	String	This business object level ASI specifies the name of a child config MO that is interpreted as meta-data, not content, by the SOAP data handler. Only cw_mo_soap specifies a child config MO that is processed as meta-data; all other cw_mo_* indicate a different component and are therefore excluded from SOAP data handler processing. All other cw_mo* is ignored.
cw_mo_soap	String	This business object level ASI specifies the name of the Child Config MO attribute that should be used when transforming this business object
cw_mo_jms	String	This business-object level ASI specifies the name of the JMS Protocol Config MO to use
cw_mo_http	String	This business-object level ASI specifies the name of the HTTP Protocol Config MO to use
wrapper	true	Specifies the attribute name of the wrapper object within this business object. Wrapper objects are used for certain schema indicators, and must not be serialized
maxoccurs	Integer	Specifies this business object attribute's maximum occurrence possibility. Depending on the value of maxoccurs, the business object may or may not have a wrapper.
minoccurs	Integer	Specifies this business object attribute's minimum occurrence possibility. Depending on the value of minoccurs, the object may or may not have a wrapper.

Table 44. SOAP object ASI summary (continued)

ASI	Possible values	Description
all	String	Specifies the child attribute that represents the all indicator in the schema.
choice	String	Specifies the child attribute that represents the choice indicator in the schema.

ASI in business-object-to-SOAP-message transformations

The SOAP data handler uses a business object's ASI to determine how to construct a SOAP message. Unless otherwise stated, all ASI discussed in the sections below refers to attribute level ASI and all string-based comparisons are performed without regard to case.

elem_name and elem_ns processing

The examples discussed in this section assume that the attribute name is OrderId and the SOAP element namespace prefix ns0.

1. When neither elem_name nor elem_ns are specified, the elem_name defaults to the attribute name, and the elem_ns defaults to the namespace of the element's parent. The ASI is not specified.

```
<OrderId>1</OrderId>
```

2. When the elem_name is specified and the elem_ns is not specified, the elem_name will be set to the ASI elem_name value, and the elem_ns will be defaulted to the namespace of the SOAP Body. The ASI is as follows:

```
elem_name=CustOrderId
<CustOrderId>2</CustOrderId>
```

3. When elem_ns is specified and elem_name is not, elem_name defaults to the attribute name and elem_ns is set to the ASI elem_ns value. The xmlns attribute is explicitly written if and only if the element namespace is not found elsewhere in the scope of this element. If the element namespace is found, the already defined namespace prefix is used. Otherwise (if the element namespace is not found), a unique prefix for the elem_ns is generated. Consider the following example, which presumes that a prefix is already defined in scope (ns1 represents a prefix corresponding to a namespace already defined in the scope of this element). The ASI is as follows:

```
elem_ns= http://www.w3.org/2001/XMLSchema
<ns1:OrderId>3</ns1:OrderId>
```

The following example presumes that prefix is not found (ns2 represents a unique prefix). The ASI is as follows:

```
elem_ns=CustOrderIdNamespace
<ns2:OrderId xmlns:ns2="CustOrderIdNamespace">3</ns2:OrderId>
```

4. When both elem_name and elem_ns are specified, elem_name and elem_ns are set to the ASI values. The same check that is performed in case 3 above regarding already defined namespaces applies. Just as in case 3, if the namespace is not already defined, a unique prefix for the elem_ns is generated. The ASI is as follows:

```
elem_name=CustOrderId;elem_ns=CustOrderIdNamespace
<ns2:CustOrderId xmlns:ns2="CustOrderIdNamespace">1</ns2:OrderId>
```

type_name and type_ns processing for simple attributes

For the examples in this section, the attribute name is `OrderId`, the SOAP element namespace prefix is `ns0`, and the attribute type is `String`.

Note: `type_name` and `type_ns` processing takes place only when the Config MO attribute `TypeInfo` is `true`.

1. When neither `type_name` nor `type_ns` are specified, `type_name` defaults to the simple type and the `type_ns` defaults to the xml schema-defined namespace (`xsd`). The ASI is not specified

```
<OrderId xsi:type="xsd:string">1</OrderId>
```

2. When `type_name` is specified and `type_ns` is not, `type_name` is set to the ASI `type_name` value and `type_ns` defaults to the namespace of the element. The ASI is as follows:

```
type_name=CustString
<OrderId xsi:type="ns0:CustString">2</OrderId>
```

3. When `type_ns` is specified and `type_name` is not, the `type_ns` defaults to the simple type name and `type_name` is set to the ASI `type_ns` value. The prefix is handled in a way that is comparable to `elem_ns` creation. A unique prefix for the type namespace is generated unless the namespace already exists in the element scope. The ASI is as follows:

```
type_ns=CustStringNamespace
<OrderId xmlns:ns2="CustStringNamespace" xsi:type="
ns2:String">3</OrderId>
```

4. When both `type_name` and `type_ns` are specified, they are set to the assigned ASI values. A unique prefix for the type namespace is generated. The ASI is as follows:

```
type_name=CustString;type_ns=CustStringNamespace
<OrderId xmlns:ns2="CustStringNamespace" xsi:type="
ns2:CustString">1</OrderId>
```

type_name and type_ns processing for single cardinality attributes

For the examples in this section, the attribute name is `OrderStaus`, the SOAP element namespace prefix is `ns0`, and the attribute type is `OrderStatus`.

Note: `type_name` and `type_ns` processing takes place only when the Config MO attribute `TypeInfo` is `true`.

1. When neither `type_name` nor `type_ns` are specified, `type_name` defaults to the business object name and the type namespace defaults to the namespace of the element. The ASI is not specified:

```
<OrderStatus xsi:type="ns0:OrderStatus">1</OrderStatus>
```

2. When `type_name` is specified and `type_ns` is not, the `type_name` is set to the assigned ASI value and `type_ns` defaults to the namespace of the element. The ASI is as follows:

```
type_name=CustOrderStatus
<OrderStatus xsi:type="ns0:CustOrderStatus">1</OrderStatus>
```

3. When `type_ns` is specified and `type_name` is not, `type_name` defaults to the business object name and `type_ns` is set to the assigned `type_ns` value. A unique prefix for the type namespace is generated. The ASI is as follows:

```
type_ns=CustTypeNS
<OrderStatus xsi:type="ns2:SOAP_OrderStatusLine
" xmlns:ns2="CustTypeNS">1</OrderStatus>
```

- When both `type_name` and `type_ns` are specified, they are set to the assigned ASI values. A unique prefix for the type namespace is generated. The ASI is as follows:

```
type_name=CustOrderStatus;type_ns=CustTypeNS
<OrderStatus
xsi:type="ns2:CustOrderStatus" xmlns:ns2="CustTypeNS">1</OrderStatus>
```

type_name and type_ns processing for multiple cardinality attributes

For all the examples given in this section assume the attribute name to be `MultiLines` and the SOAP element namespace prefix to be `ns0`. Assume the attribute type to be `OrderStatus`.

Note: `type_name` and `type_ns` processing takes place only when the Config MO attribute `TypeInfo` is true.

- When neither `type_name` nor `type_ns` are specified, `type_name` defaults to the business object name and `type_ns` defaults to the namespace of the element. The ASI is as follows:

```
<MultiLines SOAP-ENC:arrayType="ns0:OrderStatus[2]"
xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"
xsi:type="SOAP-ENC:Array">
```

- When `type_name` is specified and `type_ns` is not, `type_name` is set to the assigned ASI `type_name` value and `type_ns` defaults to the namespace of the element. The ASI is as follows:

```
type_name=CustOrderStatus
<MultiLines SOAP-ENC:arrayType="ns0:CustOrderStatus[2]"
xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"
xsi:type="SOAP-ENC:Array">
```

- When `type_ns` is specified and `type_name` is not, `type_name` defaults to the business object name, and the `type_ns` is set to the assigned ASI `type_ns` value. A unique prefix for the type namespace is generated. The ASI is as follows:

```
type_ns=CustTypeNS
<MultiLines SOAP-ENC:arrayType="ns2:OrderStatus[2]"
xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:ns2="CustTypeNS" xsi:type="SOAP-ENC:Array">
```

- When both `type_name` and `type_ns` are specified, they are set to the assigned ASI values. A unique prefix for the type namespace is generated. The ASI is as follows:

```
type_name=CustOrderStatus;type_ns=CustTypeNS
<MultiLines SOAP-ENC:arrayType="ns2:CustOrderStatus[2]"
xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:ns2="CustTypeNS" xsi:type="SOAP-ENC:Array">
```

Note: The item element representing the parent for each Array element has the same type and namespace as the `arrayType`.

xsdtype for simple, single, and multiple cardinality types

For simple, single, and multiple cardinality types, set the `xsdtype` ASI attribute to true for the type name to adhere to the current XSD for the SOAP message. The `xsdtype` property is read only when both the `type_name` and `type_ns` properties are set. Given the `type_name` and `type_ns`, the SOAP data handler first attempts to map the pair to a Java type using the SOAP API. Then the data handler attempts to convert the Java type back to a SOAP element type using the current XSD for the SOAP Message. For example, if the current XSD is

```
http://www.w3.org/2001/XMLSchema
```

and the following ASI:

```
type_name=timeInstant;type_ns=http://www.w3.org/1999/XMLSchema;xsdtype=true
```

The SOAP message type name is written as:

```
<OrderDate xsi:type="xsd:dateTime">
```

because `dateTime` is the 2001 XSD equivalent of the `timeInstant` in the 1999 XSD.

xsdtype and simple type arrays

For multiple cardinality objects, you can create a simple type array such as the following:

```
<MultiLines SOAP-ENC:arrayType="xsd:string[4]"  
xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"  
xsi:type="SOAP-ENC:Array">
```

To achieve this, set the `type_name` property to the desired simple type (for example, `string`) and set the `type_ns` property to the appropriate XSD specification. Then, set the `xsdtype` property to `true` so that the type is converted to the current XSD type. Finally, the `arrayOf` property should be set to the name of the attribute in the container which should hold the simple type value. This is an example of what the ASI would look like for a string array:

```
arrayof=size;type_name=string;type_ns=http://www.w3.org/2001/XMLSchema;xsdtype=true
```

ASI effects on fault processing

The `faultcode`, `faultactor`, `faultstring`, and `detail` elements adhere to the following rules:

1. Any `elem_name`, `elem_ns`, `type_name` and `type_ns` ASI in these attributes is ignored.
2. All children of the `detail` elements are written exactly as described in body processing.

ASI effects on header processing

You can use all ASI properties (see Table 44) at the header child object level and below.

Specifying SOAP attributes

attr_name processing for simple types

This is not supported. A business object attribute must be a complex (1 or n cardinality) type for SOAP attributes to be created.

attr_name processing for single and multiple cardinality types

You can specify ASI that translates business object attributes into soap attributes instead of into soap elements. The data handler supports adding SOAP attributes to complex single and n-card types only. Consider the following sample:

```
<CustInfo City="4" State="5" Street="2" Zip="6">  
  <Name xsi:type="xsd:string">1</Name>  
  <Street2 xsi:type="xsd:string">3</Street2>  
</CustInfo>
```

Given this business object definition structure (with the attribute level ASI specified to the right of each attribute in Figure 45), the data handler follows these processing steps:

Name	Type	App Spec Info
[-] CustInfo	CustomerInfo	
Name	String	
Street1	String	attr_name=Street
Street2	String	
City	String	attr_name=City
State	String	attr_name=State
Zip	String	attr_name=Zip

Figure 45. attr_name business object

1. When traversing a complex attribute, the data handler first generates a corresponding tag for this complex business object attribute. In this example, CustInfo represents the complex business object attribute.
2. The data handler iterates through the children of the complex business object. Only simple type attributes are considered for attribute creation. If a simple type has an ASI property named attr_name, the data handler writes this simple type as an attribute to the SOAP element. In this example, the element (CustInfo) will have four attributes; Street, City, State and Zip.
3. The rest of the attributes of the business object are written using standard BODY processing. This means that all relevant ASI will also be evaluated for the business object attributes that do not have attr_name ASI.

The logic for processing multiple cardinality types is identical to that for processing single cardinality types. Specifically, each <item> tag corresponds to each business object instance in the multiple cardinality object, and will be processed using ASI. For example, given this multiple cardinality business object definition structure with corresponding ASI:

Name	Type	Card	App Spec Info
[-] CustInfo	CustomerInfo	N	
Name	String		
Street1	String		attr_name=Street
Street2	String		
City	String		attr_name=City
State	String		attr_name=State
Zip	String		attr_name=Zip

Figure 46. attr_name multiple cardinality business object

If the event sent to the data handler had two instances of this multiple cardinality object, the SOAP message created may look like this:

```

<CustInfo>
  <item City="Armonk" Street="Main Street">
    <Name>IBM</Name>
    <Street2>None</Street2>
  </item>
  <item City="Burlingame" State="Ca" Street="577 Airport Blvd" Zip="94010">
    <Name>Burlingame Labs</Name>
    <Street2>Suite 600</Street2>
  </item>
</CustInfo>

```

Notice that the item tags are treated as the complex element type. Any attributes in the BO definition will become SOAP attributes of the corresponding item tag.

arrayof processing

You use the arrayof ASI property to assign SOAP attributes to the array element itself (not at the child tag). You add the arrayof property to the ASI of a single cardinality complex type. The value of the arrayof property must be the name of the multiple cardinality child that the SOAP message will represent. When the SOAP message is created, the multiple cardinality child represents the child tags of the array.

A business object definition with an arrayof element and corresponding ASI are shown in Figure 47

Name	Type	Card	App Spec Info
Customer	Customer	1	arrayof=CustInfo
CustID	String		attr_name=ID
CustInfo	CustomerInfo	N	
Name	String		
Street1	String		attr_name=Street
Street2	String		
City	String		attr_name=City
State	String		attr_name=State
Zip	String		attr_name=Zip

Figure 47. arrayof business object

If the event sent to the data handler had two instances of this cardinality n object, the SOAP message created may look like the following:

```
<Customer ID="12">
  <CustInfo City="4" State="5" Street="2" Zip="6">
    <Name>1</Name>
    <Street2>3</Street2>
  </CustInfo>
  <CustInfo City="10" State="11" Street="8" Zip="12">
    <Name>7</Name>
    <Street2>9</Street2>
  </CustInfo>
</Customer>
```

Notice that the arrayof property can be used to create array items with a name other than item. In this example, the item tag is replaced with CustInfo tags. This element name is derived from the name of the business object attribute that the arrayof ASI property points to.

attr_name and attr_ns processing

You may need to provide a namespace that corresponds to the SOAP attribute created. You do this by specifying the attr_ns ASI property for a simple type. The data handler processes the attr_ns property if and only if attr_name exists in the same attribute's ASI. The following rules are followed with attr_name and attr_ns:

1. When neither attr_name nor attr_ns exist, the business object attribute is translated to a SOAP element.
2. When only attr_name is set, the SOAP attribute's namespace defaults to the element's namespace:

```
<CustInfo Street="577 Airport"></CustomerInfo>
```

- When only `attr_ns` is set, the property is ignored and the business object attribute is translated to a SOAP element.
- When both `attr_name` and `attr_ns` exist, the SOAP attribute is created like the following:

```
<CustInfo ns2:Street="577 Airport" xmlns:ns2="AttrNS"></CustomerInfo>
```

dh_mimetype: calling a data handler

The SOAP data handler can call another data handler to write business objects into any format for which a data handler exists. You do this by adding encoded text to a SOAP message when transferring a SOAP child business object into a SOAP String.

An RNIF document is one of the formats in which a SOAP element's value may be encoded. To make use of this functionality, add an RNIF BO at any level of a SOAP child business object. To signal the SOAP data handler to call another data handler when transforming this RNIF business object to a string, add the `dh_mimetype` property to the attribute's ASI. The value of the `dh_mimetype` ASI property must be a legal mimeType specified in the `MO_DataHandler_Default` meta-object. The mimeType is used to determine which data handler is called to process the business object.

Figure 48 shows a SOAP child business object in which `CustomerInfo` is a complex child and `RNET_Pip3A2PriceAndAvailabilityQuery` is an RNIF business object:

Name	Type	App Spec Info
CustomerInfo	CustomerInfo	
Name	String	
CustID	String	
RNIFMsg	RNET_Pip3A2PriceAndAvailabilityQuery	elem_name=RNIFexample;dh_mimetype=application/x_rossettanet_agent;type_name=base64Binary;type_ns=http://www.w3.org/2001/XMLSchema;xsdtype=true

Figure 48. RNIF business object with `dh_mimetype`

The SOAP message created from this business object may look like this:

```
<CustomerInfo>
<Name>IBM Corporation</Name>
<CustID>95626</CustID>
<RNIFexample
xsi:type="xsd:base64Binary">1AWERYER238W98EYR9238728374871892787ASRJK23423
JKAWERJ234AWERIJHI423488R4HASF1AWERYER238W98EYR9238728374871892787ASRJK234
34JKAWERJ234AWERIJHI423488R4HASF1AWERYER238W98EYR9238728374871892787ASRJK2
4234JKAWERJ234AWERIJHI423488R4HASF1AWERYER238W98EYR9238728374871892787ASRJK
234234JKAWERJ234AWERIJHI423488R4HASFWR234
</RNIFexample>
</CustomerInfo>
```

Note that the RNIF example element contains an RNIF encoded string that has been base64 binary encoded as its element value. Also, note that `elem_name`, `elem_ns`, `type_name`, `type_ns`, and `xsdtype` ASI properties remain relevant for this business object attribute. In this example, the specified `elem_name` dictates the name of the SOAP element upon message creation.

Note: If the element value returned by the called data handler is encoded text, the `type_name` property must be set to `base64Binary`, the `type_ns` must correspond to an `xsd` namespace, and `xsdtype` must be set to `true`.

xsd:base64Binary: When you set the `type_name` and `type_ns` to resolve to `xsd:base64Binary`, the SOAP data handler encodes the value from the business object before setting the value for the corresponding element. Using the Apache API, the data handler queries the registry for a `base64Binary` serializer, serializes the string returned from the called data handler, and sets the element's value.

Schema complexType indicators

The following sections discuss the effects of schema complexType Indicators on business objects. The indicators include:

- `maxOccurs`
- `minOccurs`
- `all`
- `sequence`
- `choice`

maxOccurs and minOccurs indicators for simple types: The `maxOccurs` indicator specifies the maximum number of times an element can occur within a complex type. The `minOccurs` indicator specifies the minimum number of times an element should occur within a complexType.

Consider this Schema:

```
<xs:element name="Address" type="Address">
<xs:complexType name="Address">
  <xs:sequence>
    <xs:element name="AddressLine" type="xsd:string" maxOccurs="10"/>
    <xs:element name="SuiteNumber" type="xsd:string" minOccurs="3"
      maxOccurs="unbounded"/>
    <xs:element name="City" type="xsd:string"/>
  </xs:sequence>
</xs:complexType>
</xs:element>
```

The example above indicates that the `AddressLine` element can occur at most ten times in an `Address` element, while the `SuiteNumber` element must occur at least three times. The business object that corresponds to this schema must have an `N` cardinality wrapper object for each `maxOccurs`/`minOccurs` indicator that has the following ASI:

```
maxOccurs=N;wrapper=true
```

or

```
minOccurs=3;wrapper=true;
```

The `wrapper=true` ASI indicates that this object is a wrapper, and therefore not explicitly written to the SOAP message. Instead, there must be one child of simple type in this wrapper object. At runtime, for SOAP to business object transformations, the data handler reads the `N` child objects of the wrapper and creates a corresponding element for each one. When performing business-object-to-SOAP-message transformations, the data handler creates child objects in the `N` cardinality wrapper for every element it encounters.

The corresponding SOAP business object resembles that shown in Figure 49.

Pos.	Name	Type	Key	Card	App Spec Info
1	☐ Address	Address	<input checked="" type="checkbox"/>	1	
1.1	☐ AddressLine	AddressLine_wrap	<input checked="" type="checkbox"/>	N	maxoccurs=10;wrapper=true
1.1.1	AddressLine	String	<input checked="" type="checkbox"/>		
1.1.2	ObjectEventId	String			
1.2	☐ SuiteNumber	SuiteNumber_wrap	<input checked="" type="checkbox"/>	N	minoccurs=3;wrapper=true
1.2.1	SuiteNumber	String	<input checked="" type="checkbox"/>		
1.2.2	ObjectEventId	String			
1.3	City	String	<input type="checkbox"/>		
1.4	ObjectEventId	String			
2	ObjectEventId	String			

Figure 49. minOccurs and maxOccurs of simple type ASI in a SOAP business object

The SOAP message that corresponds to the business object shown in Figure 49 is as follows:

```
<Address xsi:type="ns0:Address">
  <AddressLine xsi:type="xsd:string">Line1</AddressLine>
  <AddressLine xsi:type="xsd:string">Line2</AddressLine>
  <SuiteNumber xsi:type="xsd:string">600</SuiteNumber>
  <SuiteNumber xsi:type="xsd:string">650</SuiteNumber>
  <SuiteNumber xsi:type="xsd:string">700</SuiteNumber>
  <City xsi:type="xsd:string">San Francisco</City>
</Address>
```

Note: The SOAP data handler processes maxOccurs and minOccurs indicators in the same way, without validating the maximum or minimum occurrences of elements. The data handler simply provides a container structure to hold multiple instances of a particular element with the maxOccurs and minOccurs indicators. This applies to simple and complex types.

maxOccurs and minOccurs indicators for complex types: The <maxOccurs> indicator specifies the maximum number of times an element can occur within a complex type. The <minOccurs> indicator specifies the minimum number of times an element should occur within a complexType. Consider the maxOccurs indicator in the following schema:

```
<xs:element name="Address" type="Address">
  <xs:complexType name="Address">
    <xs:sequence>
      <xs:element name="AddressInfo" type="AddressInfo" maxOccurs="3"/>
      <xs:element name="City" type="xsd:string"/>
    </xs:sequence>
  </xs:complexType>
</xs:element>

<xs:complexType name="AddressInfo">
  <xs:sequence>
    <xs:element name="StreetLine" type="xsd:string"/>
  </xs:sequence>
</xs:complexType>
</xs:element>
```

The example above indicates that the AddressInfo complex type element can occur at most three times in an Address element. The corresponding business object for

this schema will not have a wrapper object, since the complexType AddressInfo itself can be of N cardinality. The following ASI will be placed at the N cardinality attribute: maxOccurs=3

Figure 50 shows the corresponding SOAP business object.

Pos	Name	Type	Key	Card	App Spec Info
1	☐ Address	Address	<input checked="" type="checkbox"/>	1	
1.1	☐ AddressInfo	AddressInfo	<input checked="" type="checkbox"/>	N	maxOccurs=3
1.1.1	StreetLine	String	<input checked="" type="checkbox"/>		
1.1.2	ObjectEventId	String			
1.2	City	String	<input type="checkbox"/>		
1.3	ObjectEventId	String			
2	ObjectEventId	String			

Figure 50. minOccurs and maxOccurs of complex type ASI in a SOAP business object

The SOAP message that corresponds to the business object shown in Figure 50 is as follows:

```
<Address xsi:type="ns0:Address">
  <AddressInfo xsi:type="ns0:AddressInfo">
    <StreetLine xsi:type="xsd:string">100 Market St.</ StreetLine>
    <StreetLine xsi:type="xsd:string">Apt 15</ StreetLine>
  </AddressInfo>
  <City xsi:type="xsd:string">San Francisco</City>
</Address>
```

all indicator: The all indicator specifies by default that the child elements for this complexType can appear in any order and that each child element must occur zero or one times. Consider the following Schema:

```
<complexType name="Item">
  <all>
    <element name="quantity" type="xsd:int"/>
    <element name="product" type="xsd:string"/>
  </all>
</complexType>
```

The example above indicates that the elements quantity and product, can occur in any order in the SOAP message. The quantity element may occur first and the product element second, or vice versa.

Figure 51 shows the business object that corresponds to this schema fragment.

Pos	Name	Type	Card	App Spec Info
1	☐ Item	Item	1	all=Item_wrapper
1.1	☐ Item_wrapper	Item_wrapper	N	wrapper=true
1.1.1	quantity	String		
1.1.2	product	String		
1.1.3	ObjectEventId	String		
1.2	ObjectEventId	String		
2	ObjectEventId	String		

Figure 51. all indicator ASI in a SOAP business object

The corresponding SOAP message fragment is as follows:

```
<Item xsi:type="ns0:Item">
  <quantity xsi:type="xsd:string">12</quantity>
  <product xsi:type="xsd:string">2</product>
</Item>
```

sequence indicator: The sequence indicator specifies that child elements must appear in the order specified in the complexType.

```
<complexType name="Item">
  <sequence>
    <element name="quantity" type="int"/>
    <element name="product" type="string"/>
  </sequence>
</complexType>
```

The SOAP data handler does not require special ASI or wrapper objects for this indicator. By default, the data handler reads and writes SOAP elements in the order specified in the business object.

choice indicator: The choice indicator specifies that one and only one of the elements in a complexType can appear in the SOAP message. Consider the following schema:

```
<complexType name="Item">
  <choice>
    <element name="quantity" type="int"/>
    <element name="product" type="string"/>
  </choice>
</complexType>
```

The SOAP data handler does not require special ASI or wrapper objects for this indicator. When converting a business object to a SOAP message, the data handler defers to your choice of which elements should appear in the SOAP message. When converting a SOAP message to a business object, the data handler reads the existing element and populates the attribute to which it corresponds.

ASI in SOAP-to-business object transformations

The SOAP data handler uses a business object's ASI to read and validate an incoming SOAP message. The following rules apply to ASI validation by the SOAP data handler:

- Header and body processing are the same.
- The SOAP ConfigMO property, TypeCheck, must be set to strict and TypeInfo set to true for the data handler to perform the validation described in the sections below.
- type_name and type_ns validation are performed concurrently since type validation is generally dependent on both properties.

Note: Unless otherwise stated, all ASI discussed in the following sections is attribute-level ASI

elem_name validation

The following rules apply to validation for simple, cardinality 1 and cardinality n attributes:

1. When encountering an element while parsing a SOAP message, the data handler first searches all of the ASI at the business object level, attempting to match the element's name against the elem_name value.

2. If a match is not found, the data handler attempts to match the element's name against each of the attribute names at that business object level.
3. If neither search succeeds, the data handler fails.

elem_ns validation

The following cases apply to validation for simple, cardinality 1 and cardinality n attributes:

1. When neither elem_ns ASI nor xmlns from the SOAP message for this element exist, the element is properly validated.
2. When elem_ns ASI does not exist and the corresponding element from the SOAP message does not have an xmlns specified, the data handler defaults the elem_ns to the last elem_ns read from the business object that was in the scope. The data handler compares this value with the xmlns value from the SOAP message. If there is no match, validation fails.
3. When elem_ns ASI does exist and the corresponding element from the SOAP message does not have xmlns specified, the data handler verifies that the elem_ns specified in ASI matches one of the namespaces in the current scope of the SOAP message. If there is no match, validation fails.

type_name and type_ns validation

The sections below discuss type_name and type_ns validation.

Simple attributes: The following rules apply to type_name and type_ns validation when xsdType is true:

- **Both type_name and type_ns are specified** Using the type_name and type_ns pair, the data handler creates a corresponding java Class object. Using the incoming SOAP message typename and typenamespace, another java Class object is queried. If the two java Class objects match, validation succeeds. Otherwise, validation fails.
- **Neither type_name nor type_ns are specified** The data handler maps the simple business object attribute to a java Class object. Using the incoming SOAP message typename and typenamespace, another java Class object is queried. If the two java Class objects match, validation succeeds. Otherwise, validation fails.
- **type_name only is specified** Simple Type Validation fails. Both type_name and type_ns or neither should be specified when xsdType is true.
- **type_ns only is specified** Simple Type Validation fails. Both type_name and type_ns or neither should be specified when xsdType is true.

The following rules apply to type_name and type_ns validation when xsdType is false:

- **Both type_name and type_ns are specified** The data handler performs a direct comparison between the SOAP message typename and typenamespace pair and the type_name and type_ns values specified in ASI. If the pairs are exactly alike, validation succeeds. Otherwise, validation fails.
- **Neither type_name nor type_ns are specified** The data handler maps the simple business object attribute to a java Class object. Using the incoming SOAP message typename and typenamespace, another java Class object is queried. If the two java Class objects match, validation succeeds. Otherwise, validation fails.
- **type_name only is specified** The type_ns value defaults to the element namespace found in the business object ASI. Using this default type_ns and the type_name specified in ASI, the data handler performs a direct comparison between these values and the SOAP message typename and typenamespace. If the pairs are exactly alike, validation succeeds. Otherwise, validation fails.

- **type_ns only is specified** The type_name value defaults to the business object attribute type. Using this default type_name and the type_ns specified in ASI, the data handler performs a direct comparison between these values and the SOAP message typename and typenamespace. If the pairs are exactly alike, validation succeeds. Otherwise, validation fails.

Complex attributes (cardinality 1 and n): The following rules apply to type_name and type_ns validation when xsdType is true:

- **Both type_name and type_ns are specified** xsdType is ignored. The data handler processes as if xsdType is false.
- **Neither type_name nor type_ns are specified** xsdType is ignored. The data handler processes as if xsdType is false.
- **type_name only is specified** xsdType is ignored. The data handler processes as if xsdType is false.
- **type_ns only is specified** xsdType is ignored. The data handler processes as if xsdType is false.

The following rules apply to type_name and type_ns validation when xsdType is false:

- **Both type_name and type_ns are specified** The data handler performs a direct comparison between the SOAP message typename and typenamespace pair and the type_name and type_ns values specified in ASI. If the pairs are exactly alike, validation succeeds. Otherwise, validation fails.
- **Neither type_name nor type_ns are specified** The type_name value defaults to the business attribute type. The type_ns value defaults to the element namespace found in the business object ASI. Using this default behavior, the data handler performs a direct comparison between these values and the SOAP message typename and typenamespace pair. If the pairs are exactly alike, validation succeeds. Otherwise, validation fails.
- **type_name only is specified** The type_ns value defaults to the element namespace found in the business object ASI. Using this default type_ns and the type_name specified in ASI, the data handler performs a direct comparison between these values and the SOAP message typename and typenamespace. If the pairs are exactly alike, validation succeeds. Otherwise, validation fails.
- **type_ns only is specified** The type_name value defaults to the business object attribute type. Using this default type_name and the type_ns specified in ASI, the data handler performs a direct comparison between these values and the SOAP message typename and typenamespace. If the pairs are exactly alike, validation succeeds. Otherwise, validation fails.

attr_name and attr_ns validation

While reading SOAP message into a business object, each SOAP element is searched for SOAP attributes. If found, these attributes are compared to the attr_name property values from the corresponding BO. For example, consider this SOAP message:

```
<CustInfo City="4" State="5" Street="2" Zip="6">
  <Name xsi:type="xsd:string">1</Name>
  <Street2 xsi:type="xsd:string">3</Street2>
</CustInfo>
```

Now consider the business object definition structure (with the attribute level ASI specified to the right of each attribute) shown in Figure 52.

Name	Type	App Spec Info
☐ CustInfo	CustomerInfo	
Name	String	
Street1	String	attr_name=Street
Street2	String	
City	String	attr_name=City
State	String	attr_name=State
Zip	String	attr_name=Zip

Figure 52. attr_name and attr_ns validation

The data handler would follow these processing steps:

1. Read the element name CustInfo.
2. Resolve the business object attribute that corresponds to this element name.
3. Read the attributes of the SOAP element and attempt to match them against the ASI of the child attributes. In this case, the SOAP message Street matches the business object attribute Street1, City matches the business object attribute City and so on.
4. The child elements for CustInfo are read and processed in the same manner as the rest of the body.

Note: attr_ns is not validated.

The data handler loops through the SOAP attributes for a given element. For each attribute encountered, the data handler searches the business object for a corresponding attribute. If found, the business object attribute is populated with the value of the SOAP attribute. If a corresponding business object attribute is not found, the data handler continues to the next SOAP attribute.

Calling a data handler from within the SOAP data handler

The SOAP data handler can read an encoded element value from a SOAP message into a business object using another data handler. For example, an RNIF document may be one of the formats in which a SOAP element value is encoded. To make use of this functionality, an RNIF business object can be added at any level of a SOAP Child business object. To signify to the SOAP data handler that another data handler must be used when transforming this RNIF encoded String to an RNIF business object, you must add the dh_mimetype property to the attribute's ASI. The value of the dh_mimetype ASI should be a legal mimeType specified in the MO_DataHandler_Default business object. The mimeType is used to determine which data handler to use on the String. For example, given the following SOAP message where RNIFExample is the SOAP element that contains an RNIF encoded String:

```
<CustInfo>
<Name>IBM Corporation</Name>
<CustID>95626</CustID>
<RNIFexample xsi:type="xsd:base64Binary">
1AWERYER238W98EYR9238728374871892787ASRJK234234JKAWER
J234AWERIJHI423488R4HASF1AWERYER238W98EYR923872837487
1892787ASRJK234234JKAWERJ234AWERIJHI423488R4HASF1AWER
YER238W98EYR9238728374871892787ASRJK234234JKAWERJ234A
WERIJHI423488R4HASF1AWERYER238W98EYR92387283748718927
87ASRJK234234JKAWERJ234AWERIJHI423488R4HASFWR234
</RNIFexample>
</CustomerInfo>
```

The SOAP business object would look like that shown in Figure 53.

Name	Type	App Spec Info
[-] CustInfo	CustomerInfo	
Name	String	
Street1	String	attr_name=Street
Street2	String	
City	String	attr_name=City
State	String	attr_name=State
Zip	String	attr_name=Zip

Figure 53. RNIFExample business object

Note that the RNIFExample element contains an RNIF encoded String as its element value. Also, note that `elem_name`, `elem_ns`, `type_name`, `type_ns` and `xsdtype` ASI properties still remain relevant for this business object attribute.

Note: If the element value returned by the called data handler is encoded text, the `type_name` property must be set to `base64Binary`, the `type_ns` must correspond to an `xsd` namespace, and `xsdtype` must be set to `true`.

Default business object resolution

For SOAP to business object transformations, the SOAP data handler and web services connector adhere to a special contract of exchanging information to resolve business object names. The connector provides the SOAP data handler with a list of business object names mapped to `BodyName` and `BodyNamespace` pairs. In addition, if there is a default business object set in the TLO, this information is passed to the data handler. Given this information, the SOAP data handler processes using the following steps:

1. The data handler receives a SOAP message
2. The data handler determines if this is a SOAP request, response or fault message.
 - a. If a SOAP request or response message, the data handler reads the `BodyName` and `BodyNamespace` from the first child element of the `SOAP-ENV:Body` element.
 - b. If a SOAP fault message, the data handler reads the `BodyName` and `BodyNamespace` from the first child element of the detail element in the fault message. If there is no detail element in the fault message, the data handler uses the default business object for this transformation
3. If a default business object has not already been chosen, the data handler attempts to match the `BodyName` and `BodyNamespace` found in step 2 to the pairs found in the list provided by the connector. If a match is made, business object resolution is successful. If no match is made, the data handler fails with a meaningful error message.

Specifying a pluggable name handler

With default business object resolution, you can specify a pluggable name handler to determine the business object to be used in SOAP-message-to-business-object transformations. You do this by changing the `MO_DataHandler_DefaultSOAPConfig`.

The `MO_DataHandler_DefaultSOAPConfig` has two attributes of type string that designate:

- **ClassName** The class name for the SOAP data handler base class. You do not change this attribute value when specifying a pluggable name handler.
- **SOAPNameHandler** The `SOAPNameHandler` attribute dictates which name handler is called. The value of this property should be a class name. The `SOAPNameHandler` class is an abstract class with the following signatures:

```
public static SOAPNameHandler createNameHandler(Object moProps)
public abstract String getBOName(Envelope msgEnv, SOAPProperty prop)
```

All name handlers written for the SOAP data handler must implement the `getBOName` method. The object passed into the `createNameHandler` method sets the meta-object properties for this name handler. The `SOAPProperty` passed into the `getBOName` method sets the `SOAPProperty` passed by the connector call to the data handler. Here is how the SOAP data handler will call the methods:

```
SOAPNameHandler nh = SOAPNameHandler.createNameHandler(moProps);
String boName = nh.getBOName(msgEnv, prop);
```

If the `SOAPNameHandler` attribute has a value, the SOAP data handler calls the specified name handler. If the value does not exist, or if the specified name handler fails to get a business object name, the SOAP data handler is called by default to perform default business object resolution. Default business resolution describes a process whereby the connector delivers to the data handler a list of connector-supported business object containers with information such as Body Name, Body Namespace, and business object name. The data handler uses this information to create a business object from the SOAP message. If your name handler fails, the default business object resolution occurs.

Limitations

The sections below discuss data handler limitations.

SOAP style and use guidelines

SOAP messages are created using a style and use defined by the web service. The SOAP data handler provides the levels of support shown in Table 45.

Table 45. Style and use guidelines

Style	Use	Parts defined using	Data handler support
document	literal	element	full
document	literal	type	limited (see below)
document	encoded	element	none
document	encoded	type	limited (see below)
rpc	literal	element	none
rpc	literal	type	full
rpc	encoded	element	none
rpc	encoded	type	full

Part and part element order

When the SOAP data handler is transforming a SOAP message into a business object and the SOAP message follows either the document/literal/type or

document/encoded/type formats, the message parts must be in the order described in the WSDL. For example, consider the following WSDL:

```
<operation name="GetQuote"
  style="document" ...>
<input>
  <soap:body parts="Part1 Part2 Part3 Part4" use="literal">
</input>
</operation>

<definitions
  xmlns:stns="(SchemaTNS)"
  xmlns:wtns="(Wsd1TNS)"
  targetNamespace="(Wsd1TNS)">

<schema targetNamespace="(SchemaTNS)"
  elementFormDefault="qualified">
<element name="SimpleElement" type="xsd:int"/>
<element name="CompositeElement" type="stns:CompositeType"/>
<complexType name="CompositeType">
<all>
  <element name='elem_a' type="xsd:int"/>
  <element name='elem_b' type="xsd:string"/>
</all>
</complexType>
</schema>

<message...>
<part name='Part1' type="stns:CompositeType"/>
<part name='Part2' type="xsd:int"/>
<part name='Part3' element="stns:SimpleElement"/>
<part name='Part4' element="stns:CompositeElement"/>
</message>
0
</definitions>
```

The SOAP message must adhere to the order defined by the parts. In the SOAP example below, notice that Part1 elements precede Part2, Part3, and Part4 elements. This order must be maintained for proper BO resolution.

```
<soapenv:body... xmlns:mns="(MessageNS)"
  xmlns:stns="(SchemaTNS)">
  <stns:elem_a>123</stns:elem_a>
  <stns:elem_b>hello</stns:elem_b>
  <soapenc:int>123</soapenc:int>123</soapenc:int>123</soapenc:int>
  <stns:SimpleElement>123</stns:SimpleElement>
  <stns:CompositeElement>
    <stns:elem_a>123</stns:elem_a>
    <stns:elem_b>hello</stns:elem_b>
  </stns:CompositeElement>
</soapenv:body>
```

When the SOAP message follows either the document/literal/type or document/encoded/type formats, part elements must be in order, too. In Part1 of the example above, the elem_a tag must precede the elem_b tag. This limitation is dictated by the data handler's business object resolution process. Since default business object resolution for document style makes use of the first element's body name and namespace, these must be the same element in all SOAP messages of this particular request, response, or fault so that the same business object is resolved in each case.

Note: When the SOAP message follows either the document/literal/type or document/encoded/type formats, elements must not be optional.

XML limitations

The following XML structures, features, and notation are not supported:

- Multi-dimensional arrays
- Partially transmitted arrays
- Sparse arrays
- Mixed content
- Sequence, group, and choice model group components with maxOccurs greater than one

Chapter 6. Enabling collaborations for request processing

- “Request processing collaboration checklist”

This chapter describes the steps you must follow to enable collaborations for request processing. Collaborations use the connector to invoke web services.

Request processing collaboration checklist

Using Business Object Designer Express to generate business objects is part of the process of developing collaborations. You must perform the following tasks, described in sections below, to generate business objects that a collaboration can use to invoke web services:

1. Identify the WSDL document either from a URL, UDDI or a file system. You use third-party tools for this task—the web services connector provides no tools for this task.
2. Open Business Object Designer Express and launch the WSDL ODA. For further information, see “Starting the WSDL ODA” on page 151.
3. Configure the ODA.
4. Confirm your selections.
5. Generate a top-level business object that includes Request and (for synchronous requests) Response and Fault business objects as well as SOAP Config MOs, Protocol Config MOs, header container and child objects and application-specific information appropriate to each object and attribute. The WSDL ODA automates this process.

After you generate business objects, you must perform tasks to enable a collaboration to invoke a web service using the connector and the SOAP data handler. For steps on developing a collaboration, including creating a collaboration template and object and binding its ports, see *IBM WebSphere Business Integration Server Express and Express Plus Collaboration Development Guide*. For further information on creating maps between generic business objects and the application-specific business objects generated by the WSDL ODA, see *IBM WebSphere Business Integration Server Express and Express Plus Map Development Guide*.

Chapter 7. Exposing collaborations as web services

- “Procedure checklist”
- “Identifying or Developing Business Objects” on page 140
- “Choosing or developing a collaboration template” on page 140
- “Binding the port of a new collaboration object” on page 140
- “WSDL Configuration Wizard” on page 142
- “WSDL Configuration Wizard processing of business objects in TLO format” on page 144
- “Processing requirements and exceptions” on page 147

This chapter describes the design-time procedure of exposing a collaboration as a web service. This enables the connector to process events when a web service client invokes a collaboration.

Integrated design tools simplify the task of exposing a collaboration as a web service. After configuring the collaboration and business objects for web services, you use the WSDL Configuration Wizard. The wizard creates a WSDL document and XML schema that represent the collaboration as a web service. The WSDL outputs not only describe the collaboration but form the basis for its invocation by a web service client.

Procedure checklist

You must perform the following tasks, described in the sections below, to expose a collaboration as a web service:

1. Identify or, as needed, develop the business objects for use as request and optionally (for synchronous event processing) response and fault SOAP messages. There are two ways to generate these objects: 1) manually, using Business Object Designer Express, or 2) if a WSDL interface file exists for your web service, you can use the WSDL ODA to generate the Request and other (Response or Fault) business objects. If you are following the second approach:
 - a. Specify the name of the collaboration in the Collaboration WSDL ODA configuration property. This value dictates the `ws_collab` ASI in the TLO.
 - b. Specify either a `WSDL_URL` or `UDDI_InquiryAPI_URL` WSDL ODA configuration property for the WSDL interface file (you can also specify a directory path to this file, if it resides on your network or locally).

For further information, see “Starting the WSDL ODA” on page 151.

2. Develop a collaboration template or choose an existing one to use the business objects.
3. Create the collaboration object and its ports for the web service.

You first must ensure that the collaboration object properly populates business objects. For more information and a step-by-step procedure for creating a collaboration object, see the *Implementation Guide for WebSphere Business Integration Server Express and Express Plus*.

Note: The collaboration object must have its maps configured for the appropriate transformations. Maps convert the business object received in the SOAP request message to the business object used by the

collaboration. Maps also convert the business object returned by the collaboration to the business object that is embedded in the SOAP response message. For more information about mapping and mapping procedures, see the *Map Development Guide*.

4. Use the WSDL Configuration Wizard to create the WSDL document. The utility also configures the web services connector.

Note: The WSDL Configuration Wizard creates implementation, interface, and one or more schema files. This document refers to these outputs collectively as the WSDL document.

5. Publish the WSDL document as required.

Note: The connector provides neither tools nor support for publishing WSDL documents.

Identifying or Developing Business Objects

You use Business Object Designer Express to create business objects and Connector Configurator Express to configure the connector to support them.

For more information on Business Object Designer Express, see the *Business Object Designer Express*. For detailed information on web services business objects, see Chapter 3, "Business object requirements," on page 19.

Choosing or developing a collaboration template

The collaboration template you choose or develop must have one or more scenarios to expose as a web service. For further information on collaboration templates, see *Collaboration Development Guide*.

Binding the port of a new collaboration object

After you have configured the port of a collaboration template for a business object type you must create the collaboration object and bind its port to an instance of a web services connector.

To create a new collaboration object and bind its port to an instance of the web services connector:

1. Right click the Collaboration Objects folder and select Create New Collaboration Object. This displays the Create New Collaboration window, which displays the list of templates (as shown in Figure 54).

Figure 54. Create New Collaboration window

2. Select a collaboration template from the Template Name and enter a name for the collaboration object in Collaboration object name field. This displays the Bind Ports window as shown in Figure 55.

Figure 55. Bind Ports window

3. Select a port, click the Type arrow to display the pull down menu for the port and choose WebService (as shown in Figure 55)
All instances of the web services connector have a ConnectorType application-specific property. By default, this property is set to WebService. The

Bind Collaborations Port window in System Manager uses the value of the ConnectorType property to determine which connectors are web service connectors.

4. Click the BindWith arrow to display a list of connector instances. System Manager displays instances of connectors whose ConnectorType properties have values set to WebService. Choose an instance of the web services connector. (An example is shown in Figure 56).

Figure 56. Selecting an instance of the web services connector

5. Click Finish.

You are now ready to run the WSDL Configuration Wizard.

WSDL Configuration Wizard

After you have created the collaboration object and bound its triggering port to an instance of a web services connector, you are ready to use the WSDL Configuration Wizard. Using binding, port name, operation and other data you specified for the collaboration, business object definition, and connector, the utility produces the a WSDL implementation file (*.impl.wsdl), a WSDL interface file (*.wsdl), and an xml schema file (*.xsd). These files are a composite of the collaboration exposed as a web service, and the utility allows you to specify whether to generate these as separate files or as one file. The utility supports SOAP over HTTP, HTTPS, and JMS protocols. Configuration information for the protocol listener framework is retrieved from the connector-specific property ProtocolListenerFramework. This property also makes the list of listeners available.

Running the wizard

To run the WSDL Configuration Wizard:

1. Right-click a collaboration object that you have configured for web services and choose Expose as a web service in the popup menu. The WSDL Configuration Wizard displays as shown in Figure 57

Figure 57. WSDL Configuration Wizard

As shown in Figure 57, the columns are as follows:

- **Port (Connector)** The triggering port on the collaboration object that is bound to a web services connector. The wizard gets this information from the collaboration object.
 - **Operation** If the business object is a TLO, the wizard gets this information from the Request business object's SOAP Config Mo BodyName attribute. If the business object is a non-TLO, then the wizard combines the business object name and the port name.
 - **Business Object** Used to create the schema. The wizard gets this information from the connector's supported business objects for this triggering port.
2. Enter the following as needed:
- **Service Name** By default, the name you used to describe the collaboration object
 - **Directory Name** Where the adapter for web services and collaboration templates and objects reside
 - **Target Namespace** The URL for the collaboration being exposed as a web service.
 - **Collaboration Ports** The information in these fields are as specified in the Bind Ports window of the collaboration object configuration procedure.
 - **Collaboration Mode for Non-TLO** This does not apply if you are using TLOs. Otherwise, if you using a non-TLO object as input, you must specify synchronous or asynchronous.

- **Schema and WSDL** Specify whether you want these outputs in a single file or in separate files.
3. Click Finish. The utility generates outputs based on the inputs and specifications you entered, all of which are summarized in the next section.

WSDL Configuration Wizard processing of business objects in TLO format

The configuration wizard creates a WSDL operation for each triggering port of a collaboration object that is bound to a web services connector. The creation of the operation is based on the business objects that are associated with the invocation of this collaboration.

The configuration wizard determines that a business object is in the TLO format by reading the object-level ASI `ws_eventtlo`. If the ASI property is set to true, the business object is a TLO. Using the TLO, the following WSDL properties are found:

- **Operation Name and BodyNS** When the wizard finds business objects in TLO format, it creates an operation name using the `BodyName` property of the SOAP Config MO within the SOAP Request business object of the TLO. Similarly, the wizard determines the message namespace to be the `BodyNS` property in the same SOAP Config MO
- **Execution Mode** By inspecting the `ws_mode` property from the business object level ASI of the TLO, the wizard determines that the mode is either synchronous or asynchronous, and creates a `REQUEST_RESPONSE` or `ONE_WAY` WSDL, respectively.

To create WSDL operations based on TLOs, a collaboration can be configured in two ways, with and without maps.

TLOs with maps: A collaboration is generally configured to accept Generic Business Object (GBO) requests. That is, the collaboration template triggering ports subscribe to GBOs. To use TLOs in this case, the collaboration must be bound to a web services connector, and the connector must support the transformation of the GBO to TLOs via maps. Figure 58 shows this scenario.

Figure 58. TLO with map

When the collaboration and connector are configured in this way, the wizard determines that the TLO business object will be used to create the operations described in the WSDL document. This determination is made by inspecting the connector-supported business objects and associated maps. It is important for the run-time processing of the web services connector that the configured maps always transform the collaboration's GBO to one and only one TLO. Also, it is important that the source and destination business objects of the inbound map translate to the destination and source business objects of the outbound map, respectively.

TLOs without maps: The wizard also supports processing TLOs without maps. In this case, the collaboration template's triggering ports subscribe to TLOs directly.

Because the web services connector supports the TLOs, maps are not required. Figure 59 illustrates this scenario.

Figure 59. TLO without map

When the collaboration and connector have been configured in this way, the wizard uses the TLO business object found in the collaboration to create the operations described in the WSDL document. The wizard determines that no maps are configured for this port.

WSDL Configuration Wizard processing of business objects in non-TLO format

Support for non-TLO business objects allows you to use pre-existing collaborations and maps for exposing as web services. For this reason the wizard also supports creating WSDL operations using business objects that are not in TLO format.

Similar to the TLO process, the wizard determines that a business object is in non-TLO format by reading the object-level ASI `ws_eventtlo`. If the ASI property does not exist or exists but is set to something other than true, this business object is a non-TLO. A non-TLO is any business object that does not adhere to the web services TLO structure. Using the non-TLO, the wizard discovers the following properties:

- **Operation Name and BodyNS** When the wizard finds business objects in non-TLO format, it creates an operation name using a combination of the collaboration name, the business object name, and the port name. The Body Namespace for the WSDL operation is configured using the Target Namespace entry in the WSDL Configuration Wizard.
- **WSCollaborations** The wizard creates a hierarchy of properties in the web services connector that includes a BO Name, a SOAP Body Name, a SOAP Body Namespace, and a Mode for each WSDL operation in a port of a collaboration that is exposed as a web service. Figure 60 shows a sample WSCollaborations property:

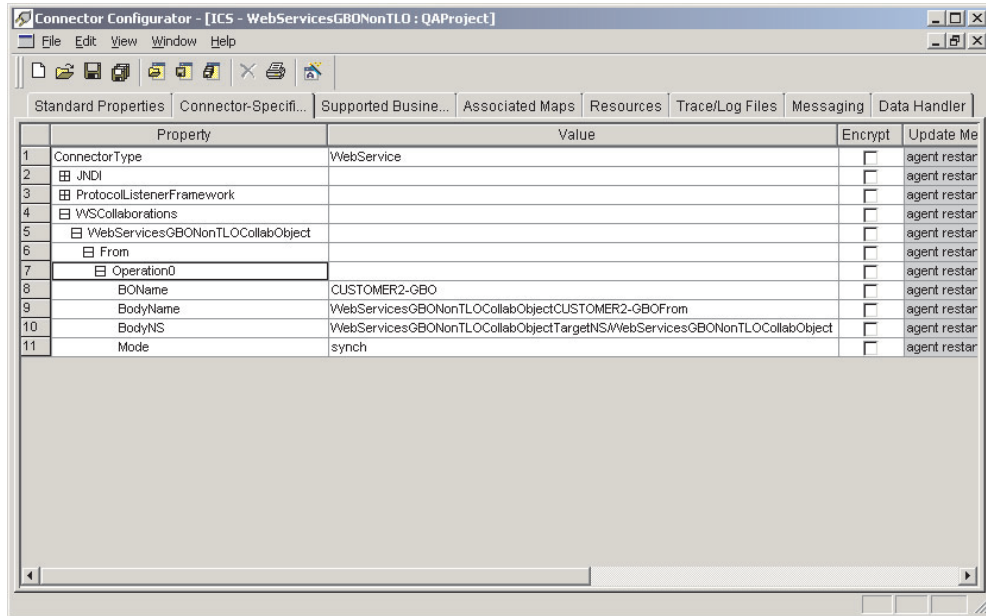

Figure 60. WSCollaborations

- **Execution Mode** The Execution mode for the WSDL operation is configured using the Collab Mode for Non-TLO selection button in the WSDL Configuration Wizard.

To create WSDL operations based on non-TLOs, a collaboration can be configured in two ways, with and without maps.

Non-TLOs with maps: Collaborations are generally configured to accept Generic Business Object (GBO) requests. At the same time, there may be pre-existing maps that transform the GBO from the collaboration to a non-TLO business object. Figure 61 shows this scenario.

Figure 61. Non-TLO with map

In this case, the wizard uses the non-TLO business object to create WSDL operations described in the WSDL document. It is important for the run-time processing of the web services connector that the configured maps always transform the collaboration's GBO to one and only one non-TLO. Also, it is important that the source and destination business objects of the inbound map translate exactly to the destination and source business objects of the outbound map respectively.

Non-TLOs without maps: In highly specialized cases, collaborations may be configured to accept requests from business objects other than GBOs. In this case,

the non-TLO is a direct business object for the collaboration, and no maps exist. Figure 62 shows this scenario.

Figure 62. Non-TLO without map

In this case, the wizard determines that no maps are configured for this port, so it uses the non-TLO business object to create WSDL operations described in the WSDL document.

Processing requirements and exceptions

The sections below discuss requirements of the WSDL Configuration Wizard that apply to all types of objects (TLOs and non-TLOs) unless otherwise explicitly mentioned. For further information on business object requirements for web services TLOs, see Chapter 3, “Business object requirements,” on page 19.

Note: Among the business object ASI that the WSDL tool reads, only the following can have internationalized characters:

- elem_name
- elem_ns
- attr_name
- attr_ns
- BodyName
- BodyNS
- type_name
- type_ns

Support for Use property in SOAP Config MO: The WSDL Configuration Wizard supports the Use property in SOAP Config MOs, but throws an error if the Use value in a SOAP Request BO and the corresponding SOAP Response BO are different. You can set the Use value to literal or encoded to generate a WSDL document. For more information on the Use property and its values, see “Style and Use impact on SOAP messages” on page 108.

Support for Style in SOAP Config MO: Only rpc style is supported for exposing collaborations as web services. If the Style is specified as document in the SOAP Config MO, the wizard will throw an error.

Fault processing: The details attribute inside a SOAP Fault business object can have one child attribute only. Otherwise, the utility generates an error.

The utility accepts Fault business objects. If it encounters multiple Fault business objects, the utility processes the header container of the first or default fault business object. Processing is as follows:

- No Namespace is specified for the soap:fault element inside the binding section.
- Fault is always specified using the document style and use literal.

- Message parts are specified using the element attribute.

Header fault processing: A header fault is processed as `soap:headerfault`, a child element of `soap:header` inside the WSDL document binding section. The header fault is processed using the `headerfault` ASI specified in the header child business object as follows:

- No Namespace is specified for the `soap:headerfault` element.
- A header fault is always specified using the document style and use literal.
- Message parts are specified using the element attribute instead of the type attribute.

Header Processing: Multiple header attributes are specified as SOAP header child business objects inside a SOAP header container business object. A Header container business object is identified by its ASI: `soap_location=SOAPHeader`. During utility processing, a `soap:header` element is created inside binding section for each of the attributes inside the header container business object and the following rules apply:

- The header is always specified using document style and use literal.
- Message parts are specified using the element attribute instead of the type attribute.
- If no `elem_ns` is specified, headers are written to the Body Namespace.

Note: The header container business object can be a child of SOAP Request, Response or Fault business objects. The namespace attribute is not specified for the `soap:header` element.

elem_ns ASI processing: The utility ignores `elem_ns` ASI at the message part level. Instead, `elem_ns` is used in second- and lower-level attributes. Second-level business object attributes can be defined in a separate namespace if `elem_ns` is specified.

JMS protocol processing: SOAP/JMS binding in the port section of the WSDL document contains the `jms:address` element. The following is an example of `jms:address` element. (Attributes suffixed with "?" are optional).

```
<jms:address
    destinationStyle = "queue"
    jmsVendorURI = "http://ibm.com/ns/mqseries"?
    initialContextFactory = "com.ibm.NamingFactory"?
    jndiProviderURL = "iiop://something:900/wherever"?
    jndiConnectionFactoryName = "orange"
    jndiDestinationName = "fred"
    jmsProviderDestinationName="trash" />
```

If the `LookupQueuesUsingJNDI` connector property is set to `true`, the value of `InputQueue` property corresponds to the `jndiDestinationName` attribute of the `jms:address` element of the SOAP/JMS binding. The `jms:address` element is specified in the `wsdl:port` section. If `LookupQueueUsingJNDI` is set to `false`, then the `jmsProviderDestinationName` attribute is set to `InputQueue`. `InputQueue` is the connector property available under the `Listener_JMS` hierarchical property. The `initialContextFactory`, `jndiProviderURL` and `jndiConnectionFactoryName` properties will be specified only for synchronous processing.

HTTP protocol processing: A sample port section from a WSDL document is shown below:

```
<service name="StockQuoteWebService">
  <port name="StockQuoteWebServicePort" binding="intf:StockQuoteBinding">
    <soap:address location="http://localhost:8080/wbia/webservices/stockquoteservice"/>
  </port>
</service>
```

The WSDL Configuration Wizard uses the value of host name and the port from the context path. If the context path contains only the relative path without the host name and port, then the value of host name and port property located under the Listener_HTTP configuration property will be used to specify the location attribute in soap:address xml element.

Chapter 8. Using the WSDL ODA

- “Starting the WSDL ODA”
- “Running the WSDL ODA” on page 152
- “Configuring the agent” on page 152
- “Specifying the WSDL document” on page 154
- “Confirming selections” on page 155
- “Generating the objects” on page 156
- “Limitations” on page 157

Note: The Web Services Description Language (WSDL) Object Discovery Agent (ODA) is used for generating business objects for request processing and, when a WSDL Interface file is available, for event processing.

Collaborations use the connector to invoke web services. Or you can expose collaborations as web services. Web services are described using WSDL (Web Services Description Language). This chapter describes how to use the Web Services Description Language (WSDL) Object Discovery Agent (ODA) to generate business objects. The connector and SOAP data handler use these business objects when collaborations invoke a web service and when exposing collaborations as web services.

You use the WSDL ODA to generate business objects for two purposes:

1. The WSDL ODA can take a WSDL implementation file and generate business objects for a collaboration to invoke an external web service.
2. The WSDL ODA can take a WSDL interface file and generate business objects for a collaboration that is exposed as a web service.

You can launch the WSDL ODA when you use the Business Object Designer Express. The WSDL ODA reads a WSDL document and creates the business objects required by the connector and SOAP data handler. The WSDL ODA simplifies the job of business object development.

Note: The WSDL ODA handles SOAP/HTTP and SOAP/JMS bindings in a WSDL.

Starting the WSDL ODA

You can start the WSDL ODA using one of the following scripts:

- Windows
 - start_WSDLODA.bat

Note: You can also start the WSDL ODA using the shortcut that the Installer automatically creates for Windows environments.

You select, configure, and run the WSDL ODA using Business Object Designer Express. Business Object Designer Express locates each ODA by the name specified in the AGENTNAME variable of each script or batch file.

Running the WSDL ODA

An Object Discovery Agent (ODA) simplifies the work of building business objects for request processing. Business Object Designer Express provides a graphical interface to all available ODAs, and helps you find the agent you need. The WSDL ODA is named, by default, WSDLODA. The name as it appears in the WSDL Wizard depends on the value of the AGENTNAME variable in the start_WSDLODA.bat file. For more on ODAs and business object definitions and how to configure, start and use ODAs, see the *IBM WebSphere Business Object Development Guide*. You are encouraged to consult that document as needed while following the procedures below.

After starting the Object Discovery Agent, follow these steps to launch the WSDL ODA:

1. Open Business Object Designer Express.
2. From the File menu, select the New Using ODA... submenu. Business Object Designer Express displays the Select Agent dialog box in the Business Object Wizard.
3. Click the Find Agents button to display all running agents and select the WSDL ODA. If Business Object Designer Express does not locate your WSDL ODA, check the setup of the ODA.
4. Select the WSDL ODA in the Located Agents pane list and click Next.
This displays the Configure Agent wizard window, which shows the configuration properties you need to specify.

Configuring the agent

Figure 63 shows the Configure Agent window of the WSDL ODA Business Object Wizard.

Table 46 lists the properties you must configure for the WSDL ODA.

	Property	Value	Description
1	WSDL_URL	C:\Testing\wsdl\MyStockQuote-implementation.wsdl	WSDL location URL or File
2	UDDI_Inquiry_API_URL		UDDI Inquiry URL
3	WebServiceProvider		Name of the Web Service Provider
4	WebService		Name of the Web Service in WSDL file
5	MimeType		The mime type for the DataHandler to invoke
6	BOPrefix	SOAP_	Default prefix for the generated business object
7	BOVerb	Create	Default verb
8	TraceFileName	WSODATrace.txt	Name of the trace file.
9	TraceLevel	5	Trace level for the agent.
10	MessageFile	WSODAAgent.txt	Path to the message file

Figure 63. Configure Agent window

Note: The first time you use the WSDL ODA, you must specify values for each configuration properties. After doing so, you can save the property values in

a profile by clicking the Save button. The next time you use the WSDL ODA, you can select the saved profile from the “Select profile” box.

Table 46. WSDL ODA configuration properties

Property	Type	Required	Default	Description
WSDL_URL	String	Yes, when not specifying a UDDI	None	The URL of the WSDL document. This value can also be set to the absolute path to a local WSDL file. You can specify the URL in a native language.
UDDI_InquiryAPI_URL	String	Yes for UDDI	None	The URL of the UDDI inquiry API.
WebServiceProvider	String	Yes for UDDI	None	The name of the target web service provider. This is normally the Business name as published on the UDDI registry. This entry is case sensitive and requires English characters only.
WebService	String	Yes for UDDI		The name of the web service. This entry is case sensitive and requires English characters only.
MimeType	String	No	xml/soap	The mime type of the data handler that the connector invokes. This is set in the business object TLO as the default value and must be in English characters only.
BOPrefix	String	No	SOAP_	This is appended to the front of every business object created. User configurable (English characters only) up to eight characters.
BOVerb	String	Yes	Create	The verb set in the SOAP Config MO of the Request, and, optionally, Response, and Fault business objects.
Collaboration	String	No	None	This value dictates the ws_collab ASI in the TLO and is mandatory when generating objects for event processing.

The next section describes how to specify the WSDL document in the Configure Agent window.

Specifying the WSDL document

Web service business objects are generated from WSDL documents. This section shows you how to select and specify the source of a WSDL document in the Configure Agent window of the ODA.

The WSDL document may reside on the local file system or at a URL location on the web or in a UDDI registry—you specify where the WSDL document resides and the WSDL ODA retrieves it. (A complete WSDL service description may consist of more than one document.)

Getting a WSDL document from a URL location

As shown in Figure 63 above:

1. Specify the URL for the WSDL document in the configuration property WSDL_URL

The ODA then retrieves the list of web services from the WSDL document, resolving the URLs of imported documents. The WSDL_URL property also allows you to specify the location of the WSDL file on the local file system using URL syntax (for example: `file://C:/test/wsdl`) or an absolute path (for example: `C:\test\wsdl`). You must ensure that the ODA has access to this document and its dependencies (all the imported documents).

2. Click Next.

The ODA queries the URL for the web service provider and retrieves the list of services defined in the WSDL at this URL location and then displays the list as shown in Figure 64.

Note: The WSDL ODA displays the ports that have SOAP/JMS or SOAP/HTTP bindings only and excludes other types of bindings.

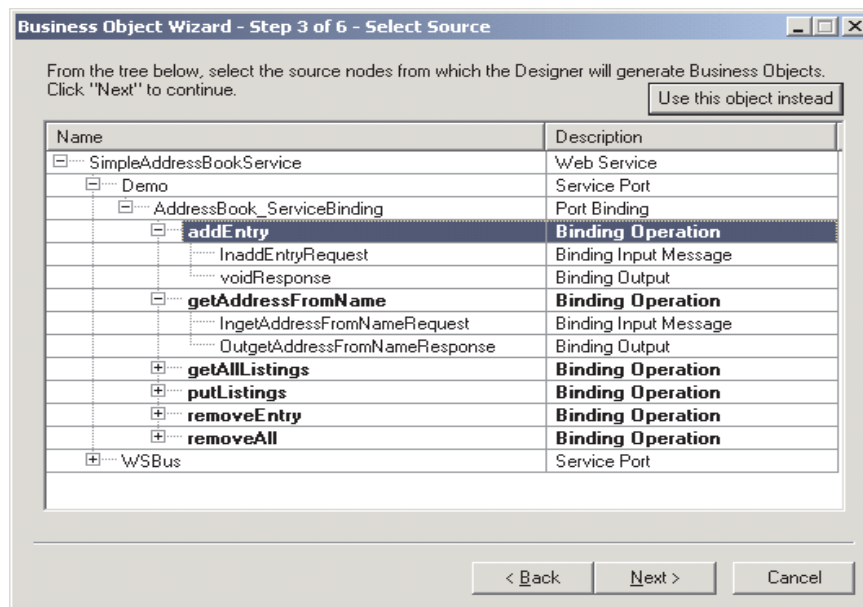

Figure 64. Select Source window

3. Select one and only one of the operations from the list for the port (the selectable operations are highlighted). You cannot select the service or port nodes, which are for display purposes only. Note that WSDL operations may be

of several types: ONE_WAY, REQUEST_RESPONSE, SOLICIT_RESPONSE, and NOTIFICATION. The WSDL ODA supports and displays only REQUEST_RESPONSE and ONE_WAY operations.

4. Click Next and go to “Confirming selections.”

Getting a WSDL document from a UDDI registry

The ODA can also retrieve a WSDL document from a UDDI registry instead of a URL location. For this to occur:

1. Specify the following properties in the Configure Agent window for your “search key”:
 - UDDI_InquiryAPI_URL (for example: <https://uddi.ibm.com/ubr/inquiryapi>)
 - WebServiceProvider (for example: IBM Corporation)
 - WebService (for example: StockQuoteService)
 - The WSDL ODA uses exact name match (findQualifier) for inquiry within the UDDI registry. Ensure that you are entering the right values for the parameters. You can use a regular UDDI browser to find services provided by the service provider.

The WSDL ODA uses these properties, which are described in Table 46, to connect to the UDDI registry.

2. Click Next.

The ODA queries the UDDI registry for the web service provider and retrieves the list of services matching the web service parameter you specified. The WSDL ODA displays the list of services offered by the web service provider in a window like that shown in Figure 64. When the UDDI query returns more than one match, the WSDL ODA displays them appended with an underscore (_) and a sequence number. For example: StockQuoteService_1, StockQuoteService_2, and so on.

Note: The WSDL ODA displays the ports that have SOAP/JMS or SOAP/HTTP bindings only.

3. Select one and only one of the operations from the list for the port. You cannot select the service or port nodes, which are for display purposes only. Note that WSDL operations may be of several types: ONE_WAY, REQUEST_RESPONSE, SOLICIT_RESPONSE, and NOTIFICATION. The WSDL ODA supports and displays only REQUEST_RESPONSE and ONE_WAY operations.
4. Click Next and go to “Confirming selections”

Note: The connector supports the UDDI Version 2 API only. Accordingly, you cannot retrieve WSDL from UDDI registries that do not support UDDI Version 2.

Confirming selections

After selecting a web service operation source, the WSDL ODA Business Object Wizard displays a confirmation screen like that shown in Figure 65:

1. Confirm your selections.
2. Click Next and go to “Generating the objects” on page 156.

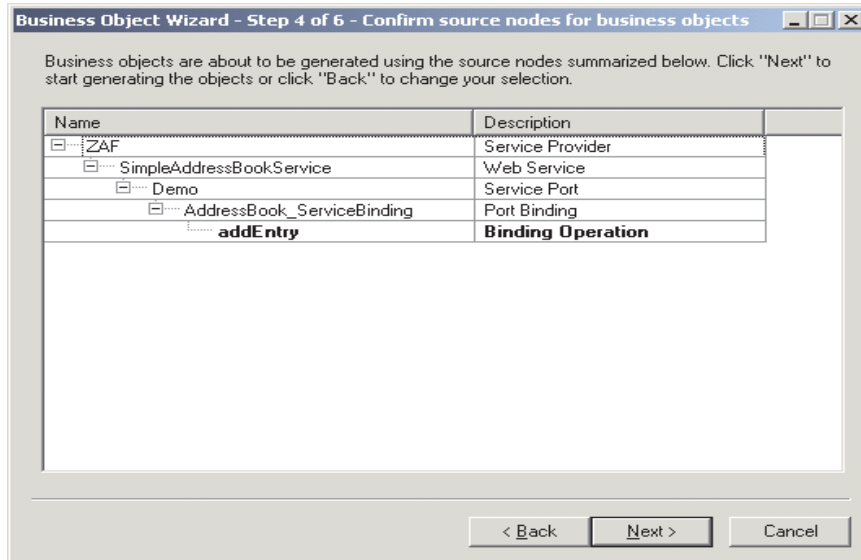

Figure 65. Confirm window

Generating the objects

After you confirm your WSDL document sources, the WSDL ODA generates the business objects and meta-objects for the web service you wish to invoke or for the collaboration you want to expose as a web service.

Note: The WSDL ODA cannot automatically select a key attribute for the top-level business object. For business objects at all other levels, the WSDL ODA sets the first attribute as the key. Accordingly, when you save WSDL ODA-generated objects in Business Object Designer Express, an error message informs you that the top-level object is missing a key attribute. Assign a key attribute that reflects your business data and business object requirements, then re-save the objects. Use caution when selecting the key attribute; it is used in event sequencing and may lead to performance issues if not selected carefully.

1. Check Save business objects to a file, or check Open the business objects in separate windows. The latter choice launches the Business Object Designer Express and opens the business objects in that application.
2. Check Shutdown ODA and click Finish.

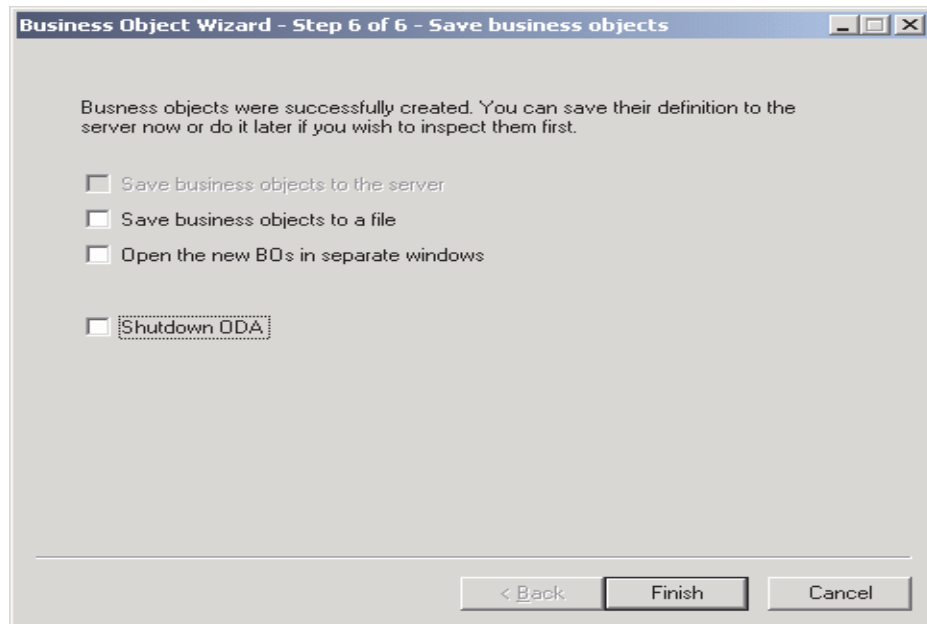

Figure 66. Save window

For request processing, the call to the web service must have a request and, if synchronous, a response and fault messages. For event processing, the collaboration exposed must have a request and, if synchronous, a response and fault messages. The WSDL ODA generates business objects for each of these including the application-specific information (ASI) at every level as well as SOAP data handler, and protocol Config MOs. The SOAP bindings in WSDL document determine the structure of SOAP message. For more on business object structure, see Chapter 3, “Business object requirements,” on page 19.

Limitations

Table 47 describes WSDL ODA support for various combinations of attributes style, use, and part definitions using type and element.

Table 47. WSDL ODA limitations

Style/Use/Parts defined using	Description
rpc/encoded/type	Supported
rpc/encoded/element	Supported
rpc/literal/type	Supported
rpc/literal/element	Supported
doc/encoded/type	Not supported
doc/encoded/element	Not supported
doc/literal/type	Supported
doc/literal/element	Supported

The WSDL ODA can retrieve WSDL files that are completely self-contained (in one file) or are separated into an implementation file containing the service element, an interface file containing all the other WSDL elements including types, messages, portTypes, and bindings, and one or more files for the schemas. The WSDL ODA is not able to successfully retrieve WSDL files that have more than one interface file, for example, with messages and portTypes in one file and bindings in another file.

Schema in the WSDL document must be self-contained in terms of namespace prefixes. You cannot use a namespace prefix that is defined in the <definitions>/<types> element of the WSDL document in the <schema> element that is a child of the <types> element. You need to re-define the namespace prefix on the <schema> element if it is to be used in the sub-elements of the <schema> element. The following is an example of a schema that is not self-contained:

```
<definitions xmlns="http://schemas.xmlsoap.org/wsdl/" xmlns:NS="NS">
  <types>
    <schema xmlns="http://www.w3.org/1999/XMLSchema">
      <element name="NSElem" type="NS:NSType"/>
    </schema>
  </types>
</definitions>
```

Namespace prefix NS is defined on the <definitions> element and is used without re-definition on the <schema> element. Hence the WSDL ODA will throw an error. To work around this limitation, re-define the namespace prefix NS on the <schema> element as shown below:

```
<definitions xmlns="http://schemas.xmlsoap.org/wsdl/" xmlns:NS="NS">
  <types>
    <schema xmlns="http://www.w3.org/1999/XMLSchema" xmlns:NS="NS">
      <element name="NSElem" type="NS:NSType"/>
    </schema>
  </types>
</definitions>
```

Chapter 9. Troubleshooting

The chapter describes problems that you may encounter when starting up or running the connector.

Start-up problems

Problem	Potential solution / explanation
Algorithm Not Supported/Algorithm 'SSL' not available	This error occurs when the SSL version specified in the Connector Configurator Express is not supported by your JSSE provider. Solution: check JSSE provider's documentation for the supported SSL versions. For IBM JSSE make sure your java.security file in the <i>ProductDir/lib/security</i> directory has the following entry <code>security.provider.<number>=com.ibm.jsse. IBMJSSEProvider</code>
Error loading keystore:Keystore file path:"<path>" incorrectly specified:KeyStore not found	where <number> is the preference order for loading the security provider. This error occurs if you specify an incorrect path for the keystore and/or truststore files. Solution: check the keystore file path specified in the SSL->KeyStore property in the Connector Configurator Express. Also, if you are using truststore, check the truststore file path specified in SSL->TrustStore property in the Connector Configurator Express.
KeyManagementError: KeyStore is tampered with, KeyManagement error	This error occurs if your keystore and/or truststore have been tampered with or otherwise corrupted. This error may also occur if you have specified an incorrect value for the password. Solution: ensure that the keystore has not been tampered. Try recreating the keystore. Also make sure you have entered a correct password in the SSL->KeyStorePassword and SSL->TrustStorePassword connector properties.
Error loading certificates from keystore	This error occurs if your certificates and/or keystore, truststore have been tampered with. This error may also occur if you have specified an incorrect value for the password. Solution: check to see if the certificate, keystore or truststore have been tampered with. Also, ensure that you have specified a correct password in the SSL->KeyStorePassword and SSL->TruststorePassword connector properties.
Error creating the server socket, terminating: error	This error occurs if the SOAP/HTTP or SOAP/HTTPS protocol listener cannot bind to the port specified in connector properties. Solution: check the ports specified for all of the SOAP/HTTP and SOAP/HTTPS protocol listeners. If the same port is specified for more than one listener, only one of the listeners can start up. Additionally, check if you have any other service running on that port. If so, then you may want to choose a different port for the protocol listeners.
KeyManagementError:UnrecoverableKeyException, Keys could not be recovered	This error occurs if the keystore or truststore cannot be used. Solution: create a new keystore.

Problem

SSL Handshake Exception: Unknown CA

You notice excessive JSSE logging in your log file.

You have specified a protocol listener but the listener is not getting initialized; you see the following warning message in the connector:

```
Skipping Protocol Listener Property Set
"SOME_LISTENER_NAME" with protocol property "":
unable to determine the protocol listener
class.]
```

You have specified a protocol handler, but it is not getting initialized; you see following warning message in the connector.

```
Unable to determine the type of the
handler; skipping initializing of current
handler. Handler property details:
Name: <Handler Name>;
Value:
```

```
  Name: Protocol; Value:
  Name: ResponseWaitTimeout; Value:
  Name: ReplyToQueue; Value: .]
```

```
java.lang.NoClassDefFoundError:
Javax/jms/JMSEException...
```

```
Fail to lookup, queue: "InProgressQueue"
for specified queue name: "<queue name>"
queue using JNDI "<queue name>"
javax.naming.NameNotFoundException:
<queue name>
```

Error in initializing, JNDI Context is not initialized, user can not use JMS protocol

Error in getting initial context

Potential solution / explanation

This occurs if you do not have a CA certificate in your truststore. Solution: check whether the CA's certificate, as well as its self-signed certificates, reside in the truststore. Also, ensure that the DN of the certificate has the host name (preferably the IP address).

If you do not want to see all of the underlying JSSE details on your console, set the value of SSL->SSLDebug property in the Connector Configurator Express to false. The connector was unable to extract a valid value for the Protocol property of the protocol listener. Valid values are soap/http, soap/https, or soap/jms. Solution: this is not an error condition. However, if you want the connector to use this listener, specify a valid Protocol property value.

The connector was unable to extract a valid value for the Protocol property of the handler. Valid values are soap/http, soap/https, or soap/jms. Solution: This is not an error condition. However, if you want connector to use this handler, specify a valid Protocol property value.

The connector cannot find jms.jar Solution: make sure that jms.jar is in the connector classpath.

If you are using SOAP/JMS web services with the connector, then this problem occurs when you do not create queues. This error may also occur, if you have set JNDI->LookupQueuesUsingJNDI to true and the connector is not able to look up the queues using JNDI. Solution: create the queues required by the connector. If JNDI->LookupQueuesUsingJNDI is set to true, make sure queues required by the connector can be looked up using JNDI.

If you have configured the connector to use a SOAP/JMS protocol listener or SOAP/JMS protocol handler, you must specify JNDI properties. Solution: make sure that you have specified required JNDI connector-specific properties. Refer to your JNDI provider documentation to determine the libraries and jar files required to connect to your JNDI provider. Make sure all of the required jar files are in the classpath of the connector. Also, make sure all of the required libraries are in the path of the connector.

If you have configured the connector to use a SOAP/JMS protocol listener or a SOAP/JMS protocol handler, you must specify JNDI properties. This error may also occur if you have not specified JNDI properties correctly. Solution: check the JNDI properties. Make sure your JNDI is configured properly. Refer to your JNDI provider documentation to determine the libraries and jar files required to connect to your JNDI provider. Make sure all of the required jar files are in the classpath of the connector. Also, make sure all of the required libraries are in the path of the connector.

Run-time errors

Problem

Error parsing HTTP response:Reached end of stream while reading HTTP response header

Error in the url mentioned , unable to extract host and port details ,destination is wrong <destination URL>

Failure in sending event business object <BO Name> with verb <Verb> to the broker. Received execution status "-1" and error message:

MapException: Unable to find the map to map business objects <BO Name> for the connector controller WebServicesConnector

Failed to transform a soap request into a request business object. Soap Fault:

Failure in generating request object - no verb could be set on the request bo

Potential solution / explanation

This error occurs when the connector invokes a SOAP/HTTP web service. It occurs because your target web service sent an incorrect HTTP response. Solution: make sure your target SOAP/HTTP web service end point address is correct.

This error occurs when the connector invokes an SOAP/HTTP Web Service. It occurs because you have specified an incorrect end point address for the SOAP/HTTP web service. Solution: make sure you have specified the correct end point address for the web service.

This error occurs when the integration broker fails to process the event because the collaboration to which the connector is sending the event synchronously either does not exist or does not accept the business object verb. Solution: if you are using a web services TLO for event notification, examine the ws_collab object-level ASI of the TLO. (The name of the TLO is given in the error message.) Check the value of the ws_collab ASI. Make sure this collaboration exists and is running. If ws_mode BO level ASI is set to synch, ws_collab ASI is required. Check the value of ws_verb object-level ASI. Make sure the collaboration specified by the ws_collab ASI can be triggered by the verb specified in the ws_verb ASI. If you are using a non-TLO for event notification, examine the WSCollaborations connector property. Find the collaboration that will be invoked synchronously by this business object. Make sure this collaboration exists and is running.

This error occurs during event notification when the connector is unable to determine the verb of the business object that the connector is attempting to send to the integration broker. Solution: if you are using a web services TLO for event notification, make sure you have specified ws_verb object-level ASI for this TLO. Specify the verb as the value of this ASI. If you are using a non-TLO for event notification, the SOAP message sent by your web service client must contain the verb element. The SOAP data handler sets the verb of the business object using the value of the verb element in the SOAP message.If the web service client does not send the verb in the SOAP message, the SOAP data handler cannot set the verb on the business object. In this case, the connector cannot deliver the business object to the integration broker. If you suspect that your web service clients may not include a verb element in the SOAP message, you may provide a DefaultVerb verb-level ASI for this business object. If you do so, the connector sets this verb on the business object before sending it to the integration broker.

Appendix A. Standard configuration properties for connectors

This appendix describes the standard configuration properties for the connector component of the adapters in WebSphere Business Integration Server Express, running on WebSphere InterChange Server Express.

Not every connector makes use of all these standard properties. When you select an integration broker from Connector Configurator Express, you will see a list of the standard properties that you need to configure for your adapter.

For information about properties specific to the connector, see the relevant adapter user guide.

Configuring standard connector properties

Adapter connectors have two types of configuration properties:

- Standard configuration properties
- Connector-specific configuration properties

This section describes the standard configuration properties. For information on configuration properties specific to a connector, see its adapter user guide.

Using Connector Configurator Express

You configure connector properties from Connector Configurator Express, which you access from System Manager. For more information on using Connector Configurator Express, refer to the Connector Configurator Express appendix.

Setting and updating property values

The default length of a property field is 255 characters.

The connector uses the following order to determine a property's value (where the highest number overrides other values):

1. Default
2. Repository
3. Local configuration file
4. Command line

A connector obtains its configuration values at startup. If you change the value of one or more connector properties during a run-time session, the property's **Update Method** determines how the change takes effect. There are four different update methods for standard connector properties:

- **Dynamic**
The change takes effect immediately after it is saved in System Manager.
- **Component restart**
The change takes effect only after the connector is stopped and then restarted in System Manager. You do not need to stop and restart the application-specific component or the integration broker.

- **Server restart**
The change takes effect only after you stop and restart the application-specific component and the integration broker.
- **Agent restart**
The change takes effect only after you stop and restart the application-specific component.

To determine how a specific property is updated, refer to the **Update Method** column in the Connector Configurator Express window, or see the Update Method column in the Property Summary table below.

Summary of standard properties

Table 48 provides a quick reference to the standard connector configuration properties. Not all the connectors make use of all these properties, and property settings may differ from integration broker to integration broker, as standard property dependencies are based on RepositoryDirectory.

You must set the values of some of these properties before running the connector. See the following section for an explanation of each property.

Table 48. Summary of standard configuration properties

Property name	Possible values	Default value	Update method	Notes
AdminInQueue	Valid JMS queue name	CONNECTORNAME /ADMININQUEUE	Component restart	Delivery Transport is JMS
AdminOutQueue	Valid JMS queue name	CONNECTORNAME/ADMINOUTQUEUE	Component restart	Delivery Transport is JMS
AgentConnections	1-4	1	Component restart	Delivery Transport is IDL
AgentTraceLevel	0-5	0	Dynamic	
ApplicationName	Application name	Value specified for the connector application name	Component restart	
BrokerType	ICS	ICS		
CharacterEncoding	ascii7, ascii8, SJIS, Cp949, GBK, Big5, Cp297, Cp273, Cp280, Cp284, Cp037, Cp437 Note: This is a subset of supported values.	ascii7	Component restart	
ConcurrentEventTriggeredFlows	1 to 32,767	1	Component restart	Repository directory is <REMOTE>
ContainerManagedEvents	No value or JMS	No value	Component restart	Delivery Transport is JMS
ControllerStoreAndForwardMode	true or false	truetrue	Dynamic	Repository directory is <REMOTE>

Table 48. Summary of standard configuration properties (continued)

Property name	Possible values	Default value	Update method	Notes
ControllerTraceLevel	0-5	0	Dynamic	Repository directory is <REMOTE>
DeliveryQueue		CONNECTORNAME/DELIVERYQUEUE	Component restart	JMS transport only
DeliveryTransport	IDL or JMS	IDL	Component restart	
DuplicateEventElimination	true or false	false	Component restart	JMS transport only: Container Managed Events must be <NONE>
EnableOidForFlowMonitoring	true or false	false	Component restart	
FaultQueue		CONNECTORNAME/FAULTQUEUE	Component restart	JMS transport only
jms.FactoryClassName	CxCommon.Messaging.jms.IBMMQSeriesFactory or any Java class name	CxCommon.Messaging.jms.IBMMQSeriesFactory	Component restart	JMS transport only
jms.MessageBrokerName	crossworlds.queue.manager	crossworlds.queue.manager	Component restart	JMS transport only
jms.NumConcurrentRequests	Positive integer	10	Component restart	JMS transport only
jms.Password	Any valid password		Component restart	JMS transport only
jms.UserName	Any valid name		Component restart	JMS transport only
JvmMaxHeapSize	Heap size in megabytes	128m	Component restart	Repository directory is <REMOTE>
JvmMaxNativeStackSize	Size of stack in kilobytes	128k	Component restart	Repository directory is <REMOTE>
JvmMinHeapSize	Heap size in megabytes	1m	Component restart	Repository directory is <REMOTE>
Locale	en_US, ja_JP, ko_KR, zh_CN, zh_TW, fr_FR, de_DE, it_IT, es_ES, pt_BR Note: This is a subset of the supported locales.	en_US	Component restart	
LogAtInterchangeEnd	true or false	false	Component restart	
MaxEventCapacity	1-2147483647	2147483647	Dynamic	Repository Directory is <REMOTE>
MessageFileName	Path or filename	InterchangeSystem.txt	Component restart	

Table 48. Summary of standard configuration properties (continued)

Property name	Possible values	Default value	Update method	Notes
MonitorQueue	Any valid queue name	CONNECTORNAME/MONITORQUEUE	Component restart	JMS transport only: DuplicateEvent Elimination must be true
OADAutoRestartAgent	true or false	false	Dynamic	Repository Directory is <REMOTE>
OADMaxNumRetry	A positive number	1000	Dynamic	Repository Directory is <REMOTE>
OADRetryTimeInterval	A positive number in minutes	10	Dynamic	Repository Directory is <REMOTE>
PollEndTime	HH:MM (HH is 0-23, MM is 0-59)	HH:MM	Component restart	
PollFrequency	A positive integer in milliseconds no (to disable polling) key (to poll only when the letter p is entered in the connector's Command Prompt window)	10000	Dynamic	
PollQuantity	1-500	1	Agent restart	JMS transport only: Container Managed Events is specified
PollStartTime	HH:MM(HH is 0-23, MM is 0-59)	HH:MM	Component restart	
RepositoryDirectory	Location of metadata repository		Agent restart	Set to <REMOTE>
RequestQueue	Valid JMS queue name	CONNECTORNAME/REQUESTQUEUE	Component restart	Delivery Transport is JMS
ResponseQueue	Valid JMS queue name	CONNECTORNAME/RESPONSEQUEUE	Component restart	Delivery Transport is JMS:
RestartRetryCount	0-99	3	Dynamic	
RestartRetryInterval	A sensible positive value in minutes: 1 - 2147483547	1	Dynamic	
SourceQueue	Valid JMS queue name	CONNECTORNAME/SOURCEQUEUE	Agent restart	Only if Delivery Transport is JMS and Container Managed Events is specified
SynchronousRequestQueue	Valid JMS queue name	CONNECTORNAME/ SYNCHRONOUSREQUESTQUEUE	Component restart	Delivery Transport is JMS

Table 48. Summary of standard configuration properties (continued)

Property name	Possible values	Default value	Update method	Notes
SynchronousRequestTimeout	0 - any number (milliseconds)	0	Component restart	Delivery Transport is JMS
SynchronousResponseQueue	Valid JMS queue name	CONNECTORNAME/ SYNCHRONOUSRESPONSEQUEUE	Component restart	Delivery Transport is JMS
WireFormat	CwB0	CwB0	Agent restart	

Standard configuration properties

This section lists and defines each of the standard connector configuration properties.

AdminInQueue

The queue that is used by the integration broker to send administrative messages to the connector.

The default value is CONNECTORNAME/ADMININQUEUE.

AdminOutQueue

The queue that is used by the connector to send administrative messages to the integration broker.

The default value is CONNECTORNAME/ADMINOUTQUEUE.

AgentConnections

The AgentConnections property controls the number of ORB connections opened by `orb.init[]`.

By default, the value of this property is set to 1. There is no need to change this default.

AgentTraceLevel

Level of trace messages for the application-specific component. The default is 0. The connector delivers all trace messages applicable at the tracing level set or lower.

ApplicationName

Name that uniquely identifies the connector's application. This name is used by the system administrator to monitor the WebSphere business integration system environment. This property must have a value before you can run the connector.

BrokerType

Identifies the integration broker that you are using, which is ICS.

CharacterEncoding

Specifies the character code set used to map from a character (such as a letter of the alphabet, a numeric representation, or a punctuation mark) to a numeric value.

Note: Java-based connectors do not use this property. A C++ connector currently uses the value `ascii7` for this property.

By default, a subset of supported character encodings only is displayed in the drop list. To add other supported values to the drop list, you must manually modify the `\Data\Std\stdConnProps.xml` file in the product directory. For more information, see the appendix on using Connector Configurator Express in this guide.

ConcurrentEventTriggeredFlows

Determines how many business objects can be concurrently processed by the connector for event delivery. Set the value of this attribute to the number of business objects you want concurrently mapped and delivered. For example, set the value of this property to 5 to cause five business objects to be concurrently processed. The default value is 1.

Setting this property to a value greater than 1 allows a connector for a source application to map multiple event business objects at the same time and deliver them to multiple collaboration instances simultaneously. This speeds delivery of business objects to the integration broker, particularly if the business objects use complex maps. Increasing the arrival rate of business objects to collaborations can improve overall performance in the system.

To implement concurrent processing for an entire flow (from a source application to a destination application), you must:

- Configure the collaboration to use multiple threads by setting its `Maximum number of concurrent events` property high enough to use multiple threads.
- Ensure that the destination application's application-specific component can process requests concurrently. That is, it must be multi-threaded, or be able to use connector agent parallelism and be configured for multiple processes. Set the `Parallel Process Degree` configuration property to a value greater than 1.

The `ConcurrentEventTriggeredFlows` property has no effect on connector polling, which is single-threaded and performed serially.

ContainerManagedEvents

This property allows a JMS-enabled connector with a JMS event store to provide guaranteed event delivery, in which an event is removed from the source queue and placed on the destination queue as a single JMS transaction.

This property only appears if the `DeliveryTransport` property is set to the value `JMS`.

The default value is `No value`.

When `ContainerManagedEvents` is set to `JMS`, you must configure the following properties to enable guaranteed event delivery:

- `PollQuantity` = 1 to 500
- `SourceQueue` = `CONNECTORNAME/SOURCEQUEUE`

You must also configure a data handler with the `MimeType`, `DHClass`, and `DataHandlerConfigMOName` (optional) properties. To set those values, use the **Data Handler** tab in Connector Configurator Express. The fields for the values under the Data Handler tab will be displayed only if you have set `ContainerManagedEvents` to `JMS`.

Note: When `ContainerManagedEvents` is set to `JMS`, the connector does *not* call its `pollForEvents()` method, thereby disabling that method's functionality.

ControllerStoreAndForwardMode

Sets the behavior of the connector controller after it detects that the destination application-specific component is unavailable.

If this property is set to `true` and the destination application-specific component is unavailable when an event reaches ICS, the connector controller blocks the request to the application-specific component. When the application-specific component becomes operational, the controller forwards the request to it.

However, if the destination application's application-specific component becomes unavailable **after** the connector controller forwards a service call request to it, the connector controller fails the request.

If this property is set to `false`, the connector controller begins failing all service call requests as soon as it detects that the destination application-specific component is unavailable.

The default is `true`.

ControllerTraceLevel

Level of trace messages for the connector controller. The default is `0`.

DeliveryQueue

Applicable only if `DeliveryTransport` is `JMS`.

The queue that is used by the connector to send business objects to the WebSphere InterChange Server Express.

The default value is `CONNECTORNAME/DELIVERYQUEUE`.

DeliveryTransport

Specifies the transport mechanism for the delivery of events. Possible values are `IDL` for CORBA IIOP or `JMS` for Java Messaging Service. The default is `IDL`.

The connector sends service call requests and administrative messages over CORBA IIOP if the value configured for the `DeliveryTransport` property is `IDL`.

JMS

Enables communication between the connector and client connector framework using Java Messaging Service (JMS).

If you select `JMS` as the delivery transport, additional JMS properties such as `jms.MessageBrokerName`, `jms.FactoryClassName`, `jms.Password`, and `jms.UserName`, appear in Connector Configurator Express. The first two of these properties are required for this transport.

Important: There may be a memory limitation if you use the `JMS` transport mechanism for a connector running on WebSphere InterChange Server Express.

In this environment, you may experience difficulty starting both the connector controller (on the server side) and the connector (on the client side) due to memory use within the WebSphere MQ client.

DuplicateEventElimination

When you set this property to true, a JMS-enabled connector can ensure that duplicate events are not delivered to the delivery queue. To use this feature, the connector must have a unique event identifier set as the business object's **ObjectEventId** attribute in the application-specific code. This is done during connector development.

This property can also be set to false.

Note: When DuplicateEventElimination is set to true, you must also configure the MonitorQueue property to enable guaranteed event delivery.

EnableOidForFlowMonitoring

When you set this property to true, the adapter framework will mark the incoming **ObjectEventId** as a foreign key for the purpose of flow monitoring.

The default is false.

FaultQueue

If the connector experiences an error while processing a message then the connector moves the message to the queue specified in this property, along with a status indicator and a description of the problem.

The default value is CONNECTORNAME/FAULTQUEUE.

JvmMaxHeapSize

The maximum heap size for the agent (in megabytes).

The default value is 128m.

JvmMaxNativeStackSize

The maximum native stack size for the agent (in kilobytes).

The default value is 128k.

JvmMinHeapSize

The minimum heap size for the agent (in megabytes).

The default value is 1m.

jms.FactoryClassName

Specifies the class name to instantiate for a JMS provider. You *must* set this connector property when you choose JMS as your delivery transport mechanism (DeliveryTransport).

The default is CxCommon.Messaging.jms.IBMMQSeriesFactory.

jms.MessageBrokerName

Specifies the broker name to use for the JMS provider. You *must* set this connector property when you choose JMS as your delivery transport mechanism (see DeliveryTransport).

The default is `crossworlds.queue.manager`.

jms.NumConcurrentRequests

Specifies the maximum number of concurrent service call requests that can be sent to a connector at the same time. Once that maximum is reached, new service calls block and wait for another request to complete before proceeding.

The default value is 10.

jms.Password

Specifies the password for the JMS provider. A value for this property is optional.

There is no default.

jms.UserName

Specifies the user name for the JMS provider. A value for this property is optional.

There is no default.

Locale

Specifies the language code, country or territory, and, optionally, the associated character code set. The value of this property determines such cultural conventions as collation and sort order of data, date and time formats, and the symbols used in monetary specifications.

A locale name has the following format:

ll_TT.codeset

where:

<i>ll</i>	a two-character language code (usually in lower case)
<i>TT</i>	a two-letter country or territory code (usually in upper case)
<i>codeset</i>	the name of the associated character code set; this portion of the name is often optional.

By default, only a subset of supported locales appears in the drop list. To add other supported values to the drop list, you must manually modify the `\Data\Std\stdConnProps.xml` file in the product directory. For more information, see the appendix on using Connector Configurator Express in this guide.

The default value is `en_US`. If the connector has not been globalized, the only valid value for this property is `en_US`. To determine whether a specific connector has been globalized, see the connector version list on these websites:

<http://www.ibm.com/software/websphere/wbiadapters/infocenter>, or
<http://www.ibm.com/websphere/integration/wicserver/infocenter>

LogAtInterchangeEnd

Specifies whether to log errors to the integration broker's log destination. Logging to the broker's log destination also turns on e-mail notification, which generates e-mail messages for the MESSAGE_RECIPIENT specified in the InterchangeSystem.cfg file when errors or fatal errors occur.

For example, when a connector loses its connection to its application, if LogAtInterChangeEnd is set to true, an e-mail message is sent to the specified message recipient. The default is false.

MaxEventCapacity

The maximum number of events in the controller buffer. This property is used by flow control.

The value can be a positive integer between 1 and 2147483647. The default value is 2147483647.

MessageFileName

The name of the connector message file. The standard location for the message file is \connectors\messages. Specify the message filename in an absolute path if the message file is not located in the standard location.

If a connector message file does not exist, the connector uses InterchangeSystem.txt as the message file. This file is located in the product directory.

Note: To determine whether a specific connector has its own message file, see the individual adapter user guide.

MonitorQueue

The logical queue that the connector uses to monitor duplicate events. It is used only if the DeliveryTransport property value is JMS and DuplicateEventElimination is set to TRUE.

The default value is CONNECTORNAME/MONITORQUEUE

OADAutoRestartAgent

Specifies whether the connector uses the automatic and remote restart feature. This feature uses the MQ-triggered Object Activation Daemon (OAD) to restart the connector after an abnormal shutdown, or to start a remote connector from System Monitor.

This property must be set to true to enable the automatic and remote restart feature. For information on how to configure the MQ-triggered OAD feature, see the *Installation Guide for Windows*.

The default value is false.

OADMaxNumRetry

Specifies the maximum number of times that the MQ-triggered OAD automatically attempts to restart the connector after an abnormal shutdown. The OADAutoRestartAgent property must be set to true for this property to take effect.

The default value is 1000.

OADRetryTimeInterval

Specifies the number of minutes in the retry-time interval for the MQ-triggered OAD. If the connector agent does not restart within this retry-time interval, the connector controller asks the OAD to restart the connector agent again. The OAD repeats this retry process as many times as specified by the OADMaxNumRetry property. The OADAutoRestartAgent property must be set to true for this property to take effect.

The default is 10.

PollEndTime

Time to stop polling the event queue. The format is *HH:MM*, where *HH* represents 0-23 hours, and *MM* represents 0-59 seconds.

You must provide a valid value for this property. The default value is *HH:MM*, but must be changed.

PollFrequency

The amount of time between polling actions. Set *PollFrequency* to one of the following values:

- The number of milliseconds between polling actions.
- The word *key*, which causes the connector to poll only when you type the letter *p* in the connector's Command Prompt window. Enter the word in lowercase.
- The word *no*, which causes the connector not to poll. Enter the word in lowercase.

The default is 10000.

Important: Some connectors have restrictions on the use of this property. To determine whether a specific connector does, see the installing and configuring chapter of its adapter guide.

PollQuantity

Designates the number of items from the application that the connector should poll for. If the adapter has a connector-specific property for setting the poll quantity, the value set in the connector-specific property will override the standard property value.

PollStartTime

The time to start polling the event queue. The format is *HH:MM*, where *HH* represents 0-23 hours, and *MM* represents 0-59 seconds.

You must provide a valid value for this property. The default value is *HH:MM*, but must be changed.

RequestQueue

The queue that is used by WebSphere InterChange Server Express to send business objects to the connector.

The default value is `CONNECTOR/REQUESTQUEUE`.

RepositoryDirectory

The location of the repository from which the connector reads the XML schema documents that store the meta-data for business object definitions.

This value must be set to <REMOTE> because the connector obtains this information from the InterChange Server Express repository.

ResponseQueue

Applicable only if DeliveryTransport is JMS.

Designates the JMS response queue, which delivers a response message from the connector framework to the integration broker. WebSphere InterChange Server Express sends the request and waits for a response message in the JMS response queue.

RestartRetryCount

Specifies the number of times the connector attempts to restart itself. When used for a parallel connector, specifies the number of times the master connector application-specific component attempts to restart the slave connector application-specific component.

The default is 3.

RestartRetryInterval

Specifies the interval in minutes at which the connector attempts to restart itself. When used for a parallel connector, specifies the interval at which the master connector application-specific component attempts to restart the slave connector application-specific component. Possible values ranges from 1 to 2147483647.

The default is 1.

SourceQueue

Applicable only if DeliveryTransport is JMS and ContainerManagedEvents is specified.

Designates the JMS source queue for the connector framework in support of guaranteed event delivery for JMS-enabled connectors that use a JMS event store. For further information, see “ContainerManagedEvents” on page 168.

The default value is CONNECTOR/SOURCEQUEUE.

SynchronousRequestQueue

Applicable only if DeliveryTransport is JMS.

Delivers request messages that require a synchronous response from the connector framework to the broker. This queue is necessary only if the connector uses synchronous execution. With synchronous execution, the connector framework sends a message to the SynchronousRequestQueue and waits for a response back from the broker on the SynchronousResponseQueue. The response message sent to the connector bears a correlation ID that matches the ID of the original message.

The default is CONNECTORNAME/SYNCHRONOUSREQUESTQUEUE

SynchronousResponseQueue

Applicable only if DeliveryTransport is JMS.

Delivers response messages sent in reply to a synchronous request from the broker to the connector framework. This queue is necessary only if the connector uses synchronous execution.

The default is CONNECTORNAME/SYNCHRONOUSRESPONSEQUEUE

SynchronousRequestTimeout

Applicable only if DeliveryTransport is JMS.

Specifies the time in minutes that the connector waits for a response to a synchronous request. If the response is not received within the specified time, then the connector moves the original synchronous request message into the fault queue along with an error message.

The default value is 0.

WireFormat

This is the message format on the transport. The setting is CwB0.

Appendix B. Connector Configurator Express

This appendix describes how to use Connector Configurator Express to set configuration property values for your adapter.

The topics covered in this appendix are:

- “Overview of Connector Configurator Express” on page 177
- “Starting Connector Configurator Express” on page 178
- “Creating a connector-specific property template” on page 178
- “Creating a new configuration file” on page 181
- “Setting the configuration file properties” on page 183
- “Using Connector Configurator Express in a globalized environment” on page 188

Overview of Connector Configurator Express

Connector Configurator Express allows you to configure the connector component of your adapter for use with WebSphere InterChange Server Express.

You use Connector Configurator Express to:

- Create a **connector-specific property template** for configuring your connector.
- Create a **connector configuration file**; you must create one configuration file for each connector you install.
- Set properties in a configuration file.
You may need to modify the default values that are set for properties in the connector templates. You must also designate supported business object definitions and maps for use with collaborations as well as specify messaging, logging and tracing, and data handler parameters, as required.

Connector configuration properties include both standard configuration properties (the properties that all connectors have) and connector-specific properties (properties that are needed by the connector for a specific application or technology).

Because **standard properties** are used by all connectors, you do not need to define those properties from scratch; Connector Configurator Express incorporates them into your configuration file as soon as you create the file. However, you do need to set the value of each standard property in Connector Configurator Express.

The range of standard properties may not be the same for all brokers and all configurations. Some properties are available only if other properties are given a specific value. The Standard Properties window in Connector Configurator Express will show the properties available for your particular configuration.

For **connector-specific properties**, however, you need first to define the properties and then set their values. You do this by creating a connector-specific property template for your particular adapter. There may already be a template set up in your system, in which case, you simply use that. If not, follow the steps in “Creating a new template” on page 179 to set up a new one.

Note: Connector Configurator Express runs only in a Windows environment. If you are running the connector in a UNIX environment, use Connector Configurator Express in Windows to modify the configuration file and then copy the file to your UNIX environment.

Starting Connector Configurator Express

You can start and run Connector Configurator Express in either of two modes:

- Independently, in stand-alone mode
- From System Manager

Running Configurator Express in stand-alone mode

You can run Connector Configurator Express independently and work with connector configuration files, irrespective of your broker.

To do so:

- From **Start>Programs**, click **IBM WebSphere Business Integration Server Express>Toolset Express>Development>Connector Configurator Express**.
- Select **File>New>Configuration File**.

You may choose to run Connector Configurator Express independently to generate the file, and then connect to System Manager to save it in a System Manager project (see “Completing a configuration file” on page 183.)

Running Configurator Express from System Manager

You can run Connector Configurator Express from System Manager.

To run Connector Configurator Express:

1. Open the System Manager.
2. In the System Manager window, expand the **Integration Component Libraries** icon and highlight **Connectors**.
3. From the System Manager menu bar, click **Tools>Connector Configurator Express**. The Connector Configurator Express window opens and displays a **New Connector** dialog box.

To edit an existing configuration file:

1. In the System Manager window, select any of the configuration files listed in the Connector folder and right-click on it.
2. Click the Standard Properties tab to see which properties are included in this configuration file.

Creating a connector-specific property template

To create a configuration file for your connector, you need a connector-specific property template as well as the system-supplied standard properties.

You can create a brand-new template for the connector-specific properties of your connector, or you can use an existing file as the template.

- To create a new template, see “Creating a new template” on page 179.
- To use an existing file, simply modify an existing template and save it under the new name.

Creating a new template

This section describes how you create properties in the template, define general characteristics and values for those properties, and specify any dependencies between the properties. Then you save the template and use it as the base for creating a new connector configuration file.

To create a template:

1. Click **File>New>Connector-Specific Property Template**.
2. The **Connector-Specific Property Template** dialog box appears, with the following fields:
 - **Template**, and **Name**
Enter a unique name that identifies the connector, or type of connector, for which this template will be used. You will see this name again when you open the dialog box for creating a new configuration file from a template.
 - **Old Template**, and **Select the Existing Template to Modify**
The names of all currently available templates are displayed in the **Template Name** display.
 - To see the connector-specific property definitions in any template, select that template's name in the **Template Name** display. A list of the property definitions contained in that template will appear in the **Template Preview** display. You can use an existing template whose property definitions are similar to those required by your connector as a starting point for your template.
3. Select a template from the **Template Name** display, enter that template name in the **Find Name** field (or highlight your selection in **Template Name**), and click **Next**.

If you do not see any template that displays the connector-specific properties used by your connector, you will need to create one.

Specifying general characteristics

When you click **Next** to select a template, the **Properties - Connector-Specific Property Template** dialog box appears. The dialog box has tabs for General characteristics of the defined properties and for Value restrictions. The General display has the following fields:

- **General:**
 - Property Type
 - Updated Method
 - Description
- **Flags**
 - Standard flags
- **Custom Flag**
 - Flag

After you have made selections for the general characteristics of the property, click the **Value** tab.

Specifying values

The **Value** tab enables you to set the maximum length, the maximum multiple values, a default value, or a value range for the property. It also allows editable values. To do so:

1. Click the **Value** tab. The display panel for Value replaces the display panel for General.

2. Select the name of the property in the **Edit properties** display.
3. In the fields for **Max Length** and **Max Multiple Values**, make any changes. The changes will not be accepted unless you also open the **Property Value** dialog box for the property, described in the next step.
4. Right-click the box in the top left-hand corner of the value table and click **Add**. A **Property Value** dialog box appears. Depending on the property type, the dialog box allows you to enter either a value, or both a value and range. Enter the appropriate value or range, and click **OK**.
5. The **Value** panel refreshes to display any changes you made in **Max Length** and **Max Multiple Values**. It displays a table with three columns:

The **Value** column shows the value that you entered in the **Property Value** dialog box, and any previous values that you created.

The **Default Value** column allows you to designate any of the values as the default.

The **Value Range** shows the range that you entered in the **Property Value** dialog box.

After a value has been created and appears in the grid, it can be edited from within the table display. To make a change in an existing value in the table, select an entire row by clicking on the row number. Then right-click in the **Value** field and click **Edit Value**.

Setting dependencies

When you have made your changes to the **General** and **Value** tabs, click **Next**. The **Dependencies - Connector-Specific Property Template** dialog box appears.

A dependent property is a property that is included in the template and used in the configuration file *only if* the value of another property meets a specific condition. For example, `PollQuantity` appears in the template only if JMS is the transport mechanism and `DuplicateEventElimination` is set to `True`.

To designate a property as dependent and to set the condition upon which it depends, do this:

1. In the **Available Properties** display, select the property that will be made dependent.
2. In the **Select Property** field, use the drop-down menu to select the property that will hold the conditional value.
3. In the **Condition Operator** field, select one of the following:
 - == (equal to)
 - != (not equal to)
 - > (greater than)
 - < (less than)
 - >= (greater than or equal to)
 - <=(less than or equal to)
4. In the **Conditional Value** field, enter the value that is required in order for the dependent property to be included in the template.
5. With the dependent property highlighted in the **Available Properties** display, click an arrow to move it to the **Dependent Property** display.
6. Click **Finish**. Connector Configurator Express stores the information you have entered as an XML document, under `\data\app` in the `\bin` directory where you have installed Connector Configurator Express.

Creating a new configuration file

You create a connector configuration file from a connector-specific template or by modifying an existing configuration file.

Creating a configuration file from a connector-specific template

Once a connector-specific template has been created, you can use it to create a configuration file:

1. Click **File>New>Connector Configuration**.

2. The **New Connector** dialog box appears, with the following fields:

- **Name**

Enter the name of the connector. Names are case-sensitive. The name you enter must be unique, and must be consistent with the file name for a connector that is installed on the system.

Important: Connector Configurator Express does not check the spelling of the name that you enter. You must ensure that the name is correct.

- **System Connectivity**

The default broker is ICS. You cannot change this value.

- **Select Connector-Specific Property Template**

Type the name of the template that has been designed for your connector. The available templates are shown in the **Template Name** display. When you select a name in the Template Name display, the **Property Template Preview** display shows the connector-specific properties that have been defined in that template.

Select the template you want to use and click **OK**.

3. A configuration screen appears for the connector that you are configuring. The title bar shows the integration broker and connector names. You can fill in all the field values to complete the definition now, or you can save the file and complete the fields later.

4. To save the file, click **File>Save>To File** or **File>Save>To Project**. To save to a project, System Manager must be running.

If you save as a file, the **Save File Connector** dialog box appears. Choose ***.cfg** as the file type, verify in the File Name field that the name is spelled correctly and has the correct case, navigate to the directory where you want to locate the file, and click **Save**. The status display in the message panel of Connector Configurator Express indicates that the configuration file was successfully created.

Important: The directory path and name that you establish here must match the connector configuration file path and name that you supply in the startup file for the connector.

5. To complete the connector definition, enter values in the fields for each of the tabs of the Connector Configurator Express window, as described later in this chapter.

Using an existing file

To use an existing file to configure a connector, you must open the file in Connector Configurator Express, revise the configuration, and then save the file as a configuration file (*.cfg).

You may have an existing file available in one or more of the following formats:

- A connector definition file.
This is a text file that lists properties and applicable default values for a specific connector. Some connectors include such a file in a \repository directory in their delivery package (the file typically has the extension .txt; for example, CN_XML.txt for the XML connector).
- An InterChange Server Express repository file.
Definitions used in a previous InterChange Server Express implementation of the connector may be available to you in a repository file that was used in the configuration of that connector. Such a file typically has the extension .in or .out.
- A previous configuration file for the connector.
Such a file typically has the extension *.cfg.

Although any of these file sources may contain most or all of the connector-specific properties for your connector, the connector configuration file will not be complete until you have opened the file and set properties, as described later in this chapter.

To use an existing file to configure a connector, you must open the file in Connector Configurator Express, revise the configuration, and then resave the file.

Follow these steps to open a *.txt, *.cfg or *.in file from a directory:

1. In Connector Configurator Express, click **File>Open>From File**.
2. In the **Open File Connector** dialog box, select one of the following file types to see the available files:
 - Configuration (*.cfg)
 - InterChange Server Express Repository (*.in, *.out)
Choose this option if a repository file was used to configure the connector. A repository file may include multiple connector definitions, all of which will appear when you open the file.
 - All files (*.*)
Choose this option if a *.txt file was delivered in the adapter package for the connector, or if a definition file is available under another extension.
3. In the directory display, navigate to the appropriate connector definition file, select it, and click **Open**.

Follow these steps to open a connector configuration from a System Manager project:

1. Start System Manager. A configuration can be opened from or saved to System Manager only if System Manager has been started.
2. Start Connector Configurator Express.
3. Click **File>Open>From Project**.

Completing a configuration file

When you open a configuration file or a connector from a project, the Connector Configurator Express window displays the configuration screen, with the current attributes and values.

Connector Configurator Express requires values for properties described in the following sections:

- “Setting standard connector properties”
- “Setting application-specific configuration properties” on page 184
- “Specifying supported business object definitions” on page 185
- “Associated maps” on page 186
- “Setting trace/log file values” on page 187

Note: For connectors that use JMS messaging, an additional category may display, for special configuration of data handlers that convert the data to business objects. For further information, see “Data handlers” on page 188.

Setting the configuration file properties

When you create and name a new connector configuration file, or when you open an existing connector configuration file, Connector Configurator Express displays a configuration screen with tabs for the categories of required configuration values.

Standard properties differ from connector-specific properties as follows:

- Standard properties of a connector are shared by both the application-specific component of a connector and its broker component. All connectors have the same set of standard properties. These properties are described in Appendix A of each adapter guide. You can change some but not all of these values.
- Application-specific properties apply only to the application-specific component of a connector, that is, the component that interacts directly with the application. Each connector has application-specific properties that are unique to its application. Some of these properties provide default values and some do not; you can modify some of the default values. The installation and configuration chapters of each adapter guide describe the application-specific properties and the recommended values.

The fields for **Standard Properties** and **Connector-Specific Properties** are color-coded to show which are configurable:

- A field with a grey background indicates a standard property. You can change the value but cannot change the name or remove the property.
- A field with a white background indicates an application-specific property. These properties vary according to the specific needs of the application or connector. You can change the value and delete these properties.
- You can configure Value fields.
- The **Update Method** displayed for each property indicates whether a component or agent restart is necessary to activate changed values.

Setting standard connector properties

To change the value of a standard property:

1. Click in the field whose value you want to set.
2. Either enter a value, or select one from the drop-down menu if it appears.

3. After entering all the values for the standard properties, you can do one of the following:
 - To discard the changes, preserve the original values, and exit Connector Configurator Express, click **File>Exit** (or close the window), and click **No** when prompted to save changes.
 - To enter values for other categories in Connector Configurator Express, select the tab for the category. The values you enter for **Standard Properties** (or any other category) are retained when you move to the next category. When you close the window, you are prompted to either save or discard the values that you entered in all the categories as a whole.
 - To save the revised values, click **File>Exit** (or close the window) and click **Yes** when prompted to save changes. Alternatively, click **Save>To File** from either the File menu or the toolbar.

Setting application-specific configuration properties

For application-specific configuration properties, you can add or change property names, configure values, delete a property, and encrypt a property. The default property length is 255 characters.

1. Right-click in the top left portion of the grid. A pop-up menu bar will appear. Click **Add** to add a property. To add a child property, right-click on the parent row number and click **Add child**.
2. Enter a value for the property or child property.
3. To encrypt a property, select the **Encrypt** box.
4. Choose to save or discard changes, as described for “Setting standard connector properties” on page 183.

The Update Method displayed for each property indicates whether a component or agent restart is necessary to activate changed values.

Important: Changing a preset application-specific connector property name may cause a connector to fail. Certain property names may be needed by the connector to connect to an application or to run properly.

Encryption for connector properties

Application-specific properties can be encrypted by selecting the **Encrypt** check box in the **Edit Property** window. To decrypt a value, click to clear the **Encrypt** check box, enter the correct value in the **Verification** dialog box, and click **OK**. If the entered value is correct, the value is decrypted and displays.

The adapter user guide for each connector contains a list and description of each property and its default value.

If a property has multiple values, the **Encrypt** check box will appear for the first value of the property. When you select **Encrypt**, all values of the property will be encrypted. To decrypt multiple values of a property, click to clear the **Encrypt** check box for the first value of the property, and then enter the new value in the **Verification** dialog box. If the input value is a match, all multiple values will decrypt.

Update method

Refer to the descriptions of update methods found in the *Standard configuration properties for connectors* appendix, under “Setting and updating property values” on page 163.

Connector properties are almost all static and the **Update Method** is Component restart. For changes to take effect, you must restart the connector after saving the revised connector configuration file.

Specifying supported business object definitions

Use the **Supported Business Objects** tab in Connector Configurator Express to specify the business objects that the connector will use. You must specify both generic business objects and application-specific business objects, and you must specify associations for the maps between the business objects.

For you to specify a supported business object, the business objects and their maps must exist in the system. Business object definitions, including those for data handler meta-objects, and map definitions should be saved into Integration Component Library (ICL) projects. For more information on ICL projects, see the *User Guide for WebSphere Business Integration Server Express*.

Note: Some connectors require that certain business objects be specified as supported in order to perform event notification or additional configuration (using meta-objects) with their applications. For more information, see the chapter on business objects in this guide as well as the *Business Object Development Guide*.

To specify that a business object definition is supported by the connector, or to change the support settings for an existing business object definition, click the **Supported Business Objects** tab and use the following fields.

Business object name

To designate that a business object definition is supported by the connector, with System Manager running:

1. Click an empty field in the **Business Object Name** list. A drop-down list displays, showing all the business object definitions that exist in the System Manager project.
2. Click on a business object to add it.
3. Set the **Agent Support** (described below) for the business object.
4. In the File menu of the Connector Configurator Express window, click **Save to Project**. The revised connector definition, including designated support for the added business object definition, is saved to the project in System Manager.

To delete a business object from the supported list:

1. To select a business object field, click the number to the left of the business object.
2. From the **Edit** menu of the Connector Configurator Express window, click **Delete Row**. The business object is removed from the list display.
3. From the **File** menu, click **Save to Project**.

Deleting a business object from the supported list changes the connector definition and makes the deleted business object unavailable for use in this implementation of this connector. It does not affect the connector code, nor does it remove the business object definition itself from System Manager.

Agent support

If a business object has Agent Support, the system will attempt to use that business object for delivering data to an application via the connector agent.

Typically, application-specific business objects for a connector are supported by that connector's agent, but generic business objects are not.

To indicate that the business object is supported by the connector agent, check the **Agent Support** box. The Connector Configurator Express window does not validate your Agent Support selections.

Maximum transaction level

The maximum transaction level for a connector is the highest transaction level that the connector supports.

For most connectors, Best Effort is the only possible choice.

You must restart the server for changes in transaction level to take effect.

Associated maps

Each connector supports a list of business object definitions and their associated maps that are currently active in InterChange Server Express. This list appears when you select the **Associated Maps** tab.

The list of business objects contains the application-specific business object which the agent supports and the corresponding generic object that the controller sends to the subscribing collaboration. The association of a map determines which map will be used to transform the application-specific business object to the generic business object or the generic business object to the application-specific business object.

If you are using maps that are uniquely defined for specific source and destination business objects, the maps will already be associated with their appropriate business objects when you open the display, and you will not need (or be able) to change them.

If more than one map is available for use by a supported business object, you will need to explicitly bind the business object with the map that it should use.

The **Associated Maps** tab displays the following fields:

- **Business Object Name**

These are the business objects supported by this connector, as designated in the **Supported Business Objects** tab. If you designate additional business objects under the Supported Business Objects tab, they will be reflected in this list after you save the changes by choosing **Save to Project** from the **File** menu of the Connector Configurator Express window.

- **Associated Maps**

The display shows all the maps that have been installed to the system for use with the supported business objects of the connector. The source business object for each map is shown to the left of the map name, in the **Business Object Name** display.

- **Explicit**

In some cases, you may need to explicitly bind an associated map.

Explicit binding is required only when more than one map exists for a particular supported business object. When InterChange Server Express boots, it tries to automatically bind a map to each supported business object for each connector.

If more than one map takes as its input the same business object, the server attempts to locate and bind one map that is the superset of the others.

If there is no map that is the superset of the others, the server will not be able to bind the business object to a single map, and you will need to set the binding explicitly.

To explicitly bind a map:

1. In the **Explicit** column, place a check in the check box for the map you want to bind.
2. Select the map that you intend to associate with the business object.
3. In the **File** menu of the Connector Configurator Express window, click **Save to Project**.
4. Deploy the project to InterChange Server Express.
5. Reboot the server for the changes to take effect.

Resources

The **Resource** tab allows you to set a value that determines whether and to what extent the connector agent will handle multiple processes concurrently, using connector agent parallelism.

Not all connectors support this feature. If you are running a connector agent that was designed in Java to be multi-threaded, you are advised not to use this feature, since it is usually more efficient to use multiple threads than multiple processes.

Setting trace/log file values

When you open a connector configuration file or a connector definition file, Connector Configurator Express uses the logging and tracing values of that file as default values. You can change those values in Connector Configurator Express.

To change the logging and tracing values:

1. Click the **Trace/Log Files** tab.
2. For either logging or tracing, you can choose to write messages to one or both of the following:
 - To console (STDOUT):
Writes logging or tracing messages to the STDOUT display.

Note: You can only use the STDOUT option from the **Trace/Log Files** tab for connectors running on the Windows platform.

- To File:
Writes logging or tracing messages to a file that you specify. To specify the file, click the directory button (ellipsis), navigate to the preferred location, provide a file name, and click **Save**. Logging or tracing message are written to the file and location that you specify.

Note: Both logging and tracing files are simple text files. You can use the file extension that you prefer when you set their file names. For tracing files, however, it is advisable to use the extension `.trace` rather than `.trc`, to avoid confusion with other files that might reside on the system. For logging files, `.log` and `.txt` are typical file extensions.

Data handlers

The data handlers section is available for configuration only if you have designated a value of JMS for DeliveryTransport and a value of JMS for ContainerManagedEvents. Adapters that make use of the guaranteed event delivery enable this tab.

See the descriptions under ContainerManagedEvents in the Standard Properties appendix for values to use for these properties.

Saving your configuration file

After you have created the configuration file and set its properties, you need to deploy it to the correct location for your connector. Save the configuration in an ICL project, and use System Manager to load the file into InterChange Server Express.

The file is saved as an XML document. You can save the XML document in three ways:

- From System Manager, as a file with a *.con extension in an Integration Component Library, or
- In a directory that you specify.
- In stand-alone mode, as a file with a *.cfg extension in a directory folder.

For details about using projects in System Manager, and for further information about deployment, see the *User Guide for IBM WebSphere Business Integration Server Express*.

Completing the configuration

After you have created a configuration file for a connector and modified it, make sure that the connector can locate the configuration file when the connector starts up.

To do so, open the startup file used for the connector, and verify that the location and file name used for the connector configuration file match exactly the name you have given the file and the directory or path where you have placed it.

Using Connector Configurator Express in a globalized environment

Connector Configurator Express is globalized and can handle character conversion between the configuration file and the integration broker. Connector Configurator Express uses native encoding. When it writes to the configuration file, it uses UTF-8 encoding.

Connector Configurator Express supports non-English characters in:

- All value fields
- Log file and trace file path (specified in the **Trace/Log files** tab)

The drop list for the CharacterEncoding and Locale standard configuration properties displays only a subset of supported values. To add other values to the drop list, you must manually modify the \Data\Std\stdConnProps.xml file in the product directory.

For example, to add the locale en_GB to the list of values for the Locale property, open the stdConnProps.xml file and add the line in boldface type below:

```
<Property name="Locale"
isRequired="true"
updateMethod="component restart">
  <ValidType>String</ValidType>
  <ValidValues>
    <Value>ja_JP</Value>
    <Value>ko_KR</Value>
    <Value>zh_CN</Value>
    <Value>zh_TW</Value>
    <Value>fr_FR</Value>
    <Value>de_DE</Value>
    <Value>it_IT</Value>
    <Value>es_ES</Value>
    <Value>pt_BR</Value>
    <Value>en_US</Value>
    <Value>en_GB</Value>
  <DefaultValue>en_US</DefaultValue>
</ValidValues>
</Property>
```

Appendix C. Adapter for Web Services tutorial

- “About the tutorial”
- “Before you start” on page 192
- “Installing and configuring” on page 193
- “Running the asynchronous scenario” on page 198
- “Running the synchronous scenario” on page 200

This appendix contains step-by-step procedures that:

- demonstrate asynchronous and synchronous event transmission for both request and event processing
- illustrate how to configure the web services connector for a SOAP/HTTPS sample
- illustrate how to configure the web services connector for a SOAP/HTTP sample
- illustrate how to configure the web services connector for a SOAP/JMS sample

About the tutorial

This tutorial is intended to demonstrate asynchronous and synchronous event transmission for both the request and event processing facets of the Adapter for Web Services with each of the supported protocols: SOAP/HTTP, SOAP/HTTPS and SOAP/JMS. In each scenario, the adapters act as:

- a web service client for collaborations that invoke a web service
- a proxy that exposes a WebSphere Business Integration Server Express and Express Plus collaboration as a web service

The tutorial is designed to show the basic functionality of the adapter in sample scenarios:

- **An asynchronous scenario** that illustrates an asynchronous (request-only) web service and its client with the connector. There are two samples in this scenario—for configuration simplicity, the same Web Services connector is used to expose a collaboration as a Web Service and invoke a Web Service as a client.
 - **A collaboration that is exposed as a web service** In this sample, the web service is simply a collaboration `SERVICE_ASYNC_Order_Collab` within WebSphere Business Integration Server Express and Express Plus that is being exposed as a web service by the connector. The web service is referred to as `Asynch Order Service`. If the connector is properly configured, this Web Service can be invoked using any (one) of the Web Services protocols: SOAP/HTTP, SOAP/HTTPS or SOAP/JMS. `SERVICE_ASYNC_Order_Collab` is a simple pass-through collaboration that takes `SERVICE_ASYNC_TLO_Order`. The triggering port (From) of this collaboration is bound to the Web Services connector. The service port (To) is bound to `SampleSiebelConnector`.
 - **A collaboration that is invoked by a web services client** In this sample, the web service client is another collaboration `CLIENT_ASYNC_Order_Collab` within WebSphere Business Integration Server Express and Express Plus that will invoke the `Web Service Asynch Order Service` using the Web Services connector. If the connector is configured properly, this web service client can invoke the Web Service over any (one) of the Web Services protocols: SOAP/HTTP, SOAP/HTTPS or SOAP/JMS. `CLIENT_ASYNC_Order_Collab` is a simple pass-through collaboration which takes `CLIENT_ASYNC_TLO_Order`. The

triggering port (From) of this collaboration is bound to SampleSAPConnector. The service port (To) is bound to the Web Services connector.

Both samples in the asynchronous scenario involve two applications:

- SampleSiebel: Creates an order for its clients.
- SampleSAP: Creates an order
- **A synchronous scenario** that illustrates a synchronous (request-response) web service and its client with the connector. There are two samples in this scenario—for configuration simplicity, the same Web Services connector is used to expose a collaboration as a Web Service and invoke a Web Service as a client.
 - A collaboration that is exposed as a web service In this sample, the Web Service is simply a collaboration SERVICE_SYNCH_OrderStatus_Collab within WebSphere Business Integration Server Express and Express Plus that is being exposed as a web service by the connector. In this sample, this web service is referred to as Synch OrderStatus Service. If the connector is properly configured, the web service can be invoked using any of the web services protocols: SOAP/HTTP, SOAP/HTTPS or SOAP/JMS. SERVICE_SYNCH_OrderStatus_Collab is a simple pass-through collaboration which takes SERVICE_SYNCH_TLO_OrderStatus. The triggering port (From) of this collaboration is bound to the Web Services connector. The service port (To) is bound to SampleSiebelConnector.
 - **A collaboration that is invoked by a web services client** In this sample, the web service client is another collaboration CLIENT_SYNCH_OrderStatus_Collab within WebSphere Business Integration Server Express and Express Plus that will invoke the web service Synch OrderStatus Service using the Web Services connector. If the connector is properly configured, this web service client can invoke the web service over any of the web services protocols: SOAP/HTTP, SOAP/HTTPS or SOAP/JMS. CLIENT_SYNCH_OrderStatus_Collab is a simple pass-through collaboration which takes CLIENT_SYNCH_TLO_OrderStatus. The triggering port (From) of this collaboration is bound to SampleSAPConnector. The service port (To) is bound to the Web Services connector.

Both samples in the synchronous scenario involve two applications:

- SampleSiebel: Retrieves the status of orders for its clients.
- SampleSAP: Requests the status of the order

Both scenarios involve simulating the SampleSiebelConnector and SampleSAPConnector using two Test Connectors.

Before you start

Before you start the tutorial, be sure that:

- You have installed, and are experienced with, WebSphere Business Integration Server Express and Express Plus 4.2.x or later.
- You have installed the WebSphere Business Integration Adapter For Web Services in the WebSphere Business Integration Server Express and Express Plus home directory.
- You are experienced with Web Services technology.
- You are experienced with SOAP technology.

Installing and configuring

In the sections that follow, *WBI_folder* refers to the folder containing your current WebSphere Business Integration Server Express and Express Plus installation. All environment variables and file separators are specified in the Windows NT/2000 format.

Start server and tool

1. Start WebSphere Business Integration Server Express and Express Plus from the shortcut.
2. Start the WebSphere Business Integration System Manager and open the Component Navigator Perspective.
3. Register and connect your server as a Server Instance in the Business Integration Server Express and Express Plus view.

Load the sample content

From the Component Navigator Perspective:

1. Create a new Integration Component Library.
2. Import the repos file named `WebServicesSample.jar` located in:
`WBI_folder\connectors\WebServices\samples\WebSphereICS\`

Compile the collaboration templates

Using WebSphere Business Integration System Manager:

- **Compile All** of the Collaboration Templates that were imported from the `WebServicesSample.jar` repos file.

Configure the connector

1. If you have not done so already, configure the connector as described in this guide and according to your system.
2. Using WebSphere Business Integration System Manager, open `WebServicesConnector` in Connector Configurator Express.
3. You must also configure `WebServicesConnector` for the protocol you want to use with the sample:
 - If you want to use SOAP/HTTP, see “Configuring for the SOAP/HTTP protocol scenario” to configure the connector for SOAP/HTTP.
 - If you want to use SOAP/HTTPS, see “Configuring for the SOAP/HTTPS protocol scenario” on page 194 to configure the connector for SOAP/HTTPS.
 - If you want to use SOAP/JMS, see “Configuring for the SOAP/JMS protocol scenario” on page 196 to configure the connector for SOAP/JMS.

Configuring for the SOAP/HTTP protocol scenario

This section shows you how to configure the connector for the SOAP/HTTP sample scenario. As described in the body of this document, the connector includes a SOAP/HTTP protocol listener and SOAP/HTTP-HTTPS protocol handler. The sample scenario exposes `SERVICE_ASYNC_Order_Collab` and `SERVICE_SYNC_OrderStatus_Collab` collaborations as SOAP/HTTP web services. To expose a collaboration as a SOAP/HTTP web service, the connector uses the SOAP/HTTP protocol listener. The sample scenario comes with the `CLIENT_ASYNC_Order_Collab` and `CLIENT_SYNC_OrderStatus_Collab` collaborations,

which are SOAP/HTTP clients of SOAP/HTTP web services. To invoke a SOAP/HTTP web service, the connector uses SOAP/HTTPHTTPS Protocol Handler.

In the steps and descriptions that follow, hierarchical connector configuration properties are represented with the " symbol. For example, A" B implies A is a hierarchical property, and B is child property of A.

To configure the SOAP/HTTP protocol listener for this sample:

1. In Connector Configurator Express, click on **Connector-Specific Properties** for the WebServicesConnector.
2. Expand the **ProtocolListenerFramework** property to display the ProtocolListeners child property.
3. Expand the **ProtocolListeners** child property to display the **SOAPHTTPListener1** child property.
4. Check the value of **SOAPHTTPListener1"Host** and **SOAPHTTPListener1"Port** property. Make sure there is no other process running on your host and listening on this TCP/IP port. Optionally, you may want to set the value of **SOAPHTTPListener1"Host** to the machine name on which you will run the connector.

You need not configure the SOAP/HTTP-HTTPS protocol handler for the sample.

Configuring for the SOAP/HTTPS protocol scenario

This section shows you how to configure the connector for the SOAP/HTTPS sample scenario. The connector includes a SOAP/HTTPS protocol listener and SOAP/HTTP-HTTPS protocol handler. The sample scenario exposes the SERVICE_ASYNC_Order_Collab and SERVICE_SYNC_OrderStatus_Collab collaborations as SOAP/HTTPS web services. To expose a collaboration as a SOAP/HTTPS web service, the connector uses the SOAP/HTTPS protocol listener. The sample scenario comes with the CLIENT_ASYNC_Order_Collab and CLIENT_SYNC_OrderStatus_Collab collaborations, which are SOAP/HTTPS clients of SOAP/HTTPS web services. To invoke a SOAP/HTTPS web service, the connector uses the SOAP/HTTPHTTPS protocol handler.

In the steps and descriptions that follow, hierarchical connector configuration properties are represented with the " symbol. For example, A" B implies A is a hierarchical property, and B is child property of A.

Note: In addition to the pre-install items listed above in "Before you start" on page 192, you should also have created and tested your keystore and truststore using your Key and Certificate management software.

Configure SSL connector-specific properties: For SOAP/HTTPS, the connector requires that you configure the SSL connector-specific hierarchical property.

1. In Connector Configurator Express, click on the **Connector-Specific Properties** tab for the WebServicesConnector.
2. Expand the **SSL** hierarchical property to view all of its children properties. Additionally, check or change the following child properties of the hierarchical SSL connector-specific property.
 - **SSL" KeyStore** Set to the complete path to your keystore file, which you must create using your Key and Certificate management software.
 - **SSL"KeyStorePassword** Set to the password required to access your KeyStore.

- **SSL"KeyStoreAlias** Set to the alias of the private key in your KeyStore.
- **SSL"TrustStore** Set to the complete path of your truststore file which you have created using your Key and Certificate management software.
- **SSL"TrustStorePassword** Set to the password required to access your TrustStore.

Note: Do not forget to save the changes in Connector Configurator Express.

Configure the SOAP/HTTPS protocol listener:

1. In Connector Configurator Express, click on **Connector-Specific Properties** for the WebServicesConnector.
2. Expand the **ProtocolListenerFramework** property to display the **ProtocolListeners** child property.
3. Expand the **ProtocolListeners** child property to display the **SOAPHTTPSListener1** child property. Check the value of the **SOAPHTTPSListener1"Host** and **SOAPHTTPSListener1"Port** properties. Make sure no other processes are running on your host and listening on this TCP/IP port. Optionally, you may want to set the value of **SOAPHTTPSListener1"Host** to the machine name on which you are running the connector.

You need not configure the SOAP/HTTP-HTTPS protocol handler for the sample.

Setting up KeyStore and TrustStore: You can quickly set up KeyStore and TrustStore to use with the sample scenario. For production systems, you must use third-party software for to set up and manage keystores as well as certificate and key generation. No tool is provided as part of the Adapter for Web Services to set up and manage these resources.

This section assumes that Java Virtual Machine is installed on your system and that you are familiar with the keytool shipped with your JVM (Java Virtual Machine). For more information or for troubleshooting problems with the keytool, please see the documentation that accompanies your JVM.

To set up KeyStore:

1. You create KeyStore using keytool. You must create a key pair in the KeyStore. To do so, enter the following at the command line:
keytool -genkey -alias wsadapter -keystore c:\security\keystore
2. keytool immediately prompts for a password. Specify the password that you entered for the value of SSL"KeyStorePassword connector property. Note that in the above example if you specified -keystore c:\security\keystore in the command line, you would enter c:\security\keystore as the value of the SSL"KeyStore property. Also, if you specified -alias wsadapter in the command line, you would enter wsadapter as the value of the SSL"KeyStoreAlias connector property. keytool would then prompt you for the details of the certificate. The following illustrates what you may enter at each of the prompts, but is an example only: always refer, and defer, to keytool documentation.

```

What is your first and last name?
[Unknown]: HostName
What is the name of your organizational unit?
[Unknown]: myunit
What is the name of your organization?
[Unknown]: myorganization
What is the name of your City or Locality?
[Unknown]: mycity

```

What is the name of your State or Province?
 [Unknown]: *mystate*
 What is the two-letter country code for this unit?
 [Unknown]: *mycountryIs <CN=HostName, OU=myunit, O=myorganization, L=mycity, ST=mystate, C=mycountry>* correct?
 [no]: *yes*

3. Note that for What is your first and last name?, you should enter the name of the machine on which you are running the connector. keytool then prompts you:
 Enter key password for <wsadapter> (RETURN if same as keystore password):
4. Press **Return** to use the same password. If you want to use a self-signed certificate, you may want to export the certificate created above. To do so, enter following on the command line:

```
C:\security>keytool -export -alias wsadapter -keystore c:\security\keystore
-file c:\security\wsadapter.cer
```
5. keytool now prompts for the keystore password. Enter the password that you entered above

To set up TrustStore:

1. To import the trusted certificates into the TrustStore, enter the following command:

```
keytool -import -alias trusted1 -keystore c:\security\truststore
-file c:\security\wsadapter.cer
```
2. keytool now prompts for the keystore password. If you entered -keystore c:\security\truststore, make sure that SSL"TrustStore property is set to c:\security\truststore. Also, set the value of the SSL"TrustStorePassword property to the password you entered above.

Configuring for the SOAP/JMS protocol scenario

This section shows you how to configure the connector for the SOAP/JMS sample scenario. The sample scenario exposes the SERVICE_ASYNC_Order_Collab and SERVICE_SYNC_OrderStatus_Collab collaborations as SOAP/JMS web services. To expose a collaboration as a SOAP/JMS web service, the connector uses the SOAP/JMS protocol listener. The sample scenario comes with the CLIENT_ASYNC_Order_Collab and CLIENT_SYNC_OrderStatus_Collab collaborations, which are SOAP/JMS clients of SOAP/JMS web services. To invoke a SOAP/JMS web service, the connector uses the SOAP/JMS protocol handler.

In the steps and descriptions that follow, hierarchical connector configuration properties are represented with the " symbol. For example, A" B implies A is a hierarchical property, and B is child property of A.

Note: In addition to the pre-install items listed above in "Before you start" on page 192, you should also have installed a JMS service provider and installed and configured your JNDI.

Configuring JNDI properties: For SOAP/JMS, you must configure JNDI connector configuration properties:

1. In Connector Configurator Express, click **Connector-Specific Properties** for the WebServicesConnector.
2. Expand the JNDI hierarchical property to display its child properties. Then check or change the child properties to match the values listed below.
 - **JNDI"JNDIProviderURL** Set this property to the URL of the JNDI Service provider. Refer to your JNDI provider documentation.

- **JNDI"InitialContextFactory** Set this property to fully qualified class name of the factory class that will create the JNDI initial context. Refer to your JNDI provider documentation.
- **JNDI"JNDIConnectionFactoryName** Set this property to the JNDI name of the connection factory to lookup using JNDI context. Make sure that this name can be looked up using the JNDI.
- Refer to your JNDI documentation to see if any of the following properties are required by your JNDI provider:
 - **JNDI"CTX_ObjectFactories**
 - **JNDI"CTX_ObjectFactories**
 - **JNDI"CTX_StateFactories**
 - **JNDI"CTX_URLPackagePrefixes**
 - **JNDI"CTX_DNS_URL**
 - **JNDI"CTX_Authoritative**
 - **JND"CTX_Batchsize**
 - **JNDI"CTX_Referral**
 - **JNDI"CTX_SecurityProtocol**
 - **JND"CTX_SecurityAuthentication**
 - **JNDI"CTX_SecurityPrincipal**
 - **JNDI"CTX_SecurityCredentials**
 - **JNDI"CTX_Language**

3. Save the changes in Connector Configurator Express.

Configure the JMS queues and SOAP/JMS protocol listener: The scenario requires that six queues be defined with your JMS service provider. Before doing so, check your JMS provider documentation; defining queues varies between providers.

1. Define (or make available via JNDI lookup) the following queues:
 - ORDER_INPUT
 - ORDER_INPROGRESS
 - ORDER_ERROR
 - ORDER_ARCHIVE
 - ORDER_UNSUBSCRIBED
 - ORDER_REPLYTO
2. From CSM open **WebServicesConnector** in Connector Configurator Express. If you have not done so already, configure the connector as described in the installation guide for your system.
3. Click **Application Config Properties** in Connector Configurator Express.
4. Expand the **ProtocolListenerFramework** property to display the **ProtocolListeners** child property.
5. Expand **ProtocolListeners** property to display the **SOAPJMSListener1** child property.
6. Check or change the values of the **SOAPJMSListner1** child properties to match those listed below:
 - **SOAPJMSListener"Protocol** Set to soap/jms
 - **SOAPJMSListener1"Protocol** Set to soap/jms
 - **SOAPJMSListener1"InputQueue** Set to ORDER_INPUT
 - **SOAPJMSListener1"InProgressQueue** Set to ORDER_INPROGRESS

- **SOAPJMSListener1"ArchiveQueue** Set to ORDER_ARCHIVE
 - **SOAPJMSListener1"UnsubscribedQueue** Set to ORDER_UNSUBSCRIBED
 - **SOAPJMSListener1"ErrorQueue** Set to ORDER_ERROR
 - **SOAPJMSListener1"ReplyToQueue** Set to ORDER_REPLYTO
7. Save the changes in Connector Configurator Express.

Configure the SOAP/JMS protocol handler:

1. From System Manager open **WebServicesConnector** in Connector Configurator Express. If you have not done so already, configure the connector as described in the installation guide for your system.
2. Click **Connector-Config Properties** in Connector Configurator Express.
3. Expand the **ProtocolHandlerFramework** property to display the ProtocolHandlers child property.
4. Expand the **ProtocolHandlers** child property to display the SOAPJMSHandler child property. Check or change the values of SOAPJMSHandler child properties to match the those below:
 - **SOAPJMSHandler"Protocol** Set to soap/jms
 - **SOAPJMSHandler"ReplyToQueue** Set to value ORDER_REPLYTO
5. Save the changes in Connector Configurator Express.

Create user project

- Using WebSphere Business Integration System Manager, create a new **User Project**. Select all of the components from the Integration Component Library that was created in "Load the sample content" on page 193.

Add and deploy the project

1. From the Server Instance view, add the **User Project** created in "Create user project" to WebSphere Business Integration Server Express and Express Plus
2. Deploy all of the components from this User Project to the Business Integration Server Express and Express Plus.

Reboot Business Integration Server Express and Express Plus

1. Reboot Business Integration Server Express and Express Plus to ensure that all changes take effect.
2. Use the System Monitor tool to ensure that all of the collaboration objects, connector controllers, and maps are in a green state.

Running the asynchronous scenario

This scenario invokes the Asynch Order Service web service. Before running the scenario, review this step-by-step synopsis of its data flow.

1. A CLIENT_ASYNC_TLO_Order.Create event originates in the application SampleSAP running in one instance of the Test Connector.
2. The event is sent from SampleSAP to the collaboration CLIENT_ASYNC_Order_Collab.
3. The event is then sent from the collaboration to the Web Services connector.
4. The Web Services connector finds the CLIENT_ASYNC_Order object that is a child of the CLIENT_ASYNC_TLO_Order object.
5. The Request business object is converted into a SOAP message using the SOAP data handler.

6. The Web Services connector sends the SOAP Message to the end-point (Destination) of the web service Asynch Order Service. The end-point is provided by the Destination attribute of the Protocol Config Meta-Object (MO). The Protocol Config MO used by the connector depends on the value of the Handler attribute of CLIENT_ASYNC_TLO_Order. If it is set to soap/http or soap/https, the Destination attribute of CLIENT_ASYNC_Order_SOAP_HTTP_CfgMO will give the end-point as the URL of the web service. Otherwise if the Handler attribute is set to soap/jms, the Destination attribute of CLIENT_ASYNC_Order_SOAP_JMS_CfgMO gives the end-point as a destination queue name.
7. The Asynch Order Service web service receives the SOAP request. As mentioned earlier, the Web Services connector is the end-point for this web service. The connector's protocol listener, listening on the end-point (to which the request was sent), receives the SOAP message.
8. The connector converts the SOAP message into SERVICE_ASYNC_Order and then creates a SERVICE_TLO_Order object. The SERVICE_ASYNC_Order object is set as a child of the SERVICE_TLO_Order object.
9. The Web Services connector now asynchronously posts the SERVICE_TLO_Order object to Business Integration Server Express and Express Plus. This completes the asynchronous web service invocation.

Because this is an asynchronous web service (request-only), no response is sent back to the web service client. When SERVICE_ASYNC_Order_Collab receives this object, the collaboration then sends the business object to the application named SampleSiebel, which is running as the second instance of Test Connector. The object is displayed in the Test Connector. When Reply Success is selected from the SampleSiebel application, the event will be sent back to SERVICE_ASYNC_Order_Collab.

To run the asynchronous scenario:

1. Start your InterChange Server Express integration broker, if it is not already running.
2. Start the Web Services connector.
3. Start two instances of the Test Connector.
4. Using the Test Connector, define a profile for the SampleSAPConnector and the SampleSiebelConnector.
5. Select **FILE"CONNECT AGENT** from each Test Connector menu to begin simulating agents.
6. While simulating the SampleSAPConnector using the Test Connector, select **EDIT"LOAD BO** from the menu. Load the following file:

```
WBI_folder\connectors\WebServices\samples\WebSphereICS\OrderStatus
\CLIENT_ASYNC_TLO_Order.bo
```

The Test Connector should show that the CLIENT_ASYNC_TLO_Order is loaded.

7. Verify the web services end-point address:
 - **For SOAP/HTTP web service** If you want to use SOAP/HTTP:
 - a. Make sure you have configured the Web Services connector for SOAP/HTTP. In your Test Connector, make sure that the value of the Handler attribute for the CLIENT_ASYNC_TLO_Order business object is set to soap/http. No quotes are allowed in this value.
 - b. Expand the Request attribute of CLIENT_ASYNC_TLO_Order. This attribute is of type CLIENT_ASYNC_Order business object.

- c. Expand the SOAPHTTPCfgMO attribute of CLIENT_ASYNC_Order. This attribute is of type CLIENT_ASYNC_Order_SOAP_HTTP_CfgMO.
 - d. Make sure the value of the Destination attribute of CLIENT_ASYNC_Order_SOAP_HTTP_CfgMO is set to `http://localhost:8080/wbia/webservices/samples`. No quotes are allowed in this value.
- **For SOAP/HTTPS web service** If you want to use SOAP/HTTPS:
 - a. Make sure that you have configured the Web Services connector for SOAP/HTTPS. In your Test Connector, make sure that the value of the Handler attribute for the CLIENT_ASYNC_TLO_Order business object is set to `soap/https`. No quotes are allowed in this value.
 - b. Expand the Request attribute of CLIENT_ASYNC_TLO_Order. This attribute is of type CLIENT_ASYNC_Order business object.
 - c. Expand the SOAPHTTPCfgMO attribute of CLIENT_ASYNC_Order. This attribute is of type CLIENT_ASYNC_Order_SOAP_HTTP_CfgMO.
 - d. Make sure the value of the Destination attribute of CLIENT_ASYNC_Order_SOAP_HTTP_CfgMO is set to `https://localhost:8443/wbia/webservices/samples`. No quotes are allowed in this value.
 - **For SOAP/JMS web service** If you want to use SOAP/JMS:
 - a. Make sure you have configured the Web Services connector for SOAP/JMS. In your Test Connector, make sure that the value of the Handler attribute of the CLIENT_ASYNC_TLO_Order business object is set to `soap/jms`. No quotes are allowed in this value.
 - b. Expand the Request attribute of CLIENT_ASYNC_TLO_Order. This attribute is of type CLIENT_ASYNC_Order business object.
 - c. Expand the SOAPJMSCfgMO attribute of CLIENT_ASYNC_Order. This attribute is of type CLIENT_ASYNC_Order_SOAP_JMS_CfgMO.
 - d. Make sure the value of the Destination attribute of CLIENT_ASYNC_Order_SOAP_JMS_CfgMO is set to `ORDER_INPUT`. No quotes are allowed in this value.
8. While simulating the SampleSAPConnector with the Test Connector, click on the loaded **Test BO**. Select **REQUEST"SEND** from the menu. See the step-by-step synopsis earlier in this section for more details regarding the flow of the event.
 9. While simulating the SampleSiebelConnector with the Test Connector, select **REQUEST"ACCEPT REQUEST**. An Event Labeled `SERVICE_ASYNC_TLO_Order.Create` is displayed in the right panel of the Test Connector.
 10. Double-click the business object. The business object opens up in a window.
 11. Expand the Request attribute of the business object. The Request attribute is of type `SERVICE_ASYNC_Order`. Inspect the `OrderId`, `Customarily` and other attributes of `SERVICE_ASYNC_Order` to verify the Order received. This completes the execution of asynchronous scenario.
 12. Once you have inspected the business object, close the window. Select **REQUEST "REPLY" SUCCESS**.

Running the synchronous scenario

This scenario invokes the Synch OrderStatus Service web service. Before running the scenario, review this step-by-step synopsis of its data flow.

1. A CLIENT_SYNCH_TLO_OrderStatus.Retrieve event originates in the application SampleSAP running in one instance of the Test Connector.
2. The event is sent from SampleSAP to the collaboration named CLIENT_SYNCH_OrderStatus_Collab.
3. The event is then sent from the collaboration to the Web Services connector.
4. The Web Services connector finds the CLIENT_SYNCH_OrderStatus_Request object, which is a child of the CLIENT_SYNCH_TLO_OrderStatus object.
5. The Web Services connector invokes the SOAP data handler to convert the CLIENT_SYNCH_OrderStatus_Request business object into a SOAP message.
6. The Web Services connector sends the SOAP message to the end-point (Destination) of the web service Synch OrderStatus Service. The end-point is provided by the Destination attribute of the Protocol Config MO. The Protocol Config MO used by the connector depends on the value of the Handler attribute of CLIENT_SYNCH_TLO_OrderStatus. If it is set to soap/http or soap/https, the Destination attribute of CLIENT_SYNCH_OrderStatus_Request_SOAP_HTTP_CfgMO will give the end-point as the URL of a web service. Otherwise, if the Handler attribute is set to soap/jms, the Destination attribute of CLIENT_SYNCH_OrderStatus_Request_SOAP_JMS_CfgMO will give the end-point as the destination queue name of the web service).
7. The Web Service Synch OrderStatus Service receives the SOAP request. As mentioned earlier, the Web Services connector is the target end-point. The connector's protocol listener, listening on the end-point (to which request was sent), receive the SOAP message.
8. The connector invokes the SOAP data handler with the SOAP message. The SOAP message is converted into a SERVICE_SYNCH_OrderStatus_Request object by the SOAP data handler. The Web Services connector then creates a SERVICE_TLO_OrderStatus object. The SERVICE_SYNCH_OrderStatus_Request object is set as the child of the SERVICE_TLO_OrderStatus object.
9. The Web Services connector now synchronously posts the SERVICE_TLO_OrderStatus object to the SERVICE_SYNCH_OrderStatus_Collab collaboration running in WebSphere Business Integration Server Express and Express Plus. Since this is a synchronous execution, the Web Services connector remains blocked until the collaboration executes and returns the response.
10. SERVICE_SYNCH_OrderStatus_Collab receives the SERVICE_TLO_OrderStatus object. The collaboration then sends the business object to the application SampleSiebel, which is running as the second instance of the Test Connector.
11. When you select Reply Success from the SampleSiebel application, the event is sent back to the SERVICE_SYNCH_OrderStatus_Collab collaboration.
12. SERVICE_SYNCH_OrderStatus_Collab receives the SERVICE_TLO_OrderStatus object. The collaboration then sends the business object to Web Services connector.
13. The Web Services connector finds the SERVICE_SYNCH_OrderStatus_Response business object (or SERVICE_SYNCH_OrderStatus_Fault, if it is populated) that is a child of the SERVICE_SYNCH_OrderStatus_TLO. This business object will be converted into a SOAP response message (or SOAP fault message) by the SOAP data handler.
14. The Web Services connector returns the SOAP response message (or SOAP fault message) to the web service client.

15. The web service client, which in this case is the connector, receives the response. The connector invokes the SOAP data handler with the response message.
16. The SOAP data handler converts the response message into either a CLIENT_SYNCH_OrderStatus_Response or CLIENT_SYNCH_OrderStatus_Fault business object, depending on what was returned by the Order Synch Service. The Web Services connector sets this object as the child of CLIENT_SYNCH_OrderStatus_TLO. CLIENT_SYNCH_OrderStatus_TLO is returned to the CLIENT_SYNCH_OrderStatus_Collab collaboration.
- 17) CLIENT_SYNCH_OrderStatus_Collab then sends CLIENT_SYNCH_OrderStatus_TLO to the SampleSAP application, which is running as the first instance of the Test Connector. The Test Connector displays this object.

To run the synchronous scenario:

1. Start your InterChange Server Express integration broker, if it is not already running.
2. Start the Web Services connector.
3. Start two instances of the Test Connector.
4. Using the Test Connector, define a profile for the SampleSAPConnector and the SampleSiebelConnector.
5. Select **FILE"CONNECT AGENT** from each Test Connector menu to begin simulating agents.
6. While simulating the SampleSAPConnector using the Test Connector, select **EDIT"LOAD BO** from the menu. Load the following file:

```
WBI_folder\connectors\WebServices\samples\WebSphereICS\OrderStatus
\CLIENT_SYNCH_TLO_OrderStatus.bo
```

The Test Connector should show that the CLIENT_SYNCH_TLO_OrderStatus is loaded.

7. Verify the web services end-point address:
 - **For SOAP/HTTP web service** If you want to use SOAP/HTTP:
 - a. Make sure you have configured the Web Services connector for SOAP/HTTP. In your Test Connector, make sure that the value of the Handler attribute for the CLIENT_SYNCH_TLO_OrderStatus business object is set to soap/http. No quotes are allowed in this value.
 - b. Expand the Request attribute of CLIENT_SYNCH_TLO_OrderStatus. This attribute is of type CLIENT_SYNCH_OrderStatus business object.
 - c. Expand SOAPHTTPCfgMO attribute of CLIENT_SYNCH_OrderStatus. This attribute is of type CLIENT_SYNCH_OrderStatus_SOAP_HTTP_CfgMO.
 - d. Make sure the value of the Destination attribute of CLIENT_SYNCH_OrderStatus_SOAP_HTTP_CfgMO is set to http://localhost:8080/wbia/webservices/samples. No quotes are allowed in this value.
 - **For SOAP/HTTPS web service** If you want to use SOAP/HTTPS:
 - a. Make sure that you have configured the Web Services connector for SOAP/HTTPS. In your Test Connector, make sure that the value of the Handler attribute for the CLIENT_SYNCH_TLO_OrderStatus business object is set to soap/https. No quotes are allowed in this value.
 - b. Expand the Request attribute of CLIENT_SYNCH_TLO_OrderStatus. This attribute is of type CLIENT_SYNCH_OrderStatus business object.

- c. Expand the SOAPHTTPCfgMO attribute of CLIENT_SYNCH_OrderStatus. This attribute is of type CLIENT_SYNCH_OrderStatus_SOAP_HTTP_CfgMO.
 - d. Make sure value of Destination attribute of CLIENT_SYNCH_OrderStatus_SOAP_HTTP_CfgMO is set to https://localhost:8443/wbia/webservices/samples. No quotes are allowed in this value.
- **For SOAP/JMS web service** If you want to use SOAP/JMS:
 - a. Make sure you have configured the Web Services connector for SOAP/JMS. In your Test Connector, make sure that the value of the Handler attribute of the CLIENT_SYNCH_TLO_OrderStatus business object is set to soap/jms. No quotes are allowed in this value.
 - b. Expand the Request attribute of CLIENT_SYNCH_TLO_OrderStatus. This attribute is of type CLIENT_SYNCH_OrderStatus business object.
 - c. Expand the SOAPJMSCfgMO attribute of CLIENT_SYNCH_OrderStatus. This attribute is of type CLIENT_SYNCH_OrderStatus_SOAP_JMS_CfgMO.
 - d. Make sure the value of the Destination attribute of CLIENT_SYNCH_OrderStatus_SOAP_JMS_CfgMO is set to ORDER_INPUT. No quotes are allowed in this value.
8. While simulating the SampleSAPConnector with the Test Connector, click on the loaded **Test BO**. Select **REQUEST"SEND** from the menu. See the step-by-step synopsis earlier in this section for more details regarding the data flow.
 9. An event labeled SERVICE_SYNCH_TLO_OrderStatus.Retrieve is displayed in the right panel of the Test Connector instance that is simulating SampleSiebelConnector. Double-click the business object to display it in a window.
 10. Expand the Request attribute of the business object. The Request attribute is of type SERVICE_SYNCH_OrderStatus_Request. Inspect the OrderId, attribute of SERVICE_ASYNC_Order to verify that this is the order for which status is required.
 - If you know the status of the order:
 - a. Click the **Response** attribute of SERVICE_SYNCH_TLO_OrderStatus. The Response attribute is of type CLIENT_SYNCH_OrderStatus_Response.
 - b. Right-click the **Response** attribute.
 - c. Click the **Add Instance** option. A new instance for the CLIENT_SYNCH_OrderStatus_Response business object is created.
 - d. Enter values for **OrderId**, **CustomerId** and all other details you know about this order. Once you have entered all the details for this order, close this window.
 - If you do not know the status of the order:
 - a. Click the **Fault** attribute of SERVICE_SYNCH_TLO_OrderStatus. The Fault attribute is of type CLIENT_SYNCH_OrderStatus_Fault.
 - b. Right-click the **Fault** attribute.
 - c. Click the **Add Instance** option. A new instance of CLIENT_SYNCH_OrderStatus_Fault is created.
 - d. Enter values for faultcode, faultstring and all other details you want to send in the SOAP fault message. Once you have entered all the values for this fault, close this window.
 11. Select **REQUEST"REPLY"SUCCESS**. An event labeled SERVICE_SYNCH_TLO_OrderStatus.Retrieve is displayed in the right panel of the Test Connector that is simulating SampleSAPConnector.

12. Double-click the **SERVICE_SYNC_TLO_OrderStatus.Retrieve** business object, which is then displayed in a window.
 - If your SampleSiebelConnector returned an order status, you should see the Response attribute of the business object populated. Expand the **Response** attribute to verify the order status.
 - If your SampleSiebelConnector returned a fault, you should see the Fault attribute of the business object populated. Expand the **Fault** attribute to determine the fault.
13. Once you have inspected the business object, close the window. Select **REQUEST"REPLY"SUCCESS**.

This completes the execution of synchronous scenario.

Appendix D. Migrating to 3.0.x

- “Backward compatibility”
- “Upgrade tasks”
- “Web Services Generation Utility”
- “SOAP data handler” on page 206
- “SOAP connector” on page 206
- “Web services connector” on page 206

This appendix describes the backwards compatibility of the 3.0.x release of the Adapter for Web Services as well as how to migrate from Web Services Adapter 1.x and 2.x releases.

Backward compatibility

The Adapter for Web Services, version 3.0.x, is not backward compatible:

- None of the new components (web services connector, SOAP data handler, WSDL ODA) can be used, either jointly or individually, with components released in prior versions of this product.
- None of the components (SOAP connector, SOAP data handler, Web Services Generation Utility) released in prior versions of this product can be used either jointly or individually with version 3.0.x.
- Artifacts created or used with the prior versions of this product solution may not be usable with the version 3.0.x.
- The 3.0.x version of this product cannot be used with a release of WebSphere Business Integration Server Express and Express Plus that is prior to version 4.2

Upgrade tasks

The sections below describe how to upgrade components from versions 1.x and 2.x of this product.

Web Services Generation Utility

The Web Services Generation Utility is no longer available. Instead, you use System Manager tools to expose collaborations as web services. None of the artifacts generated by the Web Services Generation Utility can be used with this release:

- **Proxy class** The web services connector now supports event notification. Therefore proxy classes are no longer required to expose a collaborations as a web service. A proxy class generated with the Web Services Generation Utility cannot invoke a collaboration that has been exposed as a web service using System Manager version 4.2 tools.
- **WSDL documents** The Web Services Generation Utility cannot be used to generate WSDL documents for Business Integration Server Express and Express Plus version 4.2 collaborations. Instead System Manager tools must be used to generate WSDL documents. For more information see “Running the wizard” on page 142.

When you enable a collaboration for request processing, WSDL documents that you generated using the Web Services Generation Utility may not be usable with the WSDL ODA that is available with the 3.0.x release of the connector.

SOAP data handler

You can use the SOAP data handler with the web services connector only. This data handler cannot be used by any other connector nor by Server Access Interface. The sections below discuss additional support issues.

Meta-objects

The top-level SOAP data handler meta-object used with prior releases is no longer supported. Instead you must create a new top-level meta-object for use with the 3.0.x release SOAP data handler. This meta-object must have Classname and SOAPNameHandler attributes only.

The new meta-object no longer requires child meta objects for SOAP message-to-business-object and business-object -to-SOAP-message transformations. Accordingly, make sure that your top-level meta-object does not have SOAPToBOConfigMO and BOToSOAPConfigMO attributes.

The child meta-objects that previously described SOAP message-to-business-object and business-object -to-SOAP-message transformations must now be added as children of the SOAP Request, SOAP Response and SOAP Fault business objects. For further information, see Chapter 5, "SOAP data handler," on page 105 and Chapter 3, "Business object requirements," on page 19.

Application-Specific Information

The new SOAP data handler features new application-specific information (ASI) functionality. You can take advantage of this enhancement by adding specific ASI to SOAP business objects, but doing so is not required. With the exception of adding child SOAP Config MOs to business objects, you can deploy SOAP business objects that you created with prior releases of the connector for use with the 3.0.x version.

Connector compatibility

You can use the new SOAP data handler with the 3.0.x web services connector only. The new SOAP data handler cannot be used with components from prior releases such as the SOAP connector or Server Access Interface.

You cannot use the old SOAP data handler with the 3.0.x web services connector.

SOAP connector

The SOAP connector is not supported with release 3.0.x. Instead, you must use the web services connector to invoke web services.

Web services connector

With release 3.0.x, you use the web services connector for both exposing collaborations as web services and invoking web services. New event notification functionality is used to expose collaborations as web services. New request processing features are now used to invoke web services. The sections below highlight the migration tasks that you must complete to use the web services connector.

Note: The migration tasks discussed below may not be exhaustive. Also, you can complete the tasks in any order.

Event notification

The 3.0.x connector can invoke collaborations synchronously or asynchronously with no requirement for creating and deploying a proxy class on a web server. The

connector now has a listener framework that notifies the connector of events. The listener framework supports SOAP/HTTP, SOAP/HTTPS and SOAP/JMS bindings. If you configure the listeners properly, the connector can detect and respond to web service clients on behalf of collaborations that have been exposed as web services. For further information on the listener framework and how to configure it, see “Protocol listeners” on page 59.

Business objects for event notification: You must create an event notification top-level object (TLO). The TLO is a container for a SOAP Request business object and, optionally (for synchronous request processing), a SOAP Response and SOAP Fault business object. The TLO’s structural components anticipate a single web services operation: the SOAP Request business object corresponds to a SOAP request message, the SOAP Response business object corresponds to a SOAP response message, and the SOAP Fault business object corresponds to a SOAP fault message. For further information, see “Synchronous event processing TLOs” on page 20.

Event notification and SOAP business objects: The SOAP business objects used with Server Access Interface in prior releases may be used, with modifications described in “SOAP data handler” on page 206 above, with the 3.0.x release. Note that you must specify SOAP business objects as children in the event notification TLO.

Request Processing

Like the SOAP connector in prior releases, the 3.0.x web services connector can invoke web services. In addition, the new connector supports invocation of web services with SOAP/JMS bindings. The sections below discuss further the changes in connector request processing.

Top-level objects request processing: You must create a request processing TLO. The TLO is a container for a SOAP Request business object and, optionally (for synchronous request processing), a SOAP Response and SOAP Fault business object. The TLO’s structural components anticipate a single web services operation: the SOAP Request business object corresponds to a SOAP request message, the SOAP Response business object corresponds to a SOAP response message, and the SOAP Fault business object corresponds to a SOAP fault message. In this sense the 3.0.x request processing TLO corresponds to the TLO used with the SOAP connector from prior releases. For further information on request processing TLOs, see “Synchronous request processing TLOs” on page 38.

SOAP business objects: The SOAP business objects used with the SOAP connector of prior releases may be used with modifications as described in “SOAP data handler” on page 206. You must specify these business objects as children of a request processing TLO. Note that in previous releases these business objects were children of a TLO used with SOAP connector.

The 3.0.x web services connector has an additional requirement for SOAP Request business objects. Each SOAP Request business object must have an attribute of type Protocol Config MO (meta-object). The connector uses the Protocol Config MO to determine the destination of the request message. Each Protocol Config MO has a Destination attribute that gives the address of the target web service. If you are using SOAP/HTTP or SOAP/HTTPS to invoke the target web service, then the Destination attribute corresponds to the URL attribute of the TLO used with the SOAP connector from prior releases. For further information, see “Protocol Config MO” on page 27.

Appendix E. Configuring HTTPS/SSL

- “Keystore setup”
- “TrustStore setup” on page 210
- “Generating a certificate signing request (CSR) for public key certificates” on page 210

If you are planning to use SSL, you must use third-party software to manage your keystores, certificates, and key generation. The web services connector does not come with tooling for these tasks. However, you may choose to use keytool, which ships with IBM JRE, to create self-signed certificates and to manage your keystores.

A key and certificate management utility, keytool enables you to administer your own public/private key pairs and associated certificates. These are intended for use in self-authentication (where you authenticate yourself to other users or services) or data integrity and authentication services that use digital signatures. The keytool utility also allows you to store the public keys (in the form of certificates) of peers with whom you communicate.

This appendix describes how to set up keystores using keytool. Note that this appendix is intended for illustration purposes only; it is not intended as a substitute for documentation for keytool or related products. Always refer to source documentation for the tools you use to set up keystores. For further information on keytool, see:

- <http://java.sun.com/j2se/1.3/docs/tooldocs/tools.html#security>

Keystore setup

To create KeyStore using keytool, you first must create a key pair in the KeyStore. For example, if you enter the following command line:

```
keytool -genkey -alias wsadapter -keystore c:\security\keystore
```

keytool immediately prompts you for a password. You may enter the password of your choice (within keytool parameters), but you should specify the password entered in keytool as the value of the SSL “ KeyStorePassword connector property. For further information, see “KeyStorePassword” on page 97.

The sample command creates the keystore named keystore in the c:\security\keystore directory. Accordingly, you would enter c:\security\keystore as the value of the SSL “ KeyStore connector hierarchical property. Also from the command line example above, you would enter -alias wsadapter as the value of the SSL “ KeyStoreAlias connector hierarchical property. The keytool utility then prompts you for the details of the certificate. The following illustrates what you may enter for each of the prompts. (Refer to keytool documentation.)

```
What is your first and last name?  
[Unknown]: HostName  
What is the name of your organizational unit?  
[Unknown]: wbi  
What is the name of your organization?  
[Unknown]: IBM  
What is the name of your City or Locality?  
[Unknown]: Burlingame  
What is the name of your State or Province?
```

```
[Unknown]: CA
What is the two-letter country code for this unit?
[Unknown]: US
Is <CN=HostName, OU=wbi, O=IBM, L=Burlingame,
ST=CA, C=US> correct?
[no]: yes
```

keytool then prompts you for a password:

Enter key password for <wsadapter> (RETURN if same as keystore password):

Press Return to use the same password. If you want to use a self-signed certificate, you may want to export the certificate created above. In that case, enter following on the command line:

```
keytool -export -alias wsadapter -keystore c:\security\keystore -file wsadapter.cer
```

keytool now prompts you for the keystore password. Enter the password that you entered above.

TrustStore setup

You may want to set up TrustStore for the following: If you want the SOAP/HTTPS protocol listener to authenticate the web service client, set the SSL "UseClientAuth" connector configuration property to true. In this case, the SOAP/HTTPS protocol listener expects TrustStore to contain certificates for all trusted web service clients. Note that the connector uses the JSSE default mechanism to trust clients. If you are invoking SOAP/HTTPS web services, the SOAP/HTTP-HTTPS protocol handler requires that TrustStore trust the web service. This means that TrustStore must contain the certificates of all trusted web services. Note that the connector uses the JSSE default mechanism to trust clients. To import the trusted certificates into the TrustStore, enter a command such as the following:

```
keytool -import -alias trusted1 -keystore c:\security\truststore -file
c:\security\trusted1.cer
```

keytool now prompts for the keystore password. If you enter -keystore c:\security\truststore, make sure that the SSL "TrustStore" hierarchical property is set to c:\security\truststore. Also you must set the value of the SSL "TrustStorePassword" hierarchical property to the password you entered previously.

Generating a certificate signing request (CSR) for public key certificates

If the SSL data exchange is among already trusted partners who trust your identity, self-signed certificates may be adequate. However, a certificate is more likely to be trusted by others when it is signed by a certifying authority (CA).

To get a certificate signed by the CA using the keytool utility, you first must generate a Certificate Signing Request (CSR), then give the CSR to a CA. The CA then signs the certificate and returns it to you.

You generate a CSR by entering the following command:

```
keytool -certreq -alias wsadapter -file wsadapter.csr
-keystore c:\security\keystore
```

In the command, alias is the keystore alias that you created for the private key. The keytool utility generates the CSR file, which you provide to your CA. Your CA

then provides you with the signed certificate. You will have to import this certificate into your keystore. To do so, you would enter the following command:

```
keytool -import -alias wsadapter -keystore c:\security\keystore -trustcacerts  
-file casignedcertificate.cer
```

Once you import, the self-signed certificate in keystore is replaced by the CA-signed certificate.

Notices

IBM may not offer the products, services, or features discussed in this document in all countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used.
